Upgrade path: Obligation closure requires checked carrier admission, measurable-kernel handoff, pointwise witness exactness, growth-budget routing, Banach–Sobolev consumer nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NemytskiiOperatorUp.

Chapter 6145

A Concrete Naming Certificate for $\mathsf{FiniteLipschitzIteration}^{\uparrow}$

Following Banach and Picard, the $\mathsf{FiniteLipschitzIteration}^{\uparrow}$ packet records the finite contraction-budget route by which a displayed initial point, a Lipschitz self-map, and a dyadic tolerance schedule generate an explicitly bounded Picard-prefix ledger. It sits over the metric source of chapter 57, the continuous-map row of chapter 130, the real-name seal of chapter 38, the Cauchy-modulus window of chapter 292, and the Picard contraction surface of chapter 395. The packet names finite iteration data only; it does not select a fixed point, assert ambient completeness, or export a completed limit.

Definition 6145.1 (Finite Lipschitz iteration carrier)**.** *A* $\mathsf{FiniteLipschitzIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, d, f, L, q, n, x_0, W, B, H, C, P, N)$$

with the following displayed rows:

1. X, d *are the* $\mathsf{Met}^{\uparrow}$ *source and distance rows.*
2. f *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map row over the same metric source.*
3. L *is the Lipschitz-constant row, read through the same map and source.*
4. q *is the dyadic tolerance row used to compare the finite tail budget.*
5. n *is the displayed finite iteration counter.*
6. x_0 *is the initial-point row.*
7. W *is the finite prefix row listing the displayed reads of* $x_0, f(x_0), \ldots, f^n(x_0)$.
8. B *is the contraction-budget row consumed by* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{PicardContraction}^{\uparrow}$ *consumers.*
9. H *records componentwise* hsame *transport for the metric source, map, Lipschitz constant, dyadic tolerance, counter, prefix, and budget rows.*
10. C *records displayed* Cont *replay through the metric source, continuous-map row, Lipschitz row, finite prefix, and budget row.*
11. P *is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{FiniteLipschitzIteration}^{\uparrow}}$ *row.*
The carrier compares finite prefixes only through these rows. It has no coordinate for a selected fixed point, quotient orbit, infinite limit, host completeness theorem, or ambient contraction principle.

Lean4 ✓ `BEDC.Derived.FiniteLipschitzIterationUp.FiniteLipschitzIterationTasteGate single carrier alignment`

Theorem 6145.2 (Finite Lipschitz iteration NameCert obligations)**.** *For every accepted* $\mathsf{FiniteLipschitzIteration}^{\uparrow}$ *carrier* $I = (X, d, f, L, q, n, x_0, W, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteLipschitzIteration}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source, continuous self-map, Lipschitz constant, dyadic tolerance, finite counter, initial point, finite prefix, contraction budget, transport, replay, provenance, and local naming; exactness of the displayed prefix W at counter n; budget compatibility with the same X, d, f, L, q rows; and nonescape excluding fixed-point selection, ambient completeness, quotient orbit equality, and host-level limiting.*

Proof. Project the accepted carrier. The displayed rows are precisely $X, d, f, L, q, n, x_0, W, B, H, C, P, N$, so carrier admission and local naming are direct reads from Definition 6145.1.

The exactness of W is finite. At counter 0, the prefix row exposes only the initial point x_0. At a successor counter, the next row is obtained by replaying the same continuous-map row f over the same metric source and appending that displayed read to the previous prefix.

The budget row B is attached to the same metric source, continuous-map row, Lipschitz constant row, and dyadic tolerance row. Transport through H and replay through C preserve those rows before Pkg provenance and the local NameCert expose the packet.

Since the carrier contains no selected fixed point, infinite orbit, quotient equality, host limit, or completeness coordinate, the listed rows exhaust the local obligation surface. □

Theorem 6145.3 (Finite Lipschitz contraction-budget induction)**.** *For every accepted* $\mathsf{FiniteLipschitzIteration}^{\uparrow}$ *carrier and every displayed finite counter n, the contraction-budget row B is obtained by induction on n: the base prefix reads the initial point over the metric source, and each successor step consumes the same metric source, continuous-map row, Lipschitz constant row, dyadic tolerance row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The induction exports only a finite prefix budget for* $\mathsf{CauchyModulus}^{\uparrow}$ *and* $\mathsf{PicardContraction}^{\uparrow}$ *consumers.*

Proof. Induct on the displayed counter n.

In the base case, project the carrier and read x_0 as the whole prefix. The metric source X, d, tolerance q, transport, replay, provenance, and local naming rows are present, but no application of f has yet been consumed.

For the successor case, assume the previous prefix budget has been displayed over the same rows. Replay the continuous-map row f through C, transport the metric source, Lipschitz constant, and tolerance through H, and append the next displayed read to W. The budget row B is therefore updated by the same finite rows rather than by a new source, a hidden map, or an external limit.

The induction stops at the displayed counter. It supplies a finite contraction-budget handoff to $\mathsf{CauchyModulus}^{\uparrow}$ and $\mathsf{PicardContraction}^{\uparrow}$, and it does not assert convergence, completeness, or fixed-point existence. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLipschitzIteration}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteLipschitzIteration}^{\uparrow}$ packet is generated from a Metric source, ContinuousMap self-map, Lipschitz constant, dyadic tolerance, finite counter, initial point, finite prefix, contraction budget, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteLipschitzIteration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6145.1, Definition 6145.2, and Definition 6145.3 seed the finite contraction-prefix budget route over metric, map, Lipschitz, tolerance, counter, prefix, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteLipschitzIteration}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close fixed-point existence, selected limits, ambient completeness, quotient orbit equality, Lean verification, or bridge checking for FiniteLipschitzIteration$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix exactness, contraction-budget induction, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteLipschitzIterationUp.

Chapter 6146

A Concrete Naming Certificate for $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$

The $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ packet realizes the reversible phase-surface transport direction of chapter 9463 as finite object, arrow, inverse, composition, boundary-refusal, provenance, and local naming rows. It consumes the visible phase surface of chapter 39, reversible transport through chapter 219, finite flow-style replay through chapter 195, the observer-expansion route of chapter 4167, and the boundary-far-end refusal of chapter 6142. The packet is a finite transport groupoid surface, not a host groupoid of all observers and not a completed phase space.

Definition 6146.1 (Observer phase groupoid carrier)**.** *An* $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (O, A, S, T, I, M, B, H, C, P, N)$$

with the following displayed rows:

1. *O is the finite object row of observer-side phase surfaces.*
2. *A is the finite arrow row of reversible phase transports between displayed objects.*
3. *S is the source-target incidence row tying each arrow to two displayed phase objects.*
4. *T is the reversible transport row, read through the* $\mathsf{UnitaryGroup}^{\uparrow}$ *and* $\mathsf{DynSystem}^{\uparrow}$ *surfaces.*
5. *I is the inverse row, giving the displayed reverse transport for every accepted arrow.*
6. *M is the composition row, giving the displayed composite when source and target rows match.*
7. *B is the boundary-refusal row, excluding an interior center, a global observer object, and a boundary far-end treated as a phase object.*
8. *H records componentwise* hsame *transport for object, arrow, incidence, transport, inverse, composition, and boundary-refusal rows.*
9. *C records displayed* Cont *replay through phase objects, reversible transport, inverse, composition, and refusal reads.*
10. *P is the* Pkg *provenance over* $\mathsf{Complex}^{\uparrow}$, $\mathsf{UnitaryGroup}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ObserverPhaseGroupoid}^{\uparrow}}$ *row.*

The classifier compares arrows only by the joint object-arrow-incidence, inverse, composition, refusal, transport, replay, provenance, and local naming surface. It contains no host phase groupoid, quotient observer identity, global time, or completed hyperbolic phase space.

Theorem 6146.2 (Observer phase groupoid NameCert obligations)**.** *For every accepted* $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ *carrier* $G = (O, A, S, T, I, M, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ObserverPhaseGroupoid}^{\uparrow}}$ *surface consists exactly of object admission, arrow admission, source-target incidence, reversible transport, inverse, composition, boundary refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted arrow factors through displayed phase object rows, reversible transport, inverse, composition, boundary refusal, hsame, Cont, Pkg, and NameCert rows.*

Proof. Project the carrier of Definition 6146.1. The object and arrow rows are O and A, while S records the finite source-target incidence that makes an arrow readable.

The transport, inverse, and composition rows are displayed separately as T, I, M. They are therefore part of the same finite surface rather than hidden operations on a host groupoid.

Boundary refusal is row B. It prevents the far-end boundary and observer-side focus from becoming ordinary phase objects, so accepted arrows remain reversible display transports rather than global observer identities.

Finally, H, C, P, N transport, replay, source, and name the same rows. No further row remains, so the listed obligations exhaust the local NameCert surface. □

Theorem 6146.3 (Observer phase groupoid transport composition)**.** *Whenever two accepted* $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ *arrows have matching displayed incidence rows, their composite is the row supplied by* M *after reading the same object surface* O*, arrow surface* A*, reversible transport row* T*, inverse row* I*, boundary-refusal row* B*,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The composite exports no host observer equality, quotient phase object, global clock, or completed hyperbolic geometry.*

Proof. Read the two arrows through A and their source-target incidence through S. The matching condition is therefore a displayed row comparison, not a host equality of observers.

Use the reversible transport and inverse rows T, I to keep each arrow inside the accepted phase-transport surface. The composition row M is then the only row allowed to expose the composite.

Transport through H and replay through C preserve the same object, arrow, inverse, composition, and refusal rows. Provenance and local naming through P, N certify that the composite remains in the finite packet.

Since no quotient phase object, host observer equality, global clock, or completed hyperbolic geometry is present in the carrier, composition remains a finite BEDC row. □

Falsifiable prediction: Every accepted $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ arrow factors through displayed phase object rows, reversible transport, inverse, composition, boundary refusal, hsame, Cont, Pkg, and NameCert rows.

Independence witness: complex, unitarygroup, dynsystem, hyperbolic-observer-expansion, boundary-far-end-noncenter: none is bijective to $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ because the groupoid packet jointly carries object rows, arrow rows, incidence, reversible transport, inverse, composition, boundary refusal, hsame transport, Cont replay, provenance, and local naming.

The Lean follow-up for this packet provides explicit $\mathsf{Nontrivial}\ \mathsf{ObserverPhaseGroupoid}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ObserverPhaseGroupoid}^{\uparrow}$ TasteGate instances in BEDC.Derived.ObserverPhaseGroupoidUp.TasteGate. The paper-side chapter remains a finite NameCert target; bridge checking is a separate closure axis.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverPhaseGroupoid}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ packet is generated from finite phase-object rows, arrow rows, source-target incidence, reversible transport, inverse, composition, boundary refusal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObserverPhaseGroupoid}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6146.1, Definition 6146.2, and Definition 6146.3 seed the finite reversible phase groupoid route over objects, arrows, incidence, inverse, composition, boundary refusal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObserverPhaseGroupoid}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host observer groupoid, quotient phase object, global clock, completed hyperbolic phase space, Lean verification of the paper obligations, or bridge checking for $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, object-arrow incidence, reversible transport, inverse, composition, boundary refusal, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.ObserverPhaseGroupoidUp

Chapter 6147

A Concrete Naming Certificate for PompeiuHausdorffDistanceRealizer$^{\uparrow}$

Following Pompeiu, Hausdorff, and Kelley on compact hyperspaces, the PompeiuHausdorffDistanceRealizer$^{\uparrow}$ packet records the finite NameCert surface that turns two displayed nonempty compact-subset rows into the symmetric compact-set distance read consumed by fixed-point and compact-hyperspace arguments. It sits after the host finite ledger of chapter 1660, the scalar Hausdorff distance row of chapter 3653, the finite-net HausdorffMetric interface of chapter 2086, the compact metric source of chapter 129, the diameter tolerance ledger of chapter 1503, and the Vietoris neighbourhood route of chapter 2375. The packet is a compact-subset metric realizer: it names only displayed subset rows, directed finite-cover ledgers, symmetric readback, Vietoris compatibility, transport, replay, provenance, and local naming.

Definition 6147.1 (Pompeiu-Hausdorff distance realizer carrier)**.** *A* PompeiuHausdorffDistanceRealizer$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, A, B, H, D_0, D_1, S, V, T, C, P, N)$$

with the following displayed rows:

1. *X is the shared* CompactMetric$^{\uparrow}$ *source row, including the metric observations, finite-net schedules, and diameter bound available to compact-subset distance consumers.*
2. *A and B are the two nonempty compact-subset presentation rows over X.*
3. *H is the* Hyperspace$^{\uparrow}$ *finite Hausdorff ledger row that keeps the two subset presentations attached to the same compact metric source.*
4. *D_0 is the directed finite-cover comparison from A to B, read through the* HausdorffMetric$^{\uparrow}$ *finite-net interface.*
5. *D_1 is the directed finite-cover comparison from B to A with the same source, tolerance budget, and displayed net discipline.*
6. *S is the* HausdorffDistance$^{\uparrow}$ *scalar seal that packages the two directed comparisons as one symmetric compact-set distance read.*
7. *V is the* VietorisTopology$^{\uparrow}$ *compatibility row, recording that finite Vietoris neighbourhood tests inspect the same subset rows and tolerance budget before a topological consumer may read the distance.*

8. *T records componentwise* hsame *transport for $X, A, B, H, D_0, D_1, S, V, C, P, N$.*
9. *C records displayed* Cont *replay of the route*

$$X, A, B, H \longmapsto D_0, D_1 \longmapsto S, V.$$

10. *P is the* Pkg *provenance over* PompeiuHausdorffDistanceRealizer$^{\uparrow}$, Hyperspace$^{\uparrow}$, HausdorffDistance$^{\uparrow}$, HausdorffMetric$^{\uparrow}$, CompactMetric$^{\uparrow}$, MetricDiameter$^{\uparrow}$, VietorisTopology$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{PompeiuHausdorffDistanceRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, B, H, D_0, D_1, S, V, T, C, P, N$. It has no coordinate for a host powerset, quotient compactum, selected nearest point, open-cover compactness theorem, ambient supremum, or arbitrary Vietoris basis selector.

Lean4 (statement) `BEDC.Derived.PompeiuHausdorffDistanceRealizerUp`

Theorem 6147.2 (Pompeiu-Hausdorff realizer obligations)**.** *For every accepted* PompeiuHausdorffDistanceRealizer$^{\uparrow}$ *carrier*

$$R = (X, A, B, H, D_0, D_1, S, V, T, C, P, N),$$

the local NameCert$_{\text{PompeiuHausdorffDistanceRealizer}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *compact-source admission for the shared* CompactMetric$^{\uparrow}$ *row X, including the displayed metric, finite-net, and* MetricDiameter$^{\uparrow}$ *tolerance support;*
2. *compact-subset admission for A and B, requiring both presentations to be read through the same* Hyperspace$^{\uparrow}$ *source ledger H;*
3. *bidirectional finite coverage, requiring D_0 and D_1 to be present before any symmetric compact-set distance is public;*
4. *scalar distance realization, requiring the* HausdorffDistance$^{\uparrow}$ *seal S to be obtained only from the two directed* HausdorffMetric$^{\uparrow}$ *comparisons;*
5. *Vietoris compatibility, requiring V to reuse the same subset rows, source row, and tolerance budget when a topological neighbourhood consumer reads the packet;*
6. *transport, replay, provenance, and local naming exhaustion through T, C, P, N.*

No Pompeiu-Hausdorff realizer obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.PompeiuHausdorffDistanceRealizerUp.TasteGate.PompeiuHausdorffDistanceRealizerCarri namecert obligations`

Theorem 6147.3 (Pompeiu-Hausdorff bidirectional coverage)**.** *Every compact-subset metric consumer of an accepted* PompeiuHausdorffDistanceRealizer$^{\uparrow}$ *packet reads the symmetric distance only after both directed finite-cover comparisons have been displayed:*

$$X, A, B, H \longmapsto D_0, D_1 \longmapsto S.$$

The route therefore supplies the same compact-set distance to Hyperspace$^{\uparrow}$, HausdorffDistance$^{\uparrow}$, HausdorffMetric$^{\uparrow}$, *and* VietorisTopology$^{\uparrow}$ *consumers without exporting a host powerset, quotient compactum, selected nearest point, open-cover compactness theorem, or ambient supremum principle.*

Theorem 6147.4 (Pompeiu-Hausdorff nonescape)**.** *For every accepted* PompeiuHausdorffDistanceRealizer$^{\uparrow}$ *carrier, the* MetricDiameter$^{\uparrow}$ *and* VietorisTopology$^{\uparrow}$ *support rows remain support rows for the displayed compact-subset distance route. They cannot export an additional compactness proof, a selected compact subset, a quotient equality of compacta, an arbitrary Vietoris basis selector, or a second scalar distance outside*

$$X, A, B, H, D_0, D_1, S, V, T, C, P, N.$$

Closure status for NameCert$_{\text{PompeiuHausdorffDistanceRealizer}^{\uparrow}}$.

Constructive story: A PompeiuHausdorffDistanceRealizer$^{\uparrow}$ packet is generated from a CompactMetricUp source row, two nonempty compact-subset rows, a HyperspaceUp ledger, two directed HausdorffMetricUp finite-cover comparisons, a HausdorffDistanceUp scalar seal, VietorisTopologyUp compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PompeiuHausdorffDistanceRealizer}^{\uparrow}}$, seed)

Scope closed: Definition 6147.1, Definition 6147.2, Definition 6147.3, and Definition 6147.4 seed the compact-subset metric realizer for finite Hausdorff and Vietoris consumers.

Formal verification: FormalStatus(NameCert$_{\text{PompeiuHausdorffDistanceRealizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host hyperspaces, quotient compacta, selected nearest points, open-cover compactness, ambient suprema, Lean theorem verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, compact-subset admission, bidirectional coverage, scalar distance realization, Vietoris compatibility, and support-row nonescape for BEDC.Derived.PompeiuHausdorffDistanceRealizerUp.

Chapter 6148

A Concrete Naming Certificate for CompactIntervalOscillationModulus$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CompactIntervalOscillationModulus$^{\uparrow}$ packet records the finite oscillation-modulus data by which a located compact interval read can hand a uniform tail-tolerance bound to Real-facing consumers. It sits after the located interval surface of chapter 394, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal seal discipline of chapter 38. The packet names an interval-local oscillation ledger and modulus handoff without asserting ambient Real$^{\uparrow}$ completeness, a selected supremum, host interval compactness, or quotient real equality.

Definition 6148.1 (Compact interval oscillation-modulus carrier)**.** *A* CompactIntervalOscillationModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, W, R, Q, O, M, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* LocatedInterval$^{\uparrow}$ *source row, exposing lower and upper endpoint windows together with the interval-cell ledger used by the oscillation read.*
2. *W is the finite* StreamName$^{\uparrow}$ *window row over the displayed interval cells and endpoint observations.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the finite stream window.*
4. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row that stores the dyadic budget requested by the oscillation test.*
5. *O is the oscillation ledger, recording finite comparisons of the displayed interval reads under the same W, R, Q rows.*
6. *M is the modulus handoff row, giving the finite interval-local threshold returned to downstream Cauchy or compact-interval consumers.*
7. *E is the* Real$^{\uparrow}$ *seal row, reached only after L, W, R, Q, O, M have been accepted.*
8. *H records componentwise* hsame *transport for the interval source, window, readback, tolerance, oscillation ledger, modulus handoff, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from located interval reads through stream windows, regular rational readback, dyadic tolerance, oscillation ledger, modulus handoff, and real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalOscillationModulus}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalOscillationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, W, R, Q, O, M, E, H, C, P, N$. It has no coordinate for a host compact interval, selected endpoint value, quotient real equality, selected supremum, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6148.2 (Compact interval oscillation-modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalOscillationModulus}^{\uparrow}$ *carrier*

$$I = (L, W, R, Q, O, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalOscillationModulus}^{\uparrow}}$ *surface consists exactly of located interval admission, finite stream-window exposure, regular rational readback, dyadic tolerance budgeting, oscillation-ledger exactness, modulus handoff, real-seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The certificate exports no host compact interval, selected endpoint value, quotient real equality, selected supremum, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6148.1. The analytic rows are L, W, R, Q, O, M, E, while H, C, P, N preserve, replay, source, and name the same finite packet.

The located interval admission row L supplies the interval source and endpoint-window data. The finite window row W and regular readback row R expose the only interval reads available to the oscillation ledger.

The dyadic tolerance row Q fixes the comparison budget before O is read. The oscillation ledger O records only finite comparisons over the same W, R, Q rows, and the modulus handoff M is the only downstream threshold exported by the packet.

Finally the seal row E is downstream of the accepted finite prefix, while H, C, P, N preserve the same route under transport and replay. Since no displayed coordinate names a host interval, selected endpoint, quotient real equality, selected supremum, countable choice, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CompactIntervalOscillationModulusUp.CompactIntervalOscillationModulusTasteGate`
`single carrier alignment`

Theorem 6148.3 (Compact interval oscillation-modulus handoff)**.** *Every downstream Cauchy, compact-interval, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactIntervalOscillationModulus}^{\uparrow}$ *carrier receives the finite route*

$$L, W, R, Q, O, M, E, H, C, P, N.$$

The handoff displays the $\mathsf{LocatedInterval}^{\uparrow}$ *source, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the oscillation ledger, the modulus handoff, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any consumer may use the interval-local modulus.*

Proof. Start with the NameCert obligations of Definition 6148.2. They place located interval admission, stream-window exposure, regular rational readback, dyadic tolerance budgeting, oscillation-ledger exactness, modulus handoff, and real sealing in one displayed packet.

The route to M must pass through L, W, R, Q, O. The located interval row supplies the interval source, the window and readback rows supply the finite observations, the dyadic row supplies the

tolerance, and the oscillation ledger records the finite comparisons from which the modulus handoff is read.

The route to E must pass through the same prefix. Componentwise transport and replay in H and C preserve that prefix, while P and N source and name it locally. Thus any downstream Cauchy, compact-interval, or Real-facing consumer receives the interval-local oscillation modulus only as the displayed finite handoff. □

Falsifiable prediction: Every accepted $\mathsf{CompactIntervalOscillationModulus}^{\uparrow}$ read must expose $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, the oscillation ledger, the modulus handoff, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: locatedinterval, streamname, regseqrat, dyadicratcore, real: CompactIntervalOscillationM is not bijective to any listed sibling because it binds interval-local oscillation comparisons to a finite modulus handoff before Real-facing consumers may read the seal.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalOscillationModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalOscillationModulus}^{\uparrow}$ packet is generated from a LocatedInterval source row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, an oscillation ledger, a modulus handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalOscillationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6148.1, Definition 6148.2, and Definition 6148.3 seed the finite interval-local route from located compact reads to oscillation-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalOscillationModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compact intervals, selected endpoint values, quotient real equality, selected suprema, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exactness, finite-window readback, dyadic tolerance exactness, oscillation-ledger exactness, modulus handoff, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalOscillationModulusUp.

Chapter 6149

A Concrete Naming Certificate for $\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}$ packet records the finite BEDC boundary at which a real-name consumer may see displayed comparison evidence without receiving trichotomy for constructive reals. It sits beside the terminal real-name seal of chapter 38, the regular-rational readback of chapter 301, the stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the apartness real boundary of chapter 304, and the Markov-sensitive inspection refusal of chapter 1666. The packet is a finite refusal object for Real and Completion consumers: it displays the rows that justify local apartness or equality readback, and it records that the missing third case is not filled by LPO, WLPO, Markov's principle, host equality, quotient stream equality, or selected limit data.

Definition 6149.1 (Constructive real trichotomy boundary carrier)**.** *A* $\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, S_X, S_Y, R_X, R_Y, D, A, E, L, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{Real}^{\uparrow}$ *name rows being compared.*
2. *S_X and S_Y are finite* $\mathsf{StreamName}^{\uparrow}$ *observation windows for the two names.*
3. *R_X and R_Y are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readbacks exposed inside the windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the comparison request.*
5. *A is the apartness-evidence row when a displayed dyadic gap separates the two readbacks.*
6. *E is the equality-readback row when the displayed regular-rational windows agree to the requested tolerance.*
7. *L is the refusal ledger used when neither a finite apartness row nor a finite equality-readback row is displayed.*
8. *H records componentwise* hsame *transport for the real names, stream windows, regular readbacks, dyadic ledger, apartness row, equality-readback row, refusal ledger, continuation, provenance, and local naming row.*

9. *C records displayed* Cont *replay from a real comparison request through the finite windows, readbacks, tolerance ledger, and the visible boundary row among A, E, L.*
10. *P is the* Pkg *provenance over* ConstructiveRealTrichotomyBoundary$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, ApartnessReal$^{\uparrow}$, MarkovPrincipleBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ConstructiveRealTrichotomyBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for constructive real trichotomy, LPO, WLPO, Markov's principle as an imported rule, host real equality, quotient stream equality, countable choice, selected representatives, selected limits, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ConstructiveRealTrichotomyBoundaryUp.ConstructiveRealTrichotomyBoundaryTasteGate single carrier alignment`

Theorem 6149.2 (Constructive real trichotomy boundary NameCert obligations)**.** *For every accepted* ConstructiveRealTrichotomyBoundary$^{\uparrow}$ *carrier*

$$T = (X, Y, S_X, S_Y, R_X, R_Y, D, A, E, L, H, C, P, N),$$

the local NameCert$_{\text{ConstructiveRealTrichotomyBoundary}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier formation for the displayed real names, stream windows, regular-rational readbacks, dyadic tolerance ledger, boundary rows, transport, replay, provenance, and local name;*
2. *classifier stability, requiring every comparison read to be transported componentwise through H and replayed through C;*
3. *apartness/equality handoff, allowing a consumer to use A when a finite positive gap is displayed and E when a finite equality readback is displayed;*
4. *LPO-refusal, requiring the ledger L whenever neither displayed finite side is present;*
5. *non-escape, excluding constructive real trichotomy, LPO, WLPO, Markov's principle, host equality, quotient stream equality, countable choice, selected representatives, selected limits, and ambient real completeness from the exported certificate.*

No local naming obligation is stored outside these rows.

Proof. Carrier formation is projection from Definition 6149.1. The tuple displays the two real seals, the finite stream windows, the regular readbacks, the dyadic tolerance ledger, and exactly the three boundary rows A, E, L.

Classifier stability is componentwise. The row H transports each visible coordinate, while C replays the same finite comparison request after transport.

The apartness/equality handoff is read only from the displayed boundary rows. A positive gap must cite A, and an equality readback must cite E; when neither row is present, the consumer receives the refusal ledger L instead of a third global alternative.

The non-escape clause follows from the carrier inventory. Since no excluded semi-classical or host-equality object occurs as a coordinate of T, no local NameCert row can export it. □

Theorem 6149.3 (Constructive real trichotomy LPO refusal)**.** *Let a Real or Completion consumer accept a* ConstructiveRealTrichotomyBoundary$^{\uparrow}$ *packet*

$$T = (X, Y, S_X, S_Y, R_X, R_Y, D, A, E, L, H, C, P, N).$$

If the displayed rows do not expose an apartness witness in A and do not expose an equality-readback witness in E, the consumer must read the refusal ledger L. It cannot replace the missing finite row by LPO, WLPO, Markov's principle, host real equality, quotient stream equality, selected representatives, selected limit data, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier of Definition 6149.1. The only comparison-facing outputs are the apartness row A, the equality-readback row E, and the refusal ledger L.

Apply Definition 6149.2. Its apartness/equality handoff clause permits a consumer to use A or E only when the corresponding finite row is displayed, and its LPO-refusal clause assigns the undecided finite situation to L.

The excluded principles are absent from the tuple. Transport, replay, provenance, and local naming therefore preserve the same refusal boundary rather than supplying a host-side trichotomy consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}$ packet is generated from two Real names, finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, displayed apartness or equality-readback evidence when available, a refusal ledger otherwise, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6149.1, Definition 6149.2, and Definition 6149.3 seed the finite Real/Completion boundary for displayed apartness, equality readback, and refusal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim constructive real trichotomy, LPO, WLPO, Markov's principle, host real equality, quotient stream equality, selected representatives, selected limits, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison classifier stability, apartness/equality handoff, refusal-ledger exactness, and non-escape for BEDC.Derived.ConstructiveRealTrichotomyBoundaryUp.

Chapter 6150

A Concrete Naming Certificate for $\mathsf{SeparableUltrametricSpace}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ packet records the finite NameCert data for an ultrametric space whose countable dense surface is available through displayed prefix windows. It sits after the countable-density route of chapter 1458, the strong-triangle surface of chapter 1535, the prefix geometry of chapter 3485, the Baire prefix carrier of chapter 334, and the finite name windows of chapter 126. The packet exposes separability and ultrametric comparison as one finite carrier, not as selected dense points, quotient stream equality, host metric equality, countable choice, or ambient completeness.

Definition 6150.1 (Separable ultrametric space carrier)**.** *A* $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (D, U, B, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense schedule row, recording the countable dense-name family and the finite request bounds inherited from the* $\mathsf{SeparableMetric}^{\uparrow}$ *route.*
2. *U is the ultrametric comparison row, recording parent metric reads together with the strong max-radius ledger inherited from* $\mathsf{UltrametricSpace}^{\uparrow}$*.*
3. *B is the Baire-prefix witness row, recording finite prefix cylinders and common-prefix witnesses consumed through* $\mathsf{BaireUltrametric}^{\uparrow}$ *and* $\mathsf{BaireSpace}^{\uparrow}$*.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite name coordinates inspected before a dense request or prefix comparison is accepted.*
5. *H records componentwise* hsame *transport for the dense schedule, ultrametric comparison, Baire-prefix witnesses, stream windows, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from dense requests to stream windows, from stream windows to ultrametric comparison, and from prefix witnesses to downstream Baire or completion-facing consumers.*
7. *P is the* Pkg *provenance over* $\mathsf{SeparableUltrametricSpace}^{\uparrow}$*,* $\mathsf{SeparableMetric}^{\uparrow}$*,* $\mathsf{UltrametricSpace}^{\uparrow}$*,* $\mathsf{BaireUltrametric}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparableUltrametricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, U, B, S, H, C, P, N. It contains no coordinate for choosing dense representatives from arbitrary balls, quotienting stream names, replacing the strong-triangle row by host metric equality, or importing ambient completeness.

Theorem 6150.2 (Separable ultrametric NameCert obligations)**.** *For every accepted* $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ *carrier*

$$X = (D, U, B, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparableUltrametricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the dense schedule, ultrametric comparison, Baire-prefix witnesses, finite stream windows, componentwise transport, displayed replay, provenance, and local naming rows. The certificate exports no selected dense point, quotient stream equality, host metric equality, countable choice, or ambient completeness principle.*

Proof. Project the carrier of Definition 6150.1. The analytic rows are D, U, B, S, while H, C, P, N preserve, replay, source, and name the same finite packet.

The dense schedule row D supplies only indexed dense-name data through the separable-metric route. The ultrametric row U supplies only displayed strong-triangle comparisons, and the prefix row B supplies only finite Baire-prefix witnesses.

The stream window row S is the common readback boundary. Every accepted dense request or prefix comparison must expose its inspected coordinates there before any downstream consumer reads the route.

Since the remaining rows only transport, replay, source, and name this packet, the listed rows exhaust the local NameCert surface and the excluded ambient objects have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.SeparableUltrametricSpaceUp.SeparableUltrametricSpaceTasteGate single carrier alignment`

Theorem 6150.3 (Separable ultrametric dependency obligations)**.** *Every accepted* $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ *packet reads its density, ultrametric, prefix, and stream-window evidence through*

$$\mathsf{SeparableMetric}^{\uparrow}, \quad \mathsf{UltrametricSpace}^{\uparrow}, \quad \mathsf{BaireUltrametric}^{\uparrow}, \quad \mathsf{BaireSpace}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}.$$

The route is finite and ordered by D, U, B, S, H, C, P, N: density requests pass through D and S, ultrametric comparisons pass through U and S, and Baire-prefix witnesses pass through B and S before the structural rows are consumed.

Proof. Read the dense schedule first. The row D is the only countable-density coordinate, so any separable-metric consumer must use the displayed request schedule rather than a selected dense point.

Read the ultrametric comparison next. The row U is the only strong-triangle coordinate, so ball and prefix comparisons cannot bypass the finite max-radius ledger.

Read the Baire-prefix and stream-window rows together. The row B names finite prefix witnesses and S names the inspected stream coordinates; these are the only rows from which a Baire ultrametric or Baire-space consumer can obtain prefix data.

Finally H, C, P, N preserve that dependency route without adding a second source. Thus the dependency surface is exactly the displayed sibling route. □

Theorem 6150.4 (Separable ultrametric dense-prefix transport)**.** *Let $X = (D, U, B, S, H, C, P, N)$ and $X' = (D', U', B', S', H', C', P', N')$ be accepted* $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ *carriers. If the dense schedules, ultrametric comparison rows, Baire-prefix witness rows, and finite stream windows transport componentwise under* hsame *and replay through displayed* Cont *routes, then every dense-prefix consumer of X and X' reads the same finite route through D, U, B, S and D', U', B', S' before provenance and local naming are consumed.*

Proof. Start with the NameCert obligations of Definition 6150.2. They identify the only readable analytic rows as D, U, B, S and their primed counterparts.

Use the dependency obligations of Definition 6150.3. Density, ultrametric comparison, Baire-prefix witnesses, and stream windows are already tied to the listed sibling routes before any structural row is inspected.

The componentwise hsame rows in H, H' transport those four analytic rows, and the displayed Cont rows in C, C' replay the same dense-prefix route. Provenance and local naming in P, N, P', N' then record the transported packet without adding selected representatives, quotient stream equality, host equality, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ read factors through the dense schedule, ultrametric comparison, Baire-prefix witness, StreamName window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before any consumer reads density or prefix geometry.

Independence witness: separablemetric, ultrametricspace, baire-ultrametric, bairespace, streamname: $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries countable-density scheduling, strong ultrametric comparison, Baire-prefix witnesses, finite stream windows, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparableUltrametricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparableUltrametricSpace}^{\uparrow}$ packet is generated from a dense schedule row, an ultrametric comparison row, Baire-prefix witness rows, finite StreamName windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparableUltrametricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6150.1, Definition 6150.2, Definition 6150.3, and Definition 6150.4 seed the finite separable-ultrametric route through dense schedules, strong ultrametric comparisons, Baire-prefix witnesses, and stream windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparableUltrametricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected dense representatives, quotient stream equality, host metric equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-schedule exactness, ultrametric comparison exactness, Baire-prefix witness coverage, stream-window readback, transport, replay, provenance, and local naming for BEDC.Derived.SeparableUltrametricSpaceUp.

Chapter 6151

A Concrete Naming Certificate for $\mathsf{FanTheoremBarModulus}^{\uparrow}$

Following Brouwer's fan theorem and Bishop–Bridges constructive uniform continuity, the $\mathsf{FanTheoremBarModulus}^{\uparrow}$ packet records the finite bar-modulus extraction route by which a decidable fan bar yields a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff. It sits over the finite fan certificate of chapter 400, the Bishop fan-modulus schedule of chapter 1707, the fan-modulus boundary of chapter 2379, the compact-uniform modulus carrier of chapter 2299, and the downstream consumer surface of chapter 369. The packet names only displayed finite bar coverage, local modulus rows, rational tolerance rows, and structural replay; it does not import open-cover compactness, countable choice, selected infinite branches, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6151.1 (Fan-theorem bar-modulus carrier)**.** *A* $\mathsf{FanTheoremBarModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, B, W, L, R, U, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite fan row, recording the binary prefix tree, decidable bar classifier, unary bar-depth ledger, and finite witness window.*
2. *B is the bar-coverage row, asserting that every admitted branch-prefix request enters the displayed bar before the depth named by F.*
3. *W is the finite window row that converts the bar-depth ledger into the prefix window inspected by compact-uniform and Cantor-space modulus consumers.*
4. *L is the local modulus ledger, listing the pointwise modulus rows attached to the finitely many retained prefixes or compact probes.*
5. *R is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row used to compare the local radii and to choose the tolerance-only precision exported downstream.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, exposing the extracted precision as a modulus ledger after F, B, W, L, R have all been displayed.*
7. *H records componentwise* hsame *transport for the fan, bar-coverage, window, local-modulus, rational-tolerance, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite extraction route*

$$F, B, W, L, R \longmapsto U.$$

9. *P is the* Pkg *provenance over* $\mathsf{FanTheoremBarModulus}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BishopFanModulus}^{\uparrow}$, FanModulusBoundary $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FanTheoremBarModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, B, W, L, R, U, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, a selected infinite branch, a selected subcover, quotient stream equality, a host modulus selector, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.FanTheoremBarModulusUp.FanTheoremBarModulusTasteGate single carrier alignment`

Theorem 6151.2 (Fan-theorem bar-modulus NameCert obligations)**.** *For every accepted* $\mathsf{FanTheoremBarModulus}^{\uparrow}$ *carrier $M = (F, B, W, L, R, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FanTheoremBarModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, finite fan-bar exposure through F, bar-coverage exactness through B, finite window extraction through W, local modulus exposure through L, positive rational tolerance accounting through R,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

In particular, every compact-uniform-continuity or finite fan consumer that extracts a uniform modulus from this packet must first read the finite fan row, the bar-coverage row, the finite window row, the local modulus ledger, and the rational tolerance row.

Proof. Project the carrier of Definition 6151.1. The projection lists exactly the finite fan, bar coverage, window, local modulus, rational tolerance, uniform-modulus, transport, replay, provenance, and local naming rows.

The fan and bar clauses are finite. The row F supplies the displayed tree, bar decisions, depth ledger, and witness window, while B states that branch-prefix requests meet the displayed bar before that depth. No selected branch or open cover is introduced.

The extraction clauses are W, L, R. The window row converts the bar depth into the finite family of inspected prefixes, the local modulus row attaches pointwise modulus data to that family, and the rational row stores the positive tolerance comparisons used to choose one exported precision.

Finally, U, H, C, P, N expose, transport, replay, source, and name the extracted precision as a $\mathsf{UniformModulus}^{\uparrow}$ handoff. Since the carrier has no coordinate for open-cover compactness, countable choice, selected branches, selected subcovers, quotient stream equality, host modulus selection, or ambient completeness, the stated obligations exhaust the packet. □

Theorem 6151.3 (Fan-theorem finite bar modulus extraction)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read of an accepted* $\mathsf{FanTheoremBarModulus}^{\uparrow}$ *carrier factors through*

$$F, B, W, L, R, U, H, C, P, N.$$

The exported precision is obtained only from the finite fan bar, its coverage row, the extracted prefix window, the local modulus ledger, and the positive rational tolerance ledger. The read cannot be replaced by open-cover compactness, a chosen infinite branch, a selected subcover, countable choice, quotient stream equality, a host modulus selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a $\mathsf{UniformModulus}^{\uparrow}$ read of the accepted packet. By Definition 6151.2, the read must first expose F, B, W, L, R.

The route is finite at each step. The fan theorem row bounds branch-prefix inspection by a unary depth, the coverage row certifies that the displayed bar is met within that depth, and the window row lists the prefixes that may be inspected.

The local modulus and rational tolerance rows then determine the exported precision. The finite family of local modulus rows is read through L, and the positive rational comparisons in R select the tolerance-only lower bound delivered to U.

The structural rows H, C, P, N preserve the same route under transport, continuation replay, provenance, and local naming. Because the tuple contains no stronger compactness, choice, quotient, branch-selection, subcover-selection, host-selector, or completeness coordinate, every $\mathsf{UniformModulus}^{\uparrow}$ read factors through exactly the displayed finite packet. □

Falsifiable prediction: Every accepted $\mathsf{FanTheoremBarModulus}^{\uparrow}$ uniform-modulus read factors through a finite FanTheorem row, bar-coverage row, finite window row, local modulus ledger, positive RatUp tolerance row, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: fantheorem, bishop-fan-modulus, fan-modulus-boundary, compact-uniform-modulus, uniformmodulus: $\mathsf{FanTheoremBarModulus}^{\uparrow}$ is not bijective to any listed sibling because it isolates the finite bar-coverage-to-tolerance extraction route before the UniformModulus handoff, while refusing open-cover compactness, choice, selected branches, selected subcovers, quotient stream equality, host modulus selectors, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{FanTheoremBarModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FanTheoremBarModulus}^{\uparrow}$ packet is generated from a finite FanTheorem row, bar-coverage exactness, finite window extraction, local modulus rows, positive RatUp tolerance accounting, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FanTheoremBarModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6151.1, Definition 6151.2, and Definition 6151.3 seed the finite fan-bar coverage route that extracts a tolerance-only UniformModulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FanTheoremBarModulus}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FanTheoremBarModulusUp.FanTheoremBarModulusTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected infinite branches, selected subcovers, quotient stream equality, host modulus selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bar-coverage exactness, finite window extraction, local modulus exposure, RatUp tolerance accounting, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FanTheoremBarModulusUp.

Chapter 6152

A Concrete Naming Certificate for $\mathsf{FanUniformContinuity}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FanUniformContinuity}^{\uparrow}$ packet records the constructive fan-based route from finite bars on Cantor space to uniform-modulus extraction. It consumes the Cantor-prefix surface of chapter 1475, the finite fan row of chapter 400, the tolerance handoff of chapter 391, the finite compact metric row of chapter 129, and the terminal real-name seal of chapter 38. The packet names only displayed finite prefix windows, decidable bar coverage, modulus rows, transport, replay, provenance, and local naming; it does not claim open-cover compactness, a selected branch, countable choice, quotient function equality, or ambient real completeness.

Definition 6152.1 (FanUniformContinuity carrier)**.** *A* $\mathsf{FanUniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (C, F, T, M, K, E, H, R, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *finite-prefix row, including Boolean prefix observations and retained branch-window data.*
2. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite fan row, recording the decidable bar classifier, finite bar-depth ledger, and witness window for the displayed binary spread.*
3. *T is the target tolerance row for the* $\mathsf{UniformContinuity}^{\uparrow}$ *consumer, read as displayed precision data rather than as a host real predicate.*
4. *M is the extracted modulus row, assigning one finite prefix depth sufficient for all retained Cantor histories at tolerance T.*
5. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-prefix coverage row used only as a displayed compact metric ledger for the Cantor-prefix surface.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for real-valued reads that consume the same modulus route.*
7. *H records componentwise* hsame *transport for the Cantor, fan, tolerance, modulus, compact metric, Real seal, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay of the finite route*

$$C, F, T, K \longmapsto M \longmapsto E.$$

9. *P is the* Pkg *provenance over* FanUniformContinuity$^\uparrow$, CantorSpace$^\uparrow$, FanTheorem$^\uparrow$, UniformContinuity$^\uparrow$, CompactMetric$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{FanUniformContinuity}^\uparrow}$ *row.*

The classifier compares accepted packets only through $C, F, T, M, K, E, H, R, P, N$. It has no coordinate for open-cover compactness, selected infinite branches, choice of bar witnesses, quotient equality of functions, selected real limits, or ambient Real$^\uparrow$ *completeness.*

Theorem 6152.2 (FanUniformContinuity NameCert obligations)**.** *For every accepted* FanUniformContinuity$^\uparrow$ *carrier $U = (C, F, T, M, K, E, H, R, P, N)$, the local* NameCert$_{\text{FanUniformContinuity}^\uparrow}$ *surface consists exactly of carrier admission, Cantor-prefix exposure through C, finite fan-bar exposure through F, tolerance accountability through T, modulus extraction through M, compact metric ledger exposure through K, Real-seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Every UniformContinuity$^\uparrow$ *or real-valued consumer of the packet must first read the displayed Cantor prefix row, finite fan row, tolerance row, and compact metric ledger before the modulus row or Real seal is exposed.*

Proof. Project the carrier of Definition 6152.1. The projection lists exactly the Cantor prefix, finite fan, tolerance, modulus, compact metric, Real seal, transport, replay, provenance, and local naming rows.

The fan-based step is finite. The FanTheorem$^\uparrow$ row supplies the decidable bar classifier and the finite bar-depth ledger, while the CantorSpace$^\uparrow$ row supplies the prefix windows over which the bar is inspected.

The modulus step reads T, K, M. The tolerance row fixes the requested precision, the compact metric row records only finite-prefix coverage, and the modulus row is extracted from those displayed rows before any downstream UniformContinuity$^\uparrow$ consumer can read it.

Finally E, H, R, P, N seal, transport, replay, source, and name the same finite route. Since the packet has no coordinate for open-cover compactness, selected branches, countable choice, quotient equality of functions, selected real limits, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: Every accepted FanUniformContinuity$^\uparrow$ consumer read factors through displayed CantorSpace, FanTheorem, UniformContinuity, CompactMetric, Real, BHist, hsame, Cont, Pkg, and NameCert rows before a uniform-modulus or Real-facing observation is exposed.

Independence witness: cantorspace, fantheorem, uniformcontinuity, compactmetric, real: FanUniformContinuity$^\uparrow$ is not bijective to any listed sibling because it jointly carries Cantor prefix windows, finite fan-bar depth, tolerance accountability, compact metric finite coverage, modulus extraction, Real sealing, transport, replay, provenance, and local naming while refusing open-cover compactness, selected branches, countable choice, quotient function equality, selected real limits, and ambient completeness.

Closure status for NameCert$_{\text{FanUniformContinuity}^\uparrow}$.

Constructive story: A FanUniformContinuity$^\uparrow$ packet is generated from CantorSpace finite-prefix rows, FanTheorem finite bar rows, a UniformContinuity tolerance row, a CompactMetric finite-prefix coverage row, an extracted modulus row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FanUniformContinuity}^\uparrow}$, seed)

Scope closed: Definition 6152.1 and Definition 6152.2 seed the finite fan-bar route from Cantor prefix inspection to uniform-modulus extraction and Real sealing.

Formal verification: FormalStatus(NameCert$_{\text{FanUniformContinuity}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected infinite branches, quotient function equality, selected real limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cantor-prefix exposure, finite fan-bar exposure, tolerance accountability, compact metric ledger exposure, modulus extraction, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.FanUniformContinuityUp.

Chapter 6153

A Concrete Naming Certificate for $\mathsf{DyadicToleranceComposition}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicToleranceComposition}^{\uparrow}$ packet records the finite epsilon-budget composition route used when two local tolerance handoffs must be chained before a downstream real-name or completion-facing consumer reads the final bound. It sits over the split-budget surface of chapter 1761, the scale discipline of chapter 1768, the triangle ledger of chapter 1211, the dyadic arithmetic core of chapter 291, the finite window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet gives diagonal, Cauchy, and completion routes a named finite tolerance-composition carrier rather than forcing each consumer to restate the same two-step budget handoff.

Definition 6153.1 (Dyadic tolerance-composition carrier)**.** *A* $\mathsf{DyadicToleranceComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, S_0, S_1, B_0, B_1, Q', W_0, W_1, R_0, R_1, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the request tolerance row presented to the downstream consumer before local budgets are inspected.*
2. *S_0 and S_1 are the two* $\mathsf{DyadicToleranceScale}^{\uparrow}$ *rows that expose the input and output precision scales for the two local tolerance stages.*
3. *B_0 and B_1 are the two local* $\mathsf{DyadicErrorBudget}^{\uparrow}$ *rows consumed by the first and second tolerance stages.*
4. *Q' is the composed tolerance row, recording the final dyadic request after the two scale and budget rows have been chained.*
5. *W_0 and W_1 are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows from which the two local reads are opened.*
6. *R_0 and R_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger recording the displayed dyadic sum, comparison slack, and final bound behind Q'.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the composed tolerance route has been displayed.*

9. *H records componentwise* hsame *transport for the request, two scale rows, two budget rows, composed tolerance row, windows, readbacks, dyadic arithmetic ledger, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from the request through the two scale rows, two local budgets, composed tolerance, windows, readbacks, dyadic ledger, and Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicToleranceComposition}^{\uparrow}$, $\mathsf{DyadicErrorBudget}^{\uparrow}$, $\mathsf{DyadicToleranceScale}^{\uparrow}$, $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicToleranceComposition}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, trichotomy, detached completion evidence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicToleranceCompositionUp.DyadicToleranceCompositionTasteGate single carrier alignment`

Theorem 6153.2 (Dyadic tolerance-composition NameCert obligations)**.** *For every accepted* DyadicToleranceComp *carrier $T = (Q, S_0, S_1, B_0, B_1, Q', W_0, W_1, R_0, R_1, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicToleranceComposition}^{\uparrow}}$ *surface consists exactly of carrier admission for the request tolerance, two scale rows, two local budget rows, composed tolerance row, stream windows, regular-rational readbacks, dyadic arithmetic ledger, Real seal, transport, replay, provenance, and local naming; scale-budget handoff exactness requiring S_0, B_0 and S_1, B_1 to be consumed in order; composed-tolerance exactness requiring Q' to be read through D; Real-seal compatibility requiring E to be downstream of the composed route; and nonescape excluding quotient streams, selected limits, host equality, countable choice, trichotomy, detached completion evidence, and ambient completeness.*

Proof. Carrier admission is projection from Definition 6153.1. The packet displays exactly the request row, the two scale rows, the two local budget rows, the composed tolerance row, the two windows, the two readbacks, the dyadic ledger, the Real seal, and the support rows.

Scale-budget handoff exactness is read from S_0, B_0 and S_1, B_1. The carrier gives each local stage one scale row and one budget row, so a consumer cannot insert an unrecorded tolerance stage between them.

Composed-tolerance exactness is the role of Q' and D. The final bound is visible only through the dyadic arithmetic ledger, which records the displayed sum and comparison slack before the Real seal is consumed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier omits quotient streams, host equality, selected limits, countable choice, trichotomy, detached completion evidence, and ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6153.3 (Dyadic tolerance-composition scale-budget handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *diagonal, Cauchy, or completion-facing consumer of an accepted* $\mathsf{DyadicToleranceComposition}^{\uparrow}$ *carrier must read the finite route*

$$Q \longmapsto S_0, B_0 \longmapsto S_1, B_1 \longmapsto Q', D \longmapsto W_0, W_1, R_0, R_1, E, H, C, P, N.$$

Thus the first local tolerance stage, the second local tolerance stage, and the composed dyadic bound are displayed before the Real seal is available.

Proof. Project the carrier and read the request row Q. The only local tolerance-stage rows attached to it are S_0, B_0 and S_1, B_1.

Use the sibling surfaces named in the carrier. The $\mathsf{DyadicToleranceScale}^{\uparrow}$ rows expose the precision scales, while the $\mathsf{DyadicErrorBudget}^{\uparrow}$ rows expose the two local budget consumptions.

The row D composes those local reads into the final row Q'. The stream windows and regular-rational readbacks W_0, W_1, R_0, R_1 then provide the finite observation route before E seals the real-name boundary.

Transport, replay, provenance, and local naming preserve the same order. Since no unrecorded scale, budget, selected limit, or completeness row is present, every listed consumer receives exactly this handoff. □

Theorem 6153.4 (Dyadic tolerance-composition nonescape)**.** *An accepted* $\mathsf{DyadicToleranceComposition}^{\uparrow}$ *carrier exports only the finite composition rows*

$$Q, S_0, S_1, B_0, B_1, Q', W_0, W_1, R_0, R_1, D, E, H, C, P, N.$$

It cannot export quotient stream equality, host real equality, selected limits, countable choice, trichotomy, detached completion evidence, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a hidden third tolerance stage.*

Proof. The carrier definition lists the full public inventory. Its analytic rows are the request tolerance, two scale rows, two local budget rows, composed tolerance, finite windows, regular-rational readbacks, dyadic arithmetic ledger, and Real seal.

The structural rows H, C, P, N only transport, replay, source, and name those analytic rows. They do not add a selector, quotient, host equality predicate, trichotomy decision, completion witness, or independent tolerance stage.

Therefore downstream diagonal, Cauchy, and completion routes must obtain any stronger principle from separate chapters after reading this packet. The $\mathsf{DyadicToleranceComposition}^{\uparrow}$ surface supplies only the displayed finite epsilon-budget composition route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicToleranceComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicToleranceComposition}^{\uparrow}$ packet is generated from one request tolerance, two DyadicToleranceScale rows, two DyadicErrorBudget rows, one composed tolerance row, two StreamName windows, two RegSeqRat readbacks, one DyadicRatCore arithmetic ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicToleranceComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6153.1, Definition 6153.2, Definition 6153.3, and Definition 6153.4 seed the finite epsilon-budget composition packet over two local tolerance stages and one composed Real-facing bound.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicToleranceComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, countable choice, trichotomy, detached completion evidence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{DyadicToleranceComposition}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, scale-budget handoff exactness, composed-tolerance exactness, stream-window readback, Real-seal compatibility, transport, replay, provenance, and local naming for BEDC.Derived.DyadicToleranceCompositionUp.

Chapter 6154

A Concrete Naming Certificate for $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$

Following Kuratowski's closure axioms and Kelley's topology language, the $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$ packet records a displayed closure operator by finite BEDC rows rather than by an ambient powerset primitive. It sits after the indexed-open topology surface of chapter 88, the membership discipline of chapter 3668, the metric closure route of chapter 3342, and the neighbourhood closure surface of chapter 3559. The packet names exactly the finite closure-law interface consumed by topology and metric-closure chapters; it does not import host subset extensionality, arbitrary powersets, selected closure witnesses, open-cover compactness, or ambient real completeness.

Definition 6154.1 (Kuratowski closure axiom carrier)**.** *A* $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, L, E, M, I, U, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the indexed open surface and classifier through which closed-neighbourhood requests are interpreted.*
2. *S is the* $\mathsf{SetLike}^{\uparrow}$ *subset row, recording membership, subset comparison, and classifier-respecting transport for the displayed source subset.*
3. *L is the closure row, assigning to each displayed subset row its displayed closure subset and the membership-read interface for that closure.*
4. *E is the extensivity row, requiring every displayed membership in the source subset to replay as membership in its closure.*
5. *M is the monotonicity row, requiring every displayed subset inclusion to transport to the corresponding displayed closure inclusion.*
6. *I is the idempotence row, requiring the closure of a displayed closure row to replay through the same closure membership route.*
7. *U is the finite-union and empty-compatibility row, carrying the displayed equality of the closure of a binary union with the binary union of closures and the displayed empty-closure boundary.*
8. *H records componentwise* hsame *transport for the topology source, subset row, closure row, the four closure-law rows, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a closure request through $T, S, L, E, M, I, U, H, P, N$ before any topology or metric-closure consumer reads the result.*
10. *P is the* Pkg *provenance over* $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{MetricClosure}^{\uparrow}$, $\mathsf{TopologicalClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiClosureAxiom}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, L, E, M, I, U, H, C, P, N$ and the displayed routes among those rows. It has no coordinate for a host powerset, an ambient closure primitive, subset extensionality outside the carrier, selected closure witnesses, open-cover compactness, countable choice, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.KuratowskiClosureAxiomUp.KuratowskiClosureAxiomTasteGate single carrier alignment`

Theorem 6154.2 (Kuratowski closure axiom NameCert obligations)**.** *For every accepted* $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$ *carrier*

$$K = (T, S, L, E, M, I, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KuratowskiClosureAxiom}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology source row, set-like subset row, closure row, extensivity row, monotonicity row, idempotence row, finite-union and empty-compatibility row, componentwise transport, displayed replay, provenance, and local naming. Every topology-facing or metric-closure-facing use of the packet must display those rows before it can treat a subset read as closure evidence.*

Proof. Project the carrier of Definition 6154.1. The source rows are T and S, the operation row is L, and the closure-law rows are E, M, I, U.

The law rows are finite certificate rows. Extensivity reads membership from S into L, monotonicity transports displayed subset inclusion through closure, idempotence replays the closure row through itself, and finite-union and empty compatibility provide the binary union and empty boundaries.

The structural rows H, C, P, N preserve the same finite packet by transport, continuation replay, provenance, and local naming. Since the carrier has no coordinate for host powersets, ambient closure primitives, external subset extensionality, selected witnesses, open-cover compactness, countable choice, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 6154.3 (Kuratowski closure topology handoff)**.** *Every accepted* $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$ *packet gives a topology handoff from displayed subset reads to displayed closure reads over the route*

$$T, S, L, E, M, I, U, H, C, P, N.$$

A $\mathsf{Topology}^{\uparrow}$, $\mathsf{MetricClosure}^{\uparrow}$, *or* $\mathsf{TopologicalClosure}^{\uparrow}$ *consumer may use the closure only after the topology source, set-like subset row, closure row, four Kuratowski law rows, componentwise transport, displayed replay, provenance, and local naming rows have been inspected. The handoff exports no host powerset, no ambient closure primitive, no selected closure point, no open-cover compactness theorem, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with the topology source row T and the subset row S. They determine the displayed carrier, classifier, membership reads, and subset comparisons available to a closure consumer.

Next read the closure row L together with the four law rows. The rows E, M, I, U are exactly the Kuratowski closure axioms as displayed BEDC obligations: source membership enters closure,

inclusion is preserved by closure, closure is idempotent, binary unions commute with closure, and the empty subset has the displayed boundary row.

Finally replay the structural rows. The hsame transport row H and Cont row C keep the topology, subset, closure, and law rows aligned under presentation change, while P and N source and name the packet for downstream consumers.

Thus the topology and metric-closure handoff is precisely the displayed finite route. No excluded host powerset, ambient closure primitive, selected closure witness, open-cover compactness result, or ambient Real completeness claim is available from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$ topology or metric-closure read factors through a Topology source row, SetLike subset row, closure row, extensivity row, monotonicity row, idempotence row, finite-union and empty-compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: topology, setlike, metric-closure, topological-closure: $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a displayed closure operator and the four Kuratowski law rows over one topology and subset interface, while each sibling supplies only the topology, membership, metric-closure, or neighbourhood-closure part of the route.

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiClosureAxiom}^{\uparrow}}$.

Constructive story: A $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$ packet is generated from a Topology source row, SetLike subset row, closure row, extensivity, monotonicity, idempotence, finite-union and empty compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiClosureAxiom}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6154.1, Definition 6154.2, and Definition 6154.3 seed the finite closure-operator route consumed by topology, metric-closure, and topological-closure packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiClosureAxiom}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets, ambient closure primitives, external subset extensionality, selected closure witnesses, open-cover compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closure-row exactness, extensivity, monotonicity, idempotence, finite-union and empty compatibility, transport, replay, provenance, and local naming for BEDC.Derived.KuratowskiClosureAxiom

Chapter 6155

A Concrete Naming Certificate for $\mathsf{ClusterFilter}^{\uparrow}$

Following Kelley, Bourbaki, and Bishop-style filter convergence, the $\mathsf{ClusterFilter}^{\uparrow}$ packet records the finite interface by which a displayed filter base can be read as clustering around a point or completion boundary. It sits after the Cauchy-filter surface of chapter 333, the metric-space carrier of chapter 4230, the topology carrier of chapter 88, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter supplies a standard cluster-filter neighbor for completion and compactness arguments without importing host powersets, selected adherent points, quotient filters, countable choice, or ambient completeness.

Definition 6155.1 (ClusterFilter carrier)**.** *A* $\mathsf{ClusterFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, M, T, W, R, E, A, H, C, P, N)$$

with the following displayed rows:

1. *F is the visible* $\mathsf{CauchyFilter}^{\uparrow}$ *row naming the finite filter-base requests, directed refinements, and Cauchy-readiness data that may be inspected by a completion consumer.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row recording the distance observations and metric-law ledger used by every ball-neighborhood request.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *row recording the neighbourhood reads through which clustering is observed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when the filter is probed by sequential or net-shaped observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance-readback row attached to the windows and metric requests.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal read after the filter, metric, topology, window, and tolerance rows have all been displayed.*
7. *A is the adherent-observation row. It records that every displayed neighbourhood request compatible with T has a displayed filter event in F whose metric tolerance is read through M, R, E.*
8. *H records componentwise* hsame *transport for the filter, metric, topology, window, tolerance, real-seal, adherent-observation, and structural rows.*

9. *C records displayed* Cont *replay from filter-base refinement to neighbourhood observation, from metric tolerance to regular rational readback, and from the adherent row to the real-seal and completion-facing handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{ClusterFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClusterFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, M, T, W, R, E, A, H, C, P, N$ and the displayed routes among those rows. There is no coordinate for a host powerset of neighbourhoods, a selected cluster point, quotient equality of filters, a maximal filter, countable choice, or an ambient completion theorem.

The W and R rows consume the finite-prefix observation boundary of chapter 7253: before any $\mathsf{ClusterFilter}^{\uparrow}$ read can reach the $\mathsf{Real}^{\uparrow}$ seal row E, the displayed stream prefix and its regular rational readback are already confined to the $\mathsf{FinitePrefixStream}^{\uparrow}$ window surface.

Lean4 ✓ `BEDC.Derived.ClusterFilterUp.ClusterFilterUpTasteGate single carrier alignment`

Theorem 6155.2 (ClusterFilter NameCert obligations)**.** *For every accepted* $\mathsf{ClusterFilter}^{\uparrow}$ *carrier*

$$G = (F, M, T, W, R, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClusterFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy-filter exposure through F, metric-space exposure through M, topology-neighbourhood exposure through T, finite window exposure through W, regular rational readback through R, real-seal readiness through E, adherent-observation exposure through A, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ClusterFilterUp.ClusterFilterCarrier namecert obligations`

Proof. Project the carrier of Definition 6155.1. The rows F, M, T, W, R, E, A are the only mathematical rows available to a cluster-filter read, and H, C, P, N are the only structural rows.

The filter and neighbourhood rows are read first. The row F supplies finite base requests and refinements, while T supplies only displayed neighbourhood observations over the metric carrier M.

The observation row then binds clustering to finite tolerance data. The row A can cite only the displayed filter events, neighbourhood requests, stream windows, regular rational tolerances, and real seal already present in F, M, T, W, R, E.

Finally H, C, P, N transport, replay, source, and name that same route. Since the excluded host powerset, selected cluster point, quotient filter, maximal filter, countable-choice schedule, and ambient completion theorem are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6155.3 (ClusterFilter Cauchy-completion handoff)**.** *Every Cauchy-completion-facing consumer of an accepted* $\mathsf{ClusterFilter}^{\uparrow}$ *packet must read the displayed route*

$$\mathsf{CauchyFilter}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Topology}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the carrier rows F, M, T, W, R, E before it may use the adherent-observation row A as cluster-filter evidence. The handoff supplies a finite cluster interface for completion and compactness arguments; it supplies no selected cluster point, quotient filter, host powerset of neighbourhoods, maximal-filter principle, countable choice, ambient compactness theorem, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.ClusterFilterUp.ClusterFilterCarrier cauchy completion handoff`

Proof. Start with the displayed Cauchy-filter row F. A completion-facing consumer can inspect only the finite filter-base requests and directed refinements carried by that row.

Next read the metric, topology, and window rows. The metric-space row M supplies distance observations, the topology row T supplies neighbourhood requests, and the stream row W gives the finite observation windows through which those requests are probed.

The tolerance and real-seal rows are downstream. The row R records the regular rational readback for each displayed request, and E seals the Real-facing tolerance only after the filter, metric, topology, and window data have been displayed.

Only then can the adherent-observation row A be consumed as cluster-filter evidence. The structural rows H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming, so no excluded choice, quotient, host-powerset, compactness, or completeness principle can enter the handoff. □

Falsifiable prediction: Every accepted $\mathsf{ClusterFilter}^{\uparrow}$ completion-facing read factors through a CauchyFilter row, MetricSpace row, Topology neighbourhood row, StreamName finite-window row, RegSeqRat tolerance row, Real seal, adherent-observation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: cauchyfilter, metric-space, topology, streamname, regseqrat, real: $\mathsf{ClusterFilter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a visible filter row, metric-space row, topology-neighbourhood row, finite observation windows, rational tolerance readback, real seal, and adherent-observation route.

Closure status for $\mathsf{NameCert}_{\mathsf{ClusterFilter}\uparrow}$.

Constructive story: A $\mathsf{ClusterFilter}^{\uparrow}$ packet is generated from a CauchyFilter row, MetricSpace row, Topology neighbourhood row, StreamName finite-window row, RegSeqRat tolerance row, Real seal, adherent-observation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClusterFilter}\uparrow}$, seed)

Scope closed: Definition 6155.1, Definition 6155.2, and Definition 6155.3 seed the finite cluster-filter interface consumed by Cauchy-completion and compactness routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClusterFilter}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected cluster points, quotient filters, host powersets of neighbourhoods, maximal filters, countable choice, ambient compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-filter exposure, metric-space exposure, topology-neighbourhood exposure, finite-window exposure, tolerance readback, real-seal readiness, adherent-observation nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ClusterFilterUp.

Chapter 6156

A Concrete Naming Certificate for RiemannIntegralCompletionModulus$^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the RiemannIntegralCompletionModulus$^{\uparrow}$ packet records the finite modulus route by which integration evidence becomes regular-rational and real-name readback data. It sits after the Darboux-gap evidence of chapter 1960, the tagged-gauge window surface of chapter 4115, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the reusable finite interface between integrability evidence and completion-facing reads; it does not supply a host limit, quotient equality of integrands, selected partitions, measure completion, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 6156.1 (Riemann integral completion-modulus carrier)**.** *A* RiemannIntegralCompletionModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, G, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* RiemannIntegrable$^{\uparrow}$ *row carrying Darboux-gap evidence for the inspected integrand and interval.*
2. *G is the* RiemannSumGauge$^{\uparrow}$ *row carrying tagged windows, gauge radii, mesh comparisons, and finite Riemann-sum reads.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row that records the displayed precision request, comparison slack, and dyadic bound used by the completion-facing read.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed integrability, tagged-gauge, and dyadic tolerance rows.*
5. *E is the terminal* Real$^{\uparrow}$ *seal reached only after the regular-rational readback row is public.*
6. *H records componentwise* hsame *transport for the integrability row, tagged-gauge row, dyadic tolerance row, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the integrability evidence through tagged windows, dyadic tolerance, regular readback, and Real seal.*
8. *P is the* Pkg *provenance over* RiemannIntegralCompletionModulus$^{\uparrow}$, RiemannIntegrable$^{\uparrow}$, RiemannSumGauge$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}}$ *row.*
The classifier reads accepted carriers only through $I, G, D, R, E, H, C, P, N$. It has no coordinate for host limits, quotient equality of integrands, selected partition families, measure completion, countable choice, detached integral representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6156.2 (Riemann integral completion-modulus NameCert obligations)**.** *For every accepted carrier*

$$M = (I, G, D, R, E, H, C, P, N)$$

of Definition 6156.1, the local $\mathsf{NameCert}_{\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *gap row,* $\mathsf{RiemannSumGauge}^{\uparrow}$ *tagged-window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming; gap-to-window compatibility requiring G to read the integrability evidence displayed by I; tolerance exactness requiring D to mediate every completion-facing precision request before R is read; Real-seal compatibility requiring E to be downstream of R; and nonescape excluding host limits, quotient integrand equality, selected partition families, measure completion, countable choice, detached integral representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RiemannIntegralCompletionModulusUp.RiemannIntegralCompletionModulusTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 6156.1. The packet displays exactly one integrability row, one tagged-gauge row, one dyadic tolerance row, one regular-rational readback, one Real seal, and the structural rows.

Gap-to-window compatibility is read from I and G. The integrability row supplies the finite Darboux-gap evidence, while the tagged-gauge row supplies only the windows and mesh comparisons attached to that evidence.

Tolerance exactness is the role of D. A completion-facing precision request reaches the regular readback row R only after the dyadic bound and comparison slack have been displayed.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier omits host limits, quotient integrand equality, selected partition families, measure completion, countable choice, detached representatives, and ambient completeness, the listed clauses exhaust the local NameCert surface. □

Theorem 6156.3 (Riemann integral completion-modulus handoff)**.** *Every completion-facing integration read of an accepted* $\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RiemannIntegrable}^{\uparrow} \longmapsto \mathsf{RiemannSumGauge}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the read exports only the finite rows $I, G, D, R, E, H, C, P, N$ and cannot export a host limit, quotient equality of integrands, selected partition family, measure completion, countable choice, detached integral representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a completion-facing integration read. The only source row available to it is the integrability row I, which displays Darboux-gap evidence before any tagged window or regular readback is inspected.

The next analytic row is G. It exposes tagged windows, gauge radii, mesh comparisons, and finite Riemann-sum reads, but it does not select a partition family or identify integrands by quotient equality.

The dyadic row D then mediates the precision request. Only after this displayed tolerance read may the carrier expose the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Transport, replay, provenance, and local naming preserve the same order through H, C, P, N. Because no omitted object is present as a carrier coordinate, every accepted completion-facing read factors through the displayed finite route and exports nothing beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}$ packet is generated from a RiemannIntegrableUp Darboux-gap row, a RiemannSumGaugeUp tagged-window row, a DyadicRatCoreUp tolerance row, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6156.1, Definition 6156.2, and Definition 6156.3 seed the finite integration-modulus route from integrability evidence through tagged windows, dyadic tolerance, regular readback, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RiemannIntegralCompletionModulusUp.RiemannIntegralCompletionModulusTasteGate\_single\_c`

Bridge status: none

Not claimed: This chapter does not close host limits, quotient equality of integrands, selected partition families, measure completion, countable choice, detached integral representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked gap-to-window compatibility, tolerance exactness, RegSeqRat readback, Real-seal compatibility, transport, replay, provenance, and local naming beyond the carrier-alignment theorem.

Chapter 6157

A Concrete Naming Certificate for $\mathsf{FellTopology}^{\uparrow}$

Following Fell and Kelley, the $\mathsf{FellTopology}^{\uparrow}$ packet records the finite lower-hit and compact-miss topology read on closed-subset hyperspace names. It sits over the compact-subset and closed-subset surface of chapter 1660, compares its hit/miss classifiers with the Vietoris carrier of chapter 2375, and exposes only the compact metric source rows needed by downstream convergence consumers. The packet is a BEDC NameCert for a hyperspace-facing topology object; it is not a host powerset topology, not a selected closed set, not an ambient quotient of closed subsets, and not an open-cover compactness principle.

Definition 6157.1 (Fell topology carrier)**.** *A* $\mathsf{FellTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (H, L, U, V, K, W, S, C, P, N)$$

with the following displayed rows:

1. *H is the displayed closed-subset hyperspace source. It reads every closed-subset request through the finite* $\mathsf{Hyperspace}^{\uparrow}$ *carrier before a topology consumer can inspect it.*
2. *L is the lower-hit witness row. It records finite windows showing that a displayed closed-subset name hits a displayed open probe row.*
3. *U is the upper compact-miss finite-cover witness row. It records compact source data, a displayed compact test row, and a finite cover certificate showing that the inspected closed-subset name misses that compact row.*
4. *V is the* $\mathsf{VietorisTopology}^{\uparrow}$ *comparison row. It records the overlap with the finite Vietoris hit/miss surface and marks which compact-miss reads are Fell-specific.*
5. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the* $\mathsf{Met}^{\uparrow}$ *distance witnesses and finite-net schedules on which the compact miss tests are evaluated.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to replay closed-subset names, compact tests, and hit witnesses through a bounded inspection surface.*
7. *S is componentwise* hsame *transport for H, L, U, V, K, W.*
8. *C records displayed* Cont *replay of the route*

$$H, L, U, V, K, W, S \longmapsto \mathsf{FellTopology}^{\uparrow}.$$

9. *P is the* Pkg *provenance over* $\mathsf{FellTopology}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FellTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, L, U, V, K, W, S, C, P, N$. It has no coordinate for a host powerset of closed subsets, selected closed-set representatives, ambient subset equality, quotient hyperspaces, or open-cover compactness.

Lean4 ✓ `BEDC.Derived.FellTopologyUp.FellTopologyTasteGate single carrier alignment`

Theorem 6157.2 (FellTopologyUp NameCert obligations)**.** *For every accepted* $\mathsf{FellTopology}^{\uparrow}$ *carrier*

$$F = (H, L, U, V, K, W, S, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FellTopology}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the closed-subset hyperspace source, lower-hit witnesses, upper compact-miss finite-cover witnesses, Vietoris comparison row, compact metric source, stream-name finite windows, transport row, replay row, provenance row, and local naming row;*

2. *hit and miss classifier stability, requiring the lower-hit row L and compact-miss row U to be transported through the same* BHist *route before their tests are compared;*

3. *compact-source exposure, requiring every compact miss test to reveal the* $\mathsf{CompactMetric}^{\uparrow}$ *source and the* $\mathsf{Met}^{\uparrow}$ *distance witnesses carried by K;*

4. *componentwise* hsame *transport through S for all topology-facing rows;*

5. *displayed* Cont *replay through C for the accepted hit/miss inspection route;*

6. Pkg *provenance through P for every dependency named by the carrier;*

7. *ledger nonescape through N, excluding host powersets, selected closed-set representatives, ambient subset equality, quotient hyperspaces, and open-cover compactness.*

No Fell topology obligation is stored outside these rows.

Theorem 6157.3 (Fell topology hyperspace handoff)**.** *Every* $\mathsf{FellTopology}^{\uparrow}$ *read from an accepted carrier $F = (H, L, U, V, K, W, S, C, P, N)$ factors through* $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *before any closed-set topology consumer can inspect it. The consumer receives only the displayed closed-subset hyperspace source, finite lower-hit windows, compact-miss finite-cover witnesses, compact metric source data, stream-name finite windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Proof. Start with the carrier coordinates of Definition 6157.1. A closed-set topology consumer can enter only through H, and H is already a displayed $\mathsf{Hyperspace}^{\uparrow}$ source row.

The topology classifier then splits into the lower-hit witnesses L and the compact-miss finite-cover witnesses U. The comparison row V records the shared Vietoris hit/miss part, while K supplies the $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ data needed for the compact miss tests.

It remains to account for finite inspection. The row W bounds the closed-subset names, compact tests, and hit witnesses by $\mathsf{StreamName}^{\uparrow}$ windows. Transport through S, replay through C, packaging through P, and local naming through N preserve that route and add no host powerset, selected closed-set representative, quotient hyperspace, or ambient subset equality coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{FellTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{FellTopology}^{\uparrow}$ packet is generated from a closed-subset hyperspace source, lower-hit witnesses, compact-miss finite-cover witnesses, Vietoris comparison, CompactMetric and Metric source rows, StreamName finite windows, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FellTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6157.1, Definition 6157.2, and Definition 6157.3 seed the finite Fell hit and compact-miss topology surface over Hyperspace, VietorisTopology, CompactMetric, Metric, StreamName, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FellTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host powersets, selected closed-set representatives, ambient subset equality, quotient hyperspaces, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, hit and compact-miss classifier stability, compact-source exposure, stream-window replay, transport, provenance, local naming, and ledger nonescape for BEDC.Derived.FellTopologyUp

Chapter 6158

A Concrete Naming Certificate for $\mathsf{HeatKernel}^{\uparrow}$

Following Evans and Friedman on heat kernels and Bishop–Bridges constructive analysis, the $\mathsf{HeatKernel}^{\uparrow}$ packet records only the finite kernel-window surface inspected by BEDC consumers. It is adjacent to the finite heat-equation stencil of chapter 3652: the stencil sibling names displayed difference rows, while this chapter names the finite kernel-window packet that a downstream $\mathsf{Pde}^{\uparrow}$ consumer may inspect after the kernel source, semigroup row, rational readback, $\mathsf{Real}^{\uparrow}$ seal, hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row have all been displayed. The packet uses $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ anchors for finite readback and tolerance discipline; it does not export global analytic heat-kernel existence, a host integral kernel, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6158.1 (HeatKernel carrier)**.** *A* $\mathsf{HeatKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, S, G, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the inspected kernel-window row, listing the finite time windows, spatial windows, boundary tags, and dyadic tolerances requested by the consumer.*
2. *S is the finite heat-equation stencil source row, linked to the* $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$ *sibling and exposing only displayed source, mesh, time-step, and boundary reads.*
3. *G is the semigroup-composition row, recording the finite pair of kernel windows and the displayed intermediate-window budget used to compose them.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every kernel value, intermediate value, and stencil value inspected by W, S, G.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows have been read.*
6. *H records componentwise* hsame *transport for W, S, G, Q, R, C, P, N and for the local certificate rows.*
7. *C records displayed* Cont *replay from the requested kernel windows through source-stencil, semigroup, readback, and real-seal rows.*

8. *P is the* Pkg *provenance over* $\mathsf{HeatKernel}^{\uparrow}$, $\mathsf{HeatEquationFiniteStencil}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{HeatKernel}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, S, G, Q, R, H, C, P, N$. It has no coordinate for global analytic kernel existence, host integral operators, function-space quotient equality, selected infinite partitions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6158.2 (HeatKernel NameCert obligations)**.** *For an accepted* $\mathsf{HeatKernel}^{\uparrow}$ *carrier $K = (W, S, G, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeatKernel}^{\uparrow}}$ *surface consists exactly of carrier admission, kernel-window admission, finite stencil-source admission, semigroup-row exactness, regular rational readback, real-seal nonescape, componentwise transport, displayed continuation replay, provenance, and local naming. These obligations are discharged along the finite route*

$$W, S, G \longmapsto Q \longmapsto R$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.HeatKernelUp.HeatKernelTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 6158.1. The projection exposes the inspected kernel windows, finite stencil source, semigroup row, readback row, real seal, transport rows, replay rows, provenance row, and local name.

The kernel-window and stencil-source obligations are W and S. The row W contains only the finite time, spatial, boundary, and tolerance windows that the consumer requested, and S routes those requests through the displayed finite heat-equation stencil surface of chapter 3652.

The semigroup obligation is G. It records the finite pair of kernel windows, the displayed intermediate-window budget, and the requested composition row; it is not an integral over a host continuum and does not select an infinite partition.

The readback and seal obligations are downstream. The row Q reads the displayed values through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$, and R exposes the $\mathsf{Real}^{\uparrow}$ seal only after those finite rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no row for global analytic kernel existence, host integral operators, quotient function equality, selected infinite partitions, countable choice, or ambient real completeness, the listed rows exhaust the local certificate surface. □

Theorem 6158.3 (HeatKernel semigroup handoff)**.** *Every* $\mathsf{Pde}^{\uparrow}$ *consumer of an accepted* $\mathsf{HeatKernel}^{\uparrow}$ *packet reaches a semigroup-composition read only through*

$$\mathsf{HeatEquationFiniteStencil}^{\uparrow} \longmapsto \mathsf{HeatKernel}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside the displayed finite window package. The consumer receives no global fundamental solution, host integral kernel, quotient equality of functions, countable-choice schedule, selected limiting partition, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with the finite stencil-source row S. It names the source, mesh, time-step, and boundary data that the sibling chapter 3652 exposes, so the $\mathsf{Pde}^{\uparrow}$ consumer cannot read a kernel row detached from the finite heat-equation source.

Next read the inspected kernel windows W and the semigroup row G. The handoff composes only the displayed pair of windows over the displayed intermediate-window budget, with every requested value still recorded as a finite row.

The route then passes through $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and terminal $\mathsf{Real}^{\uparrow}$ seal R, while H, C, P, N preserve the same packet under transport, replay, provenance, and local naming. Because the excluded analytic objects are absent from the carrier, every semigroup handoff remains a finite NameCert route rather than a claim of global heat-kernel existence. □

Falsifiable prediction: An accepted $\mathsf{HeatKernel}^{\uparrow}$ consumer that reaches a $\mathsf{Pde}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed kernel windows, finite heat-equation stencil source, semigroup-composition row, $\mathsf{Cauchy}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ schedules, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: heat-equation-finite-stencil, pde, regseqrat, real, cauchy, streamname, dyadicratcore: no listed sibling supplies the whole heat-kernel packet $K = (W, S, G, Q, R, H, C, P, N)$, because each sibling contributes only a stencil source, PDE consumer interface, rational readback, real seal, Cauchy discipline, stream schedule, or dyadic tolerance ledger while this chapter binds them into one finite semigroup-window route and local naming surface.

Closure status for $\mathsf{NameCert}_{\mathsf{HeatKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{HeatKernel}^{\uparrow}$ packet is generated from inspected kernel windows, a finite heat-equation stencil source row, a semigroup-composition row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeatKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6158.1, Definition 6158.2, and Definition 6158.3 seed the finite heat-kernel window boundary over finite stencil sources, semigroup-composition rows, $\mathsf{Pde}^{\uparrow}$ consumers, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Cauchy}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ schedules, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeatKernel}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HeatKernelUp.HeatKernelTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim global analytic heat-kernel existence, host integral kernels, quotient equality of functions, selected infinite partitions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked semigroup-row exactness, regular rational readback, real-seal nonescape, transport, replay, provenance, and local naming beyond the carrier-alignment theorem.

Chapter 6159

A Concrete Naming Certificate for $\mathsf{OsgoodCriterion}^{\uparrow}$

Following Osgood and Bishop–Bridges constructive analysis, the $\mathsf{OsgoodCriterion}^{\uparrow}$ packet records the finite criterion surface by which an ODE uniqueness request reads a divergence modulus before it may be handed to a Picard–Lindelof or Real-facing consumer. It sits beside the ODE source of chapter 193, the Picard–Lindelof handoff of chapter 1888, the Gronwall comparison surface of chapter 2034, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the criterion row that a uniqueness proof consumes; it is not a Lipschitz constant, not a Banach contraction theorem, not a selected solution curve, and not quotient equality of flows.

Definition 6159.1 (OsgoodCriterion carrier)**.** *An* $\mathsf{OsgoodCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, I, V, M, B, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Ode}^{\uparrow}$ *source row, carrying the time-state window, differential-equation request, and local solution-read boundary.*
2. *I is the common initial-data row read by the two solution traces whose equality is being tested.*
3. *V is the displayed vector-field continuity row on the same ODE window.*
4. *M is the Osgood modulus row, listing positive rational radii and the monotone comparison schedule used by the criterion.*
5. *B is the finite divergence-budget ledger for the reciprocal-modulus comparison; it records the checked lower windows rather than a host improper integral.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare radii, distances, reciprocal-modulus budgets, and finite error envelopes.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the solution-distance traces inspected by the criterion.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after D, I, V, M, B, Q, R have been displayed.*
9. *H records componentwise* hsame *transport for $D, I, V, M, B, Q, R, E, C, P, N$.*
10. *C records displayed* Cont *replay from the Osgood criterion request through the ODE, initial-data, vector-field, modulus, budget, dyadic, regular-rational, and Real-seal rows.*

11. *P is the* Pkg *provenance over* $\mathsf{OsgoodCriterion}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{OsgoodCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, I, V, M, B, Q, R, E, H, C, P, N$. It has no coordinate for a Lipschitz constant, contraction ratio, selected solution representative, host improper integral, quotient equality of curves, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.OsgoodCriterionUp.TasteGate.OsgoodCriterionTasteGate single carrier alignment`

Theorem 6159.2 (OsgoodCriterion NameCert obligations)**.** *For every accepted* $\mathsf{OsgoodCriterion}^{\uparrow}$ *carrier*

$$K = (D, I, V, M, B, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OsgoodCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, ODE-window visibility through D, common initial-data visibility through I, vector-field continuity visibility through V, Osgood modulus admission through M, finite divergence-budget exactness through B, dyadic tolerance exactness through Q, regular rational distance readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

These obligations bind the criterion route without adding a Lipschitz constant, Banach contraction, host Gronwall inequality, selected solution representative, quotient equality of curves, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6159.1. The displayed rows $D, I, V, M, B, Q, R, E, H, C, P, N$ are the whole local surface, so carrier admission is exactly admission of those rows.

The ODE and initial data are read before the criterion is inspected. The row D fixes the local differential-equation window, while I fixes the common initial point for the two compared solution traces.

The criterion rows are then forced in order. The vector-field row V supplies continuity on the displayed window, M supplies the Osgood modulus schedule, and B supplies only finite reciprocal-modulus budget checks. The dyadic row Q and regular readback row R turn those checks into displayed distance comparisons.

Finally the Real seal and structural rows expose no extra analytic object. Since the carrier has no coordinate for a Lipschitz constant, contraction ratio, host improper integral, host Gronwall theorem, selected solution, quotient curve equality, countable-choice schedule, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 6159.3 (OsgoodCriterion Picard handoff)**.** *Every Picard–Lindelof or ODE-uniqueness consumer of an accepted* $\mathsf{OsgoodCriterion}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Ode}^{\uparrow},\ \mathsf{PicardLindelof}^{\uparrow},\ \mathsf{GronwallInequality}^{\uparrow},\ M,\ B,\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as displayed by Definition 6159.1. The route hands a divergence-modulus criterion to the downstream uniqueness read; it does not export a Lipschitz constant, a contraction certificate, a selected solution curve, a host integral theorem, or quotient equality between flows.

Proof. Start with a Picard-facing uniqueness request. The only ODE source available in the carrier is D, and the only common initial-data coordinate is I, so the consumer is already confined to the displayed local ODE window.

Read the comparison surface next. The Picard–Lindelof and Gronwall neighbours named in the provenance can consume the packet only after the vector-field row V, modulus row M, finite budget row B, dyadic row Q, and regular readback row R have been displayed.

The handoff reaches the Real seal E only through those rows and the structural transport, replay, provenance, and naming rows. Therefore the consumer receives the stated finite criterion route and cannot replace it by a Lipschitz hypothesis, a contraction theorem, a host integral principle, a selected solution representative, or quotient equality of solution curves. □

Falsifiable prediction: Every accepted $\mathsf{OsgoodCriterion}^{\uparrow}$ uniqueness read that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ distance readback or $\mathsf{Real}^{\uparrow}$ seal displays the rows $D, I, V, M, B, Q, R, E, H, C, P, N$ first.

Independence witness: ode, picard-lindelof, gronwall-inequality, osgood-uniqueness, regseqrat, dyadicratcore, real: no listed sibling supplies the joint criterion packet containing an ODE source, common initial data, vector-field continuity row, Osgood modulus schedule, finite divergence-budget ledger, dyadic tolerance arithmetic, regular distance readback, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{OsgoodCriterion}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OsgoodCriterion}^{\uparrow}$ packet is generated from an ODE source row, common initial data, a vector-field continuity row, an Osgood modulus schedule, finite divergence-budget checks, DyadicRatCore tolerance arithmetic, RegSeqRat distance readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OsgoodCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6159.1, Definition 6159.2, and Definition 6159.3 seed the finite Osgood criterion route from displayed ODE data through Picard, Gronwall, modulus-budget, dyadic, regular-rational, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OsgoodCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, Lipschitz uniqueness, Banach contraction, selected solution representatives, quotient equality of curves, countable choice, host improper-integral theorems, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, ODE-window visibility, common initial-data visibility, vector-field readback, Osgood modulus admission, divergence-budget exactness, dyadic tolerance exactness, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.OsgoodCriterionUp.

Chapter 6160

A Concrete Naming Certificate for $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ packet records the finite NameCert bridge by which regular Cauchy data are reflected into the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits over the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the source-to-completion entry route of chapter 1934. The packet names only finite windows, tolerance rows, regular readback, reflection transport, replay, provenance, and local naming; it does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of real names, selected limits, countable choice, or a public bridge theorem.

Definition 6160.1 (Cauchy reflective embedding carrier)**.** *A* $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, S, Q, D, E, J, H, T, P, N)$$

with the following displayed rows:

1. *C is the regular Cauchy input row, displaying the finite regularity data requested by the consumer.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the Cauchy data are observed before any real seal is read.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the displayed windows into regular rational data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling each requested comparison window.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Q, D have been displayed.*
6. *J is the* $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$ *entry row that records the source-to-completion handoff consumed by completion-facing readers.*
7. *H records componentwise* hsame *transport for the regular Cauchy input, window, readback, dyadic ledger, Real seal, completion-entry, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay for consumers that inspect the regular Cauchy input, its reflected Real seal, or the completion-entry row.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyReflectiveEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of real names, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable-choice schedules, host equality, or bridge credentials.*

Theorem 6160.2 (Cauchy reflective embedding NameCert obligations)**.** *For an accepted* CauchyReflectiveEmbeddi *carrier $R = (C, S, Q, D, E, J, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyReflectiveEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission, regular Cauchy input exposure, finite stream-window locality, regular-rational readback, dyadic tolerance exactness, terminal* $\mathsf{Real}^{\uparrow}$ *handoff, completion-entry handoff through J, componentwise transport, displayed replay, provenance accounting, and local naming.*

Proof. Project the carrier of Definition 6160.1. Its analytic rows are the regular Cauchy input C, window row S, readback row Q, dyadic tolerance ledger D, terminal Real seal E, and completion-entry row J.

The finite observation route is ordered. A consumer must read the window row S before the regular readback Q and dyadic ledger D are available, and the Real seal E is downstream of those displayed rows.

The completion-facing handoff is equally explicit. The row J is the only coordinate that connects the reflected Real-facing data to the source-to-completion entry route of chapter 1934.

The rows H, T, P, N preserve and name the same route. Since no carrier coordinate contains quotient equality, selected limits, ambient completeness, countable choice, host equality, or bridge credentials, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyReflectiveEmbeddingUp.TasteGate.CauchyReflectiveEmbeddingTasteGate`
`single carrier alignment`

Theorem 6160.3 (Cauchy reflective embedding Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ *carrier receives the finite route*

$$C \longmapsto S \longmapsto Q, D \longmapsto E$$

before any completion-entry row J is consumed. The route exports a reflected Real seal for displayed regular Cauchy data, not $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality, selected limits, host equality, or countable choice.*

Proof. Start with the accepted packet $R = (C, S, Q, D, E, J, H, T, P, N)$. Projection exposes the regular Cauchy input row C and the finite observation row S.

The readback and tolerance rows Q, D are the only rows answering precision requests. Thus the terminal seal E is reached through the displayed regular-rational and dyadic route, not through an ambient completeness theorem.

Only after that seal has been displayed may a completion-facing consumer inspect J. The row J records the entry route already isolated by chapter 1934; it is not a quotient-completion equality or a selected host limit.

Transport, replay, provenance, and naming preserve this same route. Therefore Real-facing reads remain finite and do not escape into completeness, choice, quotient equality, or host equality claims. □

Theorem 6160.4 (Cauchy reflective embedding no-choice boundary)**.** *An accepted* $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ *carrier cannot be read as a selector of limits, a countable-choice schedule for Cauchy witnesses, or an equality proof between quotient real names. Any consumer that requests such data has left the displayed rows $C, S, Q, D, E, J, H, T, P, N$.*

Proof. Read the carrier inventory. The only analytic rows are the regular Cauchy input, finite windows, regular rational readback, dyadic tolerances, Real seal, and completion-entry handoff.

None of these rows is a selector, a quotient equality witness, or a countable-choice schedule. The structural rows transport, replay, package, and name the same inventory; they add no new analytic coordinate.

Thus every accepted consumer remains inside the finite row list. A request for selected limits, choice schedules, quotient equality, or host equality has no carrier row and no local NameCert obligation in this packet. □

Theorem 6160.5 (Cauchy reflective embedding public certificate)**.** *The public certificate exported by* $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ *is the finite route from displayed regular Cauchy data through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert. *It is a seed certificate for L10 Real and Completion consumers and not a completeness theorem, quotient-real theorem, selected-limit theorem, or bridge-checked public object.*

Proof. Combine the NameCert obligations of Definition 6160.2 with the Real handoff of Definition 6160.3. Together they force every public read through the regular Cauchy input, finite windows, readback, dyadic tolerance ledger, Real seal, and completion-entry row.

Use the no-choice boundary of Definition 6160.4. It removes selectors, quotient equalities, countable-choice schedules, host equality, and ambient Real completeness from the exported surface.

The remaining rows are exactly hsame, Cont, Pkg, and NameCert support for the same finite route. Hence the chapter exports a seed public certificate for the named L10 consumers and no stronger completeness or bridge claim. □

Falsifiable prediction: Every accepted $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ read reaches the $\mathsf{Real}^{\uparrow}$ seal only after the displayed $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows are present.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-completion-embedding: $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries regular Cauchy input exposure, finite stream windows, rational readback, dyadic tolerance accounting, Real sealing, completion-entry routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyReflectiveEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyReflectiveEmbedding}^{\uparrow}$ packet is generated from regular Cauchy input data, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a terminal RealUp seal, a CauchyCompletionEmbedding entry row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyReflectiveEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6160.1, Definition 6160.2, Definition 6160.3, Definition 6160.4, and Definition 6160.5 seed the finite regular-Cauchy-to-Real-seal route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyReflectiveEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of real names, selected limits, countable choice, host equality, public bridge evidence, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-window locality, regular-rational readback, dyadic tolerance exactness, Real handoff, completion-entry handoff, non-escape, and local naming for BEDC.Derived.CauchyReflectiveEmbeddi

Chapter 6161

A Concrete Naming Certificate for $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$

Following Dini and Bishop–Bridges constructive compactness, the $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$ packet records the finite BEDC route by which a monotone filter of continuous observations over a compact metric source exposes a stable tolerance boundary. It sits after the compact metric source of chapter 129, the continuous-map ledgers of chapter 130, the uniform-modulus handoff of chapter 369, the regular rational window of chapter 301, and the real-name endpoint of chapter 38. The packet names Dini-style monotone convergence as compact finite-cover and filter-threshold data, not as host-selected limits, arbitrary open covers, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6161.1 (Compact filter Dini monotone carrier)**.** *A* $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, \epsilon, \rho, M, T, R, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only compact finite-cover and finite-net data.*
2. *F is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, indexed by the displayed filter stages over the same compact source.*
3. *ϵ is the positive tolerance request, stored before any cover or threshold row is exported.*
4. *ρ is the shared radius or cover-budget row obtained from the compact-source and continuous-family ledgers.*
5. *M is the monotone-filter ledger, recording the displayed comparison that later stages stay below earlier stages at the requested tolerance.*
6. *T is the finite threshold row, giving the cover-facing stage after which every displayed center satisfies the tolerance boundary.*
7. *R records regular rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$ *and the permitted real-name endpoint through* $\mathsf{Real}^{\uparrow}$*.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactFilterDiniMonotone}^{\uparrow}}$ *row.*

The carrier has no coordinate for host-selected limits, selected subcovers, ambient compactness, quotient real equality, countable choice, or external filter convergence.

Lean4 ✓ `BEDC.Derived.CompactFilterDiniMonotoneUp.CompactFilterDiniMonotoneTasteGate single carrier alignment`

Theorem 6161.2 (Compact filter Dini monotone obligations)**.** *For every accepted* $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$ *carrier*

$$D = (K, F, \epsilon, \rho, M, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactFilterDiniMonotone}^{\uparrow}}$ *surface consists exactly of compact-source admission through* K*, continuous-family admission through* F*, tolerance admission through* ϵ*, shared radius or cover-budget admission through* ρ*, monotone-filter admission through* M*, finite threshold admission through* T*, regular rational and real-name readback through* R*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6161.1. The analytic rows are $K, F, \epsilon, \rho, M, T, R$, and the structural rows are P, N.

The compact and continuity obligations are exactly K and F. The row K supplies the compact finite-cover data, while F supplies the continuous family over that same source.

The Dini monotone obligations are ϵ, ρ, M, T. The tolerance is fixed first, ρ records the shared compact-cover budget, M records monotone filter comparison, and T records the finite threshold stage visible to downstream consumers.

The readback and naming obligations are R, P, N. Since the carrier contains no host-selected limit, selected subcover, ambient compactness, quotient real equality, countable choice, or external filter-convergence coordinate, the listed rows are the whole accepted NameCert surface. □

Theorem 6161.3 (Compact filter Dini monotone finite-cover route)**.** *For every accepted* $\mathsf{CompactFilterDiniMonoton}$ *carrier, any consumer of the Dini finite-cover conclusion must route its read through*

$$K, F, \epsilon \longmapsto \rho, M, T \longmapsto R, P, N.$$

Thus the compactness used by the packet is the displayed finite-cover route over $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$*, not an ambient open-cover principle.*

Proof. Start with the carrier rows. The compact source K, continuous family F, and tolerance ϵ are the only rows visible before the cover budget and threshold rows.

The middle stage is ρ, M, T. The row ρ stores the shared radius or cover budget, M stores monotone filter comparison, and T stores the finite threshold stage after all displayed cover centers satisfy the requested boundary.

The final stage is R, P, N. Regular rational and real-name readback can inspect only the routed threshold data, and provenance and local naming preserve that same route. Therefore an accepted consumer cannot replace the route by an arbitrary open-cover compactness argument or by a selected subcover outside the packet. □

Theorem 6161.4 (Compact filter Dini monotone nonescape)**.** *For every accepted* $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$ *carrier* $D = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the packet cannot export a host-selected limit, selected subcover, selected subsequence, host continuity proof, external filter convergence, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every exported read is confined to the displayed compact-source, continuous-family, tolerance, shared-cover, monotone-filter, threshold, readback, provenance, and naming rows.*

Proof. Inspect the row list in Definition 6161.1. None of the excluded objects appears as a carrier coordinate.

Use Definition 6161.2. It identifies the complete local NameCert surface with the rows $K, F, \epsilon, \rho, M, T, R, P, N$.

Finally use the finite-cover route of Definition 6161.3. Any accepted downstream read must preserve the displayed route, so no host-selected limit, selected subcover, selected subsequence, host continuity proof, external filter convergence, quotient real equality, countable choice, or ambient completeness can be exported. □

Falsifiable prediction: Every accepted $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$ read must expose compact-source admission, continuous-family admission, tolerance admission, shared cover-budget admission, monotone-filter admission, finite threshold admission, regular rational and real-name readback, provenance, and local naming.

Independence witness: compactmetric, continuousmap, uniformmodulus, regseqrat, real: CompactFilterDiniMon is not bijective to any listed sibling because it binds compact finite-cover data and monotone filter-threshold data before readback consumers may inspect the Dini boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFilterDiniMonotone}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactFilterDiniMonotone}^{\uparrow}$ packet is generated from CompactMetric finite-cover rows, ContinuousMap family rows, tolerance and shared cover-budget rows, monotone-filter comparison rows, finite threshold rows, RegSeqRat and Real readback, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactFilterDiniMonotone}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6161.1, Definition 6161.2, Definition 6161.3, and Definition 6161.4 seed the compact finite-cover route from monotone continuous-filter data to a displayed Dini threshold.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactFilterDiniMonotone}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host-selected limits, selected subcovers, selected subsequences, host continuity proofs, external filter convergence, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source admission, continuous-family admission, tolerance admission, shared cover-budget admission, monotone-filter admission, finite threshold admission, readback, provenance, and local naming for BEDC.Derived.CompactFilterDiniMonotoneUp.

Chapter 6162

A Concrete Naming Certificate for $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$

The $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$ packet realizes the blocked lift in chapter 9375 as finite NameCert data. It sits between the closed-normal consistency boundary of chapter 733, the reduction-boundary packet of chapter 738, the route classifier of chapter 785, and the closed-normal packet ledger of chapter 739. The packet records endpoint, discharge, obstruction, transport, replay, provenance, and local naming rows for the unavailable reduction edge; it does not turn closed-normal consistency into full closed consistency.

Definition 6162.1 (Closed-consistency reduction obstruction carrier)**.** *A* $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, E, D, B, R, K, H, C, P, N)$$

with the following displayed rows:

1. *L is the closed source proof row, naming the arbitrary closed false-proof candidate submitted to the reduction route.*
2. *E is the endpoint row, recording the beta-strong normal endpoint that would be read by a closed-normal consistency consumer.*
3. *D is the subject-reduction discharge row whose absence blocks the arbitrary closed-proof lift.*
4. *B is the boundary row inherited from* $\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}$*.*
5. *R is the route-classifier row inherited from* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$*, recording that any accepted route must expose the obstruction before the endpoint is consumed.*
6. *K is the closed-normal consistency consumer row, available only after the endpoint and discharge boundary have both been displayed.*
7. *H records componentwise* hsame *transport for the source, endpoint, discharge, boundary, route-classifier, consumer, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for every read from the closed source row to the endpoint, obstruction ledger, and closed-normal consumer.*
9. *P is the* Pkg *provenance over* $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$, $\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}$, $\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}$, $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$, $\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}}$ *row.*
The carrier contains no full closed consistency theorem, no closed subject-reduction theorem, no hidden false-type transport, no host reduction semantics, and no endpoint read detached from the obstruction row.

Theorem 6162.2 (Closed-consistency reduction obstruction NameCert obligations)**.** *For an accepted* $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$ *carrier* $O = (L, E, D, B, R, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}}$ *surface consists exactly of source exposure, endpoint exposure, subject-reduction discharge exposure, reduction-boundary inheritance, route-classifier exposure, closed-normal consumer handoff, obstruction-ledger accounting, componentwise transport, displayed replay, provenance accounting, and local naming.*

Proof. Project the carrier of Definition 6162.1. The rows L, E, D, B, R, K are the analytic rows, and H, C, P, N are the structural transport, replay, provenance, and naming rows.

The boundary and classifier rows are mandatory. The reduction-boundary row B names the blocked lift from an arbitrary closed source to the normal endpoint, while R records the subject-reduction route class that must be inspected before any endpoint consumer reads the packet.

The closed-normal consumer row K is therefore downstream of the endpoint and obstruction rows. It cannot be read as full closed consistency, because the discharge row D remains displayed as an obstruction rather than as a closed subject-reduction theorem.

No other row is available. Hence the local NameCert obligations are exactly the source, endpoint, discharge, boundary, classifier, consumer, obstruction, transport, replay, provenance, and naming rows listed in the statement. □

Theorem 6162.3 (Closed-consistency reduction obstruction frontier nonescape)**.** *Every accepted* $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$ *packet forces a closed-consistency reduction read through the displayed obstruction route*

$$L \longmapsto B, R, D \longmapsto E \longmapsto K$$

before any closed-normal consistency consumer reads the endpoint. No consumer can bypass B, R, D *to obtain full closed consistency, a closed subject-reduction theorem, host conversion semantics, or hidden false-type transport.*

Proof. Start with the carrier rows. The closed source row L has no direct route to the consumer row K; the intervening rows are the reduction boundary B, route classifier R, discharge row D, and endpoint row E.

The displayed continuation row C replays that same route. It records reads from L through the boundary and classifier rows before the endpoint is presented to the closed-normal consumer.

The structural rows do not add a shortcut. Componentwise transport preserves the same row inventory, provenance names the same sibling packets, and local naming records the packet rather than a theorem outside it.

Thus the frontier cannot escape. Any attempted bypass of B, R, D asks for data absent from the carrier and is outside the NameCert surface. □

Theorem 6162.4 (Closed-consistency reduction obstruction TasteGate surface)**.** *The* ClosedConsistencyReductionO *packet exposes a finite TasteGate surface for the blocked edge: source row, endpoint row, subject-reduction discharge row, reduction-boundary row, route-classifier row, closed-normal consumer row, transport, replay, provenance, and local naming. Lean follow-up for this surface must supply* Nontrivial *and* FieldFaithful *instances in* lean4/BEDC/Derived/ClosedConsistencyReductionObstructionUp/TasteGate. *before any checked TasteGate claim is recorded in the paper.*

Proof. The carrier inventory gives the source, endpoint, discharge, boundary, classifier, and consumer rows. These are exactly the fields inspected by the chapter-level taste surface.

The rows H, C, P, N provide the structural evidence used by NameCert packets: componentwise transport, continuation replay, provenance, and local naming. They make the surface finite and auditable without adding a closed subject-reduction theorem.

The Lean follow-up named in the statement is therefore a field-faithfulness and nontriviality task for this displayed carrier. Until those instances exist, this chapter records the paper-side finite surface only and does not claim a checked TasteGate theorem. □

Falsifiable prediction: Every accepted $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$ packet routes through the displayed subject-reduction obstruction row D and the route-classifier row R before any closed-normal consistency consumer reads the endpoint row E.

Independence witness: closed-normal-consistency-boundary, closed-consistency-reduction-boundary, subject-reduction-route-classifier, metacic-open-obligation-ledger: $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries arbitrary closed-source exposure, endpoint readback, the subject-reduction obstruction row, route classification, closed-normal consumer handoff, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}$ packet is generated from an arbitrary closed false-proof source row, beta-strong endpoint row, subject-reduction discharge obstruction, reduction-boundary row, route-classifier row, closed-normal consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6162.1, Definition 6162.2, Definition 6162.3, and Definition 6162.4 seed the finite obstruction packet for the blocked closed-consistency reduction edge.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionObstruction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full closed consistency, closed subject reduction, hidden false-type transport, host conversion semantics, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, endpoint readback, subject-reduction obstruction routing, route-classifier handoff, closed-normal consumer handoff, TasteGate instances, and local naming for BEDC.Derived.ClosedConsistencyReductionObstructionUp.

Chapter 6163

A Concrete Naming Certificate for $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$ packet records the finite interval-uniform-continuity surface for a displayed real map on a located real interval. It sits after the real-name seal of chapter 38, the endpoint-and-enclosure interval packet of chapter 4111, the located interval row of chapter 1709, the continuous-map row of chapter 130, the finite stream-window and regular-readback route of chapter 126 and chapter 301, the dyadic tolerance ledger of chapter 291, and the downstream modulus consumer of chapter 369. The packet names the finite tolerance handoff used by interval consumers; it does not claim open-cover compactness, a selected modulus from choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6163.1 (Real interval uniform continuity carrier)**.** *A* $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, L, F, T, W, R, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{RealInterval}^{\uparrow}$ *endpoint-and-enclosure row naming the source interval.*
2. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *locatedness row exposing endpoint brackets, locator reads, and interval-radius data for the same source interval.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed map from the interval-facing real input row to the real output row.*
4. *T is the tolerance request row, recording the requested output precision and the interval window in which the request is read.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the input names, output names, and endpoint observations visible to T.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row produced from the displayed windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger storing input-radius, output-tolerance, slack, and dyadic comparison data.*
8. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row; it receives a tolerance-indexed input radius only after I, L, F, T, W, R, D have been displayed.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for interval-valued input and output reads.*
10. *H records componentwise* hsame *transport for the interval, locatedness, map, tolerance, window, readback, dyadic, modulus, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a tolerance request through $I, L, F, T, W, R, D, M, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$, $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalUniformContinuity}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one displayed interval-uniform-continuity history. It has no coordinate for open-cover compactness, selected representatives, quotient real equality, host continuity, choice-selected moduli, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6163.2 (Real interval uniform continuity NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$ *carrier $U = (I, L, F, T, W, R, D, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealIntervalUniforr}}$ *surface consists exactly of carrier admission for the displayed interval, locatedness, continuous-map, tolerance-request, stream-window, regular-readback, dyadic-ledger, uniform-modulus, real-seal, transport, replay, provenance, and local naming rows.*

The obligation surface additionally requires the interval row I and locatedness row L to precede any input-radius read, the continuous-map row F to precede any output-tolerance read, and the dyadic ledger D to precede the $\mathsf{UniformModulus}^{\uparrow}$ *handoff M. No local obligation is stored outside those rows.*

```
Lean4 ✓  BEDC.Derived.RealIntervalUniformContinuityUp.RealIntervalUniformContinuityTasteGate
single carrier alignment
```

Proof. Project the accepted carrier. The packet contains only the rows $I, L, F, T, W, R, D, M, E, H, C, P, N$, so carrier admission and local naming are componentwise.

The source interval is read through I and L. These rows expose endpoint, enclosure, and locatedness data before any input-radius comparison can be treated as interval uniformity evidence.

The map and tolerance route is then finite. The row F exposes the displayed continuous map, T records the requested output precision, W and R expose the visible stream windows and regular rational observations, and D records the dyadic comparison budget.

Only after that route is displayed may M be read as a $\mathsf{UniformModulus}^{\uparrow}$ handoff. The rows E, H, C, P, N seal, transport, replay, source, and name the same finite route, while the excluded compactness, quotient, choice, and completeness objects have no carrier coordinate. □

Theorem 6163.3 (Real interval uniform continuity modulus handoff)**.** *Every uniform-modulus consumer of an accepted* $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$ *packet must pass through the displayed route*

$$\mathsf{RealInterval}^{\uparrow},\ \mathsf{LocatedRealInterval}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{UniformM}$$

Thus the consumer receives a tolerance-indexed input radius for the displayed located real interval and continuous map, without receiving open-cover compactness, a choice-selected modulus, quotient real equality, selected endpoint representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier in Definition 6163.1. The interval row I, locatedness row L, and continuous-map row F are the only rows that identify the source, the interval boundary, and the map.

Next read the tolerance data. The request row T fixes the output precision, W supplies the finite windows, R supplies regular rational readback, and D supplies the dyadic comparison ledger.

The handoff row M is downstream of those rows. Therefore any accepted $\mathsf{UniformModulus}^{\uparrow}$ consumer receives its input-radius evidence only through the displayed interval, map, window, readback, and dyadic route.

The structural rows E, H, C, P, N preserve that route and add no hidden selector. Since no excluded object is present in the carrier, the handoff cannot export open-cover compactness, quotient real equality, endpoint representatives, choice-selected moduli, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalUniformContinuity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalUniformContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6163.1, Definition 6163.2, and Definition 6163.3 seed the finite interval-uniform-continuity handoff over $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalUniformContinuity}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RealIntervalUniformContinuityUp.RealIntervalUniformContinuityTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected modulus existence, quotient real equality, selected endpoint representatives, trichotomy, countable choice, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked interval locatedness, continuous-map tolerance readback, dyadic exactness, uniform-modulus handoff, Real seal non-escape, and local naming beyond the carrier-alignment theorem.

Constructive story: A $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$ packet is generated from a RealIntervalUp source interval, a LocatedRealIntervalUp locatedness row, a ContinuousMapUp map row, tolerance requests, StreamNameUp finite windows, RegSeqRatUp readback, a DyadicRatCoreUp ledger, a UniformModulusUp handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6164

A Concrete Naming Certificate for $\mathsf{ArithmeticHierarchy}^{\uparrow}$

Following Kleene's recursion-theory hierarchy, the $\mathsf{ArithmeticHierarchy}^{\uparrow}$ packet records the finite BEDC route by which bounded first-order syntax, computability evidence, and oracle-free quantifier alternation data are named before a Real or Completion consumer may cite arithmetical complexity. It sits beside the syntactic carrier of chapter 197, the computability interface of chapter 199, the set-membership discipline of chapter 3668, the lambda-calculus syntax route of chapter 200, and the constructive-real boundary of chapter 336. The downstream use is the same finite obstruction surface read by chapter 3516: a Specker or computable-real boundary may cite a displayed arithmetical class, but it cannot import a host predicate hierarchy, quotient equality of predicates, excluded middle, countable choice, or an ambient completion theorem.

Definition 6164.1 (ArithmeticHierarchy carrier)**.** *An* $\mathsf{ArithmeticHierarchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, E, Q, B, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{FirstOrder}^{\uparrow}$ *syntax row containing the bounded formula spine, free-variable ledger, and term source read by the classifier.*
2. *E is the* $\mathsf{Computable}^{\uparrow}$ *effective-evaluation row for atomic and bounded subformula reads.*
3. *Q is the quantifier-prefix row listing a finite alternation word over existential and universal blocks, with its initial polarity and displayed block boundaries.*
4. *B is the bound ledger recording which quantifiers are bounded and which finite rows expose the requested numeric or finite-set search windows.*
5. *R is the rank row naming the local Σ^0_n, Π^0_n, or Δ^0_n class as finite data rather than as a host predicate family.*
6. *L is the stability ledger asserting that prefix padding, bounded-quantifier expansion, and componentwise formula transport preserve the displayed rank row.*
7. *H records componentwise* hsame *transport for $S, E, Q, B, R, L, C, P, N$.*
8. *C records displayed* Cont *replay from the syntax and computability rows through prefix, bound, rank, and stability reads.*

9. *P is the* Pkg *provenance over* ArithmeticalHierarchy$^\uparrow$, FirstOrder$^\uparrow$, Computable$^\uparrow$, SetLike$^\uparrow$, LambdaCalc$^\uparrow$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArithmeticalHierarchy}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, E, Q, B, R, L, H, C, P, N$. It has no coordinate for a host subset of $\mathbb{N}$, truth in the standard model, quotient equality of predicates, oracle jumps, countable choice, excluded middle, Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.ArithmeticalHierarchyUp.ArithmeticalHierarchyTasteGate single carrier alignment`

Theorem 6164.2 (ArithmeticalHierarchy NameCert obligations)**.** *For every accepted* ArithmeticalHierarchy$^\uparrow$ *carrier*

$$A = (S, E, Q, B, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ArithmeticalHierarchy}^\uparrow}$ *surface consists exactly of carrier admission for the displayed rows, syntax visibility through S, effective atomic and bounded reads through E, quantifier-prefix admission through Q, bound-ledger exactness through B, rank-row exactness through R, stability under displayed prefix padding and bounded expansion through L, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

These obligations bind the arithmetical-class route without adding host predicate semantics, quotient predicate equality, oracle jumps, unrestricted comprehension, excluded middle, countable choice, or an ambient Real$^\uparrow$ *completion claim.*

Proof. Project the carrier of Definition 6164.1. The rows $S, E, Q, B, R, L, H, C, P, N$ are the whole local surface, so carrier admission is exactly admission of those rows.

The syntactic and effective data are read first. The row S fixes the first-order formula spine and free-variable ledger, while E supplies only the effective atomic and bounded reads available to the packet.

The hierarchy data are then forced by the displayed prefix. The row Q lists the finite alternation word, B records the bounded search windows, and R names the resulting Σ^0_n, Π^0_n, or Δ^0_n rank. The stability row L is the only place where padding or bounded expansion may be replayed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for host truth, predicate quotients, oracle jumps, unrestricted comprehension, choice, excluded middle, or Real completeness, the listed clauses exhaust the local NameCert obligations. □

Theorem 6164.3 (ArithmeticalHierarchy computable-real boundary handoff)**.** *Every computable-real, Specker-sequence, or completion-boundary consumer of an accepted* ArithmeticalHierarchy$^\uparrow$ *packet must read the finite route*

$$\mathsf{FirstOrder}^\uparrow,\ \mathsf{Computable}^\uparrow,\ Q,\ B,\ R,\ L,\ \mathsf{SetLike}^\uparrow$$

as displayed by Definition 6164.1. The route exports a named arithmetical class for the downstream boundary read; it does not export host truth, a predicate quotient, an oracle jump, a selected completion point, countable choice, excluded middle, or an ambient Real$^\uparrow$ *completeness theorem.*

Proof. Start with a Real-facing or Specker-facing boundary read. The only syntax source available in the carrier is S, and the only effective-evaluation row is E, so the consumer is confined to the displayed first-order and computability data.

Read the classification surface next. The prefix row Q, bound row B, rank row R, and stability row L together expose the finite arithmetical-class route, while the set-like provenance can be cited only through P and the displayed replay C.

The structural rows do not add a hidden semantic object. Because no host predicate hierarchy, quotient equality, oracle jump, selected Real point, countable-choice schedule, excluded-middle principle, or ambient completeness theorem appears as a carrier coordinate, the consumer receives only the stated finite route. □

Falsifiable prediction: Every accepted $\mathsf{ArithmeticalHierarchy}^{\uparrow}$ boundary read that reaches a $\mathsf{ComputableReal}^{\uparrow}$, $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$, or completion-facing consumer displays the rows $S, E, Q, B, R, L, H, C, P, N$ first.

Independence witness: firstorder, computable, setlike, lambdacalc, computablereal, specker-sequence-boundary: no listed sibling supplies the joint packet containing bounded first-order syntax, effective atomic and bounded reads, quantifier-prefix data, bound ledgers, rank rows, stability transport, displayed replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{ArithmeticalHierarchy}^{\uparrow}}$.

Constructive story: An $\mathsf{ArithmeticalHierarchy}^{\uparrow}$ packet is generated from a FirstOrderUp syntax row, a ComputableUp effective-evaluation row, finite quantifier-prefix data, a bounded-search ledger, a displayed rank row, stability under prefix padding and bounded expansion, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArithmeticalHierarchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6164.1, Definition 6164.2, and Definition 6164.3 seed the finite arithmetical-class route from displayed first-order and computability rows through prefix, bound, rank, stability, and boundary-consumer reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArithmeticalHierarchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem checking, bridge checking, host predicate semantics, quotient predicate equality, oracle jumps, unrestricted comprehension, countable choice, excluded middle, selected Real points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, syntax visibility, effective readback, quantifier-prefix admission, bound-ledger exactness, rank-row exactness, stability transport, displayed replay, provenance, and local naming for BEDC.Derived.ArithmeticalHierarchyUp.

Chapter 6165

A Concrete Naming Certificate for $\mathsf{HilbertCurve}^{\uparrow}$

Beginning with Hilbert's classical space-filling curve construction, the $\mathsf{HilbertCurve}^{\uparrow}$ packet records the finite dyadic subdivision route by which interval addresses are folded into square-cell addresses. It sits beside the Peano surface of chapter 2078, the compact uniform-modulus surface of chapter 2299, the graph carrier of chapter 130, and the compact metric completion route of chapter 1687. The packet names the recursive quadrant order, orientation bit, dyadic coordinate readback, and finite continuity budget; it does not claim an unrestricted function space, arbitrary pointwise choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6165.1 (Hilbert curve carrier)**.** *A* $\mathsf{HilbertCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, Q, O, F, X, Y, B, T, C, K, N)$$

with the following displayed rows:

1. *A is the interval-address row. It records finite dyadic subintervals, their precision levels, and the associated* $\mathsf{StreamName}^{\uparrow}$ *observation windows.*
2. *Q is the quadrant row. For each displayed address, it records the selected dyadic square quadrant and its horizontal and vertical dyadic endpoints.*
3. *O is the orientation row. It records the finite turn state used by Hilbert's recursive subdivision rule, including the two endpoint orientations needed to compare sibling cells.*
4. *F is the fold-coherence row. It checks that the four child quadrants of each displayed parent square are visited in the Hilbert order and that consecutive children share an edge or an endpoint at the displayed precision.*
5. *X and Y are the coordinate readback rows. They expose the horizontal and vertical dyadic endpoints through* $\mathsf{DyadicRatCore}^{\uparrow}$*, then through the regular rational and real-name support already used by continuous-map consumers.*
6. *B is the finite-window continuity row. A square precision request is answered by an interval precision, a dyadic diameter bound, and the fold-coherence witness needed before a* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer reads the graph.*
7. *T is the compact-metric handoff row. It packages the finite square-cell cover and the dyadic diameter budget as compact metric data without using open-cover compactness.*

8. *C records componentwise* hsame *transport for interval addresses, quadrants, orientations, fold coherence, coordinate readbacks, continuity budgets, compact-metric handoffs, provenance, and local naming.*

9. *K records displayed* Cont *replay through*

$$A, Q, O, F \longmapsto X, Y, B, T \longmapsto C, K, N.$$

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HilbertCurve}^\uparrow}$ *row, sourced over* $\mathsf{HilbertCurve}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{ContinuousMap}^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert.

The classifier compares accepted packets only through $A, Q, O, F, X, Y, B, T, C, K, N$. It has no coordinate for a completed function space, arbitrary representative choice, quotient equality of real names, open-cover compactness, ambient $\mathsf{Real}^\uparrow$ *completeness, Lean verification, or a bridge credential.*

Lean4 ✓ `BEDC.Derived.HilbertCurveUp.HilbertCurveTasteGate single carrier alignment`

Theorem 6165.2 (Hilbert curve NameCert obligations)**.** *For an accepted* $\mathsf{HilbertCurve}^\uparrow$ *carrier*

$$H = (A, Q, O, F, X, Y, B, T, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{HilbertCurve}^\uparrow}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the interval-address, quadrant, orientation, fold-coherence, coordinate readback, finite-window continuity, compact-metric handoff, transport, replay, provenance, and local naming rows;*

2. *classifier exactness, requiring accepted packets to be compared only by the rows $A, Q, O, F, X, Y, B, T, C, K, N$;*

3. *subdivision coherence, requiring the quadrant and orientation rows to display the Hilbert child order before any coordinate endpoint is exposed;*

4. *finite-window continuity, requiring the fold-coherence and diameter-budget rows to answer every displayed graph request through a finite dyadic window;*

5. *compact-metric handoff, requiring the square-cell cover and dyadic diameter budget to be consumed through compact metric data rather than open-cover compactness;*

6. *ledger exhaustion, requiring C, K, N to transport, replay, source, and name only the listed finite dyadic route.*

No NameCert obligation is stored outside these rows, and none exports a host-level function space, arbitrary pointwise choice, quotient equality of real names, open-cover compactness, ambient $\mathsf{Real}^\uparrow$ *completeness, Lean verification, or a standard bridge.*

Proof. Carrier admission is projection from Definition 6165.1. The accepted packet displays the interval-address row, quadrant row, orientation row, fold-coherence row, coordinate readback rows, finite-window continuity row, compact-metric handoff row, and structural rows.

Classifier exactness follows because the definition gives the classifier no coordinate except $A, Q, O, F, X, Y, B, T, C, K, N$. Any attempted comparison through a function space, representative choice, quotient equality, open-cover compactness, completion principle, verification credential, or bridge credential therefore has no row to inspect.

Subdivision coherence is read from Q, O, F. The quadrant row names the selected square cell, the orientation row records the finite turn state, and the fold-coherence row checks the four-child Hilbert order before X or Y can expose an endpoint.

Finite-window continuity is read from F and B. The fold-coherence row supplies the edge or endpoint adjacency check for neighboring interval cells, while the budget row supplies the dyadic diameter bound requested by a continuous-map consumer.

The compact-metric handoff is read from T. It repackages the displayed finite square-cell cover and diameter budget as compact metric data, so no open-cover argument or ambient completeness principle is introduced.

Finally C, K, N add no analytic coordinate. They preserve, replay, source, and name the same finite route, which exhausts the local NameCert surface. □

Theorem 6165.3 (Hilbert curve finite-window continuity)**.** *Let*

$$H = (A, Q, O, F, X, Y, B, T, C, K, N)$$

be an accepted $\mathsf{HilbertCurve}^{\uparrow}$ *carrier. Every continuous-map or compact-metric consumer of* H *receives the Hilbert curve through the finite route*

$$A, Q, O, F \longmapsto X, Y, B, T \longmapsto C, K, N.$$

For each requested square precision, the route opens a finite $\mathsf{StreamName}^{\uparrow}$ *interval window, reads dyadic quadrant endpoints through* $\mathsf{DyadicRatCore}^{\uparrow}$*, checks sibling fold coherence by* F*, answers the diameter budget by* B*, and then hands the resulting finite graph surface to* $\mathsf{ContinuousMap}^{\uparrow}$ *and compact metric support through* T*. Thus the dyadic window handoff stays inside the finite stream, dyadic rational, and continuous-map support named by the carrier.*

Proof. Fix a requested square precision. The interval-address row A supplies only finitely many dyadic input windows, and the quadrant row Q assigns each displayed address to a dyadic square cell.

The coordinate readback is forced through X and Y. Those rows expose the horizontal and vertical endpoints as dyadic rational data before any continuous-map consumer can read the graph.

Sibling compatibility is a finite check. The orientation row O records the turn state, and the fold-coherence row F verifies that consecutive displayed child cells share an edge or endpoint at the requested precision.

The budget row B then supplies the diameter bound associated with the same displayed window. Consequently the graph read by $\mathsf{ContinuousMap}^{\uparrow}$ is a finite-window surface rather than a host-level function graph.

The compact handoff is the row T. It carries the displayed square-cell cover and the same dyadic diameter budget into compact metric support, while C, K, N preserve the route under transport, replay, provenance, and local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{HilbertCurve}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HilbertCurve}^{\uparrow}$ packet is generated from finite dyadic interval addresses, quadrant cells, orientation states, fold-coherence rows, coordinate readbacks through DyadicRatCore support, finite-window continuity budgets, compact-metric handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HilbertCurve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6165.1, Definition 6165.2, and Definition 6165.3 seed the finite dyadic subdivision route for a Hilbert curve packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HilbertCurve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host-level function spaces, arbitrary pointwise choice, quotient equality of real names, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, subdivision coherence, finite-window continuity, compact-metric handoff, and ledger exhaustion for BEDC.Derived.HilbertCurveUp.

Chapter 6166

A Concrete Naming Certificate for $\mathsf{CauchyProductBoundary}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyProductBoundary}^{\uparrow}$ packet records the finite boundary row needed before a Cauchy product read is handed to the regular-rational and real-name consumers. It sits after the product modulus ledger of **??**, the regular product criterion of chapter 3672, and the synchronized criterion of chapter 1586. The packet names a finite product-modulus handoff surface, not completed-real multiplication, quotient stream equality, a selected product limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6166.1 (Cauchy product boundary carrier)**.** *A* $\mathsf{CauchyProductBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, W_A, W_B, D, M, K, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose product is being read.*
2. *W_A and W_B are synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened at the requested product tolerance.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-scaling row, recording the source-window tolerances, magnitude bounds, and cross-error budget needed by the product request.*
4. *M is the* $\mathsf{CauchyProductModulus}^{\uparrow}$ *budget row assigning the finite source-window budgets for the product read.*
5. *K is the* $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$ *row certifying that the displayed regular source rows and budget data produce a regular Cauchy product handoff.*
6. *R is the* $\mathsf{CauchyProductCriterion}^{\uparrow}$ *real-seal handoff row.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, read only after M, K, R have been displayed.*
8. *H stores componentwise* hsame *transports for the source rows, windows, dyadic budget, product-modulus row, criterion rows, seal, provenance, and local name.*
9. *C stores displayed* Cont *replay from a product precision request through the windows, dyadic scaling row, product modulus, regular criterion, real-seal criterion, and terminal seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyProductBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyProductModulus}^{\uparrow}$, $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$, $\mathsf{CauchyProductCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, B, W_A, W_B, D, M, K, R, E, H, C, P, N$. It has no coordinate for host real multiplication, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductBoundaryUp.CauchyProductBoundaryTasteGate single carrier alignment`

Theorem 6166.2 (Cauchy product boundary bilinear modulus)**.** *For an accepted* $\mathsf{CauchyProductBoundary}^{\uparrow}$ *carrier*

$$Q = (A, B, W_A, W_B, D, M, K, R, E, H, C, P, N),$$

every bilinear product tolerance exported to a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite boundary route*

$$A, B \longmapsto W_A, W_B \longmapsto D \longmapsto M \longmapsto K \longmapsto R \longmapsto E.$$

Thus the product boundary supplies a modulus-mediated handoff from regular rational source rows to the terminal real seal, while refusing completed-real multiplication, quotient stream equality, selected product limits, countable choice, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6166.1. The only source observations available to a product request are the two $\mathsf{RegSeqRat}^{\uparrow}$ source rows and the synchronized $\mathsf{StreamName}^{\uparrow}$ finite windows W_A, W_B.

Read the $\mathsf{DyadicRatCore}^{\uparrow}$ row D. It performs the tolerance scaling for the bilinear product request by displaying the source tolerances, magnitude bounds, and cross-error budget inside finite dyadic data. The product request therefore cannot reach a downstream criterion before this scaling row is visible.

Next apply the $\mathsf{CauchyProductModulus}^{\uparrow}$ budget row M. It allocates the finite source-window budgets consumed by the product read, so the regular criterion receives a displayed modulus row rather than an external choice of convergence rate.

The $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$ row K turns the window and modulus data into the regular rational product handoff. The $\mathsf{CauchyProductCriterion}^{\uparrow}$ row R then routes that handoff to the real-seal boundary, and E is available only after this route has been displayed.

Finally, H, C, P, N transport, replay, source, and name the same finite boundary. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host multiplication, or ambient completeness, every bilinear product tolerance exported by the packet remains inside the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductBoundary}^{\uparrow}$ packet is generated from two RegSeqRat source rows, synchronized StreamName windows, a DyadicRatCore tolerance-scaling row, a CauchyProductModulus budget row, RegularCauchyProductCriterion and CauchyProductCriterion handoff rows, a RealUp seal row, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 6166.1 and Definition 6166.2 seed the finite boundary route from two regular rational source rows through StreamName windows, dyadic tolerance scaling, product modulus budgeting, product criteria, and the Real seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyProductBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real multiplication, quotient stream equality, selected product limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window exposure, dyadic tolerance scaling, product-modulus budgeting, regular product criterion handoff, Cauchy product criterion handoff, Real seal non-escape, transport, replay, provenance, and local naming for the same finite packet.

Chapter 6167

A Concrete Naming Certificate for $\mathsf{UniformLipschitzFamily}^{\uparrow}$

Following Arzela-Ascoli and the standard Lipschitz-family compactness literature, the $\mathsf{UniformLipschitzFamily}^{\uparrow}$ packet records the finite BEDC surface for a family of continuous maps controlled by one displayed Lipschitz bound across all listed members. It sits after the metric source of chapter 57, the continuous-map graph rows of chapter 130, the bound ledger of chapter 2328, the compact source of chapter 129, and the tolerance consumer of chapter 369. The packet names uniform Lipschitz control as finite family data; it does not assert ambient function-space compactness, select a convergent subsequence, or import open-cover compactness.

Definition 6167.1 (Uniform Lipschitz-family carrier)**.** *A* $\mathsf{UniformLipschitzFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, I, F, L, V, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite metric windows supply all source-distance reads.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row whose distance reads are used only through displayed continuous-map values.*
3. *I is the finite family-index row naming the inspected maps.*
4. *F is the finite list of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows, one for each displayed family member from X to Y.*
5. *L is the shared* $\mathsf{LipschitzConstant}^{\uparrow}$ *row, recording one common bound for every listed member rather than one hidden ambient bound per function.*
6. *V is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that receives the common Lipschitz bound as a tolerance-only modulus surface.*
7. *H records componentwise* hsame *transport for X, Y, I, F, L, V and the structural rows.*
8. *C records displayed* Cont *replay of the route from compact source windows through continuous-map values and the shared Lipschitz bound to the uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformLipschitzFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LipschitzConstant}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformLipschitzFamily}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient function-space topology, selected subsequence, quotient equality of functions, open-cover compactness, or a non-displayed modulus.

Lean4 ✓ `BEDC.Derived.UniformLipschitzFamilyUp.TasteGate.UniformLipschitzFamilyTasteGate single carrier alignment`

Theorem 6167.2 (Uniform Lipschitz-family NameCert obligations)**.** *For every accepted* $\mathsf{UniformLipschitzFamily}^{\uparrow}$ *carrier* $U = (X, Y, I, F, L, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformLipschitzFamily}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact source, target metric, family-index, continuous-map list, shared Lipschitz bound, uniform-modulus handoff, transport, replay, provenance, and local naming rows;*
2. *compact-source exposure, requiring every family read to pass through* X *before any pointwise value or bound row is consumed;*
3. *continuous-map exposure, requiring each listed family member in* I *to be read through a corresponding* $\mathsf{ContinuousMap}^{\uparrow}$ *row in* F*;*
4. *shared-bound exactness, requiring the single row* L *to control every listed member and forbidding a hidden per-member or ambient Lipschitz selector;*
5. *uniform-modulus handoff, requiring* V *to consume only the common bound row together with the displayed source and target metric evidence;*
6. *structural stability, requiring* H, C, P, N *to transport, replay, source, and name only the rows already listed.*

No uniform Lipschitz-family obligation is stored outside these rows.

Proof. Project the accepted packet $U = (X, Y, I, F, L, V, H, C, P, N)$. The displayed coordinates give the compact source, target metric, finite index row, listed continuous-map rows, shared Lipschitz bound, uniform-modulus handoff, and structural rows.

The source and map rows come first. The compact metric row X supplies source-distance windows, while I and F restrict inspection to the listed continuous maps.

The common bound is then read through L. Since the same row is used for every listed member, the certificate records a family-level Lipschitz constraint rather than a collection of host-level function predicates.

Finally V, H, C, P, N package the same displayed route for downstream consumers. The excluded objects do not occur as carrier coordinates, so the listed rows exhaust the local NameCert obligations. □

Theorem 6167.3 (Uniform Lipschitz-family compact-uniform handoff)**.** *Every compact-uniform or Arzela–Ascoli consumer of an accepted* $\mathsf{UniformLipschitzFamily}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{LipschitzConstant}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

Thus the shared Lipschitz bound is exported only as compact-source metric data, displayed map rows, a common LipschitzConstant row, and a UniformModulus handoff. It exports no ambient function-space topology, selected subsequence, open-cover compactness, quotient function equality, or non-displayed modulus.

Proof. Start with the source and target metric rows. The compact source X and target metric Y provide the only distance reads available to the family.

Read the finite family rows I and F. Each inspected member is attached to a displayed $\mathsf{ContinuousMap}^{\uparrow}$ row, so a consumer cannot quantify over an ambient function space.

The shared bound row L then feeds V. The downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer receives the common Lipschitz ledger as tolerance data, while H, C, P, N transport, replay, source, and name that same route.

Because the carrier lacks coordinates for subsequence selection, open-cover compactness, quotient function equality, and hidden moduli, every compact-uniform or Arzela–Ascoli read factors through the displayed handoff. □

Theorem 6167.4 (Uniform Lipschitz-family obligation surface)**.** *For every accepted* $\mathsf{UniformLipschitzFamily}^{\uparrow}$ *carrier* $U = (X, Y, I, F, L, V, H, C, P, N)$*, the displayed rows jointly discharge the obligation surface needed for obligation closure: compact-source exposure, continuous-map exposure, shared-bound exactness,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff,* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier rows $X, Y, I, F, L, V, H, C, P, N$. The compact-source and continuous-map obligations are exactly the exposure rows isolated in Definition 6167.2.

The shared-bound and modulus obligations are then read through L and V. Apply Definition 6167.2 to identify the single common Lipschitz row and Definition 6167.3 to route that row into the $\mathsf{UniformModulus}^{\uparrow}$ handoff.

Finally H, C, P, N supply transport, replay, provenance, and local naming for the same displayed packet. No additional ambient function-space, subsequence, open-cover, quotient-equality, or hidden-modulus row remains to be discharged. □

Falsifiable prediction: An accepted $\mathsf{UniformLipschitzFamily}^{\uparrow}$ read is refuted if a compact-uniform or Arzela–Ascoli consumer obtains a UniformModulusUp handoff without displaying the CompactMetric source row, target Metric row, finite family-index row, ContinuousMap rows, shared LipschitzConstant row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: metric, continuousmap, lipschitz-constant, compactmetric, uniform-modulus: no listed sibling is bijective with $\mathsf{UniformLipschitzFamily}^{\uparrow}$ because the packet jointly carries a compact source, target metric, finite family index, displayed continuous-map list, one shared Lipschitz bound, a uniform-modulus handoff, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLipschitzFamily}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLipschitzFamily}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6167.1, Definition 6167.2, Definition 6167.3, and Definition 6167.4 close the displayed obligation surface for the finite shared-Lipschitz family route from compact metric source data through continuous-map rows to a UniformModulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLipschitzFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient function-space compactness, selected subsequences, open-cover compactness, quotient function equality, non-displayed moduli, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, continuous-map exposure, shared-bound exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformLipschitz

Constructive story: A $\mathsf{UniformLipschitzFamily}^{\uparrow}$ packet is generated from a compact metric source row, target Metric row, finite family-index row, ContinuousMap rows, a shared LipschitzConstant row, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6168

A Concrete Naming Certificate for $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$ packet records the finite total-boundedness route for a displayed located real interval before compact-interval and uniform-continuity consumers may read a finite net. It sits after the endpoint surface of chapter 394, the located real interval carrier of chapter 1709, and the finite epsilon-net certificate of chapter 1767. The packet is an L10 finite-net interval object; it does not claim open-cover Heine–Borel, a choice-selected subcover, quotient real equality, endpoint trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6168.1 (Real interval total boundedness carrier)**.** *A* $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, L, \varepsilon, M, E, F, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row exposing the lower endpoint, upper endpoint, and interval-order boundary.*
2. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row for the same displayed interval, carrying real-name enclosure and locatedness data.*
3. *ε is a positive* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance ledger read as the requested net radius.*
4. *M is a finite mesh row whose cells refine the located interval at tolerance ε.*
5. *E is the finite list of displayed centers, each center read through the same located real interval rows I, L.*
6. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *handoff row asserting that every inspected interval point is covered by one center from E at radius ε.*
7. *H records componentwise* hsame *transport for the interval, locatedness, tolerance, mesh, centers, net handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a total-boundedness request through $I, L, \varepsilon, M, E, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalTotalBoundedness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for arbitrary open covers, selected finite subcovers, quotient real equality, endpoint trichotomy, countable choice, host compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealIntervalTotalBoundednessUp.TasteGate.RealIntervalTotalBoundednessTasteGate single carrier alignment`

Theorem 6168.2 (Real interval total boundedness NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$ *carrier* $T = (I, L, \varepsilon, M, E, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealIntervalTotalBoundedness}^{\uparrow}}$ *surface consists exactly of carrier admission, located endpoint admission, located real interval admission, positive tolerance admission, finite mesh admission, finite center admission, finite epsilon-net handoff, componentwise transport, replay, provenance, and local naming for the displayed rows* $I, L, \varepsilon, M, E, F, H, C, P, N$*.*

Proof. Project the accepted packet $T = (I, L, \varepsilon, M, E, F, H, C, P, N)$. Carrier admission reads the located endpoint row I, the located real interval row L, the positive tolerance ledger ε, the mesh row M, the center list E, and the finite-net handoff F.

The endpoint and located-real rows precede the net route. A point request first enters through I and L, then reads the tolerance ledger and mesh; no host interval, quotient representative, or endpoint trichotomy is selected.

The finite handoff is the row F. It is transported only through H and replayed only through C, while P records the sibling certificate provenance and N names the local packet.

Since the carrier contains no open-cover, subcover-selection, countable-choice, or ambient completeness coordinate, no $\mathsf{NameCert}_{\mathsf{RealIntervalTotalBoundedness}^{\uparrow}}$ consumer can recover those objects from the packet. □

Theorem 6168.3 (Real interval total boundedness finite-net handoff)**.** *Every compact-interval, completion, or uniform-continuity consumer of an accepted* $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$ *packet receives total boundedness only through the displayed route*

$$\mathsf{LocatedInterval}^{\uparrow},\ \mathsf{LocatedRealInterval}^{\uparrow},\ \mathsf{Rat}^{\uparrow}\ \textit{or}\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow}.$$

Thus the consumer receives a finite list of interval centers and a tolerance-indexed coverage row for the displayed located real interval, without receiving open-cover Heine–Borel, a selected subcover, quotient real equality, endpoint trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier of Definition 6168.1. The rows I and L are the only interval source, and ε is the only tolerance request visible to the consumer.

The mesh and center rows M, E are finite data. They feed the $\mathsf{FiniteEpsilonNet}^{\uparrow}$ handoff F, so coverage is read as a displayed net over the same located real interval rather than as a subcover of an arbitrary open cover.

Transport and replay do not widen the boundary. The rows H, C, P, N preserve the same finite route and add provenance and local naming, while the excluded compactness, choice, quotient, trichotomy, and completeness objects have no carrier coordinate. □

Theorem 6168.4 (Real interval total boundedness mesh refinement)**.** *Let* $T = (I, L, \varepsilon, M, E, F, H, C, P, N)$ *be an accepted* $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$ *packet. For every displayed smaller positive tolerance request* δ *admitted by the same* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance ledger with* $\delta \le \varepsilon$*, the refined request factors through a finite mesh subdivision* M_δ *and center list* E_δ *over the same located interval rows* I, L*, and then through the same* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *handoff pattern used by* F*.*

Every read of the refined packet remains visible through $I, L, \varepsilon, M, E, F, H, C, P, N$ together with the displayed subdivision witnesses M_δ, E_δ. The refinement supplies no open-cover Heine–Borel theorem, no selected subcover, no quotient real equality, no endpoint trichotomy, no countable choice, and no ambient $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 6168.1. The only interval rows available to the smaller request are still I and L, and the only tolerance ledger already admitted by the packet is ε.

Use the finite-net handoff of Definition 6168.3. A smaller positive request is served by subdividing the displayed mesh row into a finite refinement M_δ, choosing its displayed center list E_δ, and reading coverage through the same finite handoff pattern as F.

The structural rows are unchanged. Componentwise transport still passes through H, replay through C, provenance through P, and local naming through N.

Since the carrier and its refinement rows remain finite mesh data over $I, L, \varepsilon, M, E, F, H, C, P, N$, none of the excluded open-cover, selected-subcover, quotient, trichotomy, choice, or ambient-completeness principles is introduced by the refined tolerance request. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalTotalBoundedness}^\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalTotalBoundedness}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 6168.1, Definition 6168.2, and Definition 6168.3 seed the finite total-boundedness route over $\mathsf{LocatedInterval}^\uparrow$, $\mathsf{LocatedRealInterval}^\uparrow$, $\mathsf{FiniteEpsilonNet}^\uparrow$, $\mathsf{Rat}^\uparrow$, and $\mathsf{Real}^\uparrow$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalTotalBoundedness}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover Heine–Borel, selected finite subcovers, quotient real equality, endpoint trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located interval admission, positive tolerance exactness, finite mesh coverage, finite epsilon-net handoff, non-escape, and local naming for BEDC.Derived.RealIntervalTotalBoundednessUp.

Constructive story: A $\mathsf{RealIntervalTotalBoundedness}^\uparrow$ packet is generated from LocatedIntervalUp endpoints, a LocatedRealIntervalUp locatedness row, a positive RatUp or RealUp tolerance ledger, finite mesh cells, displayed centers, a FiniteEpsilonNetUp handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6169

A Concrete Naming Certificate for ClosedParallelDiamondObstruction$^{\uparrow}$

The ClosedParallelDiamondObstruction$^{\uparrow}$ packet realizes the MetaCIC confluence frontier of section 9386.3 as a finite obstruction surface. It sits beside the premise ledger of chapter 2325, the finite observation budget of chapter 5099, the residual-substitution boundary of chapter 2181, and the residual checker of chapter 3827. The packet records the missing closed parallel diamond route as a named obstruction row, separating it from both the existing premise ledger and any future proof of BetaParallelDiamondClosed.

Definition 6169.1 (Closed parallel diamond obstruction carrier)**.** *A* ClosedParallelDiamondObstruction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (P, L, R, C, B, D, H, K, Q, N)$$

with the following displayed rows:

1. *P is the closed parallel-step window whose two branches are under inspection.*
2. *L is the* ClosedParallelDiamondPremiseLedger$^{\uparrow}$ *row, recording the premise-ledger route that a conditional confluence bridge may cite.*
3. *R is the* MetaCICResidualSubstitutionBoundary$^{\uparrow}$ *row, keeping residual-substitution compatibility visible as a separate obstruction.*
4. *C is the* MetaCICConfluenceResidualChecker$^{\uparrow}$ *row, recording the finite checker status available for the displayed residual window.*
5. *B is the* FiniteObservationConfluenceBudget$^{\uparrow}$ *row, bounding the observation budget in which local joins may be inspected.*
6. *D is the obstruction row:* BetaParallelDiamondClosed *is not discharged by the packet and remains a required closed-diamond input.*
7. *H records componentwise* hsame *transport for the closed parallel window, premise ledger, residual boundary, checker, finite budget, obstruction row, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from the closed parallel window through L, R, C, B, D, H, Q, N.*
9. *Q is the* Pkg *provenance over* ClosedParallelDiamondObstruction$^{\uparrow}$, ClosedParallelDiamondPremiseLedger$^{\uparrow}$, FiniteObservationConfluenceBudget$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, MetaCICConfluenceResidualChecker BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{ClosedParallelDiamondObstruction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $P, L, R, C, B, D, H, K, Q, N$. It has no coordinate proving BetaParallelDiamondClosed*, no proof of* BetaParallelSubstitutionCompatibility*, no arbitrary closed Church–Rosser theorem, no host residual semantics, and no unchecked confluence bridge.*

Theorem 6169.2 (Closed parallel diamond obstruction obligations)**.** *For every accepted* ClosedParallelDiamondObs *carrier $O = (P, L, R, C, B, D, H, K, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedParallelDiamondObstruction}^{\uparrow}}$ *surface consists exactly of closed parallel-window admission, premise-ledger exposure, residual-substitution boundary exposure, residual-checker exposure, finite observation-budget exposure, closed-diamond obstruction retention, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6169.1. The rows P, L, R, C, B, D are the mathematical obstruction surface, and H, K, Q, N are the structural rows.

The premise-ledger and residual rows are separate. Row L records the conditional premise route, while row R keeps substitution compatibility visible as an independent boundary.

The finite observation rows C and B record bounded checker status and local observation budget. They do not discharge the closed parallel diamond row D.

Rows H, K, Q, N transport, replay, source, and name the same finite packet. Since no row proves BetaParallelDiamondClosed or BetaParallelSubstitutionCompatibility, and no row exports arbitrary closed confluence, the listed obligations exhaust the local surface. □

Theorem 6169.3 (Closed parallel diamond obstruction separation)**.** *Every MetaCIC confluence read through an accepted* $\mathsf{ClosedParallelDiamondObstruction}^{\uparrow}$ *packet factors through*

$$P \longmapsto L, R, C, B \longmapsto D \longmapsto H, K, Q, N.$$

The packet therefore separates the missing closed parallel diamond premise from the existing premise-ledger carrier: it records why the confluence endpoint is blocked, not a proof that the endpoint has been supplied.

Proof. Begin with the closed parallel window P. The carrier allows that window to be read only together with the premise ledger L, residual boundary R, residual checker C, and finite observation budget B.

The obstruction row D is downstream of those rows and remains present in the accepted packet. It names the closed parallel diamond input as not discharged by the carrier.

Apply Definition 6169.2. Transport, replay, provenance, and local naming preserve the same finite route without replacing D by a theorem.

Thus the packet can guide a confluence consumer to the precise obstruction row, while the separate premise ledger remains a cited input surface rather than a closed diamond proof. □

Falsifiable prediction: If a MetaCIC confluence consumer cites $\mathsf{ClosedParallelDiamondObstruction}^{\uparrow}$ as proof of arbitrary closed-term confluence, then the packet is refuted because the obstruction row D is still present and no closed parallel diamond proof row is displayed.

Independence witness: closed_parallel_diamond_premise_ledger, finite_observation_confluence_budget, metacic_residual_substitution_boundary, metacic_confluence_residual_checker: ClosedParallelDiamondObstruct is not bijective to any listed sibling because it simultaneously displays the premise-ledger route, residual-substitution boundary, finite residual-checker status, observation budget, and retained closed-diamond obstruction row.

The Lean TasteGate site for ClosedParallelDiamondObstruction$^{\uparrow}$ must later provide explicit Nontrivial ClosedParallelDiamondObstruction$^{\uparrow}$ and FieldFaithful ClosedParallelDiamondObstruction$^{\uparrow}$ instances. Those instances should distinguish the premise-ledger row, finite observation budget, residual-substitution boundary, residual checker, obstruction row, transport, replay, provenance, and local naming as separate fields rather than collapsing the obstruction into the existing ledger.

Closure status for NameCert$_{\text{ClosedParallelDiamondObstruction}^{\uparrow}}$.

Constructive story: A ClosedParallelDiamondObstruction$^{\uparrow}$ packet is generated from closed parallel-step windows, ClosedParallelDiamondPremiseLedger rows, MetaCICResidualSubstitutionBoundary rows, MetaCICConfluenceResidualChecker rows, FiniteObservationConfluenceBudget rows, a retained closed-diamond obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ClosedParallelDiamondObstruction}^{\uparrow}}$, seed)

Scope closed: Definition 6169.1, Definition 6169.2, and Definition 6169.3 seed the finite obstruction packet for the MetaCIC closed parallel diamond frontier.

Formal verification: FormalStatus(NameCert$_{\text{ClosedParallelDiamondObstruction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove BetaParallelDiamondClosed, BetaParallelSubstitutionCompatibility, arbitrary closed Church–Rosser, host residual semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, premise-ledger exposure, residual-substitution boundary exposure, residual-checker exposure, finite observation-budget exposure, obstruction retention, transport, replay, provenance, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.ClosedParallelDiamondObstructionUp.

Chapter 6170

A Concrete Naming Certificate for $\mathsf{UniformSpaceRealCompletion}^{\uparrow}$

Following Bourbaki, Kelley, and Bishop–Bridges, the $\mathsf{UniformSpaceRealCompletion}^{\uparrow}$ packet records the finite route by which the real uniform structure and Cauchy-filter completion data become visible to Real and Completion consumers. It sits after the real-uniformity surface of chapter 1624, the entourage interface of chapter 339, the complete-uniform-space boundary of chapter 1588, the Cauchy-filter packet of chapter 333, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed completion interface; it is not a quotient of streams, a selected limit operator, a trichotomy principle, countable choice, or an ambient completeness theorem beyond the rows it carries.

Definition 6170.1 (Uniform-space real-completion carrier)**.** *A* $\mathsf{UniformSpaceRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (R, U, F, B, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *row exposing the real-name source together with the displayed uniform structure induced on real observations.*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row for that same real-uniform source, carrying only the finite entourage comparisons visible to a completion request.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row naming the Cauchy-filter request that the completion consumer may inspect.*
4. *B is a Cauchy-filter basis or completion-basis row refining F to the finite family of filter and entourage requests used by the packet.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which real-name observations are scheduled.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row converting the scheduled stream windows into regular rational approximation data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the real-uniform source, entourage row, Cauchy-filter row, finite basis, StreamName window, and RegSeqRat readback have been displayed.*

8. *H records componentwise* hsame *transport for the real-uniform source, entourage row, Cauchy-filter row, basis row, stream windows, rational readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a real-completion request through R, U, F, B, S, Q, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformSpaceRealCompletion}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CompleteUniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformSpaceRealCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eleven rows. It has no coordinate for quotient stream equality, a selected representative of a completion, countable choice, real trichotomy, or a host-level completeness theorem.

Lean4 ✓ `BEDC.Derived.UniformSpaceRealCompletionUp.TasteGate.UniformSpaceRealCompletionTasteGate single carrier alignment`

Theorem 6170.2 (Uniform-space real-completion NameCert obligations)**.** *For every accepted* $\mathsf{UniformSpaceRealCompletion}^{\uparrow}$ *carrier $T = (R, U, F, B, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformSpaceRealCompletio}}$ *surface consists exactly of carrier admission, Real uniform-structure admission, entourage-row admission, Cauchy-filter admission, finite basis admission, StreamName finite-window admission, RegSeqRat readback, Real seal admission, componentwise transport, replay, provenance, and local naming for the displayed rows $R, U, F, B, S, Q, E, H, C, P, N$.*

Proof. Project the accepted packet. Carrier admission reads the real-uniform source R, the entourage row U, the Cauchy-filter row F, the finite basis row B, the stream-window row S, the rational readback Q, and the Real seal E.

The completion-facing rows are ordered. A request first sees the real-induced uniformity and entourage data, then the Cauchy-filter and basis rows, and only then the finite StreamName and RegSeqRat readback that can be sealed as Real data.

Transport and replay do not widen the route. The row H transports the displayed components, C replays the same route, P records the sibling provenance, and N names the local certificate.

Since no row stores quotient stream equality, a selected completion representative, countable choice, trichotomy, or host completeness, no local NameCert consumer can recover those principles from the packet. □

Theorem 6170.3 (Uniform-space real-completion Cauchy handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{UniformSpaceRealCompletion}^{\uparrow}$ *carrier receives Cauchy completion data only through the displayed route*

$$\mathsf{RealUniformStructure}^{\uparrow},\ \mathsf{UniformSpace}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff supplies a finite real-uniform source, entourage comparisons, a Cauchy-filter request, a finite basis, scheduled stream windows, regular rational readback, and a Real seal, all transported and replayed through H, C, P, N. It supplies no quotient stream, selected limit, endpoint trichotomy, countable choice, or ambient completeness theorem.

Proof. Begin with the carrier of Definition 6170.1. The only completion-facing source rows are the real-uniform row R, the entourage row U, the Cauchy-filter row F, and the basis row B.

The finite observation route is downstream of those rows. StreamName windows S schedule the visible requests, RegSeqRat readback Q exposes rational approximation data, and the Real seal E is read only after those finite rows are displayed.

Finally apply the NameCert obligations of Definition 6170.2. They force transport, replay, provenance, and local naming through H, C, P, N, and the carrier has no coordinate from which a quotient stream, selected limit, trichotomy, choice principle, or independent completeness theorem could be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformSpaceRealCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformSpaceRealCompletion}^{\uparrow}$ packet is generated from a RealUniformStructure row, a UniformSpace entourage row, a CauchyFilter row, a finite completion-basis row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformSpaceRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6170.1, Definition 6170.2, and Definition 6170.3 seed the finite real-uniform completion route over Real uniformity, entourage, Cauchy-filter, StreamName, RegSeqRat, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformSpaceRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected completion representatives, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage admission, Cauchy-filter basis exactness, finite stream-window readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.UniformSpaceRealCompletionUp.

Chapter 6171

A Concrete Naming Certificate for $\mathsf{CechCompleteSpace}^{\uparrow}$

Following Cech, Engelking, and Kelley, the $\mathsf{CechCompleteSpace}^{\uparrow}$ packet records the topological completion-facing surface of a completely regular space through finite covers, uniform envelopes, and displayed completion seals. It sits after the topology carrier of chapter 88, the complete metric boundary of chapter 128, the uniform-complete route of chapter 2211, the Polish-space consumer of chapter 1490, and the finite observation windows of chapter 126. The packet is a NameCert reconstruction of the Cech-completion surface; it does not claim ambient choice, quotient completion equality, selected ultrafilters, or open-cover compactness.

Definition 6171.1 (Cech complete space carrier)**.** *A* $\mathsf{CechCompleteSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, U, M, F, W, S, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the open-set classifier and the completely regular observation surface used by the completion request.*
2. *U is the* $\mathsf{UniformCompleteSpace}^{\uparrow}$ *envelope row, recording the uniform cover and Cauchy-filter completion data available from the same topological source.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *comparison row, used only when a metrizable sibling read is explicitly present.*
4. *F is the finite Cech-filter row. It stores the nested cover, centered finite-intersection checks, and refusal boundary for non-convergent filter branches.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row through which cover refinements, filter stages, and completion-facing observations are inspected.*
6. *S is the* $\mathsf{PolishSpace}^{\uparrow}$ *sibling handoff row, present only as a consumer-facing comparison surface and not as the definition of the packet.*
7. *R is the terminal regularization and real-boundary ledger for finite cover diameters, distance comparisons when M is present, and local completion thresholds.*
8. *H records componentwise* hsame *transport for the topology, uniform-complete, complete-metric, filter, stream-window, Polish comparison, regularization, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Cech-completion request through T, U, F, W, R and only then through M or S when those sibling consumers are used.*
10. *P is the* Pkg *provenance over* $\mathsf{CechCompleteSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{UniformCompleteSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CechCompleteSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eleven rows. It has no coordinate for ambient choice, quotient completion equality, selected ultrafilters, open-cover compactness, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CechCompleteSpaceUp.CechCompleteSpaceTasteGate single carrier alignment`

Theorem 6171.2 (Cech complete space NameCert obligations)**.** *For every accepted* $\mathsf{CechCompleteSpace}^{\uparrow}$ *carrier $Q = (T, U, M, F, W, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CechCompleteSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, topology-source admission, uniform-complete envelope admission, optional complete-metric comparison, finite Cech-filter admission, StreamName window visibility, optional Polish comparison, regularization-ledger admission, componentwise transport, replay, provenance, and local naming for the displayed rows $T, U, M, F, W, S, R, H, C, P, N$.*

Proof. Project the accepted carrier in Definition 6171.1. The projection exposes the topology source T, uniform-complete envelope U, complete-metric comparison row M, finite Cech-filter row F, StreamName windows W, Polish comparison row S, regularization ledger R, and structural rows H, C, P, N.

The completion-facing route starts from topology and uniform data. A request must read T and U before it can inspect the finite filter row F, and the stages of F are visible only through the finite windows W.

The sibling comparison rows do not define the packet. Row M supplies a complete-metric comparison only when such a comparison is displayed, and row S supplies a Polish-space consumer surface only after the Cech-filter route has already been read.

The structural rows preserve that same route. Since none of $T, U, M, F, W, S, R, H, C, P, N$ stores ambient choice, quotient completion equality, selected ultrafilters, open-cover compactness, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6171.3 (Cech complete space completion handoff)**.** *Every completion-facing, complete-metric-facing, uniform-complete-facing, or Polish-facing consumer of an accepted* $\mathsf{CechCompleteSpace}^{\uparrow}$ *carrier $Q = (T, U, M, F, W, S, R, H, C, P, N)$ reads the displayed route*

$$T, U \longmapsto F \longmapsto W \longmapsto R \longmapsto M, S \longmapsto H, C, P, N$$

before it receives the public packet. Thus the consumer sees the topological source, uniform completion envelope, finite Cech-filter evidence, StreamName observation windows, regularization ledger, optional complete-metric comparison, optional Polish comparison, transport, replay, provenance, and local naming without receiving ambient choice, quotient completion equality, selected ultrafilters, or open-cover compactness.

Proof. Start with a consumer of Q. Carrier admission gives the topology source and uniform-complete envelope as the displayed pair T, U, so the completion request cannot start from a hidden host object.

The Cech-filter evidence is then read through F and W. The finite filter row records the cover-refinement and centered finite-intersection checks, while the StreamName row exposes only finite windows of that route.

The regularization ledger R is downstream of those windows. Only after R has been read may the optional complete-metric comparison M or Polish comparison S be consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. The excluded choice, quotient, ultrafilter, open-cover compactness, host-equality, and ambient-completeness data have no coordinate in the carrier. □

Falsifiable prediction: Every $\mathsf{CechCompleteSpace}^{\uparrow}$ completion-facing read exposes a $\mathsf{Topology}^{\uparrow}$ source row, $\mathsf{UniformCompleteSpace}^{\uparrow}$ envelope row, finite Cech-filter row, $\mathsf{StreamName}^{\uparrow}$ windows, regularization ledger, optional $\mathsf{CompleteMetric}^{\uparrow}$ comparison, optional $\mathsf{PolishSpace}^{\uparrow}$ comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, complete-metric, uniform-complete-space, polishspace, streamname: $\mathsf{CechCompleteSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds a topological source, uniform-complete envelope, finite Cech-filter evidence, StreamName windows, and completion-facing comparison rows in one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CechCompleteSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CechCompleteSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6171.1, Definition 6171.2, and Definition 6171.3 seed the finite Cech-completion route through $\mathsf{Topology}^{\uparrow}$, $\mathsf{UniformCompleteSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CechCompleteSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient choice, quotient completion equality, selected ultrafilters, open-cover compactness, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topology-source admission, uniform-complete envelope admission, finite Cech-filter exactness, StreamName window visibility, comparison-row nonescape, completion handoff, and local naming for BEDC.Derived.CechCompleteSpaceUp.

Constructive story: A $\mathsf{CechCompleteSpace}^{\uparrow}$ packet is generated from a TopologyUp source, a UniformCompleteSpaceUp envelope, an optional CompleteMetricUp comparison, finite Cech-filter evidence, StreamNameUp windows, an optional PolishSpaceUp comparison, a regularization ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6172

A Concrete Naming Certificate for $\mathsf{LocatedCompactCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedCompactCompletion}^{\uparrow}$ packet records the finite completion-facing route by which located compact metric data supplies Cauchy completion consumers with explicit finite-net and real-seal rows. It sits after the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Cauchy-thread surface of chapter 128, the compact metric source of chapter 129, and the finite covering route of chapter 127. The certificate names only the located finite-net handoff into the RegSeqRat/Real completion route; it does not choose quotient representatives, host limits, or open-cover compactness data.

Definition 6172.1 (Located compact completion carrier)**.** *A* $\mathsf{LocatedCompactCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, T, D, S, Q, R, F, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric, total-boundedness, and complete-metric interfaces read by compact consumers.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, indexed by a dyadic tolerance ledger from* $\mathsf{DyadicRatCore}^{\uparrow}$.
3. *D is the dyadic radius and rounding core that measures the requested net precision.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row used to inspect candidate Cauchy threads.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same window schedule.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular-rational readback.*
7. *F records the finite net centers and coverage witnesses carried from T into the completion route.*
8. *M is the complete-metric Cauchy handoff row, read before any completion consumer treats the finite-net route as convergent data.*
9. *H records componentwise* hsame *transport for all displayed compact, net, tolerance, stream, rational, real, handoff, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a located-compact completion request through $K, T, D, S, Q, R, F, M, H, P, N$*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactCompletion}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by these displayed rows. It has no coordinate for arbitrary open covers, quotient completion equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedCompactCompletionUp.LocatedCompactCompletionTasteGate single carrier alignment`

Theorem 6172.2 (Located compact completion carrier obligations)**.** *Every accepted* $\mathsf{LocatedCompactCompletion}^{\uparrow}$ *carrier* $L = (K, T, D, S, Q, R, F, M, H, C, P, N)$ *exposes exactly the compact metric source, finite total-boundedness net, dyadic tolerance ledger, stream-window surface, regular-rational readback, Real seal, finite-net handoff, complete-metric handoff, componentwise transport, displayed replay, provenance, and local naming rows listed in Definition 6172.1. No consumer of the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactCompletion}^{\uparrow}}$ *row receives an additional open-cover compactness theorem, quotient completion object, selected limit, host real equality, or Real completeness principle.*

Proof. Project the carrier L. The compact source is K, while the finite-net data is the pair of rows T, F measured by the dyadic tolerance row D.

The completion-facing readback is not taken directly from compactness. It passes through the window row S, the regular-rational row Q, the Real seal R, and the complete-metric handoff M before a downstream consumer may read the route as completion data.

Transport and replay preserve the displayed packet only. The rows H, C, P, N keep the same finite BHist data under hsame, Cont, Pkg, and NameCert bookkeeping, so the excluded open-cover, quotient, selected-limit, host-equality, choice, and completeness objects have no row from which they could be recovered. □

Theorem 6172.3 (Located compact completion finite-net seal)**.** *Every* $\mathsf{LocatedCompactCompletion}^{\uparrow}$ *consumer that asks for a completion-facing compactness row must first display the finite-net seal*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

together with the $\mathsf{TotallyBounded}^{\uparrow}$ *net row and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row. The seal exports a finite list of inspected centers, tolerance-indexed coverage, regular-rational readback, and a terminal Real seal; it exports no open-cover subcover selector, quotient completion equality, selected limit, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier rows in order. The finite-net seal begins with T and D, so every radius request is measured by dyadic BEDC data before any stream or real row is inspected.

Next the route enters S, Q, R. These rows force the completion-facing consumer to pass through StreamName windows, RegSeqRat regular readback, and the Real seal rather than through a host completion or quotient representative.

Finally F and M bind the finite centers to the complete-metric handoff. Since replay and provenance only repackage those rows, the consumer receives the listed seal and none of the excluded compactness, quotient, selected-limit, host-equality, or completeness principles. □

Theorem 6172.4 (Located compact completion Bishop handoff)**.** *The Bishop-style handoff from compact finite-net data to completion consumers factors through chapter 301 and chapter 38 after the chapter 126 and chapter 291 rows are displayed. Thus a downstream completion packet may cite* $\mathsf{LocatedCompactCompletion}^{\uparrow}$ *only as a finite NameCert route over* BHist*,* hsame*,* Cont*,* Pkg*, finite nets, and the RegSeqRat/Real seal rows, not as a host theorem identifying a quotient completion with a selected real limit.*

Proof. Start from the compact metric and total-boundedness rows of Definition 6172.1. They supply a located compact source and finite centers, but not a host compactness theorem.

The handoff to completion consumers is then routed through dyadic tolerances, stream observations, and regular rational readback. This is exactly the finite route named by the StreamName and RegSeqRat sibling chapters before the terminal Real seal is read.

The complete-metric handoff row records where Cauchy completion consumers may attach their own local obligations. It does not identify quotient representatives, pick limits, or equate the BEDC real seal with a host real object, so the Bishop-style completion use remains a displayed NameCert route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6172.1, Definition 6172.2, Definition 6172.3, and Definition 6172.4 seed the located compact finite-net handoff into the RegSeqRat and Real completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactCompletion}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.LocatedCompactCompletionUp`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient completion equality, selected limits, host real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exactness, dyadic tolerance routing, StreamName and RegSeqRat handoff, Real seal non-escape, CompleteMetric handoff, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompactCompletionUp.

Constructive story: A $\mathsf{LocatedCompactCompletion}^{\uparrow}$ packet is generated from a CompactMetricUp source, a TotallyBoundedUp finite-net row, a DyadicRatCoreUp tolerance ledger, StreamNameUp observation windows, RegSeqRatUp readback, a RealUp seal, a CompleteMetricUp handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6173

A Concrete Naming Certificate for UniformLipschitzCompactVision$^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, and the Arzela–Ascoli habit of making one shared family bound visible before compactness is consumed, the UniformLipschitzCompactVision$^{\uparrow}$ packet records the finite NameCert data behind the Heine–Cantor finite-net route. It sits after the compact metric source of chapter 129, the shared-bound family packet of chapter 6167, the compact-net selector of chapter 914, the finite Lebesgue-number handoff of chapter 1301, and the downstream UniformModulus$^{\uparrow}$ consumer. The packet names the compact-uniform-continuity vision as finite shared-Lipschitz data; it does not import open-cover compactness, selected subcovers, host function-space compactness, or a modulus chosen outside the displayed rows.

Definition 6173.1 (Uniform Lipschitz compact-vision carrier)**.** *A* UniformLipschitzCompactVision$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (K, F, L, U, B, S, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing finite metric-net observations and compact-metric provenance for the same source.*
2. *F is the finite* ContinuousMap$^{\uparrow}$ *family row whose members are the displayed maps inspected by the consumer.*
3. *L is the shared* LipschitzConstant$^{\uparrow}$ *row, recording one family-level bound for every listed member.*
4. *U is the* UniformLipschitzFamily$^{\uparrow}$ *handoff row tying K, F, L to the existing shared-Lipschitz family certificate.*
5. *B is the* FiniteLebesgueNumber$^{\uparrow}$ *row recording the positive finite radius ledger used by the compact-net route.*
6. *S is the* CompactNetModulusSelector$^{\uparrow}$ *row selecting the finite net, center-radius witnesses, and lower precision data from K, F, L, B.*
7. *M is the* UniformModulus$^{\uparrow}$ *export row consumed by compact-uniform-continuity clients.*
8. *H records componentwise* hsame *transport for the compact source, map family, shared Lipschitz row, family handoff, Lebesgue-number row, compact-net selector, uniform-modulus export, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-uniform tolerance request through $K, F, L, U, B, S, M, H, P, N$.*
10. *P is the* Pkg *provenance over* UniformLipschitzCompactVision$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, LipschitzConstant$^{\uparrow}$, UniformLipschitzFamily$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformLipschitzCompactVision}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for open-cover compactness, selected subcovers, arbitrary cover refinements, ambient function-space topology, quotient equality of maps, choice-selected centers, or an undisplayed modulus.

Theorem 6173.2 (Uniform Lipschitz compact-vision NameCert obligations)**.** *For every accepted* UniformLipschitzCompactVision$^{\uparrow}$ *carrier $V = (K, F, L, U, B, S, M, H, C, P, N)$, the local* NameCert$_{\text{UniformLipschitzCompa}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for $K, F, L, U, B, S, M, H, C, P, N$;*
2. *compact-source exposure, requiring every finite-net and distance read to pass through the displayed* CompactMetric$^{\uparrow}$ *row K;*
3. *continuous-family exposure, requiring the inspected maps to be read through the finite* ContinuousMap$^{\uparrow}$ *family row F;*
4. *shared Lipschitz exactness, requiring the single* LipschitzConstant$^{\uparrow}$ *row L to control every listed member before the* UniformLipschitzFamily$^{\uparrow}$ *handoff U is available;*
5. *finite-radius accountability, requiring the* FiniteLebesgueNumber$^{\uparrow}$ *row B and* CompactNetModulusSelector$^{\uparrow}$ *row S to expose the same finite compact-net route;*
6. *uniform-modulus export, requiring M to consume only the shared Lipschitz row, finite radius ledger, compact-net selector, and displayed structural rows;*
7. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the rows already listed.*

No compact-uniform-continuity obligation for this packet is stored outside those rows.

Lean4 ✓ `BEDC.Derived.UniformLipschitzCompactVisionUp.UniformLipschitzCompactVisionTasteGate`
`single carrier alignment`

Proof. Project the accepted carrier $V = (K, F, L, U, B, S, M, H, C, P, N)$. Its mathematical rows are the compact source K, map family F, shared Lipschitz row L, family handoff U, finite radius row B, compact-net selector S, and uniform-modulus export M.

The compact source and map family are read first. The row K supplies the finite metric windows, while F restricts the consumer to displayed continuous-map members.

The shared bound is then forced through L and U. Because one LipschitzConstant$^{\uparrow}$ row controls every listed member, the packet records family-level Lipschitz evidence rather than a hidden memberwise selector.

The finite-net route is recorded by B and S. These rows supply the positive finite-radius ledger and selected compact-net precision consumed by M.

The structural rows H, C, P, N preserve this same route. Since the excluded open-cover, subcover-selection, function-space, quotient, choice, and hidden-modulus objects do not occur as coordinates, the displayed obligations exhaust the local certificate. □

Theorem 6173.3 (Uniform Lipschitz compact-vision modulus handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{UniformLipschitzCompactVision}^{\uparrow}$ *carrier factors through the shared Lipschitz row and the finite net modulus route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{LipschitzConstant}^{\uparrow} \longmapsto \mathsf{UniformLipschitzFamily}^{\uparrow} \longmapsto \mathsf{FiniteLebesgueNumber}^{\uparrow},\ \mathsf{Co}$$

Thus the consumer receives a uniform-modulus export from the displayed compact source, displayed family, one shared Lipschitz bound, finite radius ledger, and compact-net selector; it receives no open-cover compactness theorem, selected subcover, host compactness assertion, ambient family topology, or modulus selected outside the packet.

Proof. Start with a tolerance request. The compact source row K and map-family row F are the only rows that expose source metric windows and inspected maps.

Read the shared Lipschitz data through L and U. This step binds every listed map to one displayed family-level bound before any compact-net selector may be consumed.

Next read the finite radius route. The row B supplies the finite Lebesgue-number ledger, and S turns the compact-net observations into the selected precision data used by the downstream modulus.

The export row M is downstream of those rows. Therefore every accepted $\mathsf{UniformModulus}^{\uparrow}$ read is a finite handoff through $K, F, L, U, B, S, H, C, P, N$.

Because no open-cover compactness object, selected subcover, host compactness assertion, ambient family topology, quotient map equality, or hidden modulus occurs in the carrier, no compact-uniform-continuity consumer can factor through such data. □

Theorem 6173.4 (Compact-uniform equicontinuous family selector)**.** *An accepted* $\mathsf{UniformLipschitzCompactVision}^{\uparrow}$ *packet exports a* $\mathsf{UniformModulus}^{\uparrow}$ *row for an equicontinuous family only after the* $\mathsf{CompactMetric}^{\uparrow}$ *source,* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, shared* $\mathsf{LipschitzConstant}^{\uparrow}$ *row,* $\mathsf{UniformLipschitzFamily}^{\uparrow}$ *handoff,* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *row,* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows are all displayed. The selector supplies no selected subcover, host function-space compactness, or modulus chosen outside those displayed rows.*

Proof. Project the carrier rows $V = (K, F, L, U, B, S, M, H, C, P, N)$. The rows K and F expose the compact metric source and continuous-map family before any family-level modulus can be named.

Invoke the shared-Lipschitz route through L and U. This binds the whole displayed family to one $\mathsf{LipschitzConstant}^{\uparrow}$ row and makes the equicontinuity read a family handoff rather than a memberwise hidden choice.

Apply the finite compact-net selector. The $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ row B supplies the finite radius ledger, and S turns the compact-net observations into the precision data consumed by the $\mathsf{UniformModulus}^{\uparrow}$ row M.

Finally transport and replay the same rows through H, C, P, N. Since selected subcovers, host function-space compactness, and externally chosen moduli are absent from the carrier, the exported family selector is exactly the displayed compact-net route. □

Falsifiable prediction: An accepted $\mathsf{UniformLipschitzCompactVision}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer obtains a UniformModulusUp export without displaying the CompactMetric source row, ContinuousMap family row, shared LipschitzConstant row, UniformLipschitzFamily handoff, FiniteLebesgueNumber row, CompactNetModulusSelector row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, continuousmap, lipschitz-constant, uniform-lipschitz-family, finite-lebesgue-number, compactnetmodulusselector, and uniformmodulus: none is bijective to $\mathsf{UniformLipschitzCompactVision}^{\uparrow}$ because only this packet jointly records the shared-Lipschitz family route, finite radius ledger, compact-net selector, and UniformModulus export as one compact-uniform-continuity NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLipschitzCompactVision}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLipschitzCompactVision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6173.1, Definition 6173.2, and Definition 6173.3 seed the finite shared-Lipschitz compact-uniform route from CompactMetric data through finite net modulus selection to UniformModulus export.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLipschitzCompactVision}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, host compactness, ambient function-space topology, quotient map equality, choice-selected centers, hidden moduli, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, continuous-family exposure, shared Lipschitz exactness, finite-radius accountability, compact-net selector compatibility, uniform-modulus export, transport, replay, provenance, and local naming for BEDC.Derived.UniformLipschitzCompactVisionUp.

Constructive story: A $\mathsf{UniformLipschitzCompactVision}^{\uparrow}$ packet is generated from a CompactMetricUp source row, ContinuousMapUp family row, shared LipschitzConstantUp row, UniformLipschitzFamilyUp handoff, FiniteLebesgueNumberUp row, CompactNetModulusSelectorUp row, UniformModulusUp export, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6174

A Concrete Naming Certificate for $\mathsf{FiniteLipschitzFamily}^{\uparrow}$

Following Arzela-Ascoli and Bishop-style compact metric analysis, the $\mathsf{FiniteLipschitzFamily}^{\uparrow}$ packet records the finite BEDC surface for a listed family of continuous maps controlled by one displayed Lipschitz row. It sits after the compact source of chapter 129, the target metric of chapter 57, the displayed map rows of chapter 130, the shared bound ledger of chapter 2328, and the tolerance handoff of chapter 369. The packet gives compact-uniform and Arzela–Ascoli consumers a finite family row; it does not assert ambient function-space compactness, selected subsequences, open-cover compactness, quotient function equality, or a hidden modulus.

Definition 6174.1 (Finite Lipschitz-family carrier)**.** *A* $\mathsf{FiniteLipschitzFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, I, M, L, V, H, C, P, N)$$

with the following displayed rows:

1. X *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite metric windows supply all source-distance reads.*
2. Y *is the target* $\mathsf{Met}^{\uparrow}$ *row whose distance reads are used by the displayed map values.*
3. I *is the finite index row naming exactly the family members available for inspection.*
4. M *is the finite list of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows, one row for each index in* I*.*
5. L *is the shared* $\mathsf{LipschitzConstant}^{\uparrow}$ *row, recording one displayed bound used by every listed member.*
6. V *is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that receives the compact source, target metric, displayed maps, and common Lipschitz bound as tolerance data.*
7. H *records componentwise* hsame *transport for* X, Y, I, M, L, V *and the structural rows.*
8. C *records displayed* Cont *replay of the route from compact metric source data through the listed continuous maps and the shared Lipschitz row to the uniform-modulus handoff.*
9. P *is the* Pkg *provenance over* $\mathsf{FiniteLipschitzFamily}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{LipschitzConstant}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteLipschitzFamily}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient function-space topology, selected subsequence, open-cover compactness proof, quotient equality of functions, or non-displayed modulus.

Lean4 ✓ `BEDC.Derived.FiniteLipschitzFamilyUp.TasteGate.FiniteLipschitzFamilyTasteGate single carrier alignment`

Theorem 6174.2 (Finite Lipschitz-family NameCert obligations)**.** *For every accepted* $\mathsf{FiniteLipschitzFamily}^{\uparrow}$ *carrier* $F = (X, Y, I, M, L, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteLipschitzFamily}^{\uparrow}}$ *surface consists exactly of compact-source exposure, target-metric exposure, finite-index admission, displayed continuous-map admission, shared-bound exactness,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored in an ambient function-space object or in an unlisted modulus selector.*

Proof. Project the accepted packet $F = (X, Y, I, M, L, V, H, C, P, N)$. The rows X, Y, I, M, L, V are the only mathematical coordinates available to the family read.

The finite family part is therefore explicit. The index row I lists the inspectable members, M attaches each member to a displayed $\mathsf{ContinuousMap}^{\uparrow}$ row, and L supplies one common $\mathsf{LipschitzConstant}^{\uparrow}$ row for all of them.

The handoff part is also explicit. The row V receives only the displayed compact source, target metric, map, and bound data, while H, C, P, N transport, replay, source, and name the same packet.

Because the excluded objects do not occur among the carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 6174.3 (Finite Lipschitz-family modulus handoff)**.** *Every compact-uniform or Arzela–Ascoli consumer of an accepted* $\mathsf{FiniteLipschitzFamily}^{\uparrow}$ *carrier receives the route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{LipschitzConstant}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The common Lipschitz row is exported only as a finite-family tolerance handoff. It exports no ambient function-space compactness, selected subsequence, open-cover compactness, quotient function equality, or hidden modulus.

Proof. Begin with the rows X and Y. They provide the source and target metric reads that any later compact-uniform consumer may inspect.

Next read the family rows I and M together with the shared bound row L. Since every listed member is paired with a displayed $\mathsf{ContinuousMap}^{\uparrow}$ row and the same $\mathsf{LipschitzConstant}^{\uparrow}$ row, the consumer never ranges over a host function space.

Finally export V, H, C, P, N. The $\mathsf{UniformModulus}^{\uparrow}$ handoff receives the compact metric, target metric, listed maps, and common bound, while the structural rows preserve exactly that route for downstream replay.

The absent coordinates rule out selected subsequences, open-cover compactness, quotient function equality, and hidden moduli, so the handoff is precisely the finite BEDC family packet. □

Falsifiable prediction: An accepted $\mathsf{FiniteLipschitzFamily}^{\uparrow}$ read is refuted if a compact-uniform or Arzela–Ascoli consumer obtains a $\mathsf{UniformModulus}^{\uparrow}$ handoff without displaying the $\mathsf{CompactMetric}^{\uparrow}$ source row, target $\mathsf{Met}^{\uparrow}$ row, finite index row, $\mathsf{ContinuousMap}^{\uparrow}$ rows, shared $\mathsf{LipschitzConstant}^{\uparrow}$ row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, metric, continuousmap, lipschitz-constant, uniform-modulus, uniform-lipschitz-family: no listed sibling is bijective with $\mathsf{FiniteLipschitzFamily}^{\uparrow}$ because

the packet jointly carries finite family indexing, displayed continuous-map rows, one shared Lipschitz bound, a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLipschitzFamily}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteLipschitzFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6174.1, Definition 6174.2, and Definition 6174.3 seed the finite shared-Lipschitz family route from compact metric source data through listed continuous-map rows to a UniformModulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteLipschitzFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient function-space compactness, selected subsequences, open-cover compactness, quotient function equality, non-displayed moduli, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, finite-index admission, continuous-map exposure, shared-bound exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteLipschitzFamilyUp.

Constructive story: A $\mathsf{FiniteLipschitzFamily}^{\uparrow}$ packet is generated from a compact metric source row, target Metric row, finite family-index row, ContinuousMap rows, a shared LipschitzConstant row, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6175

A Concrete Naming Certificate for $\mathsf{TypedGalleryContextProbe}^{\uparrow}$

The $\mathsf{TypedGalleryContextProbe}^{\uparrow}$ packet realizes the typed-example context surface of chapter 9382 as finite NameCert data. It reads the gallery's sort-indexed contexts, Pi forms, applications, beta redexes, and Church examples as displayed rows rather than as an ambient test suite. The packet is a context probe for decidability and subject-reduction audit consumers; it does not prove global typechecking completeness, subject reduction, confluence, normalization, or conversion decidability.

The checker-read row K is consumed through chapter 749 before any decidability-facing reader may inspect bounded comparison or refusal data.

Definition 6175.1 (Typed gallery context-probe carrier)**.** *A* $\mathsf{TypedGalleryContextProbe}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, B, A, R, C, K, D, Q, H, T, P, N)$$

with the following displayed rows:

1. *S is the sort-indexed context row, listing the contexts used by the gallery examples.*
2. *B is the binder-shape row for Pi forms, shifted variables, dependent identity examples, and polymorphic identity examples.*
3. *A is the application row for ordinary applications, application tails, and projected applications.*
4. *R is the beta-redex row for the displayed reductions used by the gallery.*
5. *C is the Church-example row for booleans, natural numbers, pairs, options, lists, sums, and equality examples.*
6. *K is the checker-read row consumed by the MetaCIC decidability boundary and bounded typechecking budget surfaces.*
7. *D is the discharge-facing row consumed by the substitution spine and subject-reduction boundary surfaces.*
8. *Q records the boundary refusal: the probe supplies typed context data but does not supply a global preservation theorem.*
9. *H records componentwise* hsame *transport for gallery rows and structural rows.*
10. *T records displayed* Cont *replay from the typed gallery audit map through $S, B, A, R, C, K, D, Q, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{TypedGalleryContextProbe}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows together with the MetaCIC typed-gallery audit surface.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{TypedGalleryContextProbe}^{\uparrow}}$ *row.*

The classifier compares accepted probes only through $S, B, A, R, C, K, D, Q, H, T, P, N$. It has no coordinate for unrestricted typechecking completeness, unconditional subject reduction, global substitution soundness, confluence, normalization, conversion decidability, or a hidden checker oracle.

Theorem 6175.2 (Typed gallery context-probe NameCert obligations)**.** *For every accepted* TypedGalleryContextPr *carrier $G = (S, B, A, R, C, K, D, Q, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TypedGalleryContextProbe}^{\uparrow}}$ *surface consists exactly of sort-context admission, binder-shape admission, application admission, beta-redex admission, Church-example admission, checker-read exposure, discharge-facing exposure, boundary refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The proof-search and typechecking consumers receive a finite gallery probe, not an unrestricted metatheorem.*

Proof. Project the accepted packet $G = (S, B, A, R, C, K, D, Q, H, T, P, N)$. The rows S, B, A, R, C are the gallery-facing coordinates, so they give the only admitted context, binder, application, beta, and Church-example data.

The consumer-facing rows are K, D, Q. The checker-read row K is the route to decidability and bounded typechecking budget consumers, while D is the route to substitution-spine and subject-reduction boundary consumers. The refusal row Q records that these routes do not close the global metatheorems.

Finally H, T, P, N transport, replay, source, and name the same finite probe. Since no hidden checker oracle or unrestricted theorem coordinate is present, the listed rows exhaust the NameCert obligations. □

Theorem 6175.3 (Typed gallery context-probe binder handoff)**.** *Every decidability, substitution-spine, or subject-reduction audit consumer of an accepted* $\mathsf{TypedGalleryContextProbe}^{\uparrow}$ *carrier receives binder data only through the route*

$$S, B, A, R, C \longmapsto K, D, Q \longmapsto \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

In particular, sort-indexed contexts and Pi/application examples are exposed before the checker-read and discharge-facing rows are consumed.

Proof. Start with S and B. These rows display the sort-indexed contexts and binder shapes before any checker or discharge request is available.

Read A, R, C next. Application forms, beta redexes, and Church examples become probe data only as listed gallery rows, so the consumer cannot appeal to an ambient collection of examples.

The handoff then passes through K, D, Q. The checker-facing row and discharge-facing row are both guarded by the refusal row, which prevents the probe from being read as a proof of global subject reduction or global decidability.

Finally H, T, P, N preserve the same route for replay and naming. Thus binder-sensitive audit consumers receive finite context probes with explicit boundaries. □

Falsifiable prediction: A $\mathsf{TypedGalleryContextProbe}^{\uparrow}$ read is refuted if a typed-gallery, metacic-decidable-boundary, bounded-typechecking-budget, metacic-substitution-spine, or metacic-subject-reduction-boundary consumer obtains checker or discharge data without first displaying sort-context, binder-shape, application, beta-redex, Church-example, refusal, transport, replay, provenance, and local naming rows.

Independence witness: typed-gallery, metacic-decidable-boundary, bounded-typechecking-budget, metacic-substitution-spine, metacic-subject-reduction-boundary: none is bijective with $\mathsf{TypedGalleryContextProbe}^{\uparrow}$ because this packet jointly carries sort contexts, binder shapes, application forms, beta redexes, Church examples, checker-read data, discharge-facing data, refusal, transport, replay, provenance, and local NameCert.

The Lean TasteGate work for $\mathsf{TypedGalleryContextProbe}^{\uparrow}$ must provide $\mathsf{Nontrivial\ TypedGalleryContextProbe}^{\uparrow}$ and $\mathsf{FieldFaithful\ TypedGalleryContextProbe}^{\uparrow}$ instances preserving $S, B, A, R, C, K, D, Q, H, T, P, N$ as distinguishable rows.

Closure status for $\mathsf{NameCert}_{\mathsf{TypedGalleryContextProbe}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypedGalleryContextProbe}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6175.1, Definition 6175.2, and Definition 6175.3 seed the finite typed-gallery context probe from sort contexts and binder rows through checker and discharge-facing boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TypedGalleryContextProbe}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global typechecking completeness, subject reduction, confluence, normalization, conversion decidability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sort-context exposure, binder-shape exposure, application and beta-redex exposure, Church-example exposure, checker-read routing, discharge-facing routing, boundary refusal, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.TypedGalleryContextProbeUp.

Constructive story: A $\mathsf{TypedGalleryContextProbe}^{\uparrow}$ packet is generated from sort-indexed context rows, binder-shape rows, application rows, beta-redex rows, Church-example rows, checker-read rows, discharge-facing rows, boundary refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6176

A Concrete Naming Certificate for $\mathsf{GaleShapleyStableMatching}^{\uparrow}$

Following Gale and Shapley on stable marriage and deferred acceptance, the $\mathsf{GaleShapleyStableMatching}^{\uparrow}$ packet records the finite NameCert data behind a stable matching construction. It sits after the graph matching surface of chapter 234, the graph carrier of chapter 118, the finite-set enumeration machinery of chapter 112, the preference order rows of chapter 54, and the proposal-list discipline of chapter 36. The packet names the stable-matching construction as finite deferred-acceptance data; it does not import host marriage-market equality, selected optimality outside the ledger, or an unrecorded global search.

Definition 6176.1 (Gale-Shapley stable-matching carrier)**.** *A* $\mathsf{GaleShapleyStableMatching}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (U, V, P_U, P_V, L, T, R, B, M, H, C, Q, N)$$

with the following displayed rows:

1. *U and V are finite* $\mathsf{FinSet}^{\uparrow}$ *rows for the two sides of the market.*
2. *P_U and P_V are* $\mathsf{TotalOrder}^{\uparrow}$ *preference-profile rows over the finite candidate lists named by U and V.*
3. *L is a* $\mathsf{List}^{\uparrow}$ *proposal ledger recording the ordered proposal events of the deferred-acceptance run.*
4. *T is the tentative-matching ledger, recording at each proposal stage the currently held pairs as a* $\mathsf{Matching}^{\uparrow}$ *edge predicate in the bipartite* $\mathsf{Graph}^{\uparrow}$ *carrier.*
5. *R is the rejection-history ledger, recording every rejected proposal together with the displayed preference comparison that caused it.*
6. *B is the blocking-pair refusal row: every displayed unmatched pair is refused by the proposer-exhaustion row, the held-partner preference row, or the rejection-history row.*
7. *M is the terminal* $\mathsf{Matching}^{\uparrow}$ *export row read by stable-matching consumers.*
8. *H records componentwise* hsame *transport for the two finite sides, the two preference profiles, proposal ledger, tentative ledger, rejection history, blocking-pair refusal row, matching export, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a stable-matching query through $U, V, P_U, P_V, L, T, R, B, M, H, Q, N$.*

10. *Q is the* Pkg *provenance over* $\mathsf{GaleShapleyStableMatching}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{GaleShapleyStableMatching}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for host tuple matching, undisplayed preference functions, unbounded search, selected optimality outside the proposal ledger, quotient equality of matchings, or a stability proof detached from the blocking-pair refusal row.

Lean4 ✓ `BEDC.Derived.GaleShapleyStableMatchingUp.TasteGate.GaleShapleyStableMatchingTasteGate single carrier alignment`

Theorem 6176.2 (Gale-Shapley stable-matching NameCert obligations)**.** *For every accepted* GaleShapleyStableMa *carrier $G = (U, V, P_U, P_V, L, T, R, B, M, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{GaleShapleyStableMatching}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for $U, V, P_U, P_V, L, T, R, B, M, H, C, Q, N$;*
2. *finite-market exposure, requiring both sides to be read through U and V before any preference or matching row is consumed;*
3. *preference-profile exactness, requiring P_U and P_V to supply the displayed total-order comparisons used by proposal, holding, and rejection rows;*
4. *proposal-ledger accountability, requiring every proposal event consumed by the construction to occur in L with its current finite prefix;*
5. *tentative-matching compatibility, requiring every stage row in T to be a* $\mathsf{Matching}^{\uparrow}$ *edge predicate over the displayed bipartite* $\mathsf{Graph}^{\uparrow}$ *carrier;*
6. *rejection-history exactness, requiring R to pair each rejection with the preference comparison that justifies keeping or replacing a tentative partner;*
7. *blocking-pair refusal, requiring B to expose one displayed refusal reason for every finite candidate pair not exported by M;*
8. *structural stability, requiring H, C, Q, N to transport, replay, source, and name only the rows already listed.*

No stable-matching obligation for this packet is stored outside those rows.

Proof. Project the accepted carrier $G = (U, V, P_U, P_V, L, T, R, B, M, H, C, Q, N)$. The finite-market rows U and V are read first, so every participant and every candidate edge is already inside the displayed $\mathsf{FinSet}^{\uparrow}$ and $\mathsf{Graph}^{\uparrow}$ surfaces.

The preference rows P_U and P_V supply the only comparisons used by the construction. Thus proposal ordering, tentative holding, and rejection justifications cannot consult an undisplayed preference function.

Next read the dynamic rows. The proposal ledger L records the finite event order, T records the tentative $\mathsf{Matching}^{\uparrow}$ predicate at each stage, and R records the rejected proposal together with its preference comparison. These rows are enough to reconstruct the deferred-acceptance trace as finite BHist data.

Finally inspect B, M, H, C, Q, N. The row B refuses blocking pairs from the displayed trace, M exports the terminal matching row, and the structural rows preserve the same finite route. Since no hidden matching, preference, search, or quotient coordinate occurs in the carrier, the listed obligations exhaust the local certificate. □

Theorem 6176.3 (Gale-Shapley deferred-acceptance route)**.** *Every stable-matching consumer of an accepted* $\mathsf{GaleShapleyStableMatching}^{\uparrow}$ *carrier factors through the finite deferred-acceptance route*

$$\mathsf{FinSet}^{\uparrow},\ \mathsf{TotalOrder}^{\uparrow},\ \mathsf{List}^{\uparrow} \longmapsto \mathsf{Graph}^{\uparrow},\ \mathsf{Matching}^{\uparrow} \longmapsto \mathsf{GaleShapleyStableMatching}^{\uparrow}.$$

The consumer receives a terminal matching together with proposal, tentative-matching, rejection, and blocking-pair refusal rows. It receives no host marriage-market object, unrecorded search trace, external optimality selector, quotient matching representative, or stability assertion outside the displayed packet.

Proof. Start with a consumer read of the terminal matching row M. By the obligation theorem, the read is not available until the finite sides U, V and preference profiles P_U, P_V have been exposed.

The proposal sequence is then forced through L. Each proposal event has a finite prefix, and every tentative change reads its matching predicate through T in the displayed $\mathsf{Graph}^{\uparrow}$ and $\mathsf{Matching}^{\uparrow}$ surfaces.

The rejection ledger R and blocking-pair refusal row B supply the stability-facing part of the route. A pair not present in M is rejected because one side exhausted the proposal row, a held partner is preferred by a displayed total-order comparison, or the rejection history records the relevant event.

The structural rows H, C, Q, N keep this route componentwise. Therefore any stable-matching consumer factors through the finite deferred-acceptance packet and cannot obtain any excluded host-level matching, search, optimality, quotient, or detached-stability datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{GaleShapleyStableMatching}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaleShapleyStableMatching}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6176.1, Definition 6176.2, and Definition 6176.3 seed the finite deferred-acceptance NameCert route from finite preference profiles to a terminal MatchingUp export.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaleShapleyStableMatching}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host marriage-market equality, global optimality outside the displayed ledger, quotient matching representatives, unrestricted search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-market exposure, preference-profile exactness, proposal-ledger accountability, tentative-matching compatibility, rejection-history exactness, blocking-pair refusal, transport, replay, provenance, and local naming for BEDC.Derived.GaleShapleyStableMatchingUp.

Constructive story: A $\mathsf{GaleShapleyStableMatching}^{\uparrow}$ packet is generated from two FinSetUp side rows, two TotalOrderUp preference-profile rows, a ListUp proposal ledger, a MatchingUp tentative ledger over a GraphUp carrier, rejection history, blocking-pair refusal, a terminal matching export, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6177

A Concrete Naming Certificate for $\mathsf{ClosedAppArgumentStability}^{\uparrow}$

The $\mathsf{ClosedAppArgumentStability}^{\uparrow}$ packet realizes the independent-codomain branch of the closed MetaCIC application-argument frontier as finite NameCert data. It sits beside the subject-reduction discharge socket of chapter 719, the discharge ledger of chapter 720, the application-argument obstruction of chapter 9377, the closed lambda-domain packet of chapter 3381, and the closed Pi-domain packet of chapter 3352. The packet names the checked independent-codomain route; it does not turn the general dependent-codomain AppArgTypeStable obligation into an unconditional theorem.

Definition 6177.1 (Closed application-argument stability carrier)**.** *A* $\mathsf{ClosedAppArgumentStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, X, X', D, C, Y, Z, S, O, H, R, Q, N)$$

with the following displayed rows:

1. *F is the closed function row, naming a term typed by a displayed Pi type $\Pi D.\, C$.*
2. *X is the original argument row, typed by the displayed domain D.*
3. *X' is the reduced argument row, typed by the same displayed domain D.*
4. *D is the domain row read by the application typing rule.*
5. *C is the codomain row, together with the independent-codomain closedness boundary $ClosedAt(0, C)$.*
6. *Y is the typing row, recording the source and target application-argument typing premises consumed by the closed independent-codomain theorem.*
7. *Z is the closedness row for F, X, C inside the empty-context MetaCIC boundary.*
8. *S is the beta-step row from X to X'.*
9. *O is the obstruction boundary row, recording that the general dependent-codomain* AppArgTypeStable *discharge remains outside the packet.*
10. *H records componentwise* hsame *transport for $F, X, X', D, C, Y, Z, S, O, R, Q, N$.*
11. *R records displayed* Cont *replay from the application-argument congruence read through the independent-codomain stability theorem and the obstruction boundary.*

12. *Q is the* Pkg *provenance over* ClosedAppArgumentStability$^{\uparrow}$, SubjectReduction$^{\uparrow}$, SubjectReductionDischargeSocket ClosedLamDomainSubjectReduction$^{\uparrow}$, ClosedPiDomainSubjectReduction$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* NameCert$_{\text{ClosedAppArgumentStability}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying the closed function, original argument, reduced argument, domain, independent codomain, typing row, closedness row, beta step, obstruction boundary, transport, replay, provenance, and local naming. It has no coordinate for a general dependent-codomain discharge, host conversion, erased derivation semantics, quotient syntax equality, or a closed subject-reduction theorem.

Theorem 6177.2 (Closed application-argument stability NameCert obligations)**.** *For every accepted* ClosedAppArgumentStability$^{\uparrow}$ *carrier $A = (F, X, X', D, C, Y, Z, S, O, H, R, Q, N)$, the local* NameCert$_{\text{ClosedAppArgumentStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed closed function, original argument, reduced argument, domain row, independent codomain row, typing row, closedness row, beta-step row, obstruction boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The application-argument read is accepted only when C displays the independent-codomain closedness boundary and O keeps the general dependent-codomain obstruction visible.*

Proof. Project the carrier of Definition 6177.1. The rows F, X, X', D, C display the application source, the argument step, and the Pi type whose codomain is inspected.

Read Y, Z, S next. These rows provide the typing premises, closedness premises, and beta-step premise needed by the closed independent-codomain theorem, while keeping all data inside the displayed empty-context boundary.

The obstruction row O is part of the same local surface. It prevents a consumer from replacing the independent-codomain equality by the general dependent-codomain AppArgTypeStable discharge row.

Finally H, R, Q, N transport, replay, source, and name only this finite packet. Since no row stores host conversion, erased derivation semantics, quotient syntax equality, a general application-argument discharge, or a closed subject-reduction theorem, the listed rows exhaust the local certificate. □

Theorem 6177.3 (Closed application-argument independent-codomain route)**.** *Every subject-reduction discharge consumer that reads an accepted* ClosedAppArgumentStability$^{\uparrow}$ *packet as an application-argument handoff factors through the checked independent-codomain route*

$$F,\ X,\ X',\ D,\ C,\ Y,\ Z,\ S,\ O,\ H,\ R,\ Q,\ N.$$

The handoff may cite the equality supplied by the closed independent-codomain theorem `BEDC.MetaCIC.appArgType` *but only at the displayed $ClosedAt(0, C)$ boundary. It does not supply the general* AppArgTypeStable *field, the beta-substitution row, the lambda-domain row, the Pi-domain row, or an unconditional closed subject-reduction theorem.*

Proof. Start with an application-argument consumer. The rows F, X, X', D, C, Y, Z, S match the closed independent-codomain theorem: the function has Pi type $\Pi D.\, C$, both arguments have type D, and the codomain row is closed at the binder boundary.

Apply the independent-codomain route at that displayed codomain row. The result is the equality between the two substitutions of C, because a closed codomain ignores the argument readback.

Now read the obstruction row O. It records that the dependent-codomain case remains on the obstruction side of the MetaCIC ledger and that the full AppArgTypeStable field is not generated by this packet.

The structural rows H, R, Q, N preserve the same handoff for downstream ledgers. Thus the consumer obtains the independent-codomain application-argument equality and no beta, lambda-domain, Pi-domain, general application-argument, or closed subject-reduction discharge. □

Falsifiable prediction: An accepted $\mathsf{ClosedAppArgumentStability}^{\uparrow}$ read is refuted if an application-argument consumer reaches the independent-codomain substitution equality without displaying the closed function row, both argument typing rows, the closed codomain boundary, the beta-step row, the obstruction row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: ClosedLamDomainSubjectReduction, ClosedPiDomainSubjectReduction, SubjectReductionDischargeSocket, SubjectReductionRouteClassifier, and MetaCICSubjectReductionObligation are not bijective with $\mathsf{ClosedAppArgumentStability}^{\uparrow}$ because only this packet jointly carries the closed application-argument row, independent-codomain equality route, obstruction boundary for the dependent-codomain case, transport, replay, provenance, and local naming.

The Lean TasteGate file for $\mathsf{ClosedAppArgumentStability}^{\uparrow}$ must provide explicit Nontrivial ClosedAppArgumentSta and $\mathsf{FieldFaithful\ ClosedAppArgumentStability}^{\uparrow}$ instances preserving $F, X, X', D, C, Y, Z, S, O, H, R, Q, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedAppArgumentStability}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedAppArgumentStability}^{\uparrow}$ packet is generated from a closed function row, original argument row, reduced argument row, domain row, independent codomain row, typing row, closedness row, beta-step row, obstruction boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedAppArgumentStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6177.1, Definition 6177.2, and Definition 6177.3 seed the finite independent-codomain application-argument packet for the closed MetaCIC discharge route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedAppArgumentStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general AppArgTypeStable, beta-substitution preservation, lambda-domain preservation, Pi-domain preservation, unconditional closed subject reduction, host conversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, independent-codomain closedness exactness, typing-row exposure, beta-step exposure, obstruction-boundary exposure, subject-reduction ledger handoff, and TasteGate field faithfulness for BEDC.Derived.ClosedAppArgumentStabilityUp.

Chapter 6178

A Concrete Naming Certificate for $\mathsf{ContextSensitiveGrammar}^{\uparrow}$

Following Hopcroft–Ullman and Sipser on formal languages, the $\mathsf{ContextSensitiveGrammar}^{\uparrow}$ packet records the finite grammar surface for noncontracting productions and sentential-window derivations. It sits after the regular-language carrier of chapter 351, the context-free grammar carrier of chapter 356, the pushdown-automaton comparison row of chapter 6018, the list carrier of chapter 36, and the natural-number row of chapter 28. The packet names a finite grammar-and-derivation certificate; it does not import a host language set, unrestricted Turing-machine semantics, selected derivation trees, or ambient decidability.

Definition 6178.1 (Context-sensitive grammar carrier)**.** *A* $\mathsf{ContextSensitiveGrammar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, R, W, D, L, Q, M, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite alphabet and variable row, read through* $\mathsf{List}^{\uparrow}$ *and* $\mathsf{Nat}^{\uparrow}$ *indices.*
2. *R is the noncontracting production row. Each production has a finite left context, a nonempty rewritten window, a finite right context, and a length-growth witness showing that the successor sentential form is no shorter than the predecessor.*
3. *W is the sentential-window row, exposing only the finite word segment inspected by a derivation consumer.*
4. *D is the derivation ledger. It lists the applied production, occurrence window, predecessor word, and successor word for each displayed step.*
5. *L is the length-growth ledger recording the* $\mathsf{Nat}^{\uparrow}$ *comparison attached to every production use in D.*
6. *Q is the word-classifier row for generated terminal words, read only after the derivation ledger and length ledger have been replayed.*
7. *M records comparison rows to* $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, *and* $\mathsf{PushdownAutomaton}^{\uparrow}$ *consumers when a downstream formal-language packet asks for a weaker or adjacent interface.*
8. *H records componentwise* hsame *transport for the alphabet, production, window, derivation, length, classifier, comparison, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a word-membership request through $A, R, W, D, L, Q, M, H, P, N$.*
10. *P is the* Pkg *provenance over* ContextSensitiveGrammar$^{\uparrow}$, RegularLanguage$^{\uparrow}$, ContextFreeGrammar$^{\uparrow}$, PushdownAutomaton$^{\uparrow}$, List$^{\uparrow}$, Nat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{ContextSensitiveGrammar}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, R, W, D, L, Q, M, H, C, P, N$. It has no coordinate for a host language set, an unrestricted machine computation, a selected infinite derivation tree, an ambient decidability theorem, or a grammar equality quotient.

Lean4 ✓ `BEDC.Derived.ContextSensitiveGrammarUp.TasteGate.ContextSensitiveGrammarTasteGate`
`single carrier alignment`

Theorem 6178.2 (Context-sensitive grammar NameCert obligations)**.** *For every accepted* ContextSensitiveGramma *carrier*

$$G = (A, R, W, D, L, Q, M, H, C, P, N),$$

the local NameCert$_{\text{ContextSensitiveGrammar}^{\uparrow}}$ *surface consists exactly of carrier admission, monotone production stability, derivation-window replay, classifier transport, ledger nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The alphabet row A, noncontracting production row R, sentential window W, derivation ledger D, and length-growth ledger L are the only rows that can justify a generated word.

Monotone production stability is read from R together with L. Each derivation step records the applied production and the corresponding Nat$^{\uparrow}$ length comparison, so no shortening step can enter the accepted ledger.

Derivation-window replay is supplied by W, D, C. A consumer may inspect only the displayed occurrence windows and their predecessor and successor words, and replay preserves that finite route before the classifier row Q is exposed.

The comparison row M transports the same grammar data toward regular-language, context-free grammar, and pushdown-automaton consumers without replacing the local classifier. Since the carrier contains no host language set, unrestricted machine computation, selected infinite derivation, ambient decidability theorem, or quotient grammar equality, the listed obligations exhaust the NameCert surface. □

Theorem 6178.3 (Context-sensitive grammar linear-bounded handoff)**.** *Every linear-bounded-automaton consumer of an accepted* ContextSensitiveGrammar$^{\uparrow}$ *packet must read the displayed grammar, word-window,* List$^{\uparrow}$, Nat$^{\uparrow}$, PushdownAutomaton$^{\uparrow}$, *and* ContextFreeGrammar$^{\uparrow}$ *comparison rows before any language-level claim is exposed. For*

$$G = (A, R, W, D, L, Q, M, H, C, P, N),$$

the route first fixes A, R, W, D, L, then reads the comparison row M, and only then exposes the classifier row Q through H, C, P, N. The handoff exports no host language equality, unrestricted machine semantics, selected accepting computation, global decidability theorem, or hidden grammar quotient.

Proof. Read the carrier of Definition 6178.1. The grammar and word-window coordinates are A, R, W, D, L, and they are indexed only through the displayed List$^{\uparrow}$ and Nat$^{\uparrow}$ rows.

Apply Definition 6178.2. A language-facing consumer cannot see Q until the production ledger and length ledger have been replayed, because monotone production stability and derivation-window replay are local obligations.

The comparison row M is the only coordinate that connects the packet to the pushdown-automaton and context-free grammar siblings. A linear-bounded-automaton consumer therefore reads through that row before it makes any language-level use of the generated-word classifier.

Finally H, C, P, N transport, replay, source, and locally name the same finite route. The excluded host objects are not coordinates of G, so the handoff remains a finite grammar certificate rather than a semantic language theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContextSensitiveGrammar}\uparrow}$.

Constructive story: A $\mathsf{ContextSensitiveGrammar}^{\uparrow}$ packet is generated from finite alphabet and variable rows, noncontracting production rows, sentential-window rows, derivation ledgers, length-growth ledgers, formal-language comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContextSensitiveGrammar}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6178.1, Definition 6178.2, and Definition 6178.3 seed the finite noncontracting grammar route over List, Nat, RegularLanguage, ContextFreeGrammar, PushdownAutomaton, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContextSensitiveGrammar}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted machine semantics, host language equality, selected accepting computations, global decidability, or grammar quotient equality.

Upgrade path: Obligation closure requires checked carrier admission, monotone production stability, derivation-window replay, classifier transport, ledger nonescape, comparison-row handoff, transport, replay, provenance, and local naming for BEDC.Derived.ContextSensitiveGrammarUp.

Chapter 6179

A Concrete Naming Certificate for BoundedNormalizationFrontier$^{\uparrow}$

The BoundedNormalizationFrontier$^{\uparrow}$ packet realizes the MetaCIC decidability audit map of chapter 9379 as finite fuel, finished-normal, bounded-comparison, and refusal rows. It sits beside the decidable typing frontier of chapter 3616, the typed normal-form decider of chapter 3714, the bounded-normalization fuel packet of chapter 5962, the bounded normal-equality checker of chapter 752, and the finite observation fold of chapter 2236. The packet names the exact frontier where `normalizeBounded` and `decideClosedBetaConv` are finite procedures; it does not claim unrestricted beta-conversion decidability.

Falsifiable prediction: Every accepted BoundedNormalizationFrontierUp conversion consumer must expose typed term rows, a shared fuel row, normalizeBounded trace rows, finished-normal witness rows, bounded Term.eq comparison rows, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before any conversion claim is available.

Independence witness: metacic-decidable-typing-frontier, typed-normal-form-decider, bounded-normalization-fuel, bounded-normal-equality-checker, finite-observation-fold: BoundedNormalizationFrontier$^{\uparrow}$ is not bijective to any listed sibling because it binds fuel, trace, finished-normal, bounded-comparison, refusal, replay, transport, provenance, and local naming as one frontier certificate with proposed Lean TasteGate obligations.

Definition 6179.1 (Bounded normalization frontier carrier)**.** *A* BoundedNormalizationFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, U, B, X, Y, E, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed term row, carrying the closed MetaCIC terms and their displayed typing context boundary.*
2. *U is the shared finite fuel row used by the bounded normalizer.*
3. *B is the* `normalizeBounded` *trace row for both terms at fuel U.*
4. *X is the finished-normal witness row, present only when the bounded traces are certified as closed finished normal forms.*

5. *Y is the bounded* `Term.eq` *comparison row over the two bounded normalizer outputs.*
6. *E is the bounded conversion result row exposed by* `decideClosedBetaConv` *at the displayed fuel.*
7. *O is the refusal and obstruction row. It records the missing endpoint data whenever the packet cannot promote a bounded comparison to unrestricted beta-conversion.*
8. *H records componentwise* hsame *transport for typed terms, fuel, bounded traces, finished-normal witnesses, bounded equality, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a conversion request through $T, U, B, X, Y, E, O, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedNormalizationFrontier}^{\uparrow}$*, MetaCIC typed terms,* `normalizeBounded`*,* `Term.eq`*,* `decideClosedBetaConv`*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalizationFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, U, B, X, Y, E, O, H, C, P, N$. It has no coordinate for global normalization, unrestricted beta-conversion decidability, fuel-erased confluence, selected normal forms outside the trace, or a host equality oracle.

Theorem 6179.2 (Bounded normalization frontier NameCert obligations)**.** *For every accepted* $\mathsf{BoundedNormalizationFrontier}^{\uparrow}$ *carrier*

$$F = (T, U, B, X, Y, E, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedNormalizationFrontier}^{\uparrow}}$ *surface consists exactly of typed-term admission, finite-fuel admission, bounded-normalizer trace replay, finished-normal witness exposure, bounded* `Term.eq` *comparison, bounded conversion transport, refusal-row nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The typed terms are read through T, the computation budget through U, and the bounded normalizer traces through B.

Finished-normal evidence is separate. The row X records the endpoint witnesses that make the bounded traces closed normal forms; if those witnesses are absent, the refusal row O is the only exposed endpoint information.

The bounded comparison uses Y and E. It compares the two displayed bounded normalizer outputs by `Term.eq` and exposes only the finite result at fuel U.

The structural rows H, C, P, N transport, replay, source, and locally name the same route. Since the carrier contains no row for global normalization, unrestricted beta-conversion decidability, fuel-erased confluence, selected external normal forms, or host equality, the listed obligations exhaust the NameCert surface. □

Theorem 6179.3 (Bounded conversion frontier handoff)**.** *Every conversion consumer of an accepted* $\mathsf{BoundedNormalizationFrontier}^{\uparrow}$ *packet receives a bounded frontier certificate, not an unrestricted beta-conversion decider. For*

$$F = (T, U, B, X, Y, E, O, H, C, P, N),$$

the consumer must read typed terms T, finite fuel U, bounded traces B, finished-normal witnesses X when present, bounded `Term.eq` *comparison Y, bounded conversion result E, and the refusal row O before any conversion-facing claim is exposed through H, C, P, N.*

Proof. Start from the carrier inventory in Definition 6179.1. It stores a concrete fuel value and concrete bounded traces, so every conversion request is already a finite-fuel request.

Apply Definition 6179.2. The comparison route is T, U, B, X, Y, E, O in that order: typed terms and fuel determine the traces, finished-normal witnesses mark the closed endpoint case, the bounded equality row compares the displayed outputs, and the refusal row records the missing endpoint data when no global conclusion is available.

The rows H, C, P, N preserve that finite route. Because unrestricted normalization and fuel-erased beta-conversion are absent from the carrier, a consumer cannot bypass the bounded frontier by appealing to a host conversion theorem or selected normal form. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedNormalizationFrontier}\uparrow}$.

Constructive story: A $\mathsf{BoundedNormalizationFrontier}^{\uparrow}$ packet is generated from typed term rows, finite fuel rows, bounded normalizer traces, finished-normal witnesses, bounded Term.eq comparison rows, bounded conversion result rows, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedNormalizationFrontier}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6179.1, Definition 6179.2, and Definition 6179.3 seed the finite MetaCIC bounded-normalization route over typed terms, fuel, traces, finished-normal witnesses, bounded equality, refusal, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedNormalizationFrontier}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global normalization, unrestricted beta-conversion decidability, fuel-erased confluence, selected external normal forms, or host equality.

Upgrade path: Obligation closure requires checked typed-term admission, finite-fuel admission, bounded trace replay, finished-normal witness exposure, bounded equality comparison, refusal-row nonescape, conversion handoff, transport, replay, provenance, and local naming for BEDC.Derived.BoundedNormalizationFrontierUp.

Chapter 6180

A Concrete Naming Certificate for $\mathsf{BishopLocatedReal}^{\uparrow}$

From Bishop–Bridges constructive real analysis, the $\mathsf{BishopLocatedReal}^{\uparrow}$ packet records the finite located-real interface consumed by L10 Real and Completion routes. It sits after the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the located interval surface of chapter 394, the apartness evidence surface of chapter 304, the located Cauchy route of chapter 1850, and the terminal real-name seal of chapter 38. The packet supplies a displayed located-cut boundary for later completion and order consumers; it is not host real equality, quotient-class equality, trichotomy, countable choice, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6180.1 (BishopLocatedReal carrier)**.** *A* $\mathsf{BishopLocatedReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, I, A, B, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the rational cells, dyadic split radii, slack rows, and comparison budget used by every located read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected at the dyadic tolerances recorded in D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback obtained from the same stream windows and tolerance ledger.*
4. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the finite interval enclosure in which the located real may be inspected.*
5. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-separation row available only when a displayed window exhibits a strict gap from one side of the located cut.*
6. *B is the* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *row binding the located interval and regular Cauchy readback to one shared dyadic tolerance route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, R, I, A, B have been displayed.*
8. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, located interval, apartness row, located Cauchy row, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a located-cut request through D, S, R, I, A, B, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for host real equality, quotient classes, trichotomy, countable choice, selected representatives, or an ambient completeness assertion.

Lean4 ✓ `BEDC.Derived.BishopLocatedRealUp.BishopLocatedRealTasteGate single carrier alignment`

Theorem 6180.2 (BishopLocatedReal NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedReal}^{\uparrow}$ *carrier $L = (D, S, R, I, A, B, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedReal}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance admission, finite StreamName window admission, RegSeqRat readback, located interval admission, apartness-row admission, Bishop located Cauchy admission, Real seal admission, componentwise transport, displayed replay, provenance, and local naming for the displayed rows $D, S, R, I, A, B, E, H, C, P, N$.*

Proof. Project the accepted packet. The analytic rows are precisely the dyadic tolerance ledger D, the finite stream windows S, the regular rational readback R, the located interval row I, the apartness row A, the located Cauchy row B, and the terminal Real seal E.

The local certificate reads these rows in the displayed order. A located request may inspect endpoint or cut information only after the shared tolerance and window rows are visible, and a Real-facing request reaches E only after the regular readback, located interval, apartness, and located Cauchy rows have been displayed.

Transport and replay remain componentwise. The rows H, C, P, N transport, replay, source, and name the same finite packet, so no outside equality, choice principle, selected representative, trichotomy split, or ambient completeness datum can enter the local surface. □

Theorem 6180.3 (BishopLocatedReal RegSeqRat route)**.** *Every completion-facing read of an accepted* $\mathsf{BishopLocatedReal}^{\uparrow}$ *carrier factors through the route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{BishopLocatedCauchyReal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes a dyadic tolerance ledger, a finite stream window, a regular rational readback, a located Cauchy handoff, componentwise transport, replay, provenance, and local naming before any terminal real seal is consumed.

Proof. Begin with Definition 6180.1. The only regular rational source row is R, and R is downstream of the dyadic ledger D and the finite stream window S.

The located Cauchy row B is admitted only as a row of the same packet. It binds the regular readback to the displayed located interval data before the terminal Real seal E can be read.

Apply Definition 6180.2. The certificate forces every completion-facing read through $D, S, R, B, E, H, C, P, N$, and the carrier contains no row for quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 6180.4 (BishopLocatedReal located-cut stability)**.** *Let $L = (D, S, R, I, A, B, E, H, C, P, N)$ and $L' = (D', S', R', I', A', B', E', H', C', P', N')$ be accepted* $\mathsf{BishopLocatedReal}^{\uparrow}$ *carriers. If H*

records componentwise hsame *transport from each displayed row of L to the corresponding row of L', then the located-cut information of L transports to L' only through*

$$D, S, R, I, A, B, E, H, C, P, N.$$

In particular, located interval containment, positive apartness evidence, and located Cauchy compatibility remain attached to the same finite StreamName, RegSeqRat, and DyadicRatCore route.

Proof. Project both accepted carriers. The located-cut rows are I, A, B: the interval row I records the finite enclosure, the apartness row A records positive gap evidence, and the located Cauchy row B binds those observations to the regular readback.

Componentwise transport through H carries D to D', S to S', R to R', and then I, A, B to I', A', B'. The replay row C cannot change the order of these reads; it only replays the displayed route.

The NameCert obligations of Definition 6180.2 then repack the transported rows as an accepted located-cut surface for L'. Since the packet has no host equality, trichotomy, quotient, choice, or completeness coordinate, stability is exactly the displayed row-local transport. □

Theorem 6180.5 (BishopLocatedReal Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{BishopLocatedReal}^{\uparrow}$ *carrier is exhausted by the displayed rows $D, S, R, I, A, B, E, H, C, P, N$. Thus the public real-name boundary supplies only dyadic tolerance data, finite stream windows, RegSeqRat readback, located interval evidence, ApartnessReal separation rows, BishopLocatedCauchyReal compatibility, the terminal Real seal, transport, replay, provenance, and local naming.*

Proof. Read the carrier of Definition 6180.1. The terminal Real row is E, and E appears only after the dyadic, stream, regular rational, located interval, apartness, and located Cauchy rows.

The RegSeqRat route of Definition 6180.3 keeps every completion-facing read downstream of D, S, R, B. The stability result of Definition 6180.4 keeps located interval and apartness reads on the same displayed route.

Finally, Definition 6180.2 supplies H, C, P, N and excludes all non-displayed data. Therefore no consumer can read host real equality, quotient classes, trichotomy, countable choice, a selected representative, or ambient $\mathsf{Real}^{\uparrow}$ completeness from the Real-seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedReal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedReal}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a LocatedInterval row, an ApartnessReal row, a BishopLocatedCauchyReal row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6180.1, Definition 6180.2, Definition 6180.3, Definition 6180.4, and Definition 6180.5 seed the finite located-real interface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host real equality, quotient classes, trichotomy, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, RegSeqRat route exactness, located-cut transport, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealUp.

Chapter 6181

A Concrete Naming Certificate for $\mathsf{ExplanationComplexityInformation}^{\uparrow}$

The $\mathsf{ExplanationComplexityInformation}^{\uparrow}$ packet realizes the net-information calculus of section 9462.10 as finite NameCert rows. It sits beside the bounded program-cost surface of chapter 5989, the debt-aware quality surface of chapter 6117, and the classifier-shift witness of chapter 6138. The packet names a finite explanation-information read over score, benefit, debt, novelty, and quality-gate evidence; it is not a hidden semantic truth predicate, an oracle for shortest descriptions, a raw benchmark score, or a classifier novelty claim without a displayed witness.

Definition 6181.1 (Explanation-complexity information carrier)**.** *An* $\mathsf{ExplanationComplexityInformation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, B, D, K, V, Q, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the explanation score row, recording the public weight profile and the finite source, feature, circuit, classifier, stability, intervention, ledger, seal, semantic, and verification cost coordinates.*
2. *B is the benefit row, recording coverage gain, prediction gain, transfer gain, intervention gain, verification gain, and unification gain inside the declared explanation scope.*
3. *D is the explanation-debt row, separating NDNA debt, ledger debt, semantic debt, black-box debt, shortcut debt, safety debt, generalization debt, and verification debt.*
4. *K is the bounded description-cost row, read through the displayed program and code discipline of* $\mathsf{KolmogorovComplexity}^{\uparrow}$ *without importing an uncomputable minimum selector.*
5. *V is the classifier-novelty row, read through* $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ *only when two explanation states display a common source and a changed classifier judgment.*
6. *Q is the certified-quality row, read through* $\mathsf{CertifiedModelQuality}^{\uparrow}$ *when the score, debt, audit, and quality-gate rows jointly certify a model-quality comparison.*
7. *G is the net information row, displaying the accepted arithmetic comparison between benefit and the score-plus-debt surface over the same scope.*
8. *H records componentwise* hsame *transport for score, benefit, debt, description-cost, classifier-novelty, certified-quality, net-information, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from scope inspection through score, benefit, debt, description-cost, classifier novelty, certified quality, net information, provenance, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{ExplanationComplexityInformation}^{\uparrow}$, $\mathsf{KolmogorovComplexity}^{\uparrow}$, $\mathsf{CertifiedModelQuality}^{\uparrow}$, $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$, $\mathsf{EffectiveReplacementLedger}^{\uparrow}$, $\mathsf{AuditSystem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ExplanationComplexityInformation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, D, K, V, Q, G, H, C, P, N$. It has no coordinate for explanation brevity alone, private evaluator preference, hidden semantic truth, unbounded Kolmogorov minimization, raw model score, or classifier novelty without the displayed changed-judgment row.

Theorem 6181.2 (Explanation-complexity information NameCert obligations)**.** *For every accepted* $\mathsf{ExplanationComplexityInformation}^{\uparrow}$ *carrier $E = (S, B, D, K, V, Q, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ExplanationComplexityInformation}^{\uparrow}}$ *surface consists exactly of scope-coherent score exposure, benefit exposure, explanation-debt exposure, bounded description-cost handoff through* $\mathsf{KolmogorovComplexity}^{\uparrow}$, *classifier-novelty handoff through* $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$, *certified-quality handoff through* $\mathsf{CertifiedModelQuality}^{\uparrow}$, *net-information comparison, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6181.1. The analytic rows are S, B, D, K, V, Q, G, and the structural rows are H, C, P, N.

The score, benefit, and debt rows share one explanation scope. Thus the net row G may compare benefit against score and debt only after S, B, D have been displayed for that same scope.

Read the sibling rows next. The description-cost row K uses chapter 5989 only as a bounded displayed-program cost surface; the novelty row V uses chapter 6138 only when a changed classifier judgment is visible; and the quality row Q uses chapter 6117 only after its debt and audit gates are exposed.

Finally, H, C, P, N transport, replay, source, and name the same rows. Since none of the excluded objects appears in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 6181.3 (Explanation-complexity information net-score route)**.** *An accepted* ExplanationComplexityInform *packet may export positive net explanation information only after the score row S, benefit row B, debt row D, classifier-novelty row V, and certified-quality row Q have all been read through the same scope. A lower score, a shorter description, a quality-gate pass, or a classifier-novelty witness alone is therefore insufficient for the exported net-information row G.*

Proof. Start from the net-information row G. By carrier projection, G is downstream of the public score row S, benefit row B, debt row D, classifier-novelty row V, and certified-quality row Q.

The score and description rows do not determine the export alone. The row S records weighted cost, while K records bounded description-cost evidence through $\mathsf{KolmogorovComplexity}^{\uparrow}$; neither row contains the benefit and debt comparison required by G.

The novelty and quality rows are also insufficient in isolation. The row V certifies a changed classifier judgment, and Q certifies debt-aware model quality, but G must still read the shared score, benefit, and debt surface before the packet exports positive net information. □

Falsifiable prediction: Every accepted $\mathsf{ExplanationComplexityInformation}^{\uparrow}$ read exposes score, benefit, debt, bounded description-cost, classifier-novelty, certified-quality, net-information, trans-

port, replay, provenance, and local naming rows before it claims positive net explanation information.

Independence witness: kolmogorov-complexity, certified-model-quality, classifier-novelty-witness, effective-replacement-ledger, auditsystem: none is bijective with $\mathsf{ExplanationComplexityInformation}^{\uparrow}$ because the packet simultaneously binds weighted explanation score, benefit, debt, bounded description cost, classifier novelty, certified quality, net-information comparison, transport, replay, provenance, and local naming as one finite explanation-information surface.

The Lean follow-up must provide $\mathsf{Nontrivial\ ExplanationComplexityInformation}^{\uparrow}$ and $\mathsf{FieldFaithful\ ExplanationComp}$ instances before checked TasteGate markers for BEDC.Derived.ExplanationComplexityInformationUp are cited. Those instances must preserve the rows $S, B, D, K, V, Q, G, H, C, P, N$ so the checked surface separates positive net information from short descriptions, raw score movement, quality-gate success, and classifier novelty alone.

Closure status for $\mathsf{NameCert}_{\mathsf{ExplanationComplexityInformation}^{\uparrow}}$.

Constructive story: An $\mathsf{ExplanationComplexityInformation}^{\uparrow}$ packet is generated from public explanation score, benefit, debt, bounded description-cost, classifier-novelty, certified-quality, net-information, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExplanationComplexityInformation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6181.1, Definition 6181.2, and Definition 6181.3 seed the finite packet for net explanation-information reads over score, benefit, debt, bounded description cost, classifier novelty, certified quality, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExplanationComplexityInformation}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.ExplanationComplexityInformationUp`

Bridge status: none

Not claimed: This chapter does not close hidden semantic truth, unbounded shortest-description selection, raw benchmark validity, global model safety, classifier novelty without a displayed witness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, score exposure, benefit exposure, debt exposure, bounded description-cost handoff, classifier-novelty handoff, certified-quality handoff, net-information comparison, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.ExplanationComplexityInformat

Chapter 6182

A Concrete Naming Certificate for $\mathsf{WijsmanTopology}^{\uparrow}$

Following Wijsman and the Kelley hyperspace tradition, the $\mathsf{WijsmanTopology}^{\uparrow}$ packet records the finite topology read induced by distance-to-set probes on a metric hyperspace. It starts from the closed-subset source of chapter 1660, the metric source of chapter 57, and the distance comparison boundary of chapter 3653, while keeping explicit comparison rows to the hit/miss surfaces of chapter 2375 and chapter 6157. The packet is a NameCert for the Wijsman distance-evaluation topology, not a host topology on a powerset of closed subsets, a quotient of closed-set equality, a selected nearest point, or an ambient completeness principle.

Definition 6182.1 (Wijsman topology carrier)**.** *A* $\mathsf{WijsmanTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, H, D, S, R, E, V, F, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row. It supplies the only distance primitive available to the packet.*
2. *H is the closed-subset* $\mathsf{Hyperspace}^{\uparrow}$ *source row whose finite closed-set names are being inspected.*
3. *D is the finite distance-to-set evaluation row. Each entry records a displayed metric point, a displayed closed-subset name, and the bounded evaluation request for the corresponding distance value.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to replay point names, closed-subset names, and distance-evaluation probes.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite evaluation windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed distance comparisons.*
7. *V is the* $\mathsf{VietorisTopology}^{\uparrow}$ *comparison row, recording which finite hit/miss reads are visible before distance-evaluation inspection begins.*
8. *F is the* $\mathsf{FellTopology}^{\uparrow}$ *comparison row, recording which lower-hit and compact-miss reads remain separate from the Wijsman distance rows.*
9. *T records componentwise* hsame *transport for M, H, D, S, R, E, V, F.*

10. *C records displayed* Cont *replay of metric source admission, hyperspace source admission, distance-to-set evaluation, stream-window readback, regular rational readback, real comparison, Vietoris comparison, and Fell comparison.*

11. *P is the* Pkg *provenance over* $\mathsf{WijsmanTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{FellTopology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{WijsmanTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, H, D, S, R, E, V, F, T, C, P, N$ and exports no host closed-set topology, quotient closed-set equality, selected nearest point, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.WijsmanTopologyUp.WijsmanTopologyTasteGate single carrier alignment`

Theorem 6182.2 (Wijsman topology NameCert obligations)**.** *For every accepted* $\mathsf{WijsmanTopology}^{\uparrow}$ *carrier*

$$W = (M, H, D, S, R, E, V, F, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WijsmanTopology}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric source, closed-subset hyperspace source, finite distance-to-set evaluation probes, stream windows, regular rational readbacks, real comparisons, Vietoris comparison, Fell comparison, transport, replay, provenance, and local naming rows;*

2. *distance-evaluation exposure, requiring each topology-facing read to display the metric point, closed-subset name, stream window, regular rational readback, and real comparison row used by its distance-to-set probe;*

3. *metric-source compatibility, requiring every evaluation row in D to read its distance primitive through the displayed* $\mathsf{Met}^{\uparrow}$ *row M;*

4. *comparison non-collapse, requiring the Vietoris row V and Fell row F to remain visible comparison rows rather than replacements for the Wijsman distance-evaluation classifier;*

5. *componentwise* hsame *transport through T, displayed* Cont *replay through C, and* Pkg *provenance through P for the same finite route;*

6. *local naming through N, excluding host closed-set topologies, quotient closed-set equality, selected nearest points, and ambient completeness.*

No Wijsman topology obligation is stored outside these rows.

Proof. Project the carrier of Definition 6182.1. The only source rows are the metric row M and the closed-subset hyperspace row H, and the only topology-facing observation row is the finite distance-to-set ledger D.

The evaluation row is read through finite windows. The rows S, R, E force every distance-to-set probe to pass through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before it becomes a topology-facing comparison.

The comparison rows are kept separate. The Vietoris row V and Fell row F may be inspected as neighbouring hyperspace topologies, but they do not replace the distance-evaluation route M, H, D, S, R, E.

Finally, T, C, P, N transport, replay, source, and name that same route. Since the excluded host topology, quotient closed-set equality, selected nearest point, and ambient completeness coordinates are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6182.3 (Wijsman distance-evaluation handoff)**.** *Every topology-facing read from an accepted* $\mathsf{WijsmanTopology}^{\uparrow}$ *carrier factors through*

$$\mathsf{Met}^{\uparrow},\ \mathsf{Hyperspace}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{VietorisTopology}^{\uparrow},\ \mathsf{FellTopology}^{\uparrow}$$

before a hyperspace topology consumer can inspect it. The exported read is the displayed metric source, closed-subset hyperspace source, finite distance-to-set evaluation probe, stream-window replay, regular rational readback, real comparison, neighbouring Vietoris comparison, neighbouring Fell comparison, transport, replay, provenance, and local naming route; it exports no host closed-set topology, quotient closed-set equality, selected nearest point, or ambient completeness.

Proof. Start with the NameCert obligations of Definition 6182.2. Carrier admission places the metric source and closed-subset hyperspace source before any distance-evaluation row can be consumed.

Next read the evaluation route. The finite distance-to-set row D can expose a topology-facing comparison only after the stream window S, the regular rational readback R, and the real seal E have been displayed.

The surrounding hyperspace topology context is explicit. The rows V and F expose the Vietoris and Fell comparison surfaces as neighbours, while T, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. No unlisted host topology, closed-set quotient, nearest-point selector, or ambient completeness row can enter the handoff. □

Falsifiable prediction: Every accepted $\mathsf{WijsmanTopology}^{\uparrow}$ topology read factors through $\mathsf{Met}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, and $\mathsf{FellTopology}^{\uparrow}$ before any hyperspace topology consumer can inspect it.

Independence witness: metric, hyperspace, hausdorff-distance, vietoris-topology, fell-topology, streamname, regseqrat, real: $\mathsf{WijsmanTopology}^{\uparrow}$ is not bijective to any listed sibling because it binds metric distance-to-set evaluation probes to closed-subset hyperspace names while keeping Vietoris and Fell comparison rows visible.

Closure status for $\mathsf{NameCert}_{\mathsf{WijsmanTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{WijsmanTopology}^{\uparrow}$ packet is generated from a Metric row, a closed-subset Hyperspace row, finite distance-to-set evaluation probes, StreamName windows, RegSeqRat readbacks, Real comparison seals, Vietoris and Fell comparison rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WijsmanTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6182.1, Definition 6182.2, and Definition 6182.3 seed the finite Wijsman distance-evaluation topology surface over Metric, Hyperspace, StreamName, RegSeqRat, Real, VietorisTopology, FellTopology, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WijsmanTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host closed-set topologies, quotient closed-set equality, selected nearest points, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, distance-evaluation exposure, metric-source compatibility, comparison non-collapse, transport, replay, provenance, and local naming for BEDC.Derived.WijsmanTopologyUp.

Chapter 6183

A Concrete Naming Certificate for $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$

Following Bishop-style cofinal selection in constructive Cauchy arguments, the $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$ packet records the finite route by which a regular Cauchy family supplies a cofinal subnet or subsequence window for diagonal-limit consumers. It sits over the finite observation discipline of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the tail-equivalence boundary of chapter 1738, and the terminal real-name seal of chapter 38. The packet is a finite selector certificate for cofinal Cauchy windows, not countable choice, a quotient stream, a selected real limit, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6183.1 (Regular Cauchy subnet selector carrier)**.** *A* $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, I, W, R, D, E, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the source regular Cauchy family row whose visible windows are being routed to a cofinal selector.*
2. *I is the cofinal index ledger. It records the finite monotone or directed comparison data needed to show that each requested tail window is eventually reached.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source family and selected subnet windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed selected windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the dyadic budgets used by I, W, R.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the selected windows and tolerance row have been displayed.*
7. *T is the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *witness row recording that the selected cofinal windows preserve the same regular Cauchy tail route as the source family.*
8. *H records componentwise* hsame *transport for X, I, W, R, D, E, T.*
9. *C records displayed* Cont *replay of source-family admission, cofinal-index inspection, stream-window extraction, regular rational readback, dyadic tolerance comparison, real-seal handoff, and tail-equivalence transport.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubnetSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, I, W, R, D, E, T, H, C, P, N$ and exports no countable-choice selector, quotient stream equality, selected limit, host subnet object, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubnetSelectorUp.RegularCauchySubnetSelectorTasteGate single carrier alignment`

Theorem 6183.2 (Regular Cauchy subnet selector NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$ *carrier*

$$S = (X, I, W, R, D, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubnetSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the source regular Cauchy family, cofinal index ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *witness, componentwise transport, displayed replay, package provenance, and local naming rows. Every accepted selector read must expose I before it consumes W, expose W, D before it consumes R, expose R, D, T before it consumes E, and reach H, C, P, N only as structural support for that same finite route.*

Proof. Project the carrier of Definition 6183.1. The mathematical rows are exactly the source family X, the cofinal ledger I, the window row W, the readback row R, the tolerance row D, the real seal E, and the tail-equivalence row T.

The cofinal ledger is inspected before any selected window is read. This prevents the selector from acting as a free choice principle; each visible subnet window is justified by the finite comparison data already stored in I.

The regular Cauchy data then flows through W, R, D, T before reaching the real seal E. Transport through H, replay through C, provenance through P, and local naming through N preserve that route and add no quotient stream, selected limit, host subnet object, trichotomy, or ambient completeness coordinate. □

Theorem 6183.3 (Regular Cauchy subnet selector handoff)**.** *Every diagonal-limit or real-completeness read from an accepted* $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyTailEquivalence}^{\uparrow}$$

before the selected cofinal windows may be consumed. The exported route contains only the source regular Cauchy family row, cofinal index ledger, finite stream windows, regular rational readback, dyadic tolerance row, real seal, tail-equivalence witness, transport, replay, provenance, and local naming; it exports no countable choice, quotient stream equality, selected real limit, host subnet object, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubnetSelectorUp.RegularCauchySubnetSelectorCarrier handoff`

Proof. Begin with the obligation package of Definition 6183.2. A consumer cannot inspect selected windows until the cofinal index ledger I has displayed the finite directed comparison route for the requested tail.

Next route the selected windows through the regular Cauchy surface. The stream row W, regular rational readback R, dyadic tolerance row D, and tail-equivalence witness T jointly account for the finite-window extraction before the terminal $\mathsf{Real}^{\uparrow}$ seal E can be used.

The structural rows H, C, P, N transport, replay, source, and name the same handoff. Since the carrier has no coordinate for countable choice, quotient stream equality, selected limits, host subnet objects, trichotomy, or ambient completeness, the displayed route is the entire consumer surface. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$ diagonal-limit read displays a source regular Cauchy family row, a cofinal index ledger, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a CauchyTailEquivalence witness, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before real-completeness consumers can inspect it.

Independence witness: streamname, regseqrat, dyadicratcore, cauchy-tail-equivalence, real: $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$ is not bijective to any listed sibling because it binds cofinal index data to selected regular Cauchy windows and their tail-equivalence route as one finite selector packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubnetSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubnetSelector}^{\uparrow}$ packet is generated from a source regular Cauchy family, a cofinal index ledger, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance row, a RealUp seal, a CauchyTailEquivalence witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubnetSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6183.1, Definition 6183.2, and Definition 6183.3 seed the finite cofinal-window selector surface for diagonal-limit and real-completeness consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubnetSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient stream equality, selected real limits, host subnet objects, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal-ledger exposure, finite-window extraction, regular readback, dyadic tolerance accounting, Real seal handoff, tail-equivalence preservation, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySubnetSelectorUp.

Chapter 6184

A Concrete Naming Certificate for $\mathsf{FiniteStateTransducer}^{\uparrow}$

Following Hopcroft–Ullman finite transducers, the $\mathsf{FiniteStateTransducer}^{\uparrow}$ packet records the finite output-producing surface of a deterministic finite-state machine as displayed BEDC data. It sits after the acceptance-only automaton surface of chapter 2364 and the finite observation discipline of chapter 126. The packet names finite control with a synchronized output ledger; it does not assert language quotient equivalence, minimization, nondeterministic branch choice, unbounded stream processing, or a host function from all words to all output words.

Definition 6184.1 (FiniteStateTransducerUp carrier)**.** *A* $\mathsf{FiniteStateTransducer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, \Sigma, \Gamma, \delta, \lambda, q_0, w, \rho, o, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite state carrier row.*
2. *Σ is the input symbol row naming the finite alphabet window read by the packet.*
3. *Γ is the output symbol row naming the finite output alphabet window produced by the packet.*
4. *δ is the transition ledger whose displayed entries consume a state row and an input symbol row and return the next state row.*
5. *λ is the output ledger whose displayed entries consume the same state and input symbol rows and return the finite output-symbol block emitted at that step.*
6. *q_0 is the start-state row inside Q.*
7. *w is the finite input window, read through the* $\mathsf{StreamName}^{\uparrow}$ *inspection surface.*
8. *ρ is the transition trace ledger beginning at q_0 and reading w one symbol at a time through δ.*
9. *o is the accumulated output ledger obtained by replaying λ along the same trace ρ.*
10. *H records componentwise* hsame *transport for the state, input-symbol, output-symbol, transition, output, start, input-window, trace, output-ledger, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from the input window through the transition ledger and output ledger at each finite step.*

12. *P is the* Pkg *provenance over* $\mathsf{FiniteStateTransducer}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteStateTransducer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $Q, \Sigma, \Gamma, \delta, \lambda, q_0, w, \rho, o, H, C, P, N$. The carrier has no coordinate for a host word function, output-stream totality, hidden state, minimized transducer, nondeterministic branch, or language-quotient equality.

Lean4 ✓ `BEDC.Derived.FiniteStateTransducerUp.FiniteStateTransducerTasteGate single carrier alignment`

Theorem 6184.2 (FiniteStateTransducerUp NameCert obligations)**.** *For every accepted* $\mathsf{FiniteStateTransducer}^{\uparrow}$ *carrier*

$$T = (Q, \Sigma, \Gamma, \delta, \lambda, q_0, w, \rho, o, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteStateTransducer}^{\uparrow}}$ *surface consists exactly of carrier admission, finite state exposure, input-symbol exposure, output-symbol exposure, transition-ledger replay, output-ledger replay, start-state exposure, finite input-window exposure, transition-trace exposure, accumulated-output exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance over* $\mathsf{FiniteAutomaton}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$*, and local naming through N.*

Proof. Project the accepted carrier of Definition 6184.1. The rows $Q, \Sigma, \Gamma, \delta, \lambda, q_0, w, \rho, o$ name the finite control surface, the inspected input window, and the synchronized output surface.

Replay is finite. The input window w is read through the same finite-window discipline used by $\mathsf{StreamName}^{\uparrow}$ consumers, and each step reads one displayed transition entry in δ and one displayed output entry in λ over the same state and input-symbol rows.

The structural rows H, C, P, N transport, replay, package, and name exactly those rows. Since neither the carrier nor the local certificate contains a host word function, hidden state, minimized quotient, nondeterministic branch, output-stream totality, or language-quotient equality, the listed rows exhaust the NameCert surface. □

Lean4 ✓ `BEDC.Derived.FiniteStateTransducerUp.FiniteStateTransducerCarrier namecert obligations`

Theorem 6184.3 (FiniteStateTransducerUp output-ledger determinacy)**.** *Let $T = (Q, \Sigma, \Gamma, \delta, \lambda, q_0, w, \rho, o, H, C, P$ and $T' = (Q', \Sigma', \Gamma', \delta', \lambda', q_0', w', \rho', o', H', C', P', N')$ be accepted* $\mathsf{FiniteStateTransducer}^{\uparrow}$ *packets. If their finite state, input symbol, output symbol, transition ledger, output ledger, start-state, input-window, transport, replay, provenance, and local NameCert rows agree componentwise by the displayed* hsame *witnesses, then their accumulated output ledgers agree along the same finite trace. In particular, no consumer can obtain two different output ledgers from the same displayed transition and output rows.*

Proof. Use Definition 6184.1 to project both packets to their displayed rows. The only coordinates that can affect the accumulated output ledger are the finite input window, the start state, the transition ledger, and the output ledger.

Proceed along the displayed input window. At the empty window, both packets are at the displayed start-state row and the accumulated output is the empty finite ledger. At a nonempty window, the common state and input-symbol rows select the displayed transition entry in δ and the displayed output entry in λ; the Cont rows then replay the tail window over the transported next-state row.

The hsame rows transport each selected transition and output entry componentwise, while P and N keep both packets under the same $\mathsf{FiniteAutomaton}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ provenance. There is

no remaining coordinate from which a second output ledger could be selected, so the accumulated output row is determined by the displayed finite route. □

Theorem 6184.4 (FiniteStateTransducerUp stream output trace obligation)**.** *Every output-producing read of an accepted* $\mathsf{FiniteStateTransducer}^{\uparrow}$ *packet factors through one displayed finite* $\mathsf{StreamName}^{\uparrow}$ *input window, the transition trace ledger over that window, and the accumulated output ledger replayed along the same rows. Thus a consumer may read output only after displaying the rows* $Q, \Sigma, \Gamma, \delta, \lambda, q_0, w, \rho, o, H, C, P, N$ *and the finite route from* w *through* ρ *to* o*.*

Proof. Project the carrier of Definition 6184.1. The finite input window w is the only row through which an input read enters the packet, and it is already tied to the $\mathsf{StreamName}^{\uparrow}$ inspection surface.

Proceed by induction over the displayed input window. The empty window exposes the start row q_0, the empty transition trace, and the empty accumulated output row. For a nonempty window, the head symbol and current state select one displayed transition entry from δ and one displayed output entry from λ.

The replay rows C continue the same finite route through the tail of the window, while H, P, N transport, package, and name the displayed rows. Since the carrier has no host word function, infinite stream totality, hidden output coordinate, or quotient equality, every output-producing read factors through the displayed window, transition trace, and output ledger. □

Theorem 6184.5 (FiniteStateTransducerUp window composition obligation)**.** *Suppose two displayed finite input windows for an accepted* $\mathsf{FiniteStateTransducer}^{\uparrow}$ *packet are concatenated after the first window has replayed to its displayed terminal state and output ledger. The trace and accumulated output for the concatenated window are obtained only by composing the displayed* δ*,* λ*,* ρ*,* o*,* H*,* C*,* P*, and* N *rows for the first window with the corresponding displayed rows for the second window.*

Proof. Use induction on the first displayed window. In the empty case, the concatenated route is exactly the second displayed window route, starting at the displayed state and using its displayed transition trace and output ledger.

For a nonempty first window, project the head transition and head output rows selected by δ and λ. The induction hypothesis applies to the tail window followed by the second displayed window, because the Cont replay row carries the transported next-state row into that tail route.

The accumulated output ledger is therefore the displayed head output block followed by the output ledger supplied by the induction hypothesis. All transports and naming data are supplied by H, C, P, N, and no composition step can appeal to an unstored word function, infinite trace, quotient stream equality, or nondisplayed output totality. □

Falsifiable prediction: An accepted $\mathsf{FiniteStateTransducer}^{\uparrow}$ read is refuted if an output-producing consumer obtains an output row without displaying the finite state row, input symbol row, output symbol row, transition ledger, output ledger, input window, transition trace, hsame transport, Cont replay, Pkg provenance over FiniteAutomatonUp and StreamNameUp, and local naming row.

Independence witness: FiniteAutomaton and StreamName: neither is bijective to $\mathsf{FiniteStateTransducer}^{\uparrow}$ because the transducer packet jointly stores finite control, input-window replay, and a synchronized output ledger, while the automaton packet stores acceptance replay and the stream-name packet stores observation windows without an emitted output ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteStateTransducer}^{\uparrow}}$**.**

Constructive story: A FiniteStateTransducer$^{\uparrow}$ packet is generated from a finite state row, input-symbol row, output-symbol row, transition ledger, output ledger, start state, finite input window, transition trace, accumulated output ledger, componentwise hsame transport, displayed continuation replay, package provenance over FiniteAutomatonUp and StreamNameUp, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteStateTransducer}^{\uparrow}}$, seed)

Scope closed: Definition 6184.1, Definition 6184.2, Definition 6184.3, Definition 6184.4, and Definition 6184.5 seed the finite transducer packet over finite control, stream windows, transition replay, output replay, transport, continuation, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteStateTransducer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close language quotient equivalence, minimization, nondeterministic transducers, total stream functions, infinite traces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-ledger replay, output-ledger determinacy, transport, replay, provenance, and local naming for BEDC.Derived.FiniteStateTransducerUp.

Chapter 6185

A Concrete Naming Certificate for $\mathsf{FarkasLemma}^{\uparrow}$

Following Farkas and standard finite-dimensional convex analysis, the $\mathsf{FarkasLemma}^{\uparrow}$ packet names the finite alternative row by which a displayed linear-inequality system is certified either by a feasible point or by a nonnegative multiplier obstruction. It sits between the convex carrier surface of chapter 208, the finite face carrier of chapter 209, the nonnegative comparison row of chapter 2297, and the weak-duality ledger of chapter 235. The packet is a finite certificate surface; it does not assert a separation theorem, a choice principle, a selected optimizer, or full strong duality.

Definition 6185.1 (Farkas finite-alternative carrier)**.** *A* $\mathsf{FarkasLemma}^{\uparrow}$ *carrier over an ordered-field row consists of a finite* BHist *packet*

$$\mathcal{F} = (I, J, F, A, b, \rho, \nu, \eta, H, C, P, N)$$

with the following displayed rows.

1. *I and J are finite row and column carriers, and F is the scalar carrier equipped with the shared* $\mathsf{Field}^{\uparrow}$ *and* $\mathsf{TotalOrder}^{\uparrow}$ *source rows used by the surrounding convex and linear-programming chapters.*

2. *$A : I \times J \to F$ and $b : I \to F$ are the coefficient rows of a finite inequality system, with row evaluation*
$$\mathsf{Row}_i(x) := \sum_{j \in J} A_{ij} \cdot_F x_j.$$

3. *ρ is the feasibility row, asserting that a displayed point $x : J \to F$ satisfies $\mathsf{Row}_i(x) \preceq_F b_i$ for every $i \in I$.*

4. *ν is the nonnegative multiplier row, a finite vector $\lambda : I \to F$ with $\mathsf{NonNeg}_F(\lambda_i)$ for every $i \in I$, read through the* $\mathsf{PositiveCone}^{\uparrow}$ *comparison surface.*

5. *η is the infeasibility-alternative row, recording the classifier equations*
$$\sum_{i \in I} \lambda_i \cdot_F A_{ij} \sim_F 0_F \qquad (j \in J)$$
and the strict obstruction comparison
$$\sum_{i \in I} \lambda_i \cdot_F b_i \prec_F 0_F.$$

6. *H records componentwise* hsame *transport for the finite row and column carriers, scalar operations, coefficient rows, right-hand-side row, feasibility witness, multiplier witness, obstruction witness, continuation, provenance, and local naming row.*
7. *C records displayed* Cont *replay from finite coefficient rows through row evaluation, multiplier summation, positive-cone comparison, and the final infeasibility alternative.*
8. *P is the* Pkg *provenance over* $\mathsf{FarkasLemma}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{PositiveCone}^{\uparrow}$, $\mathsf{LPDuality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FarkasLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed finite rows. It has no coordinate for ambient matrix equality, quotient vector-space equality, topological separation, a selected optimizer, or full strong-duality existence.

Lean4 ✓ `BEDC.Derived.FarkasLemmaUp.FarkasLemmaTasteGate single carrier alignment`

Theorem 6185.2 (FarkasLemma obligation surface)**.** *For every accepted* $\mathsf{FarkasLemma}^{\uparrow}$ *carrier* $\mathcal{F} = (I, J, F, A, b, \rho, \nu, \eta, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FarkasLemma}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier admission for the ordered-field source, finite coefficient rows, right-hand-side row, feasibility row, multiplier row, obstruction row, transport, replay, provenance, and local naming row;*
2. *classifier transport, requiring componentwise* hsame *in H to preserve every finite scalar endpoint, row-evaluation equation, nonnegative multiplier witness, and obstruction comparison;*
3. *positive-cone stability, requiring the multiplier row ν to be read only through the* $\mathsf{PositiveCone}^{\uparrow}$ *nonnegative classifier and the shared scalar order;*
4. *finite-alternative exactness, requiring exactly one displayed branch to be exported to downstream consumers: either the feasibility row ρ or the obstruction row η;*
5. *ledger non-escape, requiring P and N to export no topological separation theorem, selected optimizer, quotient vector-space equality, ambient matrix equality, or full strong-duality existence.*

No local NameCert obligation is stored outside these rows.

Proof. Project an accepted carrier through Definition 6185.1. Carrier admission is exactly the displayed finite row, column, scalar, coefficient, feasibility, multiplier, obstruction, transport, replay, provenance, and naming data.

Classifier transport is componentwise. The hsame row in H preserves each scalar endpoint and each finite row evaluation, while the displayed Cont replay in C repeats the same coefficient-to-obstruction ledger after classified replacement.

Positive-cone stability follows from the placement of ν. A multiplier coordinate is usable only after its nonnegative witness has been read through the $\mathsf{PositiveCone}^{\uparrow}$ comparison surface over the shared ordered-field row.

The finite-alternative exactness clause is the public branch boundary. A consumer may receive a feasible point row ρ or an obstruction row η, but both are finite BHist rows tied to the same coefficient packet and neither introduces a detached separation principle.

Finally, provenance is exhausted by P and N. Since the carrier has no coordinate for topological separation, selected optimizers, quotient equality, ambient matrix equality, or full strong duality, the local certificate cannot export any such object. □

Theorem 6185.3 (Farkas finite alternative)**.** *Let a* $\mathsf{FarkasLemma}^{\uparrow}$ *carrier over a finite ordered-field row be accepted as in Definition 6185.1. For the displayed coefficient system* A, b*, every downstream convex, polytope, positive-cone, or weak-duality consumer reads the alternative through a finite row:*

$$\rho \quad or \quad \eta.$$

In the first branch the consumer receives a carried feasible point with all inequalities $\mathsf{Row}_i(x) \preceq_F b_i$*. In the second branch it receives a carried nonnegative multiplier row whose finite row sums annihilate the left-hand coefficient rows and whose right-hand-side sum is strictly negative. The proof data are confined to finite row induction, scalar classifier transport, multiplier-ledger summation, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Proceed by induction on the finite row carrier I. In the empty row case the feasibility branch is immediate: the displayed coefficient ledger has no inequalities to check, and the multiplier row is the zero finite row.

For the row-extension step, separate the last displayed inequality from the tail packet. Apply the induction hypothesis to the tail coefficient system, obtaining either a tail feasible row or a tail obstruction row.

In the tail-feasible case, inspect the last row through the ordered-field comparison. If the displayed point satisfies the last inequality, reattach the row and obtain the full feasibility branch. If it fails, the finite scalar comparison supplies the one-row obstruction coefficient; the $\mathsf{PositiveCone}^{\uparrow}$ nonnegative row and the finite-sum ledger extend it to a multiplier packet over the enlarged carrier.

In the tail-obstruction case, extend the multiplier by zero on the last row. Finite-sum transport preserves the coefficient annihilation equations, and scalar order stability preserves the strict right-hand-side obstruction.

All transports are recorded in the visible ledger. The H row moves scalar endpoints and coefficient sums by hsame, the C row replays the row induction and multiplier summation, and P, N name the resulting branch as the same $\mathsf{FarkasLemma}^{\uparrow}$ alternative. Therefore the consumer receives only the finite feasibility row or the finite obstruction row and no detached separation or optimization principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{FarkasLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{FarkasLemma}^{\uparrow}$ packet is generated from finite row and column carriers, an ordered-field scalar surface, coefficient and right-hand-side rows, a feasibility branch, a nonnegative multiplier branch, an obstruction comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FarkasLemma}^{\uparrow}}$, seed)

Scope closed: Definition 6185.1, Definition 6185.2, and Definition 6185.3 seed the finite-alternative certificate consumed by convex, polytope, cone, and weak-duality rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FarkasLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close topological separation, selected optimizers, full strong duality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires carrier admission, classifier transport, positive-cone stability, finite-alternative exactness, and ledger non-escape proofs for the same packet.

Chapter 6186

A Concrete Naming Certificate for $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$ packet records the finite modulus data by which a located interval apartness claim becomes stable under smaller Real and Completion tolerances. It sits after the interval separation surface of chapter 4362, the located endpoint packet of chapter 1709, the Bishop located-real interface of chapter 6180, the dyadic tolerance ledger of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a positive gap together with the finite threshold after which all endpoint inspections preserve the apartness certificate; it is not a trichotomy decision, quotient real equality, a chosen endpoint representative, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6186.1 (Bishop interval-apartness modulus carrier)**.** *A* $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, A, G, T, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *endpoint packet whose lower and upper endpoint rows are exposed before any modulus read.*
2. *A is the* $\mathsf{RealIntervalApartness}^{\uparrow}$ *row recording the displayed interval separation side and the endpoint rows on which the gap is read.*
3. *G is the positive apartness gap, stored as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *witness compatible with the side selected by A.*
4. *T is the modulus threshold row: every endpoint-window request at a tolerance below T preserves the positive gap row G through the same interval-apartness side.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming exactly the endpoint inspections, gap checks, and threshold requests used by the packet.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those finite endpoint and threshold windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger tying the positive gap G and the threshold row T to one dyadic budget.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after I, A, G, T, S, R, D have been displayed.*

9. *H records componentwise* hsame *transport for the interval, apartness, gap, threshold, window, readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an interval-apartness-modulus request through $I, A, G, T, S, R, D, E, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$, $\mathsf{RealIntervalApartness}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{BishopLocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalApartnessModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host interval order, trichotomy, quotient equality of completed reals, selected endpoint representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopIntervalApartnessModulusUp.BishopIntervalApartnessModulusTasteGate`
`single carrier alignment`

Theorem 6186.2 (Bishop interval-apartness modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$ *carrier $M = (I, A, G, T, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalApartnessModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, located endpoint admission, interval-apartness admission, positive-gap admission, modulus-threshold admission, finite StreamName window admission, RegSeqRat readback, DyadicRatCore tolerance compatibility, Real seal admission, componentwise transport, displayed replay, provenance, and local naming for the displayed rows $I, A, G, T, S, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 6186.1. The analytic rows are the located interval I, the interval-apartness row A, the positive gap G, the threshold row T, the finite windows S, the regular readback R, the dyadic ledger D, and the terminal Real seal E.

The local certificate reads these rows in the displayed order. The threshold row may be consumed only after the apartness side and positive dyadic gap are visible, and the Real seal may be consumed only after the endpoint windows, regular readback, and dyadic ledger have been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for host interval order, trichotomy, quotient equality, selected representatives, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6186.3 (Bishop interval-apartness modulus located-real route)**.** *Every located-order or completion-facing read of an accepted* $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$ *carrier factors through*

$\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{RealIntervalApartness}^{\uparrow}$, $\mathsf{BishopLocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, Re

The route exports a positive interval-apartness gap together with a threshold for stable endpoint inspections. It exports no host trichotomy, quotient real equality, selected endpoint representative, open-cover compactness, or ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Proof. Begin with the obligations of Definition 6186.2. They force every consumer to expose the located interval row, the interval-apartness row, and the positive dyadic gap before it may read the modulus threshold.

Next read the finite endpoint windows and regular rational readback. The $\mathsf{BishopLocatedReal}^{\uparrow}$ interface is consumed only through this same endpoint, window, readback, and dyadic-tolerance route; it cannot replace the displayed gap by a host comparison of completed reals.

Finally route through the Real seal and the structural rows. Componentwise transport and displayed replay preserve the same packet, so the located-order or completion-facing consumer receives only the named finite modulus surface and none of the excluded host-order, quotient, selection, compactness, trichotomy, or completeness data. □

Theorem 6186.4 (Bishop interval-apartness modulus stability)**.** *Let* $M = (I, A, G, T, S, R, D, E, H, C, P, N)$ *and* $M' = (I', A', G', T', S', R', D', E', H', C', P', N')$ *be accepted* $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$ *carriers. If* H *records componentwise* hsame *transport from each displayed row of* M *to the corresponding row of* M'*, then the interval-apartness modulus of* M *transports to* M' *only through*

$$I, A, G, T, S, R, D, E, H, C, P, N.$$

In particular, the positive gap and the threshold for smaller endpoint windows remain attached to the same finite $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *route.*

Proof. Project the two accepted carriers. The modulus rows are G and T: G records the positive dyadic gap, while T records the threshold below which endpoint inspections preserve the same apartness side.

Componentwise transport through H carries the located interval, apartness side, gap, threshold, window schedule, readback, dyadic ledger, and Real seal to the corresponding rows of M'. The replay row C cannot change the order of these reads; it only replays the displayed route.

The NameCert obligations of Definition 6186.2 then repack the transported rows as the accepted modulus surface for M'. Because no host interval order, trichotomy, quotient equality, representative choice, or completeness coordinate is present, stability is exactly this row-local transport. □

Theorem 6186.5 (Bishop interval-apartness modulus Real-completion handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$ *carrier reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after the displayed located interval, interval-apartness row, positive gap, threshold, finite windows, regular rational readback, and dyadic tolerance ledger have been read. Thus the handoff supplies a finite modulus for interval apartness without importing quotient real equality, selected limits, trichotomy, or ambient completion.*

Proof. Read the carrier of Definition 6186.1. The terminal Real row is E, and it appears only downstream of I, A, G, T, S, R, D.

Apply the located-real route theorem. It keeps the completion-facing read inside the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{RealIntervalApartness}^{\uparrow}$, $\mathsf{BishopLocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows before any Real seal is consumed.

Apply the stability theorem to any transported packet used by the consumer. The positive gap and threshold remain attached to the same finite route under hsame transport and Cont replay. The provenance and local NameCert rows then name the same handoff, so no quotient equality, selected limit, trichotomy branch, or ambient completeness principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalApartnessModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalApartnessModulus}^{\uparrow}$ packet is generated from a LocatedRealInterval endpoint packet, a RealIntervalApartness row, a positive DyadicRatCore gap, a modulus threshold, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalApartnessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6186.1, Definition 6186.2, Definition 6186.3, Definition 6186.4, and Definition 6186.5 seed the finite interval-apartness modulus route from located endpoint rows and a positive dyadic gap through threshold, finite-window, regular-readback, Real seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopIntervalApartnessModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host interval order, real trichotomy, quotient real equality, selected endpoint representatives, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-apartness gap exposure, threshold stability, located-real routing, Real-completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalApartnes

Chapter 6187

A Concrete Naming Certificate for $\mathsf{BairePrefixCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive metric completion, and Brouwer together with Troelstra–van Dalen on spread and prefix semantics, the $\mathsf{BairePrefixCompletion}^{\uparrow}$ packet names the finite-prefix handoff from Baire streams to the completion-facing boundary. It sits after the finite prefix carrier of chapter 334, the common-prefix distance routes of chapter 1602 and chapter 3485, the finite-window readback of chapter 126, and before the limit-boundary packet of chapter 1884. The chapter records the completion handoff as displayed finite data, not as host stream equality, a selected branch, quotient equality of streams, countable choice, or ambient completeness.

Definition 6187.1 (Baire prefix completion carrier)**.** *A* $\mathsf{BairePrefixCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, M, S, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *finite prefix row, naming the inspected prefix cylinder and the prefix length visible to the completion request.*
2. *M is the* $\mathsf{BaireMetric}^{\uparrow}$ *or* $\mathsf{BaireUltrametric}^{\uparrow}$ *distance row, recording the common-prefix dyadic distance used to compare displayed cylinders before a boundary read.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing exactly the stream coordinates opened by the prefix request and the distance request.*
4. *E is the* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *boundary row, available only after B, M, S have been displayed.*
5. *H records componentwise* hsame *transport for the prefix, distance, window, boundary, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the same finite prefix windows through the completion-facing request.*
7. *P is the* Pkg *provenance over* $\mathsf{BairePrefixCompletion}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireMetric}^{\uparrow}$, $\mathsf{BaireUltrametric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CompleteBaireSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BairePrefixCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, M, S, E, H, C, P, N. It has no coordinate for host stream equality, quotient stream equality, a selected infinite branch, countable choice, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BairePrefixCompletionUp.BairePrefixCompletionTasteGate single carrier alignment`

Theorem 6187.2 (Baire prefix completion NameCert obligations)**.** *For every accepted* $\mathsf{BairePrefixCompletion}^{\uparrow}$ *carrier* $L = (B, M, S, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BairePrefixCompletion}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the displayed Baire prefix row, prefix-distance row, finite StreamName window row, completion boundary row, transport, replay, provenance, and local naming;*
2. *prefix-window coverage, requiring every completion-facing read to expose the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row* B *and the* $\mathsf{StreamName}^{\uparrow}$ *window row* S *before any boundary row is inspected;*
3. *distance compatibility, requiring the* $\mathsf{BaireMetric}^{\uparrow}$ *or* $\mathsf{BaireUltrametric}^{\uparrow}$ *row* M *to compare only the displayed prefix cylinders and their finite common-prefix witnesses;*
4. *completion-boundary ordering, requiring the* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *row* E *to be downstream of* B, M, S *and stable under componentwise* hsame *transport and displayed* Cont *replay;*
5. *nonescape, excluding host stream equality, quotient stream equality, selected branches, countable choice, ambient completeness, Lean verification, and bridge checking.*

No BairePrefixCompletion obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 6187.1. The displayed tuple B, M, S, E, H, C, P, N is the whole public surface, so carrier admission is exactly the admission of those rows.

Prefix-window coverage is forced by B and S. The prefix row names the inspected cylinder, while the StreamName row lists every coordinate opened by that request.

Distance compatibility is read from M. Whether the consumer uses the metric or ultrametric sibling route, the distance row can compare only the prefix cylinders and finite common-prefix witnesses already displayed by B and S.

The boundary ordering is the role of E, H, C. The completion row is available only after the finite prefix, distance, and window rows, while transport and replay preserve that same route.

The provenance and local naming rows cite no selector, quotient, host equality, countable-choice operation, ambient completeness theorem, Lean credential, or bridge credential. Therefore the five rows exhaust the local NameCert surface. □

Theorem 6187.3 (Baire prefix completion finite-window exhaustion)**.** *Every* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *consumer reading a limit boundary from an accepted* $\mathsf{BairePrefixCompletion}^{\uparrow}$ *carrier* $L = (B, M, S, E, H, C, P, N)$ *must first expose the* $\mathsf{BaireSpace}^{\uparrow}$ *finite prefix row* B*, the* $\mathsf{BaireMetric}^{\uparrow}$ *or* $\mathsf{BaireUltrametric}^{\uparrow}$ *distance row* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* N*. Thus every completion-facing read exposes finite prefix windows before the boundary row* E *can be consumed.*

Proof. Begin with a completion-facing read. By the carrier definition, the only rows upstream of the boundary row are the displayed prefix, distance, and finite-window rows, followed by the structural support rows.

Apply the NameCert obligations of Definition 6187.2. Prefix-window coverage requires B and S before any boundary read, and distance compatibility places M on the same finite prefix route.

Use the completion-boundary ordering clause for E, H, C. The boundary row cannot be consumed until the finite rows have been displayed, and transport or replay can only carry the same displayed route.

Finally P and N source and name this finite handoff. Since no excluded branch, quotient, choice, host equality, or ambient completeness coordinate exists in the carrier, the consumer receives finite prefix windows before any limit boundary. □

Falsifiable prediction: Every $\mathsf{BairePrefixCompletion}^{\uparrow}$ completion-facing read factors through a displayed $\mathsf{BaireSpace}^{\uparrow}$ prefix row, a $\mathsf{BaireMetric}^{\uparrow}$ or $\mathsf{BaireUltrametric}^{\uparrow}$ distance row, a finite $\mathsf{StreamName}^{\uparrow}$ window row, a $\mathsf{CompleteBaireSpace}^{\uparrow}$ boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: bairespace, bairemetric, baire-ultrametric, streamname, complete-bairespace: $\mathsf{BairePrefixCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite Baire prefixes, prefix-distance comparison, finite StreamName windows, completion boundary ordering, transport, continuation, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BairePrefixCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BairePrefixCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6187.1, Definition 6187.2, and Definition 6187.3 seed the finite-prefix completion handoff from Baire prefix cylinders through StreamName windows and prefix distance rows into the CompleteBaireSpace boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BairePrefixCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host stream equality, quotient stream equality, selected branches, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-window coverage, distance compatibility, completion-boundary ordering, finite-window exhaustion, and nonescape for BEDC.Derived.BairePrefixCompletionUp.

Constructive story: A $\mathsf{BairePrefixCompletion}^{\uparrow}$ packet is generated from finite Baire prefix rows, prefix-distance rows, StreamName finite windows, a CompleteBaireSpace boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6188

A Concrete Naming Certificate for $\mathsf{MinimalDfa}^{\uparrow}$

Following Hopcroft and Ullman, the $\mathsf{MinimalDfa}^{\uparrow}$ packet records the canonical deterministic finite automaton presentation obtained from the finite right-congruence rows of chapter 5729. It consumes accepted-language observations from chapter 351, displayed finite control from chapter 2364, and the minimization handoff supplied by chapter 5729. The packet names the minimal deterministic presentation as finite NameCert data; it does not identify arbitrary external automata, choose nondeterministic branches, import a host quotient of all words, or assert regular-expression equivalence.

Definition 6188.1 (MinimalDfaUp carrier)**.** *A* $\mathsf{MinimalDfa}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\Sigma, L, E, C, W, Q, \delta, q_0, F, A, \alpha, \eta, \kappa, H, R, P, N)$$

with the following displayed rows:

1. Σ *is the finite alphabet row.*
2. L *is the accepted-word observation ledger supplied by a* $\mathsf{RegularLanguage}^{\uparrow}$ *packet.*
3. E *is the finite right-congruence table supplied by a* $\mathsf{MyhillNerode}^{\uparrow}$ *packet.*
4. C *is the suffix-stability replay row for* E*.*
5. W *is the distinguishability-witness ledger separating distinct rows of* E*.*
6. Q *is the finite state carrier whose states are the displayed* E*-classes.*
7. δ *is the deterministic transition row induced by appending one alphabet symbol and returning to the displayed class.*
8. q_0 *is the class of the empty word.*
9. F *is the accepting-class row determined by* L*.*
10. A *is the* $\mathsf{FiniteAutomaton}^{\uparrow}$ *presentation assembled from* $Q, \Sigma, \delta, q_0, F$ *and its finite replay rows.*
11. α *is the reachability ledger naming a representative word for each displayed state class.*
12. η *is the separation ledger naming a displayed suffix witness for every pair of distinct displayed state classes.*

13. *κ is the canonicality row binding accepted* $\mathsf{MinimalDfa}^{\uparrow}$ *packets with the same E, C, W rows to the same displayed automaton rows.*

14. *H records componentwise* hsame *transport for alphabet, language, congruence, suffix-stability, distinguishability, state, transition, start, accepting, automaton, reachability, separation, and canonicality rows.*

15. *R records displayed* Cont *replay from accepted-word queries through the right-congruence table and into the deterministic transition row.*

16. *P records* Pkg *provenance over* $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{MyhillNerode}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

17. *N is the local* $\mathsf{NameCert}_{\mathsf{MinimalDfa}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $\Sigma, L, E, C, W, Q, \delta, q_0, F, A, \alpha, \eta, \kappa, H, R, P,$ The carrier has no coordinate for a hidden automaton presentation, nondeterministic recognizer, infinite language quotient, regular-expression proof, or external state renaming oracle.

Lean4 ✓ `BEDC.Derived.MinimalDfaUp.MinimalDfaTasteGate single carrier alignment`

Theorem 6188.2 (MinimalDfaUp NameCert obligations)**.** *For every accepted* $\mathsf{MinimalDfa}^{\uparrow}$ *carrier*

$$D = (\Sigma, L, E, C, W, Q, \delta, q_0, F, A, \alpha, \eta, \kappa, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MinimalDfa}^{\uparrow}}$ *surface consists exactly of finite alphabet exposure, accepted-word observation, right-congruence exposure, suffix-stability replay, distinguishability witnesses, quotient-state exposure, induced deterministic transition replay, start-class exposure, accepting-class exposure, finite-automaton presentation, reachability representatives, pairwise separation witnesses, canonicality transport, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6188.1. The rows Σ, L, E, C, W expose the finite observation table inherited from the regular-language and Myhill–Nerode packets.

The rows Q, δ, q_0, F, A repackage that table as the deterministic finite automaton presentation consumed by $\mathsf{FiniteAutomaton}^{\uparrow}$. Reachability is recorded by α, and pairwise separation is recorded by η; these rows are the finite witnesses that no displayed state is unreachable and no two displayed states can be merged by the accepted-word classifier.

The rows κ, H, R, P, N keep canonicality, transport, replay, provenance, and local naming attached to the same finite packet. Since the carrier has no hidden presentation, nondeterministic branch, host quotient, regular-expression proof, or state-renaming oracle coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 6188.3 (MinimalDfaUp Myhill–Nerode canonicality)**.** *Let D and D' be accepted* $\mathsf{MinimalDfa}^{\uparrow}$ *packets over the same displayed alphabet, accepted-word ledger, right-congruence table, suffix-stability row, and distinguishability-witness ledger. If their* $\mathsf{MyhillNerode}^{\uparrow}$ *rows agree componentwise, then their finite state carriers, induced transition rows, start classes, accepting-class rows, reachability ledgers, separation ledgers, and* $\mathsf{FiniteAutomaton}^{\uparrow}$ *presentations agree through the canonicality rows of the two packets. Thus a* $\mathsf{RegularLanguage}^{\uparrow}$ *consumer reading through the Myhill–Nerode minimization handoff can obtain only the displayed minimal deterministic presentation named by the* $\mathsf{MinimalDfa}^{\uparrow}$ *packet.*

Proof. Use Definition 6188.2 to project both accepted packets to their displayed right-congruence data. Agreement of the $\mathsf{MyhillNerode}^{\uparrow}$ rows identifies the same finite class table, the same suffix-stability replay, and the same distinguishability witnesses.

The state carrier Q is exactly the displayed class carrier of that table. The transition row δ is forced by appending one displayed alphabet symbol and returning to the corresponding class, while q_0 and F are read from the empty-word class and the accepted-word ledger.

Reachability and separation are finite ledgers over the same displayed classes. The canonicality rows κ and κ' therefore transport the assembled $\mathsf{FiniteAutomaton}^{\uparrow}$ presentations componentwise. No further automaton can be selected because hidden presentations, state-renaming oracles, nondeterministic branches, and host quotients are absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{MinimalDfa}^{\uparrow}$ read is refuted if a minimization consumer obtains a deterministic automaton row without displaying the finite alphabet, accepted-word ledger, right-congruence table, suffix-stability row, distinguishability witnesses, quotient-state row, induced transition row, start class, accepting-class row, reachability ledger, separation ledger, canonicality row, transport rows, replay rows, provenance row, and local naming row.

Independence witness: RegularLanguage, FiniteAutomaton, and MyhillNerode: none is bijective to $\mathsf{MinimalDfa}^{\uparrow}$. The regular-language packet records accepted-word observation without a canonical finite presentation, the finite-automaton packet records one presentation without the Myhill–Nerode separation ledger, and the Myhill–Nerode packet records the minimization handoff without owning the downstream minimal deterministic automaton NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{MinimalDfa}^{\uparrow}}$.

Constructive story: A $\mathsf{MinimalDfa}^{\uparrow}$ packet is generated from a finite alphabet row, accepted-word ledger, right-congruence table, suffix-stability replay, distinguishability witnesses, quotient-state row, induced transition row, start class, accepting-class row, finite automaton presentation, reachability representatives, pairwise separation witnesses, canonicality transport, componentwise hsame transport, displayed continuation replay, package provenance over RegularLanguageUp, FiniteAutomatonUp, and MyhillNerodeUp, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinimalDfa}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6188.1, Definition 6188.2, and Definition 6188.3 seed the minimal deterministic automaton packet over finite right-congruence data, deterministic replay, reachability, separation, canonicality, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinimalDfa}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary automaton equivalence, nondeterministic minimization, regular-expression conversion, external state-renaming quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, right-congruence replay, distinguishability coverage, finite-automaton assembly, reachability, separation, canonicality, transport, replay, provenance, and local naming for BEDC.Derived.MinimalDfaUp.

Chapter 6189

A Concrete Naming Certificate for $\mathsf{BishopLocatedInterval}^{\uparrow}$

Bishop and Bridges-style located interval practice treats an interval as a finite endpoint and locatedness interface rather than as an ambient completeness principle. The $\mathsf{BishopLocatedInterval}^{\uparrow}$ packet records that interface for the L10 Real and Completion route: it reads the dyadic bracket ledger of chapter 291, the finite observation discipline of chapter 126, the regular rational handoff of chapter 301, the terminal real-name seal of chapter 38, and the located-real endpoint surface of **??**. It does not assert Heine–Borel compactness, selected finite subcovers, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6189.1 (Bishop located interval carrier)**.** *A* $\mathsf{BishopLocatedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, D, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower endpoint row, a* $\mathsf{LocatedReal}^{\uparrow}$ *packet displayed before any interval-facing request is accepted.*
2. *U is the upper endpoint row, a* $\mathsf{LocatedReal}^{\uparrow}$ *packet displayed in the same history as L.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket ledger, carrying the lower and upper dyadic cells, tolerance budget, visible slack, and comparison rows used to inspect L and U.*
4. *Q is the locatedness witness row: for each accepted finite probe it displays which endpoint bracket, dyadic subcell, or visible gap row answers the probe.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row opened at the dyadic indices recorded in D and Q.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the same StreamName windows and dyadic bracket ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal consumed only after the endpoint rows, bracket ledger, locatedness witness, finite observation row, and regular rational handoff have been displayed.*
8. *H records componentwise* hsame *transport for the endpoint rows, dyadic bracket ledger, locatedness witness, StreamName observations, RegSeqRat handoff, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for finite located-interval requests through L, U, D, Q, S, R, E, H.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedInterval}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedInterval}^{\uparrow}}$ *row.*

The classifier reads only these rows. In particular, it has no coordinate for selected subcovers, global compactness, host real equality, quotient stream equality, countable choice, or a completeness assertion for all $\mathsf{Real}^{\uparrow}$ *Cauchy data.*

Lean4 ✓ `BEDC.Derived.BishopLocatedIntervalUp.BishopLocatedIntervalTasteGate single carrier alignment`

Theorem 6189.2 (Bishop located interval NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedInterval}^{\uparrow}$ *carrier* $I = (L, U, D, Q, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedInterval}^{\uparrow}}$ *surface is exhausted by the following obligations:*

1. *endpoint admission: the lower and upper endpoint rows L, U are displayed* $\mathsf{LocatedReal}^{\uparrow}$ *packets in the same finite history;*
2. *interval order and bracket visibility: the dyadic ledger D exposes the endpoint order comparison, tolerance budget, bracket cells, and slack rows before an interval request can read them;*
3. *locatedness: the witness row Q answers each accepted finite probe by a displayed endpoint bracket, subcell, or visible gap row;*
4. *dyadic refinement stability: refining the accepted dyadic budget transports D, Q, S, R componentwise through the same* hsame *and* Cont *rows;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal nonescape: any regular rational or real-facing read must pass through S, R, E, H, C, P, N and cannot export quotient stream equality, a selected limit, countable choice, Heine–Borel data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 6189.1. The endpoint rows are L and U, and the only order or bracket data visible to an interval request is the dyadic ledger D together with the locatedness witness Q.

The finite observation and completion route is forced through S, R, E. The StreamName row S opens only the requested finite windows, the RegSeqRat row R reads back the regular rational handoff from those windows, and the terminal Real row E is sealed behind the same displayed route.

Transport and replay remain row-local. The rows H, C, P, N carry the endpoint, bracket, locatedness, observation, handoff, and seal data componentwise, so a refinement can only repack the same finite NameCert surface. Since the carrier contains no row for selected subcovers, quotient stream equality, countable choice, chosen limits, or ambient completeness, no such principle can be exported by the certificate. □

Theorem 6189.3 (Bishop located interval endpoint admission)**.** *For every accepted* $\mathsf{BishopLocatedInterval}^{\uparrow}$ *carrier* $I = (L, U, D, Q, S, R, E, H, C, P, N)$*, the lower endpoint row L and upper endpoint row U are admitted only as the displayed* $\mathsf{LocatedReal}^{\uparrow}$ *rows in the same finite* BHist*. Any endpoint-facing read of I must pass through the same* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BishopLocatedInterval}^{\uparrow}}$ *surface recorded by H, C, P, N.*

Proof. Project the carrier of Definition 6189.1. Its first two rows are precisely L and U, and the defining display already types both rows as $\mathsf{LocatedReal}^{\uparrow}$ packets in the shared finite history. The endpoint surface is therefore the located-real surface of **??**, not a host real or quotient stream row.

The remaining endpoint-facing access is controlled by the displayed certificate rows. The dyadic brackets are read through chapter 291; the finite observation windows are those of chapter 126; the regular rational handoff is the one named in chapter 301; and the terminal seal is the $\mathsf{Real}^{\uparrow}$ route of chapter 38. Since H, C, P, N are the only transport, replay, provenance, and local naming rows, endpoint admission is exhausted by these finite rows. □

Theorem 6189.4 (Bishop located interval locatedness witness)**.** *For every accepted* $\mathsf{BishopLocatedInterval}^{\uparrow}$ *carrier* $I = (L, U, D, Q, S, R, E, H, C, P, N)$*, each finite locatedness probe answered by* Q *factors through a displayed endpoint bracket, dyadic subcell, or visible gap row. No such answer can invoke selected subcovers, countable choice, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the locatedness coordinate Q. By Definition 6189.1, Q answers only accepted finite probes, and each answer names one of the visible rows already displayed by the endpoint brackets, the $\mathsf{DyadicRatCore}^{\uparrow}$ subcell ledger of chapter 291, or the visible gap rows carried in the same ledger.

The finite row-exhaustion argument then excludes the ambient principles. Stream observations may only use the finite windows of chapter 126; regular readback may only use chapter 301; endpoint reads remain in **??**; and any terminal real name must enter through chapter 38. The tuple has no coordinate for subcover selection, countable choice, quotient equality, or host completeness, so a Q-answer cannot factor through any of them. □

Theorem 6189.5 (Bishop located interval Real seal non-escape)**.** *For every accepted* $\mathsf{BishopLocatedInterval}^{\uparrow}$ *carrier* $I = (L, U, D, Q, S, R, E, H, C, P, N)$*, any* $\mathsf{Real}^{\uparrow}$ *seal read from* E *is downstream of the displayed endpoint rows* L, U*, dyadic ledger* D*, locatedness witness* Q*, finite observation row* S*, regular rational handoff* R*, and the transport, replay, provenance, and local naming rows* H, C, P, N*.*

Proof. Project the seal coordinate E. The carrier definition places E after L, U, D, Q, S, R, so a real-facing read cannot reach the seal before the endpoint, dyadic, locatedness, stream, and regular-rational rows have been displayed. This is exactly the finite L10 route through **??**, chapter 291, chapter 126, chapter 301, and chapter 38.

The certificate rows H, C, P, N preserve that order. Componentwise hsame transport, displayed Cont replay, provenance, and local naming may repack the finite route, but they add no separate seal source. Thus every $\mathsf{Real}^{\uparrow}$ read from E remains downstream of the displayed rows and cannot escape to quotient stream equality, selected limits, countable choice, Heine–Borel compactness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedInterval}^{\uparrow}$ packet is generated from lower and upper LocatedReal endpoint rows, a DyadicRatCore bracket ledger, a locatedness witness, StreamName finite observation, RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedInterval}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6189.1, Definition 6189.2, Definition 6189.3, Definition 6189.4, and Definition 6189.5 bind the finite located-interval carrier, endpoint admission, locatedness witness, and Real seal non-escape obligations over $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Heine–Borel compactness, selected finite subcovers, quotient stream equality, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked finite-row coverage for endpoint admission, locatedness factoring, RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and local naming over BEDC.Derived.BishopLocatedIntervalUp.

Chapter 6190

A Concrete Naming Certificate for KleeneKreiselContinuousFunctional$^{\uparrow}$

Following Kleene and Kreisel on continuous functionals over choice-sequence spaces, the KleeneKreiselContinuousFun packet records a higher-type finite-window interface for functionals read from countable names. It sits over the finite observation discipline of chapter 126, the binary prefix surface of chapter 1475, the bounded modulus handoff of chapter 1525, the neighborhood table of chapter 2336, and the domain-facing readback of chapter 6099. The packet is grounded in finite BEDC rows and displayed request ledgers, not in host function equality, an ambient exponential object, or a completed space of all functionals.

Definition 6190.1 (KleeneKreiselContinuousFunctional carrier)**.** *A* KleeneKreiselContinuousFunctional$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, C, F, Nb, Sc, H, T, P, N)$$

with the following displayed rows:

1. *S is the* StreamName$^{\uparrow}$ *source row, exposing the finite request windows through which countable names are inspected.*
2. *C is the* CantorSpace$^{\uparrow}$ *binary prefix row used when the functional read is restricted to a binary choice-sequence window.*
3. *F is the* FanFunctional$^{\uparrow}$ *modulus row, displaying the bounded prefix length needed before an output row may be read on compact binary windows.*
4. *Nb is the* NeighborhoodFunction$^{\uparrow}$ *table row, recording finite input-prefix requests and the output rows released by those requests.*
5. *Sc is the* ScottContinuous$^{\uparrow}$ *readback row, recording the directed-observation and Scott-open replay surface through which the same finite table is read as a continuity packet.*
6. *H records componentwise* hsame *transport for the stream, Cantor, fan, neighborhood, Scott-continuity, replay, provenance, and naming rows.*
7. *T records displayed* Cont *replay from every finite name request through S, C, F, Nb, Sc, H before an output row is exposed.*
8. *P is the* Pkg *provenance over* KleeneKreiselContinuousFunctional$^{\uparrow}$, StreamName$^{\uparrow}$, CantorSpace$^{\uparrow}$, FanFunctional$^{\uparrow}$, NeighborhoodFunction$^{\uparrow}$, ScottContinuous$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the displayed rows $S, C, F, Nb, Sc, H, T, P, N$. It has no coordinate for host equality of higher-type functions, an arbitrary map from all streams to all values, countable choice, a selected infinite path, or a semantic function-space quotient.

Lean4 (definition) `BEDC.Derived.KleeneKreiselContinuousFunctionalUp.taste gate`

Theorem 6190.2 (KleeneKreiselContinuousFunctional NameCert obligations)**.** *For every accepted* $\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}$ *carrier*

$$K = (S, C, F, Nb, Sc, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-window classifier exposure, neighborhood-function transport through Nb, fan-functional modulus handoff through F, Scott-continuity readback through Sc, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming through N, and non-escape from those displayed rows. Every accepted read must expose the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{CantorSpace}^{\uparrow}$ *request rows before it may consume the neighborhood table, fan modulus, or Scott-continuity readback.*

Proof. Project the carrier of Definition 6190.1. The source name windows are S, the binary prefix face is C, the compact modulus face is F, the finite neighborhood table is Nb, and the domain-continuity readback is Sc.

The functional read is finite at each public use. The neighborhood row Nb lists the input-prefix requests that release an output row, while the fan row F records the bounded prefix length needed on the Cantor-space face. These rows are classifier data in the BEDC packet, not host function equality or an order on completed streams.

The Scott row Sc reads the same table through directed-observation and Scott-open replay. Componentwise transport through H and displayed continuation replay through T preserve the rows already displayed; they do not create a second functional source.

Finally P and N package and name the same finite route. Since the carrier contains no host exponential, no stream quotient, no selected infinite path, and no countable-choice operator, the listed rows exhaust the local NameCert obligations. □

Theorem 6190.3 (KleeneKreiselContinuousFunctional neighborhood handoff)**.** *Every accepted* $\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}$ *read factors through the displayed* $\mathsf{NeighborhoodFunction}^{\uparrow}$ *row and the* $\mathsf{StreamName}^{\uparrow}$ *finite request rows before any output read is available. More precisely, for a carrier*

$$K = (S, C, F, Nb, Sc, H, T, P, N),$$

any public output row must first display the StreamName request window in S, the corresponding neighborhood-table entry in Nb, and the continuation replay row in T. On binary choice-sequence reads the same handoff may additionally use the $\mathsf{CantorSpace}^{\uparrow}$ *row C and the* $\mathsf{FanFunctional}^{\uparrow}$ *modulus row F; on domain-facing reads it may use the* $\mathsf{ScottContinuous}^{\uparrow}$ *row Sc. No output row is admitted from a host functional, a hidden infinite stream, or a detached equality proof.*

Proof. Start from an accepted public output read. By Definition 6190.1, the only rows that can expose an output are the finite request row S, the neighborhood table Nb, and the displayed continuation row T.

Use Definition 6190.2. It forces every accepted read through carrier admission, finite-window classifier exposure, neighborhood transport, continuation replay, provenance, and local naming before the output row is treated as public data.

For the binary face, the Cantor row C supplies the finite prefix window and the fan row F supplies the bounded modulus handoff. For the domain face, the Scott row Sc replays the same table as a continuity read. In both cases the consumer still reaches the output through S, Nb, T rather than through an ambient higher-type map.

Rows H, P, N transport, source, and name this handoff. Because host function equality, hidden infinite streams, selected paths, countable choice, and semantic function-space quotients are absent from K, no other output source remains. □

Falsifiable prediction: An accepted $\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}$ read is refuted if a consumer obtains an output row without displaying the StreamName request window, NeighborhoodFunction table entry, continuation replay, componentwise hsame transport, Pkg provenance over StreamNameUp, CantorSpaceUp, FanFunctionalUp, NeighborhoodFunctionUp, ScottContinuousUp, and local naming row.

Independence witness: streamname, cantorspace, fanfunctional, neighborhood-function, scott-continuous: $\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores source-name requests, binary prefix restriction, compact modulus handoff, a neighborhood table, Scott-continuity readback, transport, replay, provenance, and local naming in one higher-type finite-window packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}}$.

Constructive story: A $\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}$ packet is generated from StreamName request windows, CantorSpace prefix rows, FanFunctional modulus rows, NeighborhoodFunction table rows, ScottContinuous readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6190.1, Definition 6190.2, and Definition 6190.3 seed the finite-window interface for continuous higher-type functional reads over named streams.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function spaces, quotient equality of functionals, selected infinite paths, countable choice, total stream maps, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighborhood transport, fan modulus handoff, Scott-continuity readback, transport, replay, provenance, local naming, and a concrete Lean target for BEDC.Derived.KleeneKreiselContinuousF

Chapter 6191

A Concrete Naming Certificate for $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$

Following Picard, Lindelof, and Bishop–Bridges, the $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$ packet records the local ODE approximation surface that lies between the finite $\mathsf{PicardIteration}^{\uparrow}$ ledger of chapter 2359 and the local-flow endpoint of chapter 1899. It reads the ODE source of chapter 193, the Lipschitz vector-field surface of chapter 410, and the completion-facing L10 route through chapter 126, chapter 301, chapter 291, and chapter 38. The packet names a local finite iteration handoff; it is not a host solution curve, a selected fixed point, a quotient path space, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6191.1 (Picard–Lindelof local iteration carrier)**.** *A* $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (O, F, I, M, S, R, E, H, C, P_0, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *local time-state row, naming the initial cell, local interval, and state-window boundary used by all later reads.*
2. *F is the* $\mathsf{LipschitzMap}^{\uparrow}$ *vector-field row on the same local window, including the displayed graph reads and Lipschitz budget available to the Picard operator.*
3. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *finite iteration ledger, recording the inspected approximants and their one-step reads through F.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *approximant-space row, exposing the Cauchy-modulus and late-comparison data needed before a completion-facing read is allowed.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the visible approximation windows without replacing them by a host sequence object.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the same windows, local radius budgets, and regular rational readbacks.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after S and R have been displayed.*
8. *H records componentwise* hsame *transport for the ODE source, Lipschitz ledger, Picard iteration ledger, complete-metric row, stream windows, regular rational readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through*

$$O, F, I, M, S, R, E \longmapsto H, P_0, N.$$

10. *P_0 is the* Pkg *provenance over* $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardLindelofLocalIteration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, F, I, M, S, R, E, H, C, P_0, N$. It has no coordinate for a global solution, a maximal continuation interval, host function equality, selected limits, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.PicardLindelofLocalIterationUp.taste gate`

Theorem 6191.2 (Picard–Lindelof local iteration obligations)**.** *For every accepted* $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$ *carrier*

$$P = (O, F, I, M, S, R, E, H, C, P_0, N),$$

the local $\mathsf{NameCert}_{\mathsf{PicardLindelofLocalIteration}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{Ode}^{\uparrow}$ *row,* $\mathsf{LipschitzMap}^{\uparrow}$ *row,* $\mathsf{PicardIteration}^{\uparrow}$ *ledger,* $\mathsf{CompleteMetric}^{\uparrow}$ *approximant-space row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier of Definition 6191.1. The ODE and vector-field rows are O and F, so every approximation read first fixes the initial cell, local window, and displayed Lipschitz graph data.

The finite iteration and completion-facing rows are I and M. The row I records only the Picard approximants inspected in the packet, while M exposes the complete-metric Cauchy and late-comparison data needed before a completion-facing consumer can ask for a terminal read.

The L10 readback rows are S, R, E. They route the visible approximants through finite stream windows, regular rational readbacks, and the real seal boundary of the same packet, so no host sequence, selected limit, quotient equality, or ambient completeness coordinate is introduced.

Finally H, C, P_0, N transport, replay, source, and name exactly the same rows. These structural rows cannot add a global solution, a maximal continuation interval, or host function equality, so the listed rows exhaust the local obligation surface. □

Theorem 6191.3 (Picard–Lindelof RegSeqRat handoff)**.** *Every accepted* $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$ *carrier hands its visible Picard approximants to the L10 completion route only through*

$$\mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Consequently the $\mathsf{RegSeqRat}^{\uparrow}$ *row R is downstream of the finite iteration ledger I, the complete-metric row M, and the stream-name row S, and upstream of the real-seal boundary E. The handoff exports no selected local solution, quotient stream equality, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite iteration ledger I. It is the only carrier row that stores Picard approximants, and every approximant in it is read from the same ODE row O and Lipschitz row F.

The complete-metric row M is downstream of that ledger. It records the Cauchy-modulus and late-comparison surface for the displayed approximants, not a selected endpoint or an ambient completeness theorem.

Now read the L10 rows S, R, E. The stream-name row S names the finite approximation windows, the regular rational row R reads those windows with their local budgets, and the real-seal boundary E is visible only after both rows have been displayed.

The structural rows H, C, P_0, N preserve and name the same route. Since no coordinate stores a selected local solution, quotient stream equality, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every RegSeqRat handoff remains inside the displayed packet. □

Falsifiable prediction: Every $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$ read exposes one Ode local time-state row, one LipschitzMap vector-field row, one PicardIteration finite ledger, one CompleteMetric approximant-space row, one StreamName window row, one RegSeqRat readback row, one RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: picard-lindelof, picard-iteration, picard-lindelof-local-flow, streamname, regseqrat, dyadicratcore, real: $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the ODE local window, Lipschitz vector-field ledger, finite Picard iteration ledger, complete-metric approximation row, L10 stream and regular-rational readback rows, real seal boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardLindelofLocalIteration}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardLindelofLocalIteration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6191.1, Definition 6191.2, and Definition 6191.3 seed the finite local Picard iteration packet between ODE Lipschitz data, complete-metric approximation, L10 readback, and the real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardLindelofLocalIteration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global ODE existence, maximal interval continuation, selected local solutions, quotient path or stream equality, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ODE local-window compatibility, Lipschitz vector-field stability, PicardIteration ledger visibility, CompleteMetric approximation routing, StreamName and RegSeqRat readback, Real seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.PicardLindelofLocalIterationUp.

Constructive story: A $\mathsf{PicardLindelofLocalIteration}^{\uparrow}$ packet is generated from Ode, LipschitzMap, PicardIteration, CompleteMetric, StreamName, RegSeqRat, Real, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Chapter 6192

A Concrete Naming Certificate for $\mathsf{LocatedDyadicReal}^{\uparrow}$

Following Bishop and Bridges, a located real presentation is useful only when every comparison request remains tied to explicit rational tolerances. The $\mathsf{LocatedDyadicReal}^{\uparrow}$ packet realizes that presentation over the dyadic core of chapter 291, the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the located-real classifier of **??**, and the terminal Real seal of chapter 38. Its certificate is a finite bridge from dyadic tolerance data to located comparison and Real-seal readback, not a quotient stream construction or a selected limit.

Definition 6192.1 (Located dyadic real carrier)**.** *A* $\mathsf{LocatedDyadicReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, Q, L_c, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the comparison radius and the halving ledger used by finite approximation reads.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only the finite windows requested at the displayed dyadic tolerance.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, converting each finite stream window into the regular rational comparison data consumed by the located surface.*
4. *L_c is the located comparison row, recording the finite alternative required by the* $\mathsf{LocatedReal}^{\uparrow}$ *classifier at the displayed dyadic tolerance.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the dyadic tolerance, stream window, regular readback, and located comparison rows have been replayed.*
6. *H records componentwise* hsame *transport for D, S, Q, L_c, R.*
7. *C records displayed* Cont *replay from tolerance requests through stream windows, regular readbacks, located comparisons, the Real seal, and structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedDyadicReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.LocatedDyadicRealUp.taste gate`

Theorem 6192.2 (Located dyadic real NameCert obligations)**.** *For every accepted* $\mathsf{LocatedDyadicReal}^{\uparrow}$ *carrier*

$$L = (D, S, Q, L_c, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedDyadicReal}^{\uparrow}}$ *surface consists exactly of finite rows for dyadic tolerance admission, StreamName window exposure, RegSeqRat readback, located comparison, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming. No obligation row may erase* D*, infer located comparison without* S *and* Q*, identify quotient streams, select a limit, or export ambient Real completeness.*

Proof. Project the carrier of Definition 6192.1. The dyadic tolerance row is public before any stream window or regular rational readback is requested.

The window and readback rows are then forced in order. A located comparison may inspect the finite StreamName window and the RegSeqRat readback attached to the same displayed tolerance, but it cannot replace them by a quotient stream or a chosen limit.

The terminal Real seal is downstream of that located comparison. It names the sealed endpoint reached by the finite route, not a free ambient completeness principle.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since these structural rows add no selector, quotient, or host-real equality coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 6192.3 (Located dyadic real terminal seal)**.** *Every Real-facing consumer of an accepted* $\mathsf{LocatedDyadicReal}^{\uparrow}$ *packet factors through the finite route*

$$D \to S \to Q \to L_c \to R \to H, C, P, N.$$

The consumer may narrow a dyadic tolerance request and reread the corresponding finite windows and regular rational rows, but it cannot bypass the located comparison row, identify quotient streams, select a limit, use countable choice, invoke trichotomy, or export ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the obligations of Definition 6192.2. They expose the tolerance, window, readback, located comparison, and Real seal rows in a fixed finite order.

A narrowed tolerance request remains a request in the same D ledger. Replaying it may refine the finite window S and the regular readback Q, but the located comparison row L_c is still the only classifier-facing handoff.

The Real seal R is therefore terminal only for this displayed route. It records that the located dyadic presentation has reached the Real surface, while leaving quotient equality, selected limits, choice, trichotomy, and ambient completeness outside the packet.

The structural rows preserve this boundary under hsame transport, Cont replay, provenance, and local naming. Hence every Real-facing read factors through the stated finite route. □

Theorem 6192.4 (Located dyadic real comparison refinement)**.** *Let* $L = (D, S, Q, L_c, R, H, C, P, N)$ *be an accepted* $\mathsf{LocatedDyadicReal}^{\uparrow}$ *packet. If the packet is reread at a narrower positive* $\mathsf{DyadicRatCore}^{\uparrow}$

tolerance recorded by the same D ledger, then it exposes a refined $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *row through the same route*

$$D, S, Q, L_c, R, H, C, P, N.$$

The located comparison row L_c remains the only classifier-facing handoff before the terminal $\mathsf{Real}^{\uparrow}$ *row is read.*

Proof. Project the dyadic tolerance row D and its halving ledger. A narrower positive tolerance is still a read of the same displayed ledger, so it cannot introduce an external comparison oracle or an ambient real-order principle.

Replay S and Q through Cont at the narrower request. The replay exposes the refined finite StreamName window and the corresponding RegSeqRat readback before any terminal Real row is public.

Transport the located comparison row componentwise by hsame. The row L_c therefore remains attached to the refined window and readback, and no other classifier-facing handoff is available in the carrier.

Finally apply Definition 6192.3. Its terminal route excludes quotient streams, selected limits, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness before R is read. □

Falsifiable prediction: A $\mathsf{LocatedDyadicReal}^{\uparrow}$ consumer that exports ambient Real completeness, a selected limit, or quotient stream equality after deleting D, S, Q, or L_c refutes the carrier of Definition 6192.1.

Independence witness: Nearest siblings: dyadicratcore, streamname, regseqrat, locatedreal, and real. $\mathsf{LocatedDyadicReal}^{\uparrow}$ is not bijective to any one of them because it jointly carries dyadic tolerance, finite stream windows, regular rational readback, located comparison, terminal Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDyadicReal}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDyadicReal}^{\uparrow}$ packet is generated from positive DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readbacks, located comparison rows, terminal Real seal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedDyadicReal}^{\uparrow}}$, seed)

Scope closed: Definition 6192.1, Definition 6192.2, and Definition 6192.3 seed the finite located dyadic bridge from dyadic tolerances to terminal Real reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedDyadicReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, StreamName window replay, RegSeqRat readback, located comparison nonescape, terminal Real sealing, classifier transport, and local naming for BEDC.Derived.LocatedDyadicRealUp.

Chapter 6193

A Concrete Naming Certificate for $\mathsf{MomentProblem}^{\uparrow}$

Following Hausdorff, Stieltjes, and Hamburger on moment problems, the $\mathsf{MomentProblem}^{\uparrow}$ packet records the finite BEDC surface by which a truncated moment table may be inspected before any consumer asks for a representing measure. It sits after the rational and real readback rows of chapter 37 and chapter 38, the finite matrix rows of chapter 49, and the measure-facing boundary of chapter 92 and chapter 186. The certificate names only finite Hankel windows, positivity checks, transport, replay, provenance, and local naming; it does not export an ambient moment problem, a representing measure theorem, determinacy, uniqueness, or a host analytic solution principle.

Definition 6193.1 (MomentProblem carrier)**.** *A* $\mathsf{MomentProblem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, A, H_0, H_1, W, P_s, D, H, C, Q, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Rat}^{\uparrow}$ *coefficient ledger used to encode the requested finite moment entries and comparison tolerances.*
2. *A is the* $\mathsf{Real}^{\uparrow}$ *readback row that seals the inspected moment values as BEDC real-name data.*
3. *H_0 and H_1 are the first two finite* $\mathsf{Mat}^{\uparrow}$ *Hankel table rows, built from the displayed moment window.*
4. *W is the finite-window schedule naming which initial segment of the moment sequence and which principal Hankel minors are inspected.*
5. *P_s records the finite positivity certificates for the displayed Hankel windows, including the chosen rows, columns, and rational tolerance budget.*
6. *D is the optional* $\mathsf{Distribution}^{\uparrow}$ *boundary row available only as downstream probabilistic syntax; it is not a representing-measure object.*
7. *H records componentwise* hsame *transport for the rational ledger, real readbacks, Hankel matrices, finite-window schedule, positivity rows, distribution boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite moment-window request through $R, A, H_0, H_1, W, P_s, D, H$.*
9. *Q is the* Pkg *provenance over* $\mathsf{MomentProblem}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MomentProblem}^\uparrow}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for an ambient measure space, selected representing measure, moment determinacy theorem, infinite Hankel operator, or host analytic solution.

Lean4 ✓ `BEDC.Derived.MomentProblemUp.TasteGate.MomentProblemTasteGate single carrier alignment`

Theorem 6193.2 (MomentProblem NameCert obligations)**.** *For every accepted* $\mathsf{MomentProblem}^\uparrow$ *carrier* $M = (R, A, H_0, H_1, W, P_s, D, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MomentProblem}^\uparrow}$ *surface consists exactly of rational moment-entry admission, real readback admission, finite Hankel matrix admission, finite-window scheduling, displayed positivity certification, optional distribution-boundary syntax, componentwise transport, displayed replay, provenance, and local naming for the rows*

$$R, A, H_0, H_1, W, P_s, D, H, C, Q, N.$$

No consumer of the certificate receives a representing measure, an infinite moment sequence, a uniqueness theorem, a selected support, or an ambient analytic moment-problem solver.

Proof. Project the accepted packet. The numeric content is limited to the rational ledger R, the real readback row A, and the two displayed Hankel matrices H_0, H_1.

The finite-window row W determines which moments and minors may be inspected. The positivity row P_s certifies only those displayed Hankel windows with the recorded rational tolerance budget, so no infinite positivity condition or representing-measure theorem is available from the carrier.

The structural rows H, C, Q, N then transport, replay, source, and name exactly the same packet. The optional distribution row D is boundary syntax for downstream probabilistic consumers, not an analytic existence witness; hence the local certificate exposes only the listed finite rows. □

Theorem 6193.3 (MomentProblem finite Hankel window)**.** *Every finite-window read of an accepted* $\mathsf{MomentProblem}^\uparrow$ *packet factors through the displayed route*

$$\mathsf{Rat}^\uparrow,\ \mathsf{Real}^\uparrow,\ \mathsf{Mat}^\uparrow,\ \mathsf{Mat}^\uparrow$$

before a positivity consumer may inspect Hankel data. The read must use the window schedule W, the positivity ledger P_s, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MomentProblem}^\uparrow}$ *row; it cannot be strengthened to an infinite Hankel operator, a representing measure, a selected support, or an ambient moment-problem theorem.*

Lean4 ✓ `BEDC.Derived.MomentProblemUp.FiniteHankelWindow.MomentProblemCarrier finite hankel window`

Proof. Read the carrier of Definition 6193.1. The Hankel data appears only as the finite matrices H_0, H_1, and both are built from the rational and real readback rows R, A.

Apply Definition 6193.2. It forces every positivity-facing read through the window row W and the finite positivity ledger P_s before the structural rows can replay or package the request.

Because no carrier coordinate stores an infinite sequence, selected measure, support, determinacy proof, or host solver, the finite Hankel window is the whole public surface for moment-problem consumption. □

Closure status for $\mathsf{NameCert}_{\mathsf{MomentProblem}^{\uparrow}}$.

Constructive story: A $\mathsf{MomentProblem}^{\uparrow}$ packet is generated from RatUp coefficient rows, RealUp readback rows, finite MatrixUp Hankel windows, a finite-window schedule, displayed positivity certificates, an optional DistributionUp boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MomentProblem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6193.1, Definition 6193.2, and Definition 6193.3 seed the finite moment-window route over RatUp, RealUp, MatrixUp, DistributionUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MomentProblem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a representing measure theorem, determinacy, uniqueness, selected support, ambient measure-space existence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite Hankel-window exactness, positivity ledger non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MomentProblemUp.

Chapter 6194

A Concrete Naming Certificate for $\mathsf{KleeneTreeBoundary}^{\uparrow}$

Following Kleene's tree counterexample tradition and Bishop–Bridges constructive analysis, the $\mathsf{KleeneTreeBoundary}^{\uparrow}$ packet records the finite boundary at which Kleene-tree prefix data, finite bar data, and completion-facing readbacks remain visible while branch selection and compactness principles stay refused. It is read after the prefix-tree carrier of chapter 1622, the binary prefix surface of chapter 1475, the finite-bar discipline of chapter 400, the stream schedule of chapter 126, the regular-rational readback of chapter 301, and the terminal real boundary of chapter 38. The packet isolates the constructive data a consumer may inspect before any illicit branch, open-cover compactness, countable choice, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ completeness claim would be needed.

Definition 6194.1 (Kleene tree boundary carrier)**.** *A* $\mathsf{KleeneTreeBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, S, R, E, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{KleeneTree}^{\uparrow}$ *finite binary-prefix data, including the displayed tree ledger, node decisions, prefix spine, and obstruction row inherited from the Kleene-tree packet.*
2. *F is the finite* $\mathsf{FanTheorem}^{\uparrow}$ *bar data used only as displayed finite bar and modulus-facing evidence.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule through which branch-facing prefix requests are read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational observations routed through the same finite windows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the prefix, bar, stream, and regular-rational rows have been displayed.*
6. *O is the obstruction row refusing a selected branch, open-cover compactness, countable choice, quotient stream equality, and* $\mathsf{Real}^{\uparrow}$ *completeness as coordinates of the packet.*
7. *H records componentwise* hsame *transport for the tree, bar, stream, regular-rational, real-seal, obstruction, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from finite stream windows through the Kleene prefix data and finite bar rows, then through the regular-rational readback and real seal to the obstruction row.*

9. *P is the* Pkg *provenance over* $\mathsf{KleeneTreeBoundary}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KleeneTreeBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, S, R, E, O, H, C, P, N$. It has no coordinate for a completed infinite path, a Cantor-point selector, an open-cover compactness theorem, countable choice, quotient stream equality, or real completeness.

Lean4 ✓ `BEDC.Derived.KleeneTreeBoundaryUp.KleeneTreeBoundaryTasteGate single carrier alignment`

Theorem 6194.2 (Kleene tree boundary NameCert obligations)**.** *For every accepted* $\mathsf{KleeneTreeBoundary}^{\uparrow}$ *carrier $B = (K, F, S, R, E, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KleeneTreeBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, finite Kleene-prefix exposure, finite bar exposure, stream-window exposure, regular-rational readback, real-seal handoff, obstruction-row exposure, componentwise transport, displayed replay, provenance over the named dependency rows, and local naming.*

Proof. Project the carrier of Definition 6194.1. The rows K, F, S, R, E, O display the finite prefix, bar, stream, rational-readback, real-seal, and obstruction data that a consumer may inspect.

The structural rows H and C preserve this route componentwise. A request first enters through the finite $\mathsf{StreamName}^{\uparrow}$ window S, then reads the Kleene-prefix row K and the finite bar row F, then passes through R and E before reaching the obstruction row O.

The provenance and local name rows P, N package exactly that finite route. Since the carrier contains no coordinate for a selected branch, open-cover compactness, countable choice, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Lean4 ✓ `BEDC.Derived.KleeneTreeBoundaryUp.TasteGate.KleeneTreeBoundaryTasteGate single carrier alignment`

Theorem 6194.3 (Kleene tree boundary finite bar refusal)**.** *Every* $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{KleeneTreeBoundary}^{\uparrow}$ *packet factors through the finite rows $K, F, S, R, E, O, H, C, P, N$. The consumer may use the displayed finite prefix and bar data, but it cannot turn those rows into a selected branch, open-cover compactness, countable choice, quotient stream equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite-window route supplied by S. Each branch-facing request is replayed through a displayed prefix row in K and a displayed finite bar row in F; no request reads an unlisted infinite path.

Next inspect the readback rows R and E. They carry regular-rational and real-facing observations only after the finite prefix and bar evidence has already been displayed, so they cannot add a hidden selector or compactness principle.

Finally read the obstruction row O. Finite-row exhaustion leaves only the displayed route $K, F, S, R, E, O, H, C, P, N$, and O explicitly refuses branch selection, open-cover compactness, countable choice, quotient stream equality, and real completeness as packet coordinates. □

Falsifiable prediction: An accepted $\mathsf{KleeneTreeBoundary}^{\uparrow}$ read is refuted if a consumer obtains a selected branch, open-cover compactness, countable choice, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ completeness without displaying the finite Kleene-prefix row, finite bar row, stream window, regular-rational readback, real seal, obstruction row, transport, replay, provenance, and local naming row.

Independence witness: KleeneTree, FanTheorem, StreamName, RegSeqRat, and Real: none is bijective to $\mathsf{KleeneTreeBoundary}^{\uparrow}$ because the boundary packet jointly records finite prefix data,

finite bar data, completion-facing readbacks, and an explicit obstruction row refusing branch selection and compactness principles.

Closure status for $\mathsf{NameCert}_{\mathsf{KleeneTreeBoundary}\uparrow}$.

Constructive story: A $\mathsf{KleeneTreeBoundary}^{\uparrow}$ packet is generated from finite Kleene-tree prefix data, finite FanTheorem bar data, StreamName windows, RegSeqRat readbacks, a Real seal, an obstruction row, componentwise hsame transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KleeneTreeBoundary}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6194.1, Definition 6194.2, and Definition 6194.3 seed the finite boundary separating Kleene-tree and bar evidence from branch selection, compactness, choice, quotient equality, and real completeness claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KleeneTreeBoundary}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected branches, open-cover compactness, countable choice, quotient stream equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix and bar exposure, readback and real-seal handoff, obstruction-row refusal, transport, replay, provenance, and local naming for BEDC.Derived.KleeneTreeBoundaryUp.

Chapter 6195

A Concrete Naming Certificate for $\mathsf{TotalBoundednessModulus}^{\uparrow}$

Following Bishop and Bridges on constructive metric compactness, the $\mathsf{TotalBoundednessModulus}^{\uparrow}$ packet records the finite-net schedule by which a totally bounded metric source supplies explicit net rows at each displayed tolerance. It sits after the $\mathsf{Met}^{\uparrow}$ metric carrier of chapter 57, the total-boundedness certificate of chapter 127, the compact metric surface of chapter 129, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite modulus neighbour for the L10 compact-metric route; it is not an open-cover compactness theorem, a selected subcover, a quotient point equality principle, or an ambient completeness assertion.

Definition 6195.1 (Total boundedness modulus carrier)**.** *A* $\mathsf{TotalBoundednessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, N, D, R, E, H, C, P, L)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying point classifiers, distance observations, and metric comparison data.*
2. *N is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedule row, assigning each admitted positive tolerance a finite displayed center list and coverage witness.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording halving, comparison, and positivity reads used by the net schedule.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row through which metric distances and tolerance comparisons are exposed to compact-metric consumers.*
5. *E is the* $\mathsf{CompactMetric}^{\uparrow}$ *handoff row, recording that compact-metric consumers may read the modulus only after the metric, total-boundedness, dyadic, and real-seal rows are visible.*
6. *H records componentwise* hsame *transport for the metric, finite-net schedule, dyadic tolerance, real seal, compact handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a compact-metric request through M, N, D, R, E, H, P, L.*
8. *P is the* Pkg *provenance over* $\mathsf{TotalBoundednessModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. L is the local $\mathsf{NameCert}_{\mathsf{TotalBoundednessModulus}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $M, N, D, R, E, H, C, P, L$. It has no coordinate for arbitrary open covers, selected finite subcovers, countable choice, quotient point equality, host metric completeness, or an ambient $\mathsf{Real}^{\uparrow}$ *equality relation.*

Lean4 ✓ `BEDC.Derived.TotalBoundednessModulusUp.TotalBoundednessModulusTasteGate single carrier alignment`

Theorem 6195.2 (Total boundedness modulus NameCert obligations)**.** *For every accepted* TotalBoundednessModu *carrier $T = (M, N, D, R, E, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{TotalBoundednessModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for T, metric-source admission through M, finite-net schedule exposure through N, dyadic tolerance accounting through D, real-seal exposure through R, compact-metric handoff through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through L.*

Proof. Project the accepted carrier of Definition 6195.1. The metric source is M, the schedule row is N, and the tolerance arithmetic is D.

The real-facing and compact-facing rows are R and E. They expose distance and tolerance comparisons only after the metric and finite-net schedule rows are visible, so a consumer cannot replace the packet by an open-cover compactness principle or by a selected subcover.

Finally the structural rows H, C, P, L transport, replay, source, and name the same finite route. Since no additional coordinate is present, the listed rows exhaust the NameCert obligations and no quotient point equality, countable-choice schedule, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ equality can be exported. □

Lean4 ✓ `BEDC.Derived.TotalBoundednessModulusUp.TasteGate.TotalBoundednessModulusTasteGate single carrier alignment`

Theorem 6195.3 (Total boundedness modulus finite-net handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *or completion-facing consumer of an accepted* $\mathsf{TotalBoundednessModulus}^{\uparrow}$ *carrier receives finite-net data only through the displayed route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{TotallyBounded}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow}.$$

For each admitted positive dyadic tolerance, the consumer may inspect the finite center list and coverage row carried by N, the tolerance comparison ledger D, the real-valued distance seal R, and the compact-metric handoff E, together with H, C, P, L. It receives no open-cover compactness theorem, selected finite subcover, countable-choice schedule, quotient point equality, host metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *equality.*

Proof. Start from Definition 6195.1. The source metric row M and the total-boundedness row N are the only rows that can expose centers and coverage witnesses.

Read the tolerance and distance boundary through D and R. The dyadic ledger controls each positive request, and the real seal exposes the corresponding distance comparison before the compact-metric handoff is available.

Apply the obligation surface of Definition 6195.2. It forces the compact-facing row E and the structural rows H, C, P, L to remain visible for every handoff.

Because the carrier contains no open-cover, subcover-selection, choice, quotient, host-completeness, or ambient-real-equality coordinate, the finite-net handoff cannot export any of those objects. □

Theorem 6195.4 (Total boundedness modulus schedule induction)**.** *Let $T = (M, N, D, R, E, H, C, P, L)$ be an accepted* $\mathsf{TotalBoundednessModulus}^{\uparrow}$ *carrier. For every finite displayed request list*

$$\varepsilon_1, \ldots, \varepsilon_k$$

whose entries are admitted positive dyadic tolerances in D, the carrier answers the list by finite induction over the displayed order. The empty list uses the empty schedule read. The cons step reads the next tolerance through D, obtains the finite center list and coverage witness for that tolerance from N, exposes the distance comparison through R, passes it across the compact-metric handoff row E, and keeps the rows H, C, P, L as the transport, replay, provenance, and local naming data for the same request.

Proof. Induct on the displayed request list. For the empty list, no tolerance is requested, so the empty schedule read is the unique finite response and no row outside $M, N, D, R, E, H, C, P, L$ is inspected.

For the cons step, assume the tail list has already been answered by the induction hypothesis. The head tolerance is admitted by D, so N supplies its finite center list and coverage row. The comparison used by that coverage row is exposed through R, and the compact-facing access is routed through E.

The structural rows H, C, P, L transport, replay, source, and name the head response together with the tail response. Thus the enlarged finite list is answered by the same displayed rows, and the induction constructs the whole tolerance-indexed net schedule without invoking open covers, selected subcovers, countable choice, quotient point equality, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ equality. □

Theorem 6195.5 (Total boundedness modulus request monotonicity)**.** *Let $T = (M, N, D, R, E, H, C, P, L)$ be an accepted* $\mathsf{TotalBoundednessModulus}^{\uparrow}$ *carrier. If an admitted positive dyadic tolerance request is refined through the ledger row D, then the finite center list read from N for the refined request is obtained by reusing the earlier displayed list when the ledger records equality of tolerance reads, or by reading the refined finite list and coverage row from N when D records a proper refinement. In both cases the refined request remains inside the same $M, N, D, R, E, H, C, P, L$ carrier surface.*

Proof. Apply Definition 6195.4 to the two-request list consisting of the original tolerance and its displayed refinement. The first request produces the earlier finite center list and coverage row through N, with its tolerance comparison controlled by D and sealed through R.

For the second request, the ledger D decides whether the displayed refinement is the same tolerance read or a proper smaller request. In the equal-read case, the first center list may be reused because the schedule row is indexed by the same admitted tolerance. In the proper-refinement case, the second induction step reads the refined finite center list and coverage row from N.

The projection to the second request keeps the compact-facing handoff E and the structural rows H, C, P, L attached to the refined row. Hence request refinement changes only the tolerance-indexed read inside D and N; it does not leave the accepted $\mathsf{TotalBoundednessModulus}^{\uparrow}$ carrier surface. □

Falsifiable prediction: Every accepted $\mathsf{TotalBoundednessModulus}^{\uparrow}$ finite-net read factors through one $\mathsf{Met}^{\uparrow}$ source row, one $\mathsf{TotallyBounded}^{\uparrow}$ schedule row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{Real}^{\uparrow}$ distance seal, one $\mathsf{CompactMetric}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming.

Independence witness: metric, totallybounded, compactmetric, dyadicratcore, real: $\mathsf{TotalBoundednessModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds metric observations, tolerance-indexed finite-net schedules, dyadic tolerance arithmetic, Real-facing distance seals, compact-metric handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TotalBoundednessModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotalBoundednessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6195.1, Definition 6195.2, Definition 6195.3, Definition 6195.4, and Definition 6195.5 seed the finite-net modulus route over MetricSpace, TotallyBounded, CompactMetric, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotalBoundednessModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected finite subcovers, countable choice, quotient point equality, host metric completeness, ambient Real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source admission, finite-net schedule exposure, dyadic tolerance exactness, Real seal handoff, compact-metric handoff, structural transport, replay, provenance, and local naming for BEDC.Derived.TotalBoundednessModulusUp.

Constructive story: A $\mathsf{TotalBoundednessModulus}^{\uparrow}$ packet is generated from a MetricSpaceUp source row, a TotallyBoundedUp finite-net schedule, a DyadicRatCoreUp tolerance ledger, a RealUp distance seal, a CompactMetricUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6196

A Concrete Naming Certificate for $\mathsf{HyperbolicSet}^{\uparrow}$

Following Smale and Katok–Hasselblatt, the $\mathsf{HyperbolicSet}^{\uparrow}$ packet records the finite BEDC surface for an invariant set whose displayed tangent data split into stable and unstable rows with bounded contraction and expansion budgets. It sits over the finite routed dynamics of chapter 195, the metric observation surface of chapter 57, the compact-metric source discipline of chapter 129, and the stable-manifold consumer boundary of chapter 1649. The packet names a finite hyperbolic-set certificate; it does not assert global structural stability, shadowing, measure recurrence, or complete stable-manifold theory.

Definition 6196.1 (Hyperbolic set carrier)**.** *A* $\mathsf{HyperbolicSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, D, M, K, E^s, E^u, \Lambda_s, \Lambda_u, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the invariant-set carrier row, naming the inspected subset and the finite membership windows through which it is read.*
2. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *row whose displayed transition data preserve the invariant-set row X.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *observation row for the source distances used by the finite estimates.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *support row, recording the compact metric windows on which the estimates are certified.*
5. *E^s and E^u are the stable and unstable splitting rows, displaying the two named directions over the inspected invariant-set windows.*
6. *Λ_s is the finite contraction-budget row for stable directions, and Λ_u is the finite expansion-budget row for unstable directions.*
7. *A is the* $\mathsf{StableManifold}^{\uparrow}$ *handoff row, exposing only the local splitting data that a stable-manifold consumer may read.*
8. *H records componentwise* hsame *transport for invariant-set, dynamical-system, metric, compact-metric, splitting, budget, handoff, provenance, replay, and local naming rows.*
9. *C records displayed* Cont *replay from a hyperbolic-set request through $X, D, M, K, E^s, E^u, \Lambda_s, \Lambda_u, A, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicSet}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StableManifold}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for global structural stability, shadowing, measure recurrence, complete stable-manifold theory, a host tangent bundle, or an ambient smooth manifold theorem.

Lean4 ✓ `BEDC.Derived.HyperbolicSetUp.HyperbolicSetTasteGate single carrier alignment`

Theorem 6196.2 (Hyperbolic set NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicSet}^{\uparrow}$ *carrier* $Q = (X, D, M, K, E^s, E^u, \Lambda_s, \Lambda_u, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSet}^{\uparrow}}$ *surface is exhausted by the following obligation rows:*

1. *carrier admission for invariant-set, dynamical-system, metric, compact-metric, stable-splitting, unstable-splitting, contraction-budget, expansion-budget, handoff, transport, replay, provenance, and local naming rows;*
2. *invariant-set preservation, requiring the displayed* $\mathsf{DynSystem}^{\uparrow}$ *row to preserve the inspected membership windows of X;*
3. *metric and compact support, requiring M and K to expose the finite distance and compact-window data before any splitting estimate is read;*
4. *splitting visibility, requiring E^s and E^u to remain separate named rows rather than aliases of the invariant-set or metric rows;*
5. *budget exactness, requiring Λ_s and Λ_u to record finite contraction and expansion estimates for the displayed splitting rows;*
6. *stable-manifold handoff, requiring A to expose only the local splitting-and-budget data consumed by* $\mathsf{StableManifold}^{\uparrow}$*;*
7. *ledger nonescape, requiring H, C, P, N to export no global structural stability, shadowing theorem, measure recurrence theorem, complete stable-manifold theory, host tangent bundle, or ambient smooth-manifold principle.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 6196.1. The accepted rows are exactly $X, D, M, K, E^s, E^u, \Lambda_s, \Lambda_u, A, H, C, P$ so carrier admission exposes only finite invariant-set, dynamical-system, metric, compact-support, splitting, budget, handoff, transport, replay, provenance, and local naming data.

The route first reads X through D. Thus invariant-set preservation is a displayed $\mathsf{DynSystem}^{\uparrow}$ obligation, not a host theorem about all orbits of an ambient dynamical system.

The metric and compact rows M, K are then read before the splitting rows. They bind the stable and unstable estimates to finite distance windows and compact-metric support.

Finally the separate rows $E^s, E^u, \Lambda_s, \Lambda_u$ provide the splitting and its budgets, while A, H, C, P, N only hand off, transport, replay, source, and name that same finite packet. Since none of these rows adds global structural stability, shadowing, measure recurrence, complete stable-manifold theory, a host tangent bundle, or an ambient smooth-manifold theorem, the listed obligations exhaust the NameCert surface. □

Theorem 6196.3 (Hyperbolic set splitting transport)**.** *Every stable-manifold or dynamical-systems consumer of an accepted* $\mathsf{HyperbolicSet}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{DynSystem}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow} \longmapsto E^s, E^u, \Lambda_s, \Lambda_u \longmapsto \mathsf{StableManifold}^{\uparrow} \longmapsto H, C, P, N.$$

Thus the consumer may transport stable and unstable splitting data, finite contraction and expansion budgets, compact-metric support, componentwise hsame*, displayed* Cont *replay,* Pkg *provenance, and local naming. It obtains no global structural stability theorem, shadowing theorem, measure recurrence theorem, or complete stable-manifold theory.*

Proof. Begin with a downstream consumer. By Definition 6196.2, the consumer must first read the invariant-set and $\mathsf{DynSystem}^{\uparrow}$ preservation rows, then the $\mathsf{Met}^{\uparrow}$ and $\mathsf{CompactMetric}^{\uparrow}$ support rows.

Next read $E^s, E^u, \Lambda_s, \Lambda_u$. These rows carry the stable and unstable splitting together with their finite budgets, so transport along hsame preserves the displayed splitting fields rather than replacing them by a host tangent-bundle construction.

The $\mathsf{StableManifold}^{\uparrow}$ handoff row A is downstream of those displayed fields. It exposes local splitting-and-budget data only, while C, P, N replay, source, and name the same packet.

No row in the carrier is a global structural-stability argument, a shadowing principle, a recurrence theorem, or a complete stable-manifold construction. The transported surface is therefore exactly the finite BEDC route displayed above. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicSet}^{\uparrow}$ packet is refuted if a consumer obtains global structural stability, shadowing, measure recurrence, or complete stable-manifold theory without first displaying invariant-set, DynSystem, Metric, CompactMetric, stable-splitting, unstable-splitting, contraction-budget, expansion-budget, handoff, transport, replay, provenance, and local NameCert rows.

Independence witness: dynsystem, metric, compactmetric, stablemanifold: none is bijective to $\mathsf{HyperbolicSet}^{\uparrow}$ because this packet jointly carries invariant set preservation, metric and compact support, stable and unstable splitting, finite contraction and expansion budgets, stable-manifold handoff, transport, replay, package sourcing, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicSet}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicSet}^{\uparrow}$ packet is generated from an invariant-set carrier row, DynSystem transition data, Metric and CompactMetric support rows, stable and unstable splitting rows, finite contraction and expansion budgets, a StableManifold handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicSet}^{\uparrow}}$, seed)

Scope closed: Definition 6196.1, Definition 6196.2, and Definition 6196.3 seed the finite hyperbolic-set NameCert packet over invariant-set, dynamics, metric, compact-support, splitting, and budget rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global structural stability, shadowing, measure recurrence, complete stable-manifold theory, host tangent bundles, ambient smooth-manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked invariant-set preservation, metric and compact support, splitting visibility, contraction and expansion budgets, stable-manifold handoff, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicSetUp.

Chapter 6197

A Concrete Naming Certificate for $\mathsf{LocatedDecimalStreamNormal}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the standard decimal-expansion normalization practice, the $\mathsf{LocatedDecimalStreamNormal}^{\uparrow}$ packet records the finite surface by which a located decimal stream is accepted in normal form before it is read as regular rational or Real-facing data. It sits downstream of the decimal stream carrier of chapter 4191, the signed decimal expansion route of chapter 5150, the endpoint normalization packet of chapter 1429, the finite-window naming discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names an L10 finite normalization interface only; it does not import quotient streams, selected limits, host real equality, digit-choice omniscience, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6197.1 (LocatedDecimalStreamNormal carrier)**.** *A* $\mathsf{LocatedDecimalStreamNormal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, E, W, R, Y, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DecimalStream}^{\uparrow}$ *source row, naming the inspected signed digit stream and the finite digit windows available to the packet.*
2. *S is the* $\mathsf{SignedDecimalExpansion}^{\uparrow}$ *sign-and-digit row, exposing the sign convention and digit ledger used by the same windows.*
3. *E is the* $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ *endpoint row, recording the finite trailing-nine or trailing-zero normalization decisions visible at the inspected endpoints.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, listing the finite stages, digit positions, and endpoint windows read before the normal-form request is accepted.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the normalized windows.*
6. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying dyadic radii and endpoint residues attached to the readback row R.*
7. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, E, W, R, Y have been displayed.*
8. *H records componentwise* hsame *transport for decimal streams, signed expansions, endpoint normalization, schedules, regular readbacks, dyadic tolerances, Real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a located decimal-stream normal-form request through* D, S, E, W, R, Y, T, H.
10. *P is the* Pkg *provenance over* LocatedDecimalStreamNormal$^{\uparrow}$, DecimalStream$^{\uparrow}$, SignedDecimalExpansion$^{\uparrow}$, DecimalEndpointNormalization$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{LocatedDecimalStreamNormal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, a selected limiting real, host real equality, a hidden digit-choice principle, or ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedDecimalStreamNormalUp.TasteGate.LocatedDecimalStreamNormalTasteGate single carrier alignment`

Theorem 6197.2 (LocatedDecimalStreamNormal NameCert obligations)**.** *For every accepted* LocatedDecimalStreamNormal$^{\uparrow}$ *carrier*

$$Q = (D, S, E, W, R, Y, T, H, C, P, N),$$

the local NameCert$_{\text{LocatedDecimalStreamNormal}^{\uparrow}}$ *surface consists exactly of carrier admission for the decimal-stream source D, signed expansion exposure through S, endpoint normalization exposure through E, finite* StreamName$^{\uparrow}$ *schedule exposure through W, regular rational readback through R, dyadic tolerance access through Y, terminal* Real$^{\uparrow}$ *seal admission through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6197.1. The decimal source is D, and the only signed digit data available to a consumer is the row S attached to the same inspected stream windows.

The endpoint and schedule rows then fix the normal-form boundary. The row E records the finite endpoint normalization decisions, while W lists the stages and positions at which those decisions are visible.

The rational and real-facing rows are downstream of that boundary. The readback row R is produced from the normalized windows, the dyadic ledger Y records the tolerance data used by that readback, and the Real seal T is reached only after the preceding rows have been displayed.

Finally H, C, P, N transport, replay, source, and name exactly the same finite packet. Since the carrier has no row for quotient stream equality, selected limits, host real equality, digit-choice omniscience, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6197.3 (LocatedDecimalStreamNormal regular readback handoff)**.** *Every* RegSeqRat$^{\uparrow}$ *or* Real$^{\uparrow}$ *read exported by an accepted* LocatedDecimalStreamNormal$^{\uparrow}$ *carrier factors through the finite route*

DecimalStream$^{\uparrow}$, SignedDecimalExpansion$^{\uparrow}$, DecimalEndpointNormalization$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRa

Thus a downstream completion or real-name consumer receives only the displayed decimal stream, signed digit ledger, endpoint normalization row, finite schedule, regular rational readback, dyadic tolerance ledger, Real seal, and structural rows H, C, P, N.

Proof. Read the decimal and signed-expansion rows first. The source row D supplies the inspected stream windows, and the row S fixes the sign and digit ledger used by those same windows.

The normal-form handoff cannot bypass endpoint normalization. The row E records the finite trailing-endpoint decisions, and the schedule row W records the stages and digit positions at which those decisions are visible.

The downstream readback is therefore forced to pass through R, Y, T. The regular rational row R is the only readback row in the carrier, the dyadic row Y is the only tolerance ledger attached to it, and the terminal row T is the only Real-facing seal.

The structural rows H, C, P, N transport, replay, source, and name that same route. No refused object is a coordinate of the carrier, so no consumer can read quotient stream equality, a selected limit, host real equality, digit-choice omniscience, or ambient Real completeness through this handoff. □

Falsifiable prediction: An accepted $\mathsf{LocatedDecimalStreamNormal}^{\uparrow}$ consumer that reads a regular rational or Real-facing row without first displaying the decimal stream, signed expansion, endpoint normalization, finite schedule, dyadic tolerance ledger, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: decimal-stream, signed-decimal-expansion, decimal-endpoint-normalization, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedDecimalStreamNormal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries decimal-stream source rows, signed expansion rows, endpoint normalization rows, finite StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerances, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDecimalStreamNormal}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDecimalStreamNormal}^{\uparrow}$ packet is generated from decimal-stream source rows, signed expansion rows, endpoint normalization rows, finite StreamName schedule rows, RegSeqRat readbacks, DyadicRatCore tolerance rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedDecimalStreamNormal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6197.1, Definition 6197.2, and Definition 6197.3 seed the finite located decimal-stream normal-form route over decimal streams, signed expansions, endpoint normalization, schedules, regular readbacks, dyadic tolerances, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedDecimalStreamNormal}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedDecimalStreamNormalUp.TasteGate.LocatedDecimalStreamNormalTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, digit-choice omniscience, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signed expansion exposure, endpoint normalization exactness, RegSeqRat readback handoff, dyadic tolerance stability, Real seal nonescape, and structural transport for BEDC.Derived.LocatedDecimalStreamNormalUp.

Chapter 6198

A Concrete Naming Certificate for $\mathsf{ChurchRosser}^{\uparrow}$

Following Church and Rosser, the $\mathsf{ChurchRosser}^{\uparrow}$ packet records confluence as a named finite route from local join evidence to equality of normal forms, rather than as host syntax quotienting or evaluator equality. In the MetaCIC route it sits after the local-diamond witness of chapter 3595, the residual-substitution boundary of chapter 2181, the closed-normal fragment of chapter 737, the parallel-diamond frontier of chapter 4238, and the dependency ledger of chapter 765. The packet gives a traditional Church–Rosser naming surface for the conditional MetaCIC confluence route; it refuses quotient syntax, host evaluator equality, arbitrary subject reduction, full consistency, and any claim that the current frontier rows already prove confluence for all closed terms.

Definition 6198.1 (Church–Rosser carrier)**.** *A* $\mathsf{ChurchRosser}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, L, S, NF, P, D, C, O, H, Q, G, M)$$

with the following displayed rows:

1. *T is the closed source-term row whose confluence request is being named.*
2. *L is the local-diamond ledger row, read through* $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$ *and retaining the displayed peak and candidate-join evidence.*
3. *S is the residual-substitution row, read through* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *and any separate compatibility handoff available to the route.*
4. *NF is the closed-normal-fragment row, read through* $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$ *before a normal-form comparison can be consumed.*
5. *P is the parallel-diamond frontier row, read through* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *as conditional frontier data.*
6. *D is the critical-path dependency row, read through* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *and keeping subject reduction, normalization, confluence, decidability, and consistency boundaries visible as dependencies rather than as supplied theorems.*
7. *C is the Church–Rosser conclusion row: it records the bounded common-reduct or normal-form agreement certified by L, S, NF, P, D for the displayed request.*
8. *O is the obstruction row naming endpoints not carried by this packet: quotient syntax, host evaluator equality, arbitrary subject reduction, full consistency, premise-free parallel diamond, and unconditional confluence for every closed term.*

9. *H records componentwise* hsame *transport for T, L, S, NF, P, D, C, O.*
10. *Q records displayed* Cont *replay for Church–Rosser requests through the same rows.*
11. *G is the* Pkg *provenance over* $\mathsf{ChurchRosser}^{\uparrow}$, $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBound}$ $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *M is the local* $\mathsf{NameCert}_{\mathsf{ChurchRosser}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, L, S, NF, P, D, C, O, H, Q, G, M$. It has no coordinate for quotient syntax, host evaluator equality, arbitrary subject reduction, full consistency, premise-free parallel diamond, or an unrestricted confluence theorem over all closed MetaCIC terms.

Lean4 ✓ `BEDC.Derived.ChurchRosserUp.ChurchRosserTasteGate single carrier alignment`

Theorem 6198.2 (Church–Rosser diamond ledger)**.** *For every accepted* $\mathsf{ChurchRosser}^{\uparrow}$ *carrier $R = (T, L, S, NF, P, D, C, O, H, Q, G, M)$, any Church–Rosser read must expose the local-diamond ledger L, residual-substitution row S, closed-normal-fragment row NF, parallel-diamond frontier row P, and MetaCIC critical-path row D before the conclusion row C is consumed. The conclusion is therefore ledger-scoped: it records the displayed join route for T and does not export quotient syntax, host evaluator equality, arbitrary subject reduction, full consistency, or unrestricted closed-term confluence.*

Proof. Project the carrier of Definition 6198.1. The confluence-facing rows are L, S, NF, P, D, C, O, and the source row T determines which closed request those rows address.

The local-diamond and residual-substitution rows are read first. The row L supplies only displayed local peaks and candidate joins, while S keeps the substitution premise visible; neither row is allowed to erase its boundary into a premise-free global theorem.

Next the closed-normal fragment and parallel-diamond frontier are read. The row NF supplies the normal-source and atom-source fragment, and P supplies conditional frontier data rather than a completed parallel diamond.

Finally the critical-path row D keeps the surrounding MetaCIC obligations visible before C is consumed. Since the obstruction row O remains part of the same packet and the structural rows H, Q, G, M only transport, replay, source, and name the displayed route, no refused endpoint can be exported by the ledger. □

Theorem 6198.3 (Church–Rosser normal-form confluence)**.** *If an accepted* $\mathsf{ChurchRosser}^{\uparrow}$ *carrier $R = (T, L, S, NF, P, D, C, O, H, Q, G, M)$ reaches a conclusion row C whose endpoints are both displayed normal-form reads, then the normal-form agreement factors through the closed-normal fragment NF and the same local-diamond, residual-substitution, parallel-frontier, and critical-path rows L, S, P, D. The agreement is a certified normal-form confluence read for the displayed source T; it is not host evaluator equality, quotient term equality, arbitrary subject reduction, full consistency, or an unrestricted Church–Rosser theorem for all closed terms.*

Proof. Begin with the diamond ledger of Definition 6198.2. It forces any read of C through L, S, NF, P, D and keeps the obstruction row O in scope.

The normal-form hypothesis only selects the NF branch of that same ledger. Thus the agreement between endpoints is read through the closed-normal fragment together with the displayed local-diamond and residual-substitution rows, not through a host evaluator or a quotient of term syntax.

The parallel frontier and critical path remain visible. They record which conditional confluence and dependency rows have been consumed before the normal-form agreement is named, so the result stays attached to the displayed source request T and does not become a global subject-reduction, consistency, or unrestricted confluence theorem. □

Theorem 6198.4 (Church–Rosser MetaCIC route boundary)**.** *Every downstream MetaCIC consumer of an accepted* $\mathsf{ChurchRosser}^{\uparrow}$ *packet receives only the finite route*

$$T, L, S, NF, P, D, C, O, H, Q, G, M.$$

In particular, the consumer may cite the packet as a Church–Rosser NameCert surface for the displayed local-diamond, residual-substitution, closed-normal-fragment, parallel-frontier, and critical-path route, but it may not reinterpret that surface as quotient syntax, host evaluator equality, arbitrary subject reduction, full consistency, or arbitrary closed Church–Rosser.

Proof. Use the obligation surface of Definition 6198.1. The only rows available to a consumer are the displayed source, local-diamond, residual-substitution, closed-normal-fragment, parallel-frontier, critical-path, conclusion, obstruction, transport, replay, provenance, and local naming rows.

Apply the diamond ledger to the confluence-facing part of the route, then apply the normal-form confluence theorem when the consumer asks for a normal-form endpoint comparison. Both reads keep O visible and retain the same finite row order.

The structural rows do not add semantic coordinates. They transport and replay the packet already named by G and M, so a downstream consumer that claims quotient syntax, host evaluator equality, arbitrary subject reduction, full consistency, or arbitrary closed Church–Rosser has left the packet. □

Falsifiable prediction: Every accepted $\mathsf{ChurchRosser}^{\uparrow}$ confluence read exposes local-diamond, residual-substitution, closed-normal-fragment, parallel-frontier, critical-path, and obstruction rows before its conclusion row is consumed.

Independence witness: metacic-local-diamond-witness, metacic-residual-substitution-boundary, metacic-confluence-normal-fragment, metacic-parallel-diamond-frontier, metacic-critical-path: these siblings respectively expose local peaks, substitution premises, closed-normal joins, conditional frontier data, and dependency pressure. None is bijective to a packet that jointly names the traditional Church–Rosser conclusion row together with all five route rows and an explicit obstruction row.

Closure status for $\mathsf{NameCert}_{\mathsf{ChurchRosser}^{\uparrow}}$.

Constructive story: A $\mathsf{ChurchRosser}^{\uparrow}$ packet is generated from a closed source row, local-diamond ledger, residual-substitution row, closed-normal-fragment row, parallel-diamond frontier row, MetaCIC critical-path row, conclusion row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChurchRosser}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6198.1, Definition 6198.2, Definition 6198.3, and Definition 6198.4 seed the traditional Church–Rosser NameCert surface for the displayed MetaCIC local-diamond, residual-substitution, closed-normal-fragment, parallel-frontier, and critical-path route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChurchRosser}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient syntax, host evaluator equality, arbitrary subject reduction, full consistency, premise-free parallel diamond, arbitrary closed Church–Rosser, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-diamond ledger exposure, residual-substitution retention, closed-normal-fragment routing, parallel-frontier handoff, critical-path retention, conclusion-row exactness, obstruction-row exposure, transport, replay, provenance, and local naming for BEDC.Derived.ChurchRosserUp.

Chapter 6199

A Concrete Naming Certificate for $\mathsf{LocatedIntervalRefinement}^{\uparrow}$

Bishop-style interval refinement treats nested located intervals as finite endpoint, mesh, and containment data before any real-completion argument reads a limit. The $\mathsf{LocatedIntervalRefinement}^{\uparrow}$ packet records that route for the L10 Real and Completion surface: it refines the located interval carrier of chapter 394, uses the dyadic one-step route of chapter 1831, inherits the bisection discipline of chapter 2081, reads endpoint tolerances through chapter 1933, and keeps the arithmetic budget inside chapter 291. The packet supplies a finite refinement surface for interval, compactness, and regular-Cauchy consumers without importing open-cover compactness, quotient equality, selected branches, or ambient completeness.

Definition 6199.1 (Located interval refinement carrier)**.** *A* $\mathsf{LocatedIntervalRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, U, M, F, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower located-endpoint row, a* $\mathsf{LocatedReal}^{\uparrow}$ *packet visible before any refinement request is accepted.*
2. *U is the upper located-endpoint row, a* $\mathsf{LocatedReal}^{\uparrow}$ *packet displayed in the same history as L.*
3. *M is the dyadic mesh row supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*; it records the active mesh cells, radius budget, midpoint cells, slack, and comparison tolerances used by the refinement.*
4. *F is the refinement map row, sending each accepted parent located interval cell to its displayed child cells through the finite* $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ *route.*
5. *Q is the containment witness row, recording parent-to-child inclusion, endpoint order, and visible gap checks for every accepted finite refinement request.*
6. *A is the apartness and tolerance ledger, tying endpoint apartness, mesh diameter, positive slack, and requested completion tolerance to the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget.*
7. *H records componentwise* hsame *transport for located endpoints, dyadic mesh, refinement map, containment witnesses, apartness and tolerance ledgers, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay for finite refinement requests through L, U, M, F, Q, A, H.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalRefinement}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicIntervalRefinement}^{\uparrow}$, $\mathsf{BishopIntervalHalving}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalRefinement}^{\uparrow}}$ *row.*

The classifier reads only these rows. It has no coordinate for open-cover compactness, quotient equality of real names, selected branches of an infinite bisection tree, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedIntervalRefinementUp.LocatedIntervalRefinementTasteGate single carrier alignment`

Theorem 6199.2 (Located interval refinement cover transport)**.** *For every accepted* $\mathsf{LocatedIntervalRefinement}^{\uparrow}$ *carrier* $R = (L, U, M, F, Q, A, H, C, P, N)$*, any interval-cover or compactness-facing consumer that transports a refinement cover must expose the located endpoint rows* L, U*, the dyadic mesh row* M*, the refinement map* F*, the containment witnesses* Q*, and the apartness and tolerance ledger* A *before reading the transported cover. The transport is componentwise along* H *and replayed by* C*; it exports no host open cover, selected finite subcover, quotient endpoint equality, or ambient compactness principle.*

Proof. Project the carrier of Definition 6199.1. The endpoints L, U supply the only located-real boundary, and the dyadic mesh M supplies the only finite scale at which a refinement can be inspected.

The refinement map and containment witnesses are then read as F and Q. Thus a transported cover first sees the same parent cell, child cells, endpoint order, and visible gap checks that are already present in the finite refinement packet.

Finally the ledger A binds the apartness and tolerance reads to the same dyadic budget. Componentwise transport through H and replay through C can only repack these displayed rows, so no host open-cover compactness, selected subcover, quotient endpoint equality, or ambient compactness coordinate can enter the transported cover. □

Theorem 6199.3 (Located interval refinement NameCert obligations)**.** *For every accepted* LocatedIntervalRefineme *carrier* $R = (L, U, M, F, Q, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalRefinement}^{\uparrow}}$ *surface consists exactly of located endpoint admission, dyadic mesh admission, refinement-map admission, containment witness admission, apartness and tolerance ledger admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the displayed rows* $L, U, M, F, Q, A, H, C, P, N$.

Proof. Carrier admission is projection from Definition 6199.1. The endpoint rows are L, U, the finite arithmetic surface is M, the one-step refinement route is F, and the containment and tolerance evidence is Q, A.

The sibling routes determine how these rows may be consumed. The $\mathsf{LocatedInterval}^{\uparrow}$ packet supplies endpoint and interval-cell visibility, $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ supplies the child-cell refinement row, $\mathsf{BishopIntervalHalving}^{\uparrow}$ supplies the bisection reading discipline, $\mathsf{LocatedReal}^{\uparrow}$ supplies the endpoint tolerance surface, and $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the arithmetic ledger.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no row for selected branches, open-cover compactness, quotient equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalRefinement}^{\uparrow}$ packet is generated from located endpoint rows, a DyadicRatCore mesh, a finite refinement map, containment witnesses, an apartness and tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6199.1, Definition 6199.2, and Definition 6199.3 seed the finite located-interval refinement surface over LocatedInterval$^{\uparrow}$, DyadicIntervalRefinement$^{\uparrow}$, BishopIntervalHalving$^{\uparrow}$, LocatedReal$^{\uparrow}$, and DyadicRatCore$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedIntervalRefinement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected finite subcovers, selected refinement branches, quotient real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, dyadic mesh admission, refinement-map coverage, containment witnesses, tolerance ledger exactness, cover transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalRefinementUp.

Chapter 6200

A Concrete Naming Certificate for $\mathsf{DifferentialPrivacy}^{\uparrow}$

Following Dwork and Roth on differential privacy, the $\mathsf{DifferentialPrivacy}^{\uparrow}$ packet records the finite randomized-mechanism surface through which a BEDC consumer may inspect adjacent inputs, paired output distributions, a rational privacy budget, privacy-loss comparisons, postprocessing, transport, replay, provenance, and local naming. It depends on the finite probability spaces of chapter 184, the random-variable rows of chapter 185, the distribution readback surface of chapter 186, and the rational budget discipline of chapter 37. The certificate is intentionally finite: it names only displayed rows and does not export measure-theoretic Radon–Nikodym derivatives, selected probability kernels, host function equality, or amplification theorems.

Definition 6200.1 (DifferentialPrivacy carrier)**.** *A* $\mathsf{DifferentialPrivacy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, M, O_0, O_1, E, L, F, H, C, P, N)$$

with the following displayed rows:

1. *A is the adjacent-input relation row, naming the two displayed input histories, their finite database boundary, and the local adjacency witness used by the privacy comparison.*
2. *M is the randomized mechanism graph row, listing the inspected finite graph of input names, output names, and rational transition weights for the requested mechanism surface.*
3. *O_0 and O_1 are the two* $\mathsf{Distribution}^{\uparrow}$ *output-distribution rows obtained by reading M at the adjacent inputs displayed by A.*
4. *E is the positive rational epsilon-budget row, recorded through the* $\mathsf{Rat}^{\uparrow}$ *comparison discipline and available only as the displayed privacy tolerance.*
5. *L is the privacy-loss comparison ledger, pairing every displayed output atom with the rational inequalities that compare the O_0 and O_1 masses against the budget E.*
6. *F is the postprocessing map row, naming the finite output relabeling or coarsening that may be applied after the mechanism has been read through O_0 and O_1.*
7. *H records componentwise* hsame *transport for $A, M, O_0, O_1, E, L, F, C, P, N$ and for the local certificate rows.*

8. *C records displayed* Cont *replay from an adjacent-input request through the mechanism graph, paired distributions, privacy-loss ledger, postprocessing row, transport, provenance, and local name.*
9. *P is the* Pkg *provenance over* $\mathsf{DifferentialPrivacy}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DifferentialPrivacy}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient measurable space, a selected stochastic kernel, host equality of functions, Radon–Nikodym density, adaptive composition theorem, or privacy amplification principle.

Lean4 ✓ `BEDC.Derived.DifferentialPrivacyUp.TasteGate.DifferentialPrivacyTasteGate single carrier alignment`

Theorem 6200.2 (DifferentialPrivacy NameCert obligations)**.** *For every accepted* $\mathsf{DifferentialPrivacy}^{\uparrow}$ *carrier $D = (A, M, O_0, O_1, E, L, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DifferentialPrivacy}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed packet D;*
2. *adjacency exposure through A and no other neighboring-input relation;*
3. *paired distribution readback through O_0 and O_1 after reading the randomized mechanism graph M;*
4. *epsilon privacy-loss bounding through the positive rational budget E and the comparison ledger L;*
5. *postprocessing non-escape through the displayed map row F;*
6. *provenance exhaustion through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local name row N.*

No consumer of the certificate receives a measure-theoretic density, an unlisted probability kernel, host function equality, adaptive composition, subsampling amplification, or an external privacy proof.

Proof. Carrier admission is projection from Definition 6200.1. The projection exposes exactly the adjacent-input row, mechanism graph, paired distribution rows, rational epsilon budget, privacy-loss ledger, postprocessing row, and structural certificate rows.

The adjacency and readback obligations are A, M, O_0, O_1. The row A names the only adjacent input pair, M is the only randomized mechanism graph, and O_0, O_1 are the only output distributions read from that graph for the adjacent inputs.

The privacy-loss obligation is E, L. The budget E is a positive rational row, and L records only the displayed output-atom comparisons against that budget, so the certificate cannot infer a density or an unlisted kernel.

Finally F, H, C, P, N preserve the same displayed packet under postprocessing, transport, replay, provenance, and local naming. Since the excluded analytic and semantic objects are absent from the carrier, these rows exhaust the local NameCert surface. □

Theorem 6200.3 (DifferentialPrivacy postprocessing stability)**.** *Let $D = (A, M, O_0, O_1, E, L, F, H, C, P, N)$ be an accepted* $\mathsf{DifferentialPrivacy}^{\uparrow}$ *carrier. Any consumer that applies the displayed postprocessing row F preserves the same epsilon privacy ledger E, L, because F reads the mechanism only through the paired output-distribution rows O_0, O_1 and structural transport through H, C, P, N.*

Proof. Read F from the carrier of Definition 6200.1. The postprocessing row is downstream of the mechanism graph and has access only to the output names already displayed in O_0 and O_1.

Apply Definition 6200.2. The epsilon budget and privacy-loss comparisons are fixed by E, L before postprocessing is inspected, and the structural rows H, C, P, N replay and source the same packet rather than adding a new probability comparison.

Thus every displayed postprocessing read preserves the same privacy ledger. A consumer may relabel or coarsen the displayed outputs through F, but it cannot replace E, L or strengthen the certificate into amplification, adaptive composition, selected kernel equality, or host measure theory. □

Closure status for $\mathsf{NameCert}_{\mathsf{DifferentialPrivacy}^{\uparrow}}$.

Constructive story: A $\mathsf{DifferentialPrivacy}^{\uparrow}$ packet is generated from adjacent-input rows, a randomized mechanism graph, paired DistributionUp output rows, a positive RatUp epsilon budget, a displayed privacy-loss ledger, a postprocessing map row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DifferentialPrivacy}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6200.1, Definition 6200.2, and Definition 6200.3 seed the finite differential-privacy route over ProbSpaceUp, RandomVarUp, DistributionUp, RatUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DifferentialPrivacy}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DifferentialPrivacyUp.TasteGate.DifferentialPrivacyTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not claim measure-theoretic Radon–Nikodym machinery, selected probability kernels, host function equality, privacy amplification, adaptive composition, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjacency exposure, paired distribution readback, epsilon privacy-loss bounding, postprocessing non-escape, provenance exhaustion, and local naming for BEDC.Derived.DifferentialPrivacy

Chapter 6201

A Concrete Naming Certificate for $\mathsf{UniformCauchySubnet}^{\uparrow}$

Following Bishop-style constructive analysis, the $\mathsf{UniformCauchySubnet}^{\uparrow}$ packet records the finite modulus data by which a displayed regular sequence exposes a uniform subnet route for completion-facing consumers. It sits between the $\mathsf{CauchyModulus}^{\uparrow}$ tolerance surface, the finite-window discipline of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the real-name seal of chapter 38, and the located-limit route of chapter 1420. The packet names a finite subnet modulus for displayed requests; it is not a countable-choice subsequence, a host subnet object, quotient stream equality, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 6201.1 (Uniform Cauchy subnet carrier)**.** *A* $\mathsf{UniformCauchySubnet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, W, D, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular sequence surface, read only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row assigning a displayed threshold to each dyadic precision request.*
3. *W is the subnet-window ledger; for each displayed request it records the finite source windows and the finite subnet index comparisons needed for the request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by M and W.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled windows and tolerances.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, M, W, D, R have been read.*
7. *L is the* $\mathsf{LocatedLimit}^{\uparrow}$ *handoff row exposing the same finite schedule as located-limit data.*
8. *H records componentwise* hsame *transport for S, M, W, D, R, E, L.*
9. *C records displayed* Cont *replay for source-window inspection, modulus lookup, subnet-window projection, dyadic tolerance comparison, regular rational readback, Real sealing, and located-limit handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformCauchySubnet}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchySubnet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $S, M, W, D, R, E, L, H, C, P, N$. It has no coordinate for countable choice, a selected infinite subsequence, a host subnet, quotient equality of streams, trichotomy, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.UniformCauchySubnetUp.TasteGate.UniformCauchySubnetTasteGate single carrier alignment`

Theorem 6201.2 (Uniform Cauchy subnet NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchySubnet}^{\uparrow}$ *carrier*

$$U = (S, M, W, D, R, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCauchySubnet}^{\uparrow}}$ *surface consists exactly of carrier admission for the source sequence, modulus row, subnet-window ledger, dyadic tolerance row, regular rational readback, Real seal, located-limit handoff, componentwise transport, displayed replay, package provenance, and local naming. Every accepted consumer read must inspect M and D before reading a subnet window in W, must inspect W before extracting R, and must pass through R before consuming E or L.*

Proof. Project the carrier of Definition 6201.1. The only rows that can answer a precision request before readback are the modulus row M, the dyadic tolerance row D, and the subnet-window ledger W.

The proof is by induction over the displayed subnet requests. The base request reads the first stored tolerance, uses M to locate the finite threshold, and then projects the matching source and subnet windows from W.

For the step, a stronger displayed request carries a refined dyadic tolerance in D. The same modulus row M supplies a later threshold, and W appends only the finite comparisons needed to show that the new subnet window lies beyond the previous one.

After each request has been projected, the readback row R is determined by the scheduled windows and dyadic data. The Real seal E and located-limit handoff L are downstream of that readback, while H, C, P, N transport, replay, source, and name the same finite route. Since the excluded choice, host-subnet, quotient, trichotomy, and completeness objects have no carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6201.3 (Uniform Cauchy subnet RegSeqRat handoff)**.** *Every completion-facing read from an accepted* $\mathsf{UniformCauchySubnet}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{CauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{LocatedLimit}^{\uparrow}.$$

Concretely, the consumer first reads the source surface S, the modulus row M, the subnet-window ledger W, and the dyadic tolerance row D; it then obtains the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R and only afterward reaches the* $\mathsf{Real}^{\uparrow}$ *seal E or the* $\mathsf{LocatedLimit}^{\uparrow}$ *handoff row L.*

Proof. Start with the obligation package of Definition 6201.2. It forces every precision request to expose M, D, W before any regular rational readback is available.

Use finite-window projection on the displayed request. The stream windows in W are not chosen by an external subsequence principle; they are the windows explicitly stored with the modulus threshold supplied by M and the dyadic tolerance supplied by D.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is then the only readback row available to the consumer. The terminal rows E and L read that same R, and the structural rows H, C, P, N preserve the route under transport and replay. Thus the handoff reaches Real and located-limit consumers without exporting countable choice, a host subnet, quotient stream equality, trichotomy, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{UniformCauchySubnet}^{\uparrow}$ completion read displays a CauchyModulus row, finite StreamName windows, DyadicRatCore tolerances, a RegSeqRat readback, a Real seal, a LocatedLimit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before it can be consumed by Real-completion or located-limit routes.

Independence witness: cauchymodulus, streamname, regseqrat, dyadicratcore, real, locatedlimit: $\mathsf{UniformCauchySubnet}^{\uparrow}$ is not bijective to any listed sibling because it binds a uniform precision-to-window modulus, subnet-window comparisons, regular readback, Real sealing, and located-limit handoff in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchySubnet}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchySubnet}^{\uparrow}$ packet is generated from a displayed source sequence, a CauchyModulus row, a subnet-window ledger, DyadicRatCore tolerances, a RegSeqRat readback, a Real seal, a LocatedLimit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchySubnet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6201.1, Definition 6201.2, and Definition 6201.3 seed the finite uniform subnet modulus route for completion-facing and located-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchySubnet}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformCauchySubnetUp.TasteGate.UniformCauchySubnetTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close countable choice, selected host subsequences, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exposure, subnet-window projection, dyadic tolerance accounting, regular readback, Real seal handoff, located-limit handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchySubnetUp.

Chapter 6202

A Concrete Naming Certificate for $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$

The $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$ packet realizes the certified-discovery and positive-cost-protocol surface of section 9462.13 as finite classifier-shift, ledger, debt, and NameCert rows. It sits beside the classifier-shift witness of chapter 6138, the pipeline calculus of chapter 5914, the net-information packet of chapter 6181, and the effective replacement ledger of chapter 568. The packet classifies a discovery claim only after the changed classifier, cost protocol, debt profile, and local not-claimed boundary are all displayed.

Definition 6202.1 (Positive interpretability classifier carrier)**.** *A* $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (E_0, E_1, J, \Delta, W, L, D, B, Q, H, C, R, N)$$

with the following displayed rows:

1. E_0 *is the source explanation-state row before the interpretability claim is classified.*
2. E_1 *is the target explanation-state row after the claim is classified.*
3. J *is the* $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ *row exposing a common source and a changed classifier judgment.*
4. Δ *is the classifier-shift row read by the discovery pipeline calculus.*
5. W *is the public cost-protocol weight row for benefit, score, debt, source scope, target scope, and not-claimed boundary.*
6. L *is the effective replacement ledger row recording which classifier and explanation rows have real downstream use.*
7. D *is the explanation-debt row separating ledger, semantic, verification, intervention, and generalization debts.*
8. B *is the benefit row for coverage, prediction, transfer, intervention, verification, and unification gains.*
9. Q *is the* $\mathsf{ExplanationComplexityInformation}^{\uparrow}$ *net-information row comparing benefit against score and debt under* W*.*
10. H *records componentwise* hsame *transport for* $E_0, E_1, J, \Delta, W, L, D, B, Q$*.*

11. *C records displayed* Cont *replay through classifier-shift inspection, cost-protocol accounting, ledger lookup, debt exposure, benefit exposure, and net-information comparison.*
12. *R is the* Pkg *provenance over* $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$, $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$, DiscoveryPipelineCalculu ExplanationComplexityInformation$^{\uparrow}$, $\mathsf{EffectiveReplacementLedger}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for prose-only classifier novelty, ledger-only completion, raw score movement, hidden semantic truth, uncounted cost, undisplayed debt, or a positive discovery claim without the displayed classifier-shift row J, Δ and the cost-protocol row W.

Theorem 6202.2 (Positive interpretability classifier NameCert obligations)**.** *For every accepted* $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$ *carrier*

$$P = (E_0, E_1, J, \Delta, W, L, D, B, Q, H, C, R, N),$$

the local $\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission for the two explanation states, classifier-novelty witness, classifier-shift row, public cost protocol, effective replacement ledger, debt row, benefit row, net-information row, componentwise transport, displayed replay, package provenance, and local naming. A positive interpretability classification is accepted only when J, Δ display classifier novelty and Q reads B, D, W, L under the same scope.*

Proof. Project the carrier of Definition 6202.1. The classifier-shift surface is not implicit: the rows J and Δ display the common source, changed judgment, and pipeline-facing shift.

Next read the cost protocol. The weight row W fixes the scope and the benefit-score-debt accounting convention, while L, D, B expose replacement use, debt, and benefit inside that scope.

The row Q can classify the claim as positive only after those rows have been read together. This separates a true classifier shift with positive net information from ledger-only completion, formal hardening, raw score motion, or hidden semantic claims.

Finally, H, C, R, N transport, replay, source, and name the same finite packet. Since none of the excluded objects appears in the carrier, the NameCert obligations are exactly the listed rows. □

Theorem 6202.3 (Positive interpretability falsifiable shift)**.** *An accepted* $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$ *consumer is refuted if it classifies a claim as positive interpretability discovery while any one of the classifier-shift rows J, Δ, the public cost-protocol row W, the replacement ledger row L, the debt row D, the benefit row B, or the net-information row Q is absent. Conversely, a ledger-only or formal-hardening improvement with unchanged classifier rows is not accepted by this classifier.*

Proof. Apply Definition 6202.2. The obligations place classifier novelty and net-information accounting in the same carrier, so a consumer cannot obtain the positive classification from one side alone.

If J or Δ is absent, the carrier has no displayed classifier shift. If W, L, D, B, or Q is absent, the carrier has no complete positive cost-protocol read.

The remaining rows H, C, R, N preserve the same classification route under transport, replay, provenance, and local naming. Therefore a claim missing any named row is rejected, and a classifier-unchanged improvement is classified outside positive interpretability discovery. □

Falsifiable prediction: Every accepted $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$ positive-discovery read displays two explanation states, a classifier novelty witness, a classifier-shift row, a public cost

protocol, effective replacement ledger rows, debt and benefit rows, net explanation information, transport, replay, provenance, and local NameCert naming.

Independence witness: classifier-novelty-witness, explanation-complexity-information, discovery-pipeline-calculus, effective-replacement-ledger: none is bijective to $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$ because this packet jointly carries the before-and-after explanation states, classifier-shift witness, public cost protocol, replacement ledger, debt accounting, benefit accounting, net-information comparison, transport, replay, provenance, and local naming as one classifier for positive interpretability discovery.

The Lean follow-up must provide $\mathsf{Nontrivial\ PositiveInterpretabilityClassifier}^{\uparrow}$ and $\mathsf{FieldFaithful\ PositiveInterpretabil}$ instances before checked markers for BEDC.Derived.PositiveInterpretabilityClassifierUp are cited. Those instances must preserve the rows $E_0, E_1, J, \Delta, W, L, D, B, Q, H, C, R, N$ so classifier novelty, ledger evidence, debt accounting, and positive net information remain separate fields.

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$ packet is generated from two explanation states, a classifier novelty witness, a classifier-shift row, public cost protocol weights, an effective replacement ledger, debt and benefit rows, net explanation information, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6202.1, Definition 6202.2, and Definition 6202.3 seed the finite classifier for positive interpretability discovery claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global interpretability quality, hidden semantic truth, prose-only classifier novelty, uncounted costs, undisplayed debts, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier-shift exactness, cost-protocol exposure, ledger and debt accounting, net-information comparison, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for BEDC.Derived.PositiveInterpretabilityClassifierUp.

Chapter 6203

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterReal}^{\uparrow}$

Following Bishop and Bridges, a real completion interface may be presented by regular filters only when each tolerance read remains finite, rounded, and tied to an explicit rational window. The $\mathsf{RegularCauchyFilterReal}^{\uparrow}$ packet sits between the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the filter surface of chapter 333. It names a selection-free regular Cauchy filter route to a displayed real seal; it is not quotient filter equality, a chosen representative, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6203.1 (Regular Cauchy filter real carrier)**.** *A* $\mathsf{RegularCauchyFilterReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, carrying the rounded filter base and its finite tolerance requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected at the displayed filter tolerance.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite windows.*
4. *D is the dyadic or rational diameter ledger proving that the inspected filter windows are regular at the requested precision.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, S, Q, D have been displayed.*
6. *H records componentwise* hsame *transport for the filter, window, readback, diameter, real-seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a tolerance request through the filter base, finite windows, regular rational readback, diameter ledger, and real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFilterReal}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for quotient filters, selected subfilters, chosen representatives, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterRealUp.RegularCauchyFilterRealTasteGate single carrier alignment`

Theorem 6203.2 (Regular Cauchy filter real NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilterReal}^{\uparrow}$ *carrier* $R = (F, S, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterReal}^{\uparrow}}$ *surface consists exactly of carrier admission, rounded CauchyFilter admission, StreamName finite-window admission, RegSeqRat readback, regular diameter verification, Real seal admission, componentwise transport, displayed replay, provenance, and local naming for the displayed rows* $F, S, Q, D, E, H, C, P, N$*.*

Proof. Project the accepted carrier of Definition 6203.1. The analytic rows are precisely the rounded filter row F, the finite stream window row S, the regular rational readback Q, the diameter ledger D, and the terminal real seal E.

The local certificate reads these rows in order. A filter tolerance request can reach a regular rational readback only through the finite window row, and the Real seal can be inspected only after the diameter ledger has witnessed the displayed regularity at the same request.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since they add no quotient, selector, chosen representative, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate, the listed rows exhaust the local naming obligations. □

Theorem 6203.3 (Regular Cauchy filter real completion route)**.** *Every completion-facing read of an accepted* $\mathsf{RegularCauchyFilterReal}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More explicitly, the consumer reads F*, then the finite windows* S*, then the regular rational readback* Q *and diameter ledger* D*, and finally the Real seal* E*, with* H, C, P, N *preserving the same route. The route supplies a filter-form completion boundary without quotient filter equality, selected subfilters, selected limits, chosen representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the obligation surface of Definition 6203.2. It exposes the rounded CauchyFilter row before any finite window or regular rational readback is available.

The StreamName and RegSeqRat rows supply the finite observation route. The diameter ledger is attached to that same observation, so a completion-facing consumer cannot replace it by a quotient filter, a selected subfilter, or a chosen representative.

Finally the Real seal is downstream of the displayed readback. Transport, replay, provenance, and local naming preserve the same packet, and the carrier contains no coordinate for selected limits, countable choice, host real equality, or ambient completeness. Hence every completion-facing read factors through the stated finite route. □

Falsifiable prediction: A $\mathsf{RegularCauchyFilterReal}^{\uparrow}$ consumer that exports a selected limit, quotient filter equality, countable-choice schedule, host real equality, or ambient Real completeness after deleting F, S, Q, or D refutes the carrier of Definition 6203.1.

Independence witness: Nearest siblings: StreamName, RegSeqRat, Real, and CauchyFilter. $\mathsf{RegularCauchyFilterReal}^{\uparrow}$ is not bijective to any one of them because it jointly carries rounded filter admission, finite windows, regular rational readback, a diameter ledger, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterReal}^{\uparrow}}$**.**

Constructive story: A RegularCauchyFilterReal$^{\uparrow}$ packet is generated from rounded CauchyFilter rows, StreamName finite windows, RegSeqRat readbacks, regular diameter ledgers, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyFilterReal}^{\uparrow}}$, seed)

Scope closed: Definition 6203.1, Definition 6203.2, and Definition 6203.3 seed the finite filter-form route from rounded CauchyFilter requests to terminal Real reads.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyFilterReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, selected subfilters, selected limits, chosen representatives, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rounded filter exactness, StreamName window replay, RegSeqRat readback, diameter-ledger nonescape, Real seal admission, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFilterRealUp.

Chapter 6204

A Concrete Naming Certificate for $\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}$

Following Bishop and Bridges on constructive intervals and finite nets, the $\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}$ packet records the explicit dyadic mesh by which a closed real interval is read as totally bounded before any open-cover compactness claim is available. It sits after the dyadic arithmetic of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the interval-net surface of chapter 1250, and the finite-net interface of chapter 127. The packet is a choice-free finite mesh certificate for the L10 real-and-completion route; it is not open-cover compactness, selected subcovers, countable choice, quotient interval equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6204.1 (Dyadic totally bounded interval carrier)**.** *A* $\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, M, Z, \rho, F, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint rows, each read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint interface and sealed only later as* $\mathsf{Real}^{\uparrow}$ *data;*
2. *M is the unary mesh-scale row naming the dyadic precision used for the interval net;*
3. *Z is the finite center list, carried as a closed* $\mathsf{ProbeBundle}$ *of dyadic center rows between the displayed endpoints;*
4. *ρ is the dyadic radius ledger assigning the mesh radius used by the centers of Z;*
5. *F is the finite coverage row saying that every interval read enters one displayed center of Z within the dyadic radius ρ;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect endpoint, center, and radius names at the mesh scale;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the endpoint, center, and radius windows;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after $L, U, M, Z, \rho, F, S, R$ are displayed;*
9. *H stores componentwise* hsame *transport for endpoints, mesh, centers, radii, coverage rows, windows, readback, seal, provenance, and local name;*

10. *C stores the displayed* Cont *replay from endpoints to mesh selection, from mesh to finite centers and radii, from coverage to window readback, and from readback to the real seal;*
11. *P records* Pkg *provenance over* $\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for an open cover, a selected finite subcover, countable choice, quotient interval equality, real trichotomy, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.DyadicTotallyBoundedIntervalUp.DyadicTotallyBoundedIntervalTasteGate single carrier alignment`

Theorem 6204.2 (Dyadic totally bounded interval NameCert obligations)**.** *For the carrier of Definition 6204.1, the local* $\mathsf{NameCert}_{\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for $I = (L, U, M, Z, \rho, F, S, R, E, H, C, P, N)$, finite-net coverage through Z, ρ, F, endpoint containment for L and U, mesh-radius compatibility between M and ρ,* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through S and R,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.DyadicTotallyBoundedIntervalUp.DyadicTotallyBoundedIntervalCarrier namecert obligations`

Proof. Project the carrier. The endpoint rows L, U, mesh row M, finite center bundle Z, dyadic radius ledger ρ, and coverage row F are displayed before any stream, regular-Cauchy, or real seal row is available.

The finite-net obligations are read from those rows. Endpoint containment uses the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, mesh-radius compatibility ties M to ρ, and the coverage row F routes each interval read to one center of Z at that radius. This is the same kind of finite mesh handoff consumed by the $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ and $\mathsf{TotallyBounded}^{\uparrow}$ sibling surfaces.

The readback and seal obligations are downstream. The $\mathsf{StreamName}^{\uparrow}$ row S and $\mathsf{RegSeqRat}^{\uparrow}$ row R expose only the displayed endpoint, center, and radius windows, and the $\mathsf{Real}^{\uparrow}$ seal E is reached only after that readback. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the excluded compactness, choice, equality, trichotomy, and completeness principles have no carrier coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}$ packet is generated from dyadic endpoint rows, a unary dyadic mesh scale, a finite center ProbeBundle, a dyadic radius ledger, finite coverage rows, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}}$, seed)

Scope closed: Definition 6204.1 and Definition 6204.2 name the finite carrier and its local obligation surface for the dyadic totally bounded interval route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicTotallyBoundedInterval}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.DyadicTotallyBoundedIntervalUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, quotient interval equality, trichotomy, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Scoped closure requires checked endpoint containment, finite-net coverage, mesh-radius compatibility, readback handoff, Real seal nonescape, transport stability, replay, provenance, and local naming for the same finite packet.

Chapter 6205

A Concrete Naming Certificate for $\mathsf{ArithmeticoGeometricSequence}^{\uparrow}$

Following Hardy and Knopp, the $\mathsf{ArithmeticoGeometricSequence}^{\uparrow}$ packet records the finite BEDC surface for a sequence whose next observation is generated from an initial value, a fixed multiplier, and an inhomogeneous geometric row. It reads the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names the recurrence evidence used by downstream $\mathsf{Real}^{\uparrow}$ sequence calculus; it does not assert a closed-form host equality, selected infinite stream, quotient sequence identity, countable choice, or ambient real completeness.

Definition 6205.1 (Arithmetico-geometric sequence carrier)**.** *An* $\mathsf{ArithmeticoGeometricSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, M, G, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the initial-value row, recording the first named rational or real-facing approximation from which the recurrence is read.*
2. *M is the multiplier row, displaying the fixed scalar used by each recurrence step.*
3. *G is the inhomogeneous geometric row, carrying the finite geometric contribution read at the displayed step.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, listing the finite sequence windows and indices exposed to a consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, converting the displayed windows into regular rational evidence before any real seal is consumed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the initial, multiplier, geometric, stream-window, and regular-readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the initial value, multiplier, inhomogeneous geometric row, stream observations, regular readback, real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a finite index and tolerance request through the same recurrence rows.*

9. *P is the* Pkg *provenance over* $\mathsf{ArithmeticoGeometricSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArithmeticoGeometricSequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, M, G, W, R, E, H, C, P, N$. It has no coordinate for a completed infinite sequence object, host closed-form equality, quotient stream equality, selected limit, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ArithmeticoGeometricSequenceUp.ArithmeticoGeometricSequenceTasteGate single carrier alignment`

Theorem 6205.2 (Arithmetico-geometric sequence NameCert obligations)**.** *For every accepted* $\mathsf{ArithmeticoGeometricSequence}^{\uparrow}$ *carrier*

$$A = (I, M, G, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ArithmeticoGeometricSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the initial value, fixed multiplier, inhomogeneous geometric row, StreamName observations, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming; recurrence visibility requiring every displayed step to read I, M, G, W before R; seal discipline requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to pass through R before E; and nonescape excluding host closed forms, quotient stream equality, selected limits, countable choice, and ambient real completeness.*

Proof. Carrier admission is projection from Definition 6205.1. The accepted packet displays exactly the rows $I, M, G, W, R, E, H, C, P, N$.

The recurrence read starts with I, M, G, W. The initial-value row fixes the displayed starting observation, the multiplier row records the scalar reused by the finite recurrence route, the inhomogeneous geometric row supplies the finite forcing term, and the StreamName row lists the inspected sequence windows.

The regular readback and seal rows are downstream. A consumer must pass through R before it can read the $\mathsf{Real}^{\uparrow}$ seal E, and componentwise hsame transport in H together with displayed Cont replay in C preserves the same recurrence route.

Finally, P and N only source and name the displayed packet. Since the carrier has no coordinate for a completed infinite stream, a host closed-form equality, quotient sequence identity, countable choice, selected limits, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArithmeticoGeometricSequence}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ArithmeticoGeometricSequence}^{\uparrow}$ packet is generated from an initial-value row, a fixed multiplier row, an inhomogeneous geometric row, finite StreamName observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ArithmeticoGeometricSequence}^{\uparrow}}$, seed)

Scope closed: Definition 6205.1 and Definition 6205.2 seed the finite recurrence route from initial value and inhomogeneous geometric evidence through StreamName windows, RegSeqRat readback, and the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ArithmeticoGeometricSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host closed-form equality, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, recurrence visibility, StreamName observation coverage, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.ArithmeticoGeometric

Chapter 6206

A Concrete Naming Certificate for InverseFunctionTheorem$^{\uparrow}$

Following Cartan, Rudin, and Bishop–Bridges, the InverseFunctionTheorem$^{\uparrow}$ packet records the theorem-level local inverse route exposed after a differentiable map, an invertible derivative row, a quantitative neighbourhood ledger, and the Real completion route have all been displayed. It sits above the local carrier boundary of chapter 2055, consumes the Newton–Kantorovich theorem route of chapter 1785 and the graph-window route of chapter 1834, and reaches observable endpoint data only through chapter 126, chapter 301, and chapter 38. The packet names a finite BEDC route from displayed analytic hypotheses to a local inverse theorem certificate; it does not assert a host inverse theorem, select a germ, identify quotient function spaces, import ambient completeness, or provide bridge verification.

Definition 6206.1 (Inverse function theorem carrier)**.** *An* InverseFunctionTheorem$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, U, D, L, K, G, W, S, Q, R, H, C, P, N)$$

with the following rows:

1. *F is the displayed map row together with the source and target classifier windows.*
2. *U is the base-point and neighbourhood row, naming the point, value, source radius, target radius, and local domain of the theorem read.*
3. *D is the derivative-control row over the displayed neighbourhood.*
4. *L is the invertible-linear row for the derivative at the base point, including the finite inverse witness used by the quantitative route.*
5. *K is the* NewtonKantorovich$^{\uparrow}$ *row that supplies the contraction and root-existence certificate for nearby target values.*
6. *G is the* ImplicitFunction$^{\uparrow}$ *graph-window row for the equation $F(x) - y = 0$.*
7. *W is the* InverseFunction$^{\uparrow}$ *local inverse-window row obtained from the same analytic and solving data.*
8. *S is the* StreamName$^{\uparrow}$ *finite observation row for source, target, and endpoint windows.*
9. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the rational approximation data exposed by S.*
10. *R is the terminal* Real$^{\uparrow}$ *seal row for the theorem-facing completion route.*

11. *H records componentwise* hsame *transport for all displayed analytic, solving, completion, replay, provenance, and naming rows.*
12. *C records displayed* Cont *replay through*

$$F, U, D, L, K, G, W, S, Q, R \longmapsto \mathsf{NameCert}_{\mathsf{InverseFunctionTheorem}^{\uparrow}}.$$

13. *P is the* Pkg *provenance over* InverseFunctionTheorem$^{\uparrow}$, InverseFunction$^{\uparrow}$, NewtonKantorovich$^{\uparrow}$, ImplicitFunction$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{InverseFunctionTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, U, D, L, K, G, W, S, Q, R, H, C, P, N$. The carrier has no coordinate for a host theorem schema, selected inverse germ, quotient function-space equality, global bijection theorem, ambient Real completeness principle, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.InverseFunctionTheoremUp.InverseFunctionTheoremTasteGate single carrier alignment`

Theorem 6206.2 (Inverse function theorem NameCert obligations)**.** *For every accepted* InverseFunctionTheorem$^{\uparrow}$ *carrier*

$$T = (F, U, D, L, K, G, W, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{InverseFunctionTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for T, derivative-control exposure through D, invertible-linear exactness through L, Newton–Kantorovich solving through K, implicit graph-window handoff through G, local inverse-window handoff through W, stream observation through S, regular rational readback through Q, terminal Real sealing through R, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6206.1. The analytic rows F, U, D, L are the only source of map, neighbourhood, derivative, and invertibility data.

The solving rows are then forced. The Newton–Kantorovich row K supplies the finite contraction route, the implicit-function row G repacks the same equation as a graph window, and the inverse-function row W exposes the resulting local inverse window.

The completion-facing rows come last. The stream row S provides finite observations, Q reads them as regular rational data, and R seals the theorem-facing Real endpoint. The structural rows H, C, P, N transport, replay, source, and name exactly this route, so no additional theorem schema, selected germ, quotient equality, global bijection, or ambient completeness coordinate is present. □

Theorem 6206.3 (Inverse function theorem Real completion route)**.** *Every accepted* InverseFunctionTheorem$^{\uparrow}$ *theorem read exported as a local inverse statement factors through the finite route*

$$\mathsf{NewtonKantorovich}^{\uparrow} \longmapsto \mathsf{ImplicitFunction}^{\uparrow} \longmapsto \mathsf{InverseFunction}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as instantiated by K, G, W, S, Q, R and the analytic rows F, U, D, L. The Real-facing conclusion receives local window data, derivative and inverse-witness data, theorem-level solving data, finite observations, regular rational readback, terminal Real sealing, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row; it receives no host inverse theorem, global inverse, selected germ, quotient function-space equality, or ambient completeness shortcut.*

Proof. Start with the accepted carrier $T = (F, U, D, L, K, G, W, S, Q, R, H, C, P, N)$. The rows F, U, D, L display the map, neighbourhood, derivative control, and invertible-linear witness before any theorem conclusion is read.

Apply the theorem-level solving route. The row K gives the Newton–Kantorovich certificate, G reads the same local equation as an implicit graph window, and W opens the local inverse-window carrier from chapter 2055.

Finally pass through the completion route. The stream, regular-rational, and Real rows S, Q, R are read in that order, and H, C, P, N preserve the same displayed path. Since no carrier coordinate stores a host inverse theorem, global inverse, selected germ, quotient function-space equality, or ambient completeness shortcut, the route is exhausted by the finite BEDC packet. □

Falsifiable prediction: Every $\mathsf{InverseFunctionTheorem}^{\uparrow}$ theorem-facing read factors through one displayed map row, one neighbourhood row, one derivative-control row, one invertible-linear row, one NewtonKantorovich row, one ImplicitFunction row, one InverseFunction row, one StreamName finite-observation row, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: inverse-function, newton-kantorovich, implicitfunction, streamname, regseqrat: $\mathsf{InverseFunctionTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries theorem-level analytic hypotheses, Newton solving, implicit graph-window handoff, local inverse-window export, finite observation, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{InverseFunctionTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{InverseFunctionTheorem}^{\uparrow}$ packet is generated from a displayed map row, base neighbourhood row, derivative-control row, invertible-linear row, NewtonKantorovich theorem row, ImplicitFunction graph-window row, InverseFunction local-window row, StreamName observations, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InverseFunctionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6206.1, Definition 6206.2, and Definition 6206.3 seed the finite theorem-level local inverse route over analytic, solving, inverse-window, observation, regular rational, and Real completion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InverseFunctionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse theorems, global inverses, selected inverse germs, quotient function spaces, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-control exposure, invertible-linear exactness, Newton solving, implicit graph-window handoff, local inverse-window handoff, Real completion routing, provenance exactness, and local naming for BEDC.Derived.InverseFunctionTheoremUp.

Chapter 6207

A Concrete Naming Certificate for CompactIntervalUniformModulus$^{\uparrow}$

Following Bishop and Bridges, the CompactIntervalUniformModulus$^{\uparrow}$ packet records the finite-net route by which a compact interval consumer reads a uniform modulus claim before any open-cover or selected-subcover principle is available. It sits after the dyadic arithmetic core of chapter 291, the finite dyadic interval nets of chapter 5966, the StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet gives later compactness and uniform-continuity arguments a finite landing surface: a modulus is named only when the required dyadic mesh, endpoint reads, regular rational tolerances, and Real-facing seal rows have all been displayed.

Definition 6207.1 (Compact interval uniform modulus carrier)**.** *A* CompactIntervalUniformModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, J, E, S, R, U, Q, H, C, P, N)$$

with the following rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *endpoint and precision row. It records dyadic endpoints, mesh widths, successor comparisons, and the arithmetic needed to compare a requested tolerance with a displayed mesh.*
2. *J is the* DyadicIntervalNet$^{\uparrow}$ *row. It lists the finite dyadic interval cells covering the named compact interval by displayed endpoint incidence.*
3. *E is the local endpoint-boundary row. It records that the first and last cells of J bracket the compact interval endpoints named through D.*
4. *S is the* StreamName$^{\uparrow}$ *window row read when a function value or endpoint name is inspected on a listed cell.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the rational values and tolerance schedule attached to those windows.*
6. *U is the finite modulus row. It records that a requested output tolerance is answered by one displayed dyadic mesh bound and by the finite cell checks listed in J.*
7. *Q is the terminal* Real$^{\uparrow}$ *seal row reached only after D, J, E, S, R, U have been displayed.*
8. *H records componentwise* hsame *transport for the displayed rows.*

9. *C records displayed* Cont *replay of the finite route*

$$D, J, E \longmapsto S, R \longmapsto U \longmapsto Q, H, P, N.$$

10. *P is the* Pkg *provenance over* CompactIntervalUniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{CompactIntervalUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, J, E, S, R, U, Q, H, C, P, N$. It has no coordinate for open-cover compactness, selected finite subcovers, real trichotomy, quotient equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CompactIntervalUniformModulusUp.CompactIntervalUniformModulusTasteGate`
`single carrier alignment`

Theorem 6207.2 (Compact interval uniform modulus obligations)**.** *For every accepted* CompactIntervalUniformMo *carrier $M = (D, J, E, S, R, U, Q, H, C, P, N)$, the local* NameCert$_{\text{CompactIntervalUniformModulus}^{\uparrow}}$ *surface is exhausted by the following finite obligations:*

1. *carrier admission for the dyadic endpoint row, dyadic interval-net row, endpoint-boundary row, StreamName window row, RegSeqRat readback row, finite modulus row, Real seal row, transport row, replay row, provenance row, and local naming row;*

2. *dyadic mesh exactness, requiring every modulus request to use a mesh width and endpoint comparison displayed in D;*

3. *finite-net coverage, requiring every interval read to pass through a listed cell of J and its endpoint incidence in E;*

4. *StreamName and RegSeqRat readback routing, requiring every inspected value to be exposed through S and then read through R before U may answer the tolerance request;*

5. *Real seal nonescape, requiring Q to be consumed only after the finite-net, readback, and modulus rows are displayed;*

6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No obligation exports open-cover compactness, selected finite subcovers, real trichotomy, quotient equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Proof. Project the carrier of Definition 6207.1. The projection exposes the dyadic arithmetic row, the finite interval-net row, the endpoint-boundary row, the StreamName and RegSeqRat rows, the finite modulus row, the Real seal row, and the structural support rows.

The mesh and coverage obligations are finite. A modulus request first selects a displayed dyadic mesh comparison from D, then checks the listed cells of J and the bracketing incidences of E. No step asks for an arbitrary open cover or a selected subcover.

The value-facing obligations are routed through finite observations. Function and endpoint reads pass through S, rational readback passes through R, and only then does U answer the requested tolerance by the displayed mesh bound.

Finally Q, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the packet has no row for quotient equality, selected limits, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking, the listed obligations exhaust the local NameCert surface. □

Theorem 6207.3 (Compact interval uniform modulus finite-net handoff)**.** *Every compact-interval uniform-continuity consumer of an accepted* $\mathsf{CompactIntervalUniformModulus}^{\uparrow}$ *carrier* $M = (D, J, E, S, R, U, Q, H, C$ *factors through the finite route*

$$D, J, E \longmapsto S, R \longmapsto U \longmapsto Q, H, C, P, N.$$

The consumer first reads dyadic endpoint and mesh arithmetic from $\mathsf{DyadicRatCore}^{\uparrow}$*, then the listed finite cells from* $\mathsf{DyadicIntervalNet}^{\uparrow}$*, then the finite windows and regular rational readback from* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, and only then reaches the* $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports a named finite modulus surface, not open-cover compactness, selected finite subcovers, real trichotomy, quotient equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.*

Proof. Start with the finite-net rows of the carrier. The rows D, J, E provide the mesh width, listed interval cells, and endpoint incidence needed by a compact-interval consumer before any value read occurs.

Next route every inspected value through S and R. The StreamName row supplies only finite windows, while the RegSeqRat row supplies the regular rational readback attached to those windows.

The modulus row U can then answer the consumer by the displayed mesh and cell checks. The answer remains a finite NameCert route because it is replayed by C, transported by H, sourced by P, and named by N before the Real seal Q is consumed.

The carrier contains no open-cover, selected-subcover, quotient, selected-limit, choice, trichotomy, completeness, Lean-verification, or bridge-checking coordinate. Thus every consumer receives exactly the finite-net handoff displayed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalUniformModulus}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{CompactIntervalUniformModulus}^{\uparrow}$ packet is generated from dyadic endpoint arithmetic, finite dyadic interval nets, endpoint bracketing, StreamName windows, RegSeqRat readback, a finite modulus row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6207.1, Definition 6207.2, and Definition 6207.3 seed the finite-net uniform-modulus carrier over dyadic endpoint arithmetic, listed interval cells, endpoint incidence, StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, real trichotomy, quotient equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh exactness, finite-net coverage, StreamName and RegSeqRat readback routing, finite modulus response, Real seal ordering, provenance, and local naming for BEDC.Derived.CompactIntervalUniformModulusUp.

Chapter 6208

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailGauge}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyTailGauge}^{\uparrow}$ packet records the finite tail-gauge row by which a regular rational Cauchy name exposes an explicit precision rate before a $\mathsf{Real}^{\uparrow}$ consumer reads the seal. It sits after the finite window route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the rate-extraction sibling of chapter 2085, and the terminal real-name seal of chapter 38. The packet names the displayed tail gauge itself; it does not assert quotient stream equality, host Cauchy completeness, selected moduli, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6208.1 (Regular Cauchy tail-gauge carrier)**.** *A* $\mathsf{RegularCauchyTailGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, R, D, G, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the inspected windows, observation indices, and point cells used by the tail request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic precision request, comparison budget, and endpoint cells used by R.*
4. *G is the explicit tail-gauge row, assigning each displayed precision request to the finite window after which the R readback is certified within the D tolerance.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, R, D, and G have been displayed.*
6. *H records componentwise* hsame *transport for windows, readbacks, tolerance rows, tail gauges, Real seals, replay rows, provenance rows, and local naming rows.*
7. *C records displayed* Cont *replay from a tail request through window inspection, regular readback, dyadic tolerance inspection, gauge selection, Real-seal consumption, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailGauge}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailGauge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, R, D, G, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host Cauchy completeness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6208.2 (Regular Cauchy tail-gauge NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailGauge}^{\uparrow}$ *carrier*

$$T = (W, R, D, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailGauge}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the explicit tail-gauge row, the* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport, displayed replay, provenance, and local naming. No tail-gauge obligation is stored outside those finite rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailGaugeUp.RegularCauchyTailGaugeTasteGate single carrier alignment`

Proof. Project the accepted carrier of Definition 6208.1. The analytic rows are W, R, D, G, E, and the structural rows are H, C, P, N.

Read the window and regular-rational rows first. The $\mathsf{StreamName}^{\uparrow}$ row fixes the finite observations available to the request, and the $\mathsf{RegSeqRat}^{\uparrow}$ row attaches the rational readback to those observations.

The dyadic ledger and gauge row then provide the tolerance accounting. The row D records the displayed precision budget, and G records the finite tail stage after which that budget is met.

Finally the seal and structural rows package the same route. Since the carrier has no coordinate for quotient streams, selected limits, host completeness, countable choice, trichotomy, or ambient Real completeness, none can become a local NameCert obligation. □

Theorem 6208.3 (Regular Cauchy tail-gauge Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyTailGauge}^{\uparrow}$ *packet must first read the finite route*

$$W \longmapsto R \longmapsto D \longmapsto G \longmapsto E$$

together with the transport, replay, provenance, and local naming rows H, C, P, N. The handoff is therefore an explicit finite tail gauge over StreamName, RegSeqRat, and DyadicRatCore data, not a host completeness argument or a selected limit.

Proof. Begin with a Real-facing read. Carrier admission exposes W before any regular rational or Real-facing row can be consumed, so the read starts from displayed finite windows.

Apply the readback and tolerance rows. The row R supplies the regular rational observation for those windows, while D supplies the dyadic precision ledger used by the request.

Now use the tail-gauge row G. It is the only row that names the finite stage at which the requested tolerance is reached, and it is stored before the Real seal E is exposed.

The rows H, C, P, N preserve and name the same dependency order. Thus the Real-facing consumer receives a finite tail-gauge route rather than quotient stream equality, a selected modulus outside the packet, or ambient Real completeness. □

Theorem 6208.4 (Regular Cauchy tail-gauge window determinacy)**.** *If two accepted* $\mathsf{RegularCauchyTailGauge}^{\uparrow}$ *packets agree componentwise on their* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows through the displayed* hsame *transport, then their explicit tail-gauge rows name the same finite tail stage for every displayed precision request before either* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Proof. Project the two accepted carriers and compare their W, R, D rows. Agreement on W fixes the finite observations, agreement on R fixes the regular rational readback, and agreement on D fixes the dyadic precision ledger.

Read the gauge row next. Since G is attached only to those displayed windows, readbacks, and tolerance rows, a matching W, R, D route leaves no second tail stage for the classifier to choose.

Finally inspect the seal boundary. The $\mathsf{Real}^{\uparrow}$ rows are downstream of G, and the structural rows transport only the displayed packet. Hence window, readback, and tolerance agreement determines the tail gauge before the Real seal is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailGauge}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6208.1, Definition 6208.2, Definition 6208.3, and Definition 6208.4 seed the finite tail-gauge route from StreamName windows through RegSeqRat readback, DyadicRatCore tolerance, explicit gauge rows, and the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailGauge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host Cauchy completeness, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback exactness, dyadic tolerance compatibility, gauge determinacy, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailGaug

Constructive story: A $\mathsf{RegularCauchyTailGauge}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, an explicit tail-gauge row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6209

A Concrete Naming Certificate for $\mathsf{PoincareDiskMetric}^{\uparrow}$

The $\mathsf{PoincareDiskMetric}^{\uparrow}$ packet realizes the displayed disk-map, metric-read, boundary, provenance, and refusal rows of chapter 9463 as finite NameCert data. It sits after the disk carrier of chapter 377, the phase-transport route of chapter 3455, the metric interface of chapter 57, the circle boundary source of chapter 58, and the terminal real-name seal of chapter 38. The packet names a metric-reading route on displayed disk rows; it is not a completed hyperbolic plane, quotient ideal boundary, selected geodesic, host analytic distance, or global compactification.

Definition 6209.1 (Poincare disk metric carrier)**.** *A* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (U, T, Q, R, S, B, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row for the finite source and target disk observations.*
2. *T is the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *route carrying disk-surface transport and phase provenance between displayed observations.*
3. *Q is the* $\mathsf{Met}^{\uparrow}$ *read row, recording the finite metric comparison requested for the displayed disk observations.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the metric readback.*
5. *S is the* $\mathsf{S}^{1\uparrow}$ *boundary row used when the metric read approaches or cites the visible boundary source.*
6. *B records boundary refusal data: no interior disk point, ideal boundary quotient, selected global endpoint, or completed hyperbolic plane is exposed by the packet.*
7. *H records componentwise* hsame *transport for disk rows, phase transport, metric reads, Real seals, boundary rows, refusal rows, replay rows, provenance rows, and local naming rows.*
8. *C records displayed* Cont *replay from a metric request through disk-coordinate inspection, phase transport, metric read, Real-seal consumption, boundary read, refusal, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{PoincareDiskMetric}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $U, T, Q, R, S, B, H, C, P, N$. It has no coordinate for a host analytic metric, a completed disk, quotient ideal-boundary equality, selected geodesics, physical horizons, or global compactification.

Theorem 6209.2 (Poincare disk metric NameCert obligations)**.** *For every accepted* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *carrier*

$$M = (U, T, Q, R, S, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareDiskMetric}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, phase-transport admission, metric-read admission, Real-seal boundary,* $\mathsf{S}^{1\uparrow}$ *boundary readback, refusal rows, componentwise transport, displayed replay, provenance, and local naming. No metric obligation is stored outside those finite rows.*

Proof. Project the accepted carrier of Definition 6209.1. The visible geometric rows are U, T, Q, R, S, B, and the structural rows are H, C, P, N.

Read disk coordinates and phase transport first. The metric row Q is available only after the displayed $\mathsf{UnitDisk}^{\uparrow}$ observations and the $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ route have been exposed.

The Real and boundary rows are downstream. The row R seals the metric read as a finite Real-facing datum, while S and B record the boundary source and the refusal of completed ideal-boundary or global-geometry data.

Transport, replay, provenance, and local naming preserve exactly that route. Since no carrier coordinate stores a host analytic metric, completed disk, quotient boundary, selected geodesic, physical horizon, or global compactification, none can become a local NameCert obligation. □

Theorem 6209.3 (Poincare disk metric transport nonescape)**.** *Every accepted* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *transport of a metric read must remain inside the displayed route*

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{PoincareDiskPhaseTransport}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow}$$

together with boundary refusal, BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows. It cannot export a completed disk, quotient ideal-boundary equality, selected global endpoint, or host analytic distance.*

Proof. Start with the transport rows H and C. They can move only the displayed disk observations, phase-transport route, metric read, Real seal, boundary row, refusal row, provenance, and local naming.

Apply carrier admission. The route reaches the metric read Q only through U and T, and reaches the Real and boundary rows only after that metric read has been displayed.

The refusal row B remains attached to the same route. Thus transported metric data cannot escape into a completed disk, quotient ideal boundary, selected endpoint, host analytic distance, or global compactification. □

Theorem 6209.4 (Poincare disk metric phase-transport handoff)**.** *Every phase-transport consumer of an accepted* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *packet receives the metric read only after the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row, the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *route, the* $\mathsf{Met}^{\uparrow}$ *comparison row, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{S}^{1\uparrow}$ *boundary row, and the refusal row have been displayed. The handoff is a finite Poincare-disk metric packet over BEDC rows, not a host-level hyperbolic metric.*

Proof. Begin with the phase-transport request. The carrier exposes the disk coordinates U and the transport route T before any metric or boundary-facing row is available.

Read the metric row next. The comparison Q is tied to those displayed disk observations, and the Real seal R records only the finite readback attached to Q.

Finally read the boundary and refusal rows. The row S supplies the visible circle boundary source, while B prevents the handoff from becoming a completed hyperbolic plane, quotient ideal boundary, selected geodesic, physical horizon, or global compactification. □

Falsifiable prediction: An accepted $\mathsf{PoincareDiskMetric}^{\uparrow}$ read is refuted if a metric consumer obtains a completed disk, quotient ideal-boundary equality, selected global endpoint, host analytic distance, or global compactification without displaying UnitDisk coordinates, PoincareDiskPhase-Transport routing, Metric rows, Real seals, SOne boundary rows, boundary refusal, transport, replay, provenance, and local naming.

Independence witness: unitdisk, poincare-disk-phase-transport, metric, s1: no listed sibling is bijective to $\mathsf{PoincareDiskMetric}^{\uparrow}$ because this packet jointly carries disk coordinates, phase transport, metric reads, Real seals, circle-boundary rows, refusal data, transport, replay, provenance, and local naming as one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDiskMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6209.1, Definition 6209.2, Definition 6209.3, and Definition 6209.4 seed the finite Poincare disk metric route over UnitDisk, PoincareDiskPhaseTransport, Metric, Real, SOne, refusal, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDiskMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a completed hyperbolic plane, quotient ideal-boundary equality, selected geodesics, host analytic distance, physical horizon data, global compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-coordinate admission, phase-transport admission, metric-read exactness, Real-seal handoff, boundary refusal, transport, replay, provenance, and local naming for BEDC.Derived.PoincareDiskMetricUp.

Constructive story: A $\mathsf{PoincareDiskMetric}^{\uparrow}$ packet is generated from UnitDisk coordinates, PoincareDiskPhaseTransport rows, Metric readbacks, RealUp seals, SOne boundary rows, boundary-refusal data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6210

A Concrete Naming Certificate for $\mathsf{UniformPolygonalApproximation}^{\uparrow}$

Following Bishop–Bridges constructive approximation theory, the $\mathsf{UniformPolygonalApproximation}^{\uparrow}$ packet records the finite mesh-level certificate by which a displayed uniformly continuous map on a closed bounded interval is read through polygonal data. It sits after the interval source of chapter 1591, the mesh surfaces of chapter 1863 and chapter 2033, the affine-cell carrier of chapter 3906, the located-modulus handoff of chapter 1859, the continuous-map boundary of chapter 130, the terminal real-name seal of chapter 38, and the dyadic tolerance ledger of chapter 291. The chapter names a finite uniform approximation route; it does not assert open-cover compactness, choose a limit polygonal sequence, identify host functions by quotient equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6210.1 (Uniform polygonal approximation carrier)**.** *A* $\mathsf{UniformPolygonalApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, M, L, Q, F, R, D, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, displaying the endpoint real names and the bounded interval window on which the approximation is read.*
2. *M is a* $\mathsf{DyadicPartition}^{\uparrow}$ *or* $\mathsf{UniformPartition}^{\uparrow}$ *mesh row, including the ordered boundary ledger, endpoint-coverage route, and positive mesh-width evidence.*
3. *L is the* $\mathsf{PiecewiseLinearApproximation}^{\uparrow}$ *polygonal row whose affine cells, endpoint values, and local slope ledger are read over the mesh M.*
4. *Q is the* $\mathsf{LocatedUniformContinuity}^{\uparrow}$ *modulus row, exposing a located tolerance-to-mesh request for the same interval source and displayed map.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose graph and pointwise continuity data are consumed only through I, M, Q, L.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint and value-readback row reached after the mesh, modulus, and polygonal rows have been displayed.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic request, mesh bound, cell-width comparison, and uniform error budget used by downstream consumers.*

8. *H records componentwise* hsame *transport for the interval source, mesh, polygonal row, located modulus, continuous-map handoff, real readbacks, dyadic ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$I, M, Q, L, D \longmapsto F, R \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* UniformPolygonalApproximation$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, DyadicPartition$^{\uparrow}$, UniformPartition$^{\uparrow}$, PiecewiseLinearApproximation$^{\uparrow}$, LocatedUniformContinuity$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Real$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{UniformPolygonalApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, L, Q, F, R, D, H, C, P, N$ and their displayed transports. It has no coordinate for open-cover compactness, selected limiting polygonal sequence, host function graph, quotient equality of maps, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformPolygonalApproximationUp.UniformPolygonalApproximationTasteGate`
`single carrier alignment`

Theorem 6210.2 (Uniform polygonal approximation NameCert obligations)**.** *For every accepted* UniformPolygonalApproximation$^{\uparrow}$ *carrier*

$$U = (I, M, L, Q, F, R, D, H, C, P, N),$$

the local NameCert$_{\text{UniformPolygonalApproximation}^{\uparrow}}$ *surface consists exactly of interval-source admission through I, mesh coverage through M, polygonal-cell admission through L, located modulus exposure through Q, continuous-map handoff through F, real readback through R, dyadic tolerance accounting through D, componentwise transport through H, replay through C, provenance through P, and local naming through N. No local obligation may read open-cover compactness, a selected limiting polygonal sequence, host function equality, quotient map equality, countable choice, or ambient real completeness.*

Proof. Project the accepted carrier of Definition 6210.1. The displayed analytic rows are precisely the closed bounded interval I, mesh M, piecewise-linear row L, located modulus Q, continuous-map handoff F, real readback R, and dyadic ledger D.

The mesh and modulus rows determine the finite approximation request. The row M supplies the visible cells, while Q supplies the located uniform-continuity budget that makes the requested mesh adequate for the same interval and continuous map.

The polygonal row L and dyadic ledger D then exhaust the approximation data. They record endpoint values, affine-cell interpolation, cell-width comparisons, and the error budget before F or R is public.

Finally H, C, P, N transport, replay, source, and name this same packet. Since no further carrier coordinate remains, the excluded compactness, limit-selection, quotient, choice, host-function, and completeness objects cannot become local NameCert obligations. □

Theorem 6210.3 (Uniform polygonal approximation mesh handoff)**.** *Every* PiecewiseLinearApproximation$^{\uparrow}$, LocatedUniformContinuity$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Real$^{\uparrow}$, *or* DyadicRatCore$^{\uparrow}$ *consumer of an accepted* UniformPolygonalApproximation$^{\uparrow}$ *carrier receives only the finite route*

ClosedBoundedInterval$^{\uparrow}$, DyadicPartition$^{\uparrow}$ or UniformPartition$^{\uparrow}$, LocatedUniformContinuity$^{\uparrow}$, PiecewiseLinearApproxim

Thus the consumer may read a uniform error budget over the displayed mesh, but it cannot replace that handoff by an open-cover compactness theorem, a selected polygonal limit, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the mesh row M and the interval source I. They display the finite cell boundary ledger and endpoint coverage over the closed bounded interval.

Read the located modulus row Q next. It connects the requested tolerance to a mesh-width bound for the same displayed continuous map, so the approximation request is routed through finite modulus data rather than through open-cover compactness.

The piecewise-linear row L and dyadic ledger D provide the polygonal handoff. They expose affine cells, endpoint-value rows, slope bounds, and error accounting before the continuous-map and real readback rows are visible.

The structural rows H, C, P, N preserve the same route for every downstream consumer. Any read that omits M, Q, L, or D would use a coordinate absent from the carrier, so it is not a read of the accepted packet. □

Theorem 6210.4 (Uniform polygonal approximation nonescape)**.** *Let* $U = (I, M, L, Q, F, R, D, H, C, P, N)$ *be an accepted* $\mathsf{UniformPolygonalApproximation}^{\uparrow}$ *carrier. Every real-facing or continuous-map-facing read from* U *factors through the displayed mesh* M*, located modulus* Q*, polygonal row* L*, and dyadic tolerance ledger* D *before it reaches* F *or* R*. Consequently the packet exports no ambient real completeness, selected uniform limit, quotient function equality, open-cover compactness, countable-choice schedule, or host function-space equality.*

Proof. The carrier lists F and R only after the mesh, modulus, polygonal, and dyadic rows. A continuous-map or real-facing consumer therefore cannot inspect those terminal rows before the finite approximation evidence has been displayed.

The located modulus row Q is tied to the same interval source and continuous-map handoff as L. It supplies the requested mesh adequacy inside the packet, not an external compactness theorem.

The dyadic row D records the numerical tolerance and cell-width comparison used by the handoff. Thus every error claim exposed to F or R is a finite dyadic readback from the carrier.

Transport, replay, provenance, and local naming do not add analytic data. They keep the read inside $I, M, L, Q, F, R, D, H, C, P, N$, so the excluded limit, quotient, choice, host-function, compactness, and completeness surfaces remain outside the certificate. □

Theorem 6210.5 (Uniform polygonal approximation mesh refinement)**.** *Let* $U = (I, M, L, Q, F, R, D, H, C, P, N)$ *be an accepted* $\mathsf{UniformPolygonalApproximation}^{\uparrow}$ *packet. If the packet is reread on a dyadic mesh* M' *refining* M *and satisfying the same located modulus row* Q *at the requested tolerance, then the refined polygonal row* L' *and dyadic ledger* D' *remain inside the route*

$$I, M, Q, L, D \to F, R \to H, P, N$$

and preserve the same finite approximation handoff to $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the mesh row M and the located modulus row Q. The refined mesh M' is accepted only as a refinement of the displayed cell ledger and only at a tolerance admitted by the same located modulus request.

Use the dyadic comparison ledger to relate the cell widths of M' to those of M. The refined dyadic row D' is therefore a replay of the packet's finite error accounting, not a separate compactness or choice argument.

Replay the piecewise-linear row over the refined mesh. The resulting L' supplies affine-cell data over the smaller cells while remaining tied to the original interval source I, modulus row Q, and continuous-map handoff F.

Finally apply Definition 6210.4. It blocks selected polygonal limits, quotient map equality, choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness, so the refined read preserves the finite approximation route. □

Falsifiable prediction: A $\mathsf{UniformPolygonalApproximation}^{\uparrow}$ consumer that reaches $\mathsf{ContinuousMap}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ approximation data without displaying the mesh row M, located modulus row Q, polygonal row L, and dyadic tolerance row D refutes the carrier surface.

Independence witness: Nearest siblings: closedboundedinterval, dyadic-partition, uniform-partition, piecewise-linear-approximation, located-uniform-continuity, continuousmap, real, dyadicratcore. Those chapters supply interval, mesh, affine-cell, modulus, map, real-readback, and dyadic-tolerance rows separately; this chapter binds them into the single eleven-row finite uniform approximation route $U = (I, M, L, Q, F, R, D, H, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformPolygonalApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformPolygonalApproximation}^{\uparrow}$ packet is generated from a ClosedBoundedInterval source row, a DyadicPartition or UniformPartition mesh row, a PiecewiseLinearApproximation polygonal row, a LocatedUniformContinuity modulus row, a ContinuousMap handoff row, RealUp readback rows, a DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformPolygonalApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6210.1, Definition 6210.2, Definition 6210.3, and Definition 6210.4 seed the finite uniform polygonal approximation route over interval, mesh, polygonal, located-modulus, continuous-map, real-readback, dyadic-ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformPolygonalApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected uniform limits, quotient function equality, countable choice, host function spaces, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh coverage, polygonal-cell admission, located modulus exposure, continuous-map handoff, real readback, dyadic tolerance accounting, transport, replay, provenance, and local naming for BEDC.Derived.UniformPolygonalApproximationUp.

Chapter 6211

A Concrete Naming Certificate for $\mathsf{ItoIntegral}^{\uparrow}$

Following Ito and standard constructive stochastic-integration presentations, the $\mathsf{ItoIntegral}^{\uparrow}$ packet records the finite adapted-step surface by which a Brownian cell-difference row calculation may be named before any host measure completion, almost-sure quotient, or selected limiting integral is invoked. It sits over the probability-space rows of $\mathsf{ProbSpace}^{\uparrow}$ in chapter 184, the random-variable rows of $\mathsf{RandomVar}^{\uparrow}$ in chapter 185, the adapted-sequence ledger of $\mathsf{Martingale}^{\uparrow}$ in chapter 190, and the finite Brownian prefix rows of $\mathsf{Brownian}^{\uparrow}$ in chapter 191. The certificate names only displayed partitions, step integrand values, Brownian cell-difference rows, finite sums, martingale transport, replay, provenance, and local naming rows.

Definition 6211.1 (ItoIntegral carrier)**.** *An* $\mathsf{ItoIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (\Omega, X, B, \Pi, A, \Delta, S, M, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row on which all probability-facing data are read.*
2. X *is a finite family of adapted step-integrand* $\mathsf{RandomVar}^{\uparrow}$ *rows over the displayed filtration schedule.*
3. B *is the* $\mathsf{Brownian}^{\uparrow}$ *finite-prefix row whose adjacent Brownian cell-difference rows are available on the same schedule.*
4. Π *is a rational partition row, with each cell endpoint named through the rational and dyadic-rational ledger already visible to the packet.*
5. A *records adaptedness of each step-integrand value before the matching Brownian cell-difference row is consumed.*
6. Δ *records the Brownian cell-difference rows associated to the cells of* Π.
7. S *is the finite sum row pairing each adapted step value with its displayed Brownian cell-difference row.*
8. M *is the martingale transport row exposing the finite martingale comparison for the step-integral sums.*
9. H *records componentwise* hsame *transport for the probability, random-variable, Brownian, partition, adaptedness, cell-difference, finite-sum, and martingale rows.*

10. *C is the displayed* Cont *replay row for the same finite packet.*

11. *P is the* Pkg *provenance over* ItoIntegral$^{\uparrow}$, ProbSpace$^{\uparrow}$, RandomVar$^{\uparrow}$, Martingale$^{\uparrow}$, Brownian$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ItoIntegral}^{\uparrow}}$ *row.*

The carrier exports no host stochastic process equality, no almost-sure quotient, no selected refining partition, no measure-theoretic completion, no L^2 completion theorem, and no ambient stochastic-integral object beyond the displayed finite sum route.

Theorem 6211.2 (ItoIntegral NameCert obligations)**.** *For every accepted* ItoIntegral$^{\uparrow}$ *carrier $I = (\Omega, X, B, \Pi, A, \Delta, S, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ItoIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission through Ω, X, B, Π, adapted finite step exposure through A, Brownian cell-difference row exposure through Δ, finite-sum exposure through S, martingale transport through M, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Any consumer of the packet must read the integrand value, the matching Brownian cell-difference row, and the finite sum row before it can inspect the martingale transport row. The packet therefore names the finite Ito step integral route, not a completed stochastic integral in an ambient measure model.

Lean4 ✓ `BEDC.Derived.ItoIntegralUp.ItoIntegralTasteGate single carrier alignment`

Proof. Project the carrier of Definition 6211.1. Its only probability-facing source is Ω, its only integrand rows are the adapted step rows X, A, and its only Brownian data are the finite-prefix and cell-difference rows B, Δ.

The finite sum row S is indexed by the same rational partition Π. Each summand pairs one adapted step value with the Brownian cell-difference row displayed on that partition cell, so the certificate cannot replace the visible step sum by a selected limiting partition or a host stochastic-integral object.

The martingale-facing read is mediated by M. Since M is transported through H and replayed through C inside the same provenance row P, it preserves the finite sum route already named by S rather than adding an almost-sure quotient, measure completion, L^2 completion, or ambient Brownian path equality.

Thus the NameCert obligations are exactly the listed carrier, adaptedness, cell-difference, finite-sum, martingale-transport, replay, provenance, and naming rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{ItoIntegral}^{\uparrow}}$**.**

Constructive story: An ItoIntegral$^{\uparrow}$ packet is generated from a ProbSpaceUp source row, adapted finite-step RandomVarUp integrand rows, BrownianUp finite-prefix cell-difference rows, rational partition rows, finite sums, martingale transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ItoIntegral}^{\uparrow}}$, seed)

Scope closed: Definition 6211.1 and Definition 6211.2 seed the finite adapted-step Ito integral NameCert route over ProbSpaceUp, RandomVarUp, MartingaleUp, BrownianUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ItoIntegral}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host stochastic process equality, almost-sure quotients, selected refining partitions, measure completion, L2 completion, Lean verification, standard bridges, or an ambient stochastic-integral object.

Upgrade path: Obligation closure requires checked carrier admission, adapted finite-step exposure, Brownian cell-difference row exposure, rational partition accountability, finite-sum exactness, martingale transport, replay, provenance, and local naming for BEDC.Derived.ItoIntegralUp.

Chapter 6212

A Concrete Naming Certificate for $\mathsf{ItoIsometry}^{\uparrow}$

Following Ito's stochastic-integration isometry and standard martingale Hilbert-space treatments, the $\mathsf{ItoIsometry}^{\uparrow}$ packet records the finite L^2 stability surface by which simple adapted stochastic-integral rows compare their squared norm ledger with the quadratic-variation ledger of the driving Brownian cell differences. It sits downstream of the finite adapted-step integral route of chapter 6211, the probability and Brownian rows of chapter 184 and chapter 191, the martingale ledger of chapter 190, and the Hilbert and norm-facing rows of chapter 91 and chapter 89. The packet names only finite simple-process rows, Brownian cell-difference rows, quadratic-variation comparisons, L^2 norm comparisons, transport, replay, provenance, and local naming; it does not build a completed stochastic-integral space.

Definition 6212.1 (ItoIsometry carrier)**.** *An* $\mathsf{ItoIsometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (\Omega, I, X, B, \Delta, V, L, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row on which the probability-facing readback is interpreted.*
2. I *is the consumed* $\mathsf{ItoIntegral}^{\uparrow}$ *simple adapted-step integral packet.*
3. X *is the finite simple adapted-process row, indexed by the same displayed partition and filtration windows as* I*.*
4. B *is the* $\mathsf{Brownian}^{\uparrow}$ *finite-prefix source row exposing the Brownian cell-difference schedule.*
5. Δ *is the Brownian cell-difference row aligned with the simple-process cells.*
6. V *is the quadratic-variation ledger for the displayed Brownian cell differences and step-process coefficients.*
7. L *is the* L^2 *norm-comparison row, read through the* $\mathsf{Hilbert}^{\uparrow}$ *and* $\mathsf{Norm}^{\uparrow}$ *sibling surfaces, that compares the finite integral-sum norm ledger with* V*.*
8. H *records componentwise* hsame *transport for the source, integral, simple-process, Brownian, cell-difference, quadratic-variation, and norm-comparison rows.*
9. C *is the displayed* Cont *replay row for the same finite packet.*

10. *P is the* Pkg *provenance over* $\mathsf{ItoIsometry}^{\uparrow}$, $\mathsf{ItoIntegral}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Brownian}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ItoIsometry}^{\uparrow}}$ *row.*

The carrier exports no selected refining partition, no almost-sure quotient, no completed L^2 space, no ambient stochastic-integral operator, and no measure-completion theorem.

Theorem 6212.2 (ItoIsometry NameCert obligations)**.** *For every accepted* $\mathsf{ItoIsometry}^{\uparrow}$ *carrier* $Q = (\Omega, I, X, B, \Delta, V, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ItoIsometry}^{\uparrow}}$ *surface consists exactly of probability-source exposure through Ω, simple-integral exposure through I, simple adapted-process exposure through X, Brownian source and cell-difference exposure through B, Δ, quadratic-variation ledger exposure through V, finite L^2 norm-comparison exposure through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6212.1. The source, integral, simple-process, and Brownian rows are displayed before any norm comparison can be read.

The quadratic-variation row V and norm-comparison row L are tied to the same finite partition and cell-difference schedule. Thus the certificate compares the visible simple integral sum with the visible quadratic-variation ledger, not with a selected completed stochastic integral.

Transport, replay, provenance, and local naming preserve that packet rowwise. Since the carrier has no coordinate for almost-sure quotienting, measure completion, selected refinement, or completed L^2 operator theory, the listed rows exhaust the local NameCert surface. □

Theorem 6212.3 (ItoIsometry finite L2 stability)**.** *Every accepted* $\mathsf{ItoIsometry}^{\uparrow}$ *consumer that reads a finite L^2 stability claim must preserve the simple adapted-process row X, Brownian cell-difference row Δ, quadratic-variation ledger V, and norm-comparison row L as one displayed packet over the consumed* $\mathsf{ItoIntegral}^{\uparrow}$ *row I. It cannot replace the finite comparison by a host L^2 completion, a selected limiting integral, or a quotient equality of stochastic processes.*

Proof. Use the NameCert obligations of Definition 6212.2. They make X, Δ, V, L public only as rows of the same accepted packet over I.

The martingale and Hilbert-facing dependencies are provenance rows, not hidden completions. They allow the finite norm comparison to be consumed through the displayed sibling surfaces while keeping the Brownian cell-difference and quadratic-variation ledgers visible.

Therefore a stability read that changes X, Δ, V, or L leaves the carrier. No completed L^2 space, selected limiting integral, or quotient process equality is available from transport, replay, provenance, or local naming. □

Theorem 6212.4 (ItoIsometry nonescape)**.** *Every* $\mathsf{ItoIsometry}^{\uparrow}$ *consumer factors through*

$$\Omega, I, X, B, \Delta, V, L, H, C, P, N.$$

In particular, stochastic-integral stability can be consumed only as the finite simple-process and Brownian cell-difference comparison named by the packet; it cannot escape to an ambient probability completion, host Hilbert-space completion, almost-sure quotient, selected refinement sequence, or unlogged martingale theorem.

Proof. Start with the carrier inventory. Each accepted packet displays exactly the probability source, ItoIntegral dependency, simple adapted-process row, Brownian source, cell-difference row, quadratic-variation ledger, norm-comparison row, transport, replay, provenance, and local name.

The sibling references to $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Brownian}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, and $\mathsf{Norm}^{\uparrow}$ are consumed through P and the displayed rows. They do not add a coordinate for completed probability spaces, completed Hilbert spaces, almost-sure quotients, selected refinements, or detached martingale theorems.

Thus any consumer of the isometry surface must preserve the listed finite rows. A read that requires an ambient completion or quotient equality is outside the $\mathsf{ItoIsometry}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ItoIsometry}^{\uparrow}}$.

Constructive story: An $\mathsf{ItoIsometry}^{\uparrow}$ packet is generated from a ProbSpaceUp source row, consumed ItoIntegralUp simple adapted-step integral row, simple adapted-process row, BrownianUp finite-prefix and cell-difference rows, quadratic-variation ledger, finite L2 norm-comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ItoIsometry}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6212.1, Definition 6212.2, Definition 6212.3, and Definition 6212.4 seed the finite L2-stability route for simple adapted stochastic-integral rows over ItoIntegralUp, ProbSpaceUp, BrownianUp, MartingaleUp, HilbertUp, NormUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ItoIsometry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed stochastic-integral construction, almost-sure quotients, selected refining partitions, measure completion, host Hilbert-space completion, Lean verification, axiom-clean audit, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, simple adapted-process exposure, Brownian cell-difference exposure, quadratic-variation accounting, finite L2 norm comparison, transport, replay, provenance, and local naming for BEDC.Derived.ItoIsometryUp.

Chapter 6213

A Concrete Naming Certificate for $\mathsf{MaximumModulusPrinciple}^{\uparrow}$

Following Ahlfors and Conway on the maximum-modulus principle for holomorphic functions, the $\mathsf{MaximumModulusPrinciple}^{\uparrow}$ packet records the boundary-maximum route as finite NameCert data. It consumes the complex carrier of chapter 39, the holomorphic source rows of chapter 68, the circle-boundary surface of chapter 58, the terminal real-name seal of chapter 38, and the three-circle annulus ledger of chapter 3892. The packet names a displayed boundary upper-bound certificate; it is not an ambient supremum theorem, a selected maximizer, analytic continuation beyond the named domain, quotient function equality, or a bridge certificate.

Definition 6213.1 (Maximum-modulus principle carrier)**.** *A* $\mathsf{MaximumModulusPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, F, B, R, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the named complex domain or annulus row, read through* $\mathsf{Complex}^{\uparrow}$ *and the relevant boundary carrier.*
2. *F is the* $\mathsf{Holomorphic}^{\uparrow}$ *map row over D, with values in the same* $\mathsf{Complex}^{\uparrow}$ *carrier.*
3. *B is the finite boundary-read ledger, using* $\mathsf{S}^{1\uparrow}$ *or an equivalent displayed boundary source to expose the inspected boundary probes.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *modulus-read row for the boundary and interior comparison values.*
5. *U is the boundary upper-bound row, recording the displayed maximum-modulus inequality available to downstream consumers.*
6. *H stores componentwise* hsame *transport for the domain, holomorphic map, boundary reads, modulus reads, upper-bound row, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a maximum-modulus request through D, F, B, R, U, H.*
8. *P is the* Pkg *provenance over* $\mathsf{MaximumModulusPrinciple}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HadamardThreeCircle}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *dependency rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MaximumModulusPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. No coordinate stores a host compactness theorem, selected boundary point, ambient supremum, quotient function equality, analytic continuation outside D, or countable-choice schedule.

Lean4 ✓ BEDC.Derived.MaximumModulusPrincipleUp.MaximumModulusPrincipleTasteGate single carrier alignment

Theorem 6213.2 (Maximum-modulus principle NameCert obligations)**.** *For every accepted* MaximumModulusPrin *carrier* $M = (D, F, B, R, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MaximumModulusPrinciple}^{\uparrow}}$ *surface consists exactly of domain admission, holomorphic-map exposure, boundary-read visibility, real modulus readback, boundary upper-bound compatibility, componentwise transport, displayed replay, package provenance, and local naming. A consumer may not read a maximum-modulus bound until these rows are displayed, and the certificate does not export an ambient supremum theorem, selected maximizer, quotient function equality, analytic continuation, or countable choice.*

Proof. Project the carrier of Definition 6213.1. The domain row D and holomorphic row F fix the complex source before any boundary comparison is available.

The boundary and modulus data are then read in order. The row B exposes only the finite boundary probes, while R turns the inspected values into $\mathsf{Real}^{\uparrow}$ modulus rows. The upper-bound row U is therefore attached to the displayed boundary ledger rather than to an external supremum.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of these rows adds a selected boundary point, host compactness proof, analytic continuation coordinate, quotient equality, or countable-choice schedule, the listed obligations exhaust the NameCert surface. □

Theorem 6213.3 (Maximum-modulus principle Hadamard boundary handoff)**.** *Every* $\mathsf{HadamardThreeCircle}^{\uparrow}$ *or holomorphic-boundary consumer that reads an accepted* $\mathsf{MaximumModulusPrinciple}^{\uparrow}$ *packet receives the displayed route*

$$\mathsf{Complex}^{\uparrow} \longmapsto \mathsf{Holomorphic}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{MaximumModulusPrinciple}^{\uparrow}$$

together with the rows $D, F, B, R, U, H, C, P, N$*. When the consumer is an annulus packet, the boundary read may be handed to Definition 3892.3; the handoff preserves the same finite boundary ledger and does not add selected maximizers, host analytic continuation, quotient equality, or an ambient maximum theorem.*

Proof. Start with the holomorphic source rows D and F. They determine the complex carrier and displayed map row that any boundary consumer is allowed to inspect.

Next read the boundary ledger B and the modulus row R. These rows expose the finite boundary probes and real modulus comparisons before U can be consumed as an upper-bound row.

For an annulus consumer, use Definition 3892.3. The Hadamard packet receives exactly the displayed boundary maximum row already attached to B, R, U, so the three-circle ledger is a downstream read of the same finite data.

The structural rows H, C, P, N keep the handoff inside the NameCert route. No row supplies a selected extremal point, an ambient supremum proof, analytic continuation beyond the named source, quotient equality, or countable choice. □

Falsifiable prediction: An accepted $\mathsf{MaximumModulusPrinciple}^{\uparrow}$ read is refuted if the boundary upper-bound row U is preserved while the displayed domain D, holomorphic map row F, boundary ledger B, and Real modulus row R are removed.

Independence witness: complex, holomorphic, sone, real, hadamard-three-circle: none is bijective with $\mathsf{MaximumModulusPrinciple}^{\uparrow}$ because this packet jointly carries a complex source, holomorphic map row, finite boundary ledger, Real modulus readback, boundary upper-bound row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MaximumModulusPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{MaximumModulusPrinciple}^{\uparrow}$ packet is generated from a displayed complex source, a holomorphic map row, finite boundary probes, Real modulus reads, a boundary upper-bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MaximumModulusPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6213.1, Definition 6213.2, and Definition 6213.3 seed the finite boundary-maximum route for holomorphic NameCert consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MaximumModulusPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an ambient maximum theorem, selected extremal points, analytic continuation beyond the named source, quotient function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked domain admission, holomorphic-map exposure, boundary-read visibility, Real modulus readback, boundary upper-bound compatibility, transport, replay, provenance, and local naming for BEDC.Derived.MaximumModulusPrincipleUp.

Chapter 6214

A Concrete Naming Certificate for $\mathsf{UniversalCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completion, the $\mathsf{UniversalCauchyCompletion}^{\uparrow}$ packet records the universal-property boundary of a Cauchy completion as finite NameCert data. It sits between the Cauchy-filter carrier of chapter 1569, the universal extension surface of chapter 2319, the metric completion route of chapter 1506, the separated boundary of chapter 1612, and the displayed readback chain through chapter 126, chapter 301, and chapter 38. The packet gives downstream completion chapters one named carrier for dense extension and uniqueness without importing quotient completion equality, selected representatives, countable choice, or ambient Real completeness.

Definition 6214.1 (Universal Cauchy completion carrier)**.** *A* $\mathsf{UniversalCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, E, Q, Z, W, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric and Cauchy packet row, naming the metric source, its displayed Cauchy evidence, and the finite tolerance requests read by the completion construction.*
2. *D is the dense embedding row from the source carrier into the completion-facing carrier.*
3. *E is the extension-arrow row, carrying the displayed continuous arrow out of the completed carrier into a separated target.*
4. *Q is the uniqueness row, recording that two accepted extension arrows with the same source action are identified by the stored NameCert route rather than by quotient equality.*
5. *Z is the separated-reflection row, exposing the separated target boundary before uniqueness is read.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and extension data at the displayed tolerance.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows.*
8. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the StreamName windows and RegSeqRat readback are visible.*
9. *H records componentwise* hsame *transport for the source, embedding, extension, uniqueness, separated-reflection, window, readback, real-seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from a source tolerance request through the dense embedding, extension arrow, separated boundary, finite windows, regular rational readback, and real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{UniversalCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, CauchyCompletionUniversalI MetricCompletion$^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniversalCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, selected limits, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniversalCauchyCompletionUp.UniversalCauchyCompletionTasteGate single carrier alignment`

Theorem 6214.2 (Universal Cauchy completion NameCert obligations)**.** *For every accepted* UniversalCauchyCompl *carrier $U = (S, D, E, Q, Z, W, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniversalCauchyCompletion}^{\uparrow}}$ *surface consists exactly of source metric and Cauchy admission, dense embedding admission, extension-arrow admission, uniqueness-row admission, separated-reflection admission, StreamName finite-window admission, RegSeqRat readback, Real seal admission, componentwise transport, displayed replay, provenance, and local naming for the displayed rows $S, D, E, Q, Z, W, R, L, H, C, P, N$.*

Proof. Project the accepted carrier of Definition 6214.1. The analytic rows are the source metric and Cauchy row S, the dense embedding D, the extension arrow E, the uniqueness row Q, the separated-reflection boundary Z, the finite windows W, the regular rational readback R, and the terminal real seal L.

The certificate reads these rows in order. A completion-facing request first sees the source and dense embedding, then the extension arrow into the separated boundary, then the finite windows and regular rational readback used by the real-facing seal.

The rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no quotient equality, selected representative, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate, the listed rows exhaust the local naming obligations. □

Theorem 6214.3 (Universal Cauchy completion density route)**.** *Every density-facing read of an accepted* $\mathsf{UniversalCauchyCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyFilterCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More explicitly, the consumer reads the source metric and Cauchy packet S, the dense embedding D, the StreamName windows W, the RegSeqRat readback R, and finally the Real seal L, with H, C, P, N preserving the same route. The route supplies a density handoff for $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{SeparatedCompletion}^{\uparrow}$ *consumers without quotient completion equality, selected representatives, selected limits, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the obligation surface of Definition 6214.2. It exposes the source metric and Cauchy packet before any dense embedding or completion-facing read is available.

The dense embedding row then fixes the route from source observations to completion observations. The StreamName row supplies finite windows, and the RegSeqRat row repacks those windows as regular rational readback before the terminal Real seal is visible.

Transport, replay, provenance, and local naming keep the same packet throughout the route. Thus a density-facing consumer can cite the completion route only through $S, D, W, R, L, H, C, P, N$, and no excluded host-side datum is introduced. □

Theorem 6214.4 (Universal Cauchy completion extension uniqueness)**.** *Let $U = (S, D, E, Q, Z, W, R, L, H, C, P, N$ be an accepted* $\mathsf{UniversalCauchyCompletion}^{\uparrow}$ *carrier. Any two accepted extension-arrow reads over the same source action and the same separated target boundary are forced through the stored uniqueness row Q, after first exposing the dense embedding D, separated-reflection row Z, StreamName windows W, RegSeqRat readback R, Real seal L, and structural rows H, C, P, N. The conclusion is an equality of accepted NameCert routes, not a quotient equality of completed points or a selected representative.*

Proof. Expose the two extension-arrow reads through the carrier of Definition 6214.1. The shared source action is read through S and the dense embedding row D, while the common separated target boundary is read through Z.

The uniqueness row Q is only available after these rows have been displayed. Its replay uses the same finite windows W, the same regular rational readback R, and the same Real seal L for both extension arrows.

Finally H, C, P, N transport and name the comparison as an accepted route comparison. Because the carrier contains no quotient equality of completed points, selected representative, selected limit, host equality, countable-choice selector, or ambient completeness coordinate, the conclusion is exactly the displayed route uniqueness. □

Falsifiable prediction: A $\mathsf{UniversalCauchyCompletion}^{\uparrow}$ consumer that exports quotient completion equality, a selected representative, a selected limit, a countable-choice schedule, host equality of completed points, or ambient Real completeness after deleting D, Q, W, or R refutes the carrier of Definition 6214.1.

Independence witness: Nearest siblings: CauchyFilterCompletion, CauchyCompletionUniversalProperty, MetricCompletion, SeparatedCompletion, StreamName, RegSeqRat, and Real. UniversalCauchyCompl is not bijective to any one of them because it jointly carries source Cauchy data, dense embedding, extension arrow, uniqueness row, separated reflection, finite windows, regular readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniversalCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniversalCauchyCompletion}^{\uparrow}$ packet is generated from source metric and Cauchy rows, dense embedding rows, extension-arrow rows, uniqueness rows, separated-reflection rows, StreamName windows, RegSeqRat readbacks, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniversalCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6214.1, Definition 6214.2, Definition 6214.3, and Definition 6214.4 seed the finite universal-property route from source Cauchy data to dense extension uniqueness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniversalCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient completion equality, selected representatives, selected limits, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense embedding exactness, extension-arrow replay, uniqueness-row nonescape, separated-reflection routing, StreamName window replay, RegSeqRat readback, Real seal admission, transport, replay, provenance, and local naming for BEDC.Derived.UniversalCauchyCompletionUp.

Chapter 6215

A Concrete Naming Certificate for $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$

Following Minty and Browder, the $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$ packet records the finite certificate surface for a monotone operator argument in Hilbert and functional-analysis settings. It reads the Hilbert carrier of chapter 91, the functional-analysis ledger of chapter 94, the weak derivative boundary of chapter 2210, the PDE-facing route of chapter 194, and the operator-ideal dependency of chapter 213. The packet names only the displayed monotone-operator and resolvent ledger rows; it does not assert host maximality, selected weak limits, spectral calculus, or ambient Hilbert-space compactness.

Definition 6215.1 (Minty–Browder monotone-operator carrier)**.** *A* $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, A, G, R, W, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Hilbert}^{\uparrow}$ *source row, including the inner-product, norm, and metric rows inspected by the monotonicity test.*
2. *A is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *operator row carrying the displayed graph schedule, domain window, and action ledger.*
3. *G is the monotone graph row, listing the inspected pairs and the nonnegative pairing comparisons.*
4. *R is the resolvent ledger, recording the finite approximation route for the equation carried by $I + \lambda A$ at displayed positive rational parameters.*
5. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *compatibility row used when the same graph is read by weak-form PDE consumers.*
6. *D is the* $\mathsf{Pde}^{\uparrow}$ *boundary row that records forcing terms, weak test windows, and coercive estimate requests consumed downstream.*
7. *H stores componentwise* hsame *transport for Hilbert, operator, graph, resolvent, weak-derivative, PDE, replay, provenance, and naming rows.*
8. *C stores displayed* Cont *replay from Hilbert source data through the monotone graph and resolvent ledger to the PDE-facing rows.*

9. *P is the* Pkg *provenance over* $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{OperatorIdeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, G, R, W, D, H, C, P, N$. It has no coordinate for a host-level maximal-monotone principle, choice-selected solution, quotient graph equality, spectral theorem, or compactness theorem.

Theorem 6215.2 (Minty–Browder monotone-operator NameCert obligations)**.** *For every accepted* $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$ *carrier $M = (X, A, G, R, W, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MintyBrowderMonotone}}$ *surface consists exactly of carrier admission for the displayed Hilbert source row, functional-analysis operator row, monotone graph row, resolvent ledger, weak-derivative compatibility row, PDE boundary row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.MintyBrowderMonotoneOperatorUp.MintyBrowderMonotoneOperatorTasteGate`
`single carrier alignment`

Proof. Project the carrier of Definition 6215.1. The analytic data are exactly the Hilbert row X, the operator row A, the monotone graph row G, the resolvent ledger R, and the weak-form rows W, D.

The monotone graph and resolvent obligations are read before any PDE-facing consumer receives the packet. Thus the weak-derivative and forcing rows are downstream of the displayed graph comparisons and resolvent approximations, not independent host principles.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since no other coordinate occurs in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 6215.3 (Minty–Browder resolvent ledger)**.** *Every* $\mathsf{Pde}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, *or* $\mathsf{OperatorIdeal}^{\uparrow}$ *consumer of an accepted* $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$ *packet reads the monotone-operator witness only through the finite route*

$$\mathsf{Hilbert}^{\uparrow}, \mathsf{FunctionalAnalysis}^{\uparrow} \longmapsto G \longmapsto R \longmapsto \mathsf{WeakDerivative}^{\uparrow}, \mathsf{Pde}^{\uparrow}, \mathsf{OperatorIdeal}^{\uparrow}$$

together with H, C, P, N. The route exports a resolvent ledger and monotonicity certificate, not a choice-selected weak solution, host graph equality, spectral decomposition, or ambient compactness claim.

Proof. Start with the Hilbert and functional-analysis rows. They provide the source metric, pairing, operator graph schedule, and action ledger used by the monotonicity comparison.

Read the monotone graph row G next. Its finite pairing comparisons are the only admissible monotonicity evidence, so a downstream consumer cannot replace them by an unrecorded maximality or compactness theorem.

The resolvent ledger R is then consumed before the weak-derivative and PDE rows. Rows W and D therefore receive only the displayed approximation and forcing-route data, while H, C, P, N preserve provenance and local naming without adding excluded solution-selection or spectral coordinates. □

Falsifiable prediction: An accepted $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$ read is refuted if a PDE or operator-ideal consumer exports a monotone-operator conclusion without displaying Hilbert source

rows, functional-analysis operator rows, monotone graph comparisons, a resolvent ledger, weak-derivative compatibility, PDE boundary rows, transport, replay, provenance, and local naming.

Independence witness: hilbert, functional-analysis, weak-derivative, pde, operator-ideal: none alone is bijective with $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$ because the packet jointly carries Hilbert source data, operator graph rows, monotonicity comparisons, resolvent ledgers, weak-form compatibility, PDE boundary rows, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}$ packet is generated from Hilbert source rows, functional-analysis operator rows, monotone graph comparisons, a resolvent ledger, weak-derivative compatibility, PDE boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6215.1, Definition 6215.2, and Definition 6215.3 seed the finite monotone-operator and resolvent certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MintyBrowderMonotoneOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host maximal monotonicity, selected weak solutions, quotient graph equality, spectral calculus, or ambient compactness.

Upgrade path: Obligation closure requires checked carrier admission, monotone graph stability, resolvent ledger exactness, weak-form compatibility, PDE boundary handoff, provenance, and local naming for BEDC.Derived.MintyBrowderMonotoneOperatorUp.

Chapter 6216

A Concrete Naming Certificate for $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$

Following the Heine–Cantor finite-net route, the $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$ packet records the diameter-decay step that turns pointwise compact-cover moduli into a tolerance-only uniform-modulus ledger. It sits over the metric carrier of chapter 57, the compact metric source of chapter 129, the continuous-map surface of chapter 130, the rational fold of chapter 37, and the uniform-modulus consumer of chapter 369. The packet names finite compact-net diameter control; it does not choose points from a cover, assert host compactness, identify functions by quotient equality, or import ambient real completeness.

Definition 6216.1 (Compact uniform diameter-decay carrier)**.** *A* $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, K, F, N, L, T, U, H, C, P)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row, recording the source and target distance ledgers used by the triangle estimate.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the inspected centers and cover radii.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row displayed at the finite centers.*
4. *N is the finite net schedule whose cells carry the local diameter rows.*
5. *L is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row that produces the positive radius budget from the finite local ledgers.*
6. *T is the triangle ledger combining source-net distance, local modulus radius, and target-distance tolerance.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row reached after the finite diameter rows and rational lower-bound fold are displayed.*
8. *H stores componentwise* hsame *transport for metric, compact-net, continuous-map, net schedule, rational fold, triangle, uniform-modulus, replay, provenance, and naming rows.*
9. *C stores displayed* Cont *replay from compact source data through pointwise moduli and diameter decay into the uniform-modulus row.*

10. *P is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformDiameterDecay}^{\uparrow}}$ *row together with the* Pkg *provenance over* $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

The classifier compares accepted packets only through $M, K, F, N, L, T, U, H, C, P$ and has no coordinate for external modulus selection, host function equality, arbitrary cover choice, quotient representation, or ambient compactness.

Lean4 ✓ `BEDC.Derived.CompactUniformDiameterDecayUp.CompactUniformDiameterDecayTasteGate single carrier alignment`

Theorem 6216.2 (Compact uniform diameter-decay NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$ *carrier $D = (M, K, F, N, L, T, U, H, C, P)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformDiameterD}}$ *surface consists exactly of carrier admission for the metric comparison row, compact finite-net row, continuous-map pointwise row, finite diameter schedule, rational lower-bound fold, triangle ledger, uniform-modulus output row, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6216.1. Its displayed analytic rows are exactly the metric comparison row M, compact finite-net row K, pointwise continuous-map row F, finite diameter schedule N, rational fold L, triangle ledger T, and uniform-modulus row U.

The lower-bound fold and triangle ledger are read after the compact-net and pointwise-modulus rows. Hence the output uniform modulus is sourced by finite diameter-decay data rather than by a detached compactness or continuity theorem.

Rows H, C, P transport, replay, source, and name the same route. Since no other coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 6216.3 (Compact uniform diameter-decay uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$ *packet factors through*

$$\mathsf{Met}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow} \longmapsto N, L, T \longmapsto \mathsf{UniformModulus}^{\uparrow}$$

together with H, C, P. Thus the consumer receives a tolerance-only modulus ledger after finite compact-net diameter decay, not an external modulus selector, host compactness theorem, arbitrary cover choice, quotient function equality, or ambient real-completeness claim.

Proof. Begin with the compact metric source and metric comparison rows. The finite net K and distance ledger M determine the source-side cells that will be inspected by the diameter-decay route.

Read the continuous-map row F at the displayed centers. The finite schedule N records the local diameter rows, while the rational fold L supplies the positive radius budget used by the common tolerance request.

The triangle ledger T combines source-cell control with target-distance estimates before U is exported. The structural rows H, C, P preserve this finite route and contain no selector, host equality, arbitrary cover-choice, quotient, compactness, or completeness coordinate. □

Falsifiable prediction: An accepted $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer exports a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying metric comparisons, compact finite-net rows, ContinuousMap pointwise moduli, finite diameter schedules, RatUp lower-bound folds, triangle ledgers, transport, replay, provenance, and local naming.

Independence witness: metric, compactmetric, continuousmap, rat, uniformmodulus: none alone is bijective with $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$ because the packet jointly carries metric comparisons, compact finite nets, pointwise moduli, finite diameter rows, rational lower-bound folds, triangle ledgers, uniform-modulus output, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformDiameterDecay}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformDiameterDecay}^{\uparrow}$ packet is generated from Metric distance rows, CompactMetric finite-net rows, ContinuousMap pointwise-modulus rows, finite diameter schedules, RatUp lower-bound folds, triangle ledgers, a UniformModulus output row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformDiameterDecay}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6216.1, Definition 6216.2, and Definition 6216.3 seed the finite compact-net diameter-decay handoff into UniformModulus.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformDiameterDecay}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, external modulus selection, host function equality, arbitrary cover choice, quotient representation, ambient compactness, or RealUp completeness.

Upgrade path: Obligation closure requires checked compact-net exposure, pointwise-modulus visibility, rational lower-bound fold exactness, triangle ledger compatibility, uniform-modulus handoff, provenance, and local naming for BEDC.Derived.CompactUniformDiameterDecayUp.

Chapter 6217

A Concrete Naming Certificate for $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$

Following Bishop and Bridges, a bounded monotone real-completion argument is useful only when each displayed positive tolerance yields a finite tail window before the completed real name is read. The $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ packet records that tolerance-to-tail surface between the bounded monotone Cauchy witness of chapter 535, the convergence-seal boundary of chapter 918, the dyadic tolerance core of chapter 291, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. It names the finite modulus row consumed by Real and Completion-facing readers; it is not a selected-limit principle, a quotient stream equality, or an ambient completeness theorem.

Definition 6217.1 (Bounded monotone real modulus carrier)**.** *A* $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, T, D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *source row, exposing the bounded monotone witness before any completion-facing read.*
2. *T is the finite tail-modulus row assigning each displayed positive dyadic tolerance a tail-window bound for the same bounded monotone source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including positivity, halving, comparison, and upper-bound rows used by the tail request.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed at the bound named by T.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reading the same finite window as regular rational approximation data.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, T, D, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for W, T, D, S, Q, R.*
8. *C records displayed* Cont *replay from tolerance requests through tail bounds, finite windows, regular rational readbacks, the Real seal, and structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$, $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneRealModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $W, T, D, S, Q, R, H, C, P, N$. It has no coordinate for selected limits, quotient stream equality, trichotomy, countable choice, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.BoundedMonotoneRealModulusUp.BoundedMonotoneRealModulusUp`

Theorem 6217.2 (Bounded monotone real modulus NameCert obligations)**.** *For every accepted* $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ *carrier*

$$M = (W, T, D, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedMonotoneRealModulus}^{\uparrow}}$ *surface consists exactly of carrier admission through M, bounded monotone witness exposure through W, tail-modulus exposure through T, dyadic tolerance accounting through D, StreamName window exposure through S, RegSeqRat handoff through Q, terminal Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N. No local obligation may select a limit, identify quotient streams, infer a tail bound without the dyadic tolerance row, bypass the finite window, invoke trichotomy or countable choice, or export ambient real completeness.*

Proof. Project the carrier of Definition 6217.1. Its analytic rows are precisely the bounded monotone witness, tail modulus, dyadic tolerance ledger, finite stream window, regular rational readback, and Real seal.

The tolerance request is public before the tail row is consumed. The row D supplies the positive dyadic request and its comparison ledger, while T answers with a finite tail-window bound for the same witness row W.

The rows S and Q then expose only the finite window and regular rational readback determined by that bound. The Real seal R is downstream of those rows, so it cannot be used as an external completeness source.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since these structural rows add no selector, quotient, choice, trichotomy, host-real, compactness, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6217.3 (Bounded monotone real Cauchy modulus)**.** *Every accepted* $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ *packet exposes, for each positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance read from D, a finite tail-window bound through T before any* $\mathsf{Real}^{\uparrow}$ *row is readable. The corresponding* $\mathsf{StreamName}^{\uparrow}$ *window S and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff Q are read at that bound, so the Cauchy-facing modulus is a finite route through*

$$W, D, T, S, Q \to R, H, C, P, N.$$

Proof. Start with a positive dyadic tolerance in D. By the carrier definition, this request is part of the displayed tolerance ledger and is not inferred from the terminal Real seal.

Read the tail row T next. It assigns the request to a finite tail-window bound for the same bounded monotone witness W; the construction therefore produces an explicit window before any Real-facing row can be consumed.

The rows S and Q replay that finite bound as a StreamName window and a RegSeqRat readback. The structural rows preserve the route under hsame, Cont, provenance, and local naming, while the excluded selector and quotient surfaces remain absent. □

Theorem 6217.4 (Bounded monotone real terminal seal)**.** *Every completion-facing consumer of an accepted* $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ *packet factors through* W, T, D, S, Q *before the terminal* $\mathsf{Real}^{\uparrow}$ *row* R *is readable. Consequently the packet exports a finite bounded-monotone tolerance-to-tail modulus and not a selected limit, quotient stream equality, trichotomy principle, countable-choice schedule, host real equality, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Proof. Apply Definition 6217.2. It fixes the order in which the bounded witness, tail modulus, dyadic tolerance ledger, stream window, and regular rational readback become available.

A completion-facing consumer can therefore read R only after the finite modulus route has been displayed. If it omits one of W, T, D, S, Q, it asks for a Real seal coordinate without the carrier rows that make the seal local to the packet.

The structural rows H, C, P, N do not add analytic content. They keep every read inside the named route, so the excluded limit, quotient, choice, trichotomy, host-real, compactness, and ambient-completeness surfaces remain outside the certificate. □

Falsifiable prediction: A $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ consumer that reads $\mathsf{Real}^{\uparrow}$ before displaying W, T, D, S, Q, or that exports selected limits, quotient stream equality, trichotomy, countable choice, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, refutes the carrier of Definition 6217.1.

Independence witness: Nearest siblings: boundedmonotonecauchywitness, bounded-monotone-convergence-seal, dyadicratcore, streamname, regseqrat, and real. $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ is not bijective to any one sibling because it jointly carries the bounded monotone witness, tolerance-to-tail row, dyadic ledger, finite stream window, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedMonotoneRealModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedMonotoneRealModulus}^{\uparrow}$ packet is generated from a BoundedMonotoneCauchyWitness source row, a finite tail-modulus row, a DyadicRatCore tolerance ledger, a StreamName window row, a RegSeqRat readback row, a terminal RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedMonotoneRealModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6217.1, Definition 6217.2, Definition 6217.3, and Definition 6217.4 seed the finite bounded-monotone tolerance-to-tail route before terminal Real reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedMonotoneRealModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient stream equality, trichotomy, countable choice, host real equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded monotone witness exposure, tail-modulus exactness, dyadic tolerance accounting, StreamName window replay, RegSeqRat readback, terminal Real sealing, classifier transport, displayed replay, provenance, and local naming for BEDC.Derived.BoundedMonotoneRealModulusUp.

Chapter 6218

A Concrete Naming Certificate for $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$

Following Moore–Smith, Kelley, and Bourbaki on directed nets and completion by tails, the $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ packet records the finite L10 handoff by which a displayed Moore–Smith net completion route reaches the regular rational and real-name corridor. It sits after the directed-net carrier of chapter 3403, the Cauchy-net completion boundary of chapter 3794, the filter-base surface of chapter 1601, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite BEDC bridge object for Real and Completion consumers; it does not select limits, quotient nets, cofinal functions, ambient completions, host equalities, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6218.1 (Moore–Smith L10 completion-net carrier)**.** *A* $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, T, F, W, R, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed-index row inherited from the accepted* $\mathsf{MooreSmithNet}^{\uparrow}$ *surface, including finite index vertices, displayed preorder comparisons, and common-upper witnesses.*
2. *T is the tail-window row, recording the finite late-index requests and the displayed tails that answer completion-facing reads.*
3. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *row generated from the displayed directed tails D, T.*
4. *W is the* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *row, exposing the same directed tail data as a Cauchy-net completion boundary.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the retained tail windows and tolerance reads.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, T, F, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the directed-index, tail-window, filter-base, Cauchy-net completion, regular readback, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-net request through D, T, F, W, R, A.*
9. *P is the* Pkg *provenance over* $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$*,* $\mathsf{MooreSmithNet}^{\uparrow}$*,* $\mathsf{CauchyNetCompletion}^{\uparrow}$*,* $\mathsf{FilterBase}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithL10CompletionNet}^{\uparrow}}$ *row.*

The carrier exports only this finite L10 route. It has no coordinate for selected limits, quotient nets, cofinal choice, ambient completion objects, host equality of completed values, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MooreSmithLTenCompletionNetUp.MooreSmithLTenCompletionNetTasteGate single carrier alignment`

Theorem 6218.2 (Moore–Smith L10 completion-net NameCert obligations)**.** *For an accepted* $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ *carrier* $L = (D, T, F, W, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithL10CompletionN}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the directed-index, tail-window, filter-base, Cauchy-net completion, regular readback, real-seal, transport, replay, provenance, and local naming rows;*
2. *directed-tail coverage, requiring every completion-net request to consume D and T before F, W, R, A can be inspected;*
3. *filter-base generation, requiring F to be assembled only from the displayed directed tails;*
4. *Cauchy-net completion handoff, requiring W to expose the same completion boundary consumed by chapter 3794;*
5. *regularization, requiring R to be read before the terminal real seal A;*
6. *non-escape for selected limits, quotient nets, cofinal choice, ambient completion, host equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside $D, T, F, W, R, A, H, C, P, N$.

Proof. Carrier admission is projection from Definition 6218.1. The analytic rows are D, T, F, W, R, A, and the structural rows are H, C, P, N.

Directed-tail coverage comes first. A completion-net request reads a displayed index and late-window request through D and T before any filter, completion, regularization, or real-seal row can be used.

The filter-base and Cauchy-net obligations then use the sibling routes. The row F is generated from the same directed tails, and W exposes those tails as the Cauchy-net completion boundary consumed by the existing completion chapter.

Finally R and A provide the regular rational readback and terminal real seal. Transport and replay preserve the same route through H and C, while P, N name it as the local certificate surface. Since the excluded completion principles have no carrier coordinate, they cannot become local NameCert obligations. □

Theorem 6218.3 (Moore–Smith L10 regularization)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read from an accepted* $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ *packet factors through the directed-tail and completion route*

$$D, T \longmapsto F, W \longmapsto R.$$

Thus the regular rational row is attached to the same Moore–Smith tail windows and Cauchy-net completion boundary; it is not a separate sequence selector, quotient of nets, cofinal-choice schedule, or host-level limit name.

Proof. Begin with the NameCert obligations of Definition 6218.2. Directed-tail coverage forces every read of the packet to expose D and T before downstream rows are inspected.

Apply filter-base generation and Cauchy-net completion handoff. The rows F and W are downstream of the same displayed tails, so the regular readback cannot receive an independent source.

The row R is therefore a readback of the retained finite route. The carrier inventory contains no sequence selector, quotient-net row, cofinal-choice function, or host limit coordinate, so the regularization is exhausted by D, T, F, W, R. □

Theorem 6218.4 (Moore–Smith L10 filter handoff)**.** *Every filter-facing consumer of an accepted* $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ *packet reads its* $\mathsf{FilterBase}^{\uparrow}$ *data through the displayed Moore–Smith tail rows*

$$D, T \longmapsto F \longmapsto W, R, A, H, C, P, N.$$

The handoff preserves the directed-net origin of the completion boundary and does not import an external filter, ultrafilter, quotient net, selected limit, or ambient completion object.

Proof. Project the accepted carrier. Its only filter-facing coordinate is F, and the carrier definition presents F as generated from D and T.

The Cauchy-net completion and regularization rows are downstream of that same filter-base row. Thus a consumer that reaches W, R, A has already passed through the displayed directed-tail route.

The structural rows do not add an external filter. They transport, replay, source, and name the same finite package, so no ultrafilter, quotient net, selected limit, or ambient completion object can bypass D, T, F. □

Theorem 6218.5 (Moore–Smith L10 real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ *packet factors through*

$$D, T, F, W, R, A, H, C, P, N.$$

The seal A is terminal for the displayed L10 route only: it does not assert completeness of $\mathsf{Real}^{\uparrow}$*, identify quotient-net representatives, select a limit, compare host real values, or provide a cofinal choice function.*

Proof. Use the regularization theorem. By Definition 6218.3, every regular rational read reaches R only after the directed tails, filter-base row, and Cauchy-net completion row have been displayed.

The real seal is downstream of that readback. The carrier definition gives A as the terminal $\mathsf{Real}^{\uparrow}$ row after D, T, F, W, R, and the NameCert obligations leave no other route to a real-facing read.

It remains to exclude escape data. The packet has no coordinate for $\mathsf{Real}^{\uparrow}$ completeness, quotient-net representatives, selected limits, host equality, cofinal choice, or ambient completion, and H, C, P, N preserve only the rows already displayed. □

Falsifiable prediction: If a Real and Completion consumer reads a $\mathsf{Real}^{\uparrow}$ seal from a directed-net completion boundary without first displaying the $\mathsf{MooreSmithNet}^{\uparrow}$ tail row, the $\mathsf{FilterBase}^{\uparrow}$ handoff, the $\mathsf{CauchyNetCompletion}^{\uparrow}$ boundary, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback, it is not a $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ packet.

Independence witness: moore-smith-net, cauchynetcompletion, filterbase, regseqrat, real: MooreSmithL10Compl is not bijective to any listed sibling because it binds directed tails, filter-base generation, Cauchy-net completion, regular rational readback, terminal real sealing, transport, replay, provenance, and local naming in one finite L10 route.

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithL10CompletionNet}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithL10CompletionNet}^{\uparrow}$ packet is generated from a MooreSmithNet directed-index row, finite tail-window data, a FilterBase handoff, a CauchyNetCompletion boundary, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreSmithL10CompletionNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6218.1, Definition 6218.2, Definition 6218.3, Definition 6218.4, and Definition 6218.5 seed the finite L10 completion-net handoff from Moore–Smith tails to regular rational readback and the real-name seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreSmithL10CompletionNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient nets, cofinal choice, ambient completion, host equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail coverage, filter-base generation, Cauchy-net completion handoff, regularization, real-seal nonescape, transport preservation, and ledger refusal for BEDC.Derived.MooreSmithLTenCompletionNetUp.

Chapter 6219

A Concrete Naming Certificate for CauchyModulusEnvelope$^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy moduli, the CauchyModulusEnvelope$^{\uparrow}$ packet records a finite majorant envelope for the modulus rows used by regular rational and real-name convergence arguments. It sits over the dyadic arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet names cofinal modulus majorants and finite-family merges before any Real$^{\uparrow}$ seal is read; it is not a quotient of Cauchy streams, a selected completion point, countable choice, or an ambient real-completeness theorem.

Definition 6219.1 (Cauchy modulus envelope carrier)**.** *A* CauchyModulusEnvelope$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, W, R, F, M, U, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare requested precision levels and dyadic tail bounds.*
2. *W is the* StreamName$^{\uparrow}$ *finite observation window containing the named sequence entries inspected by the envelope.*
3. *R is the* RegSeqRat$^{\uparrow}$ *regular-rational readback row attached to the same window.*
4. *F is a finite family of displayed Cauchy-modulus rows whose thresholds are all read through D, W, R.*
5. *M is the finite majorant row assigning a single envelope threshold to each requested dyadic precision.*
6. *U is the finite merge row that combines a displayed finite subfamily of modulus rows into the same majorant envelope.*
7. *S is the downstream* Real$^{\uparrow}$ *seal handoff available only after D, W, R, F, M, U are accepted.*
8. *H records componentwise* hsame *transport for dyadic tolerances, stream windows, regular-rational readback, modulus rows, envelope majorants, finite merges, seal handoffs, replay, provenance, and naming.*
9. *C records displayed* Cont *replay from precision requests through the finite envelope route and then to the real-name seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusEnvelope}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $D, W, R, F, M, U, S, H, C, P, N$. There is no coordinate for an infinite modulus choice, a quotient stream equality, a selected limit, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyModulusEnvelopeUp.CauchyModulusEnvelopeTasteGate single carrier alignment`

Theorem 6219.2 (Cauchy modulus envelope NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusEnvelope}^{\uparrow}$ *carrier $E = (D, W, R, F, M, U, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, finite stream window, regular-rational readback row, finite family of modulus rows, envelope majorant row, finite merge row, real-name seal handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6219.1. Its analytic coordinates are exactly D, W, R, F, M, U, S, and its structural coordinates are exactly H, C, P, N.

The dyadic, stream, and regular-rational rows supply the only observable precision and tail-window data. The modulus family F and majorant row M are read after those rows, so an envelope threshold cannot be supplied by an external modulus selector.

The merge row U is finite and stays attached to the same displayed family. Rows H, C, P, N transport, replay, source, and name the same packet, with no additional coordinate for quotient streams, selected limits, countable choice, or ambient real completeness. Hence the listed rows exhaust the NameCert surface. □

Theorem 6219.3 (Cauchy modulus envelope majorization)**.** *Let $E = (D, W, R, F, M, U, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusEnvelope}^{\uparrow}$ *carrier. Every modulus row in the displayed finite family F is majorized only through the envelope row M over the same dyadic tolerance row D, stream window W, and regular-rational readback row R. A consumer cannot read a threshold from F without also reading the common envelope row M and the structural rows H, C, P, N.*

Proof. Begin with the carrier. The finite family F is not a free list of host functions; it is a displayed family of modulus rows attached to D, W, R.

The envelope row M is the only row that assigns a common threshold to the requested dyadic precision. Thus a majorization read must inspect D, W, R first, then read the relevant modulus row from F, and then compare it with M inside the same packet.

Transport and replay through H and C preserve this dependency, while P, N only source and name it. Since the carrier has no external modulus coordinate, every accepted majorization remains inside the finite envelope route. □

Theorem 6219.4 (Cauchy modulus envelope finite-family merge)**.** *For every accepted* $\mathsf{CauchyModulusEnvelope}^{\uparrow}$ *carrier $E = (D, W, R, F, M, U, S, H, C, P, N)$, the merge row U combines only finite displayed subfamilies of F into the same envelope row M. The merge may reuse dyadic tolerance comparisons from D and tail-window reads from W, R, but it exports no infinite family choice, no quotient equality of modulus functions, and no selected completion witness.*

Proof. Read F and U from the carrier. The family row is finite, and the merge row is listed as a row of that same finite packet rather than as an ambient operation over all moduli.

Use the majorization theorem Definition 6219.3. Each component modulus in the displayed family is compared with M only after D, W, R are visible.

The merge row therefore combines already displayed comparisons. The structural rows H, C, P, N preserve and name the finite merge route, but they add no infinite selector, quotient equality, selected limit, or completion object. □

Theorem 6219.5 (Cauchy modulus envelope Real-seal nonescape)**.** *Let $E = (D, W, R, F, M, U, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusEnvelope}^{\uparrow}$ *carrier. Every downstream* $\mathsf{Real}^{\uparrow}$ *consumer of the seal row S must first expose the dyadic tolerance row D, stream window W, regular-rational readback row R, finite modulus family F, envelope majorant row M, and finite merge row U. The seal exports no quotient Cauchy stream, selected real value, countable-choice modulus selection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the seal row S from the carrier. It appears only after D, W, R, F, M, U, so it is a handoff reached from the accepted finite envelope packet rather than an independent real object.

Apply Definition 6219.3. It keeps every threshold read tied to the same dyadic tolerance, stream window, regular-rational readback, and envelope row.

Apply Definition 6219.4. The merge route remains finite and displays the family members whose thresholds are being bounded.

Rows H, C, P, N transport, replay, source, and name only that finite route. Thus a real-name consumer must pass through the envelope packet before reading S, and none of the refused quotient, choice, selected-limit, or ambient-completeness data is exported. □

Falsifiable prediction: An accepted $\mathsf{CauchyModulusEnvelope}^{\uparrow}$ read is refuted if a $\mathsf{Real}^{\uparrow}$ or Cauchy-convergence consumer exports a seal row without displaying DyadicRatCore tolerance, StreamName tail windows, RegSeqRat readback, finite modulus-family rows, a common envelope majorant, finite merge data, transport, replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real: none alone is bijective with $\mathsf{CauchyModulusEnvelope}^{\uparrow}$ because the packet jointly carries dyadic precision, named tail windows, regular-rational readback, finite modulus families, envelope majorants, finite merges, Real seal handoff, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusEnvelope}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusEnvelope}^{\uparrow}$ packet is generated from DyadicRatCore tolerances, StreamName finite windows, RegSeqRat readback, finite Cauchy-modulus rows, a common majorant envelope, finite merge data, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyModulusEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 6219.1, Definition 6219.2, Definition 6219.3, Definition 6219.4, and Definition 6219.5 seed the finite majorant-envelope surface for Cauchy moduli before Real sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyModulusEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient Cauchy completion, countable choice for moduli, selected real limits, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked dyadic tolerance exposure, finite stream-window readback, regular-rational dependency, majorant exactness, finite merge exactness, Real-seal nonescape, provenance, and local naming for BEDC.Derived.CauchyModulusEnvelopeUp.

Chapter 6220

A Concrete Naming Certificate for $\mathsf{RealArctangent}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealArctangent}^{\uparrow}$ packet records arctangent as a finite Cauchy-stream certificate rather than as a host transcendental function. The construction reads the alternating arctangent series on bounded windows through $\mathsf{RealAnalytic}^{\uparrow}$ and the standalone $\mathsf{RealSine}^{\uparrow}$ trigonometric route of chapter 6126, then seals the endpoint through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. It is placed beside the exponential and logarithm packets of chapter 1816 and chapter 2315: all three expose explicit real-analysis stream data before any public endpoint is consumed.

Definition 6220.1 (RealArctangent Cauchy carrier)**.** *A* $\mathsf{RealArctangent}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, S, R, D, E, T, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Real}^{\uparrow}$ *input row, read only through the displayed real-name boundary and bounded-window request.*
2. *S is the alternating arctangent Cauchy stream row with inspected terms $(-1)^k x^{2k+1}/(2k+1)$ on the active bounded window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row for the rational partial-sum readback of S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording denominator growth, bounded-window estimates, and alternating-remainder comparisons.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after the stream, regularity, and dyadic tolerance rows have been displayed.*
6. *T is the* $\mathsf{RealAnalytic}^{\uparrow}$ *and* $\mathsf{RealSine}^{\uparrow}$ *transport row that identifies the local arctangent stream with the real-analytic trigonometric dependency surface, without importing a host inverse tangent.*
7. *Q is the endpoint classifier row comparing accepted readbacks through the displayed* $\mathsf{Real}^{\uparrow}$ *boundary.*
8. *H is the componentwise* hsame *transport for $X, S, R, D, E, T, Q, C, P, N$.*
9. *C is the displayed* Cont *replay from bounded real input to stream windows, from windows to regular readback, from readback to dyadic tolerance, and from tolerance to the endpoint seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RealArctangent}^{\uparrow}$, $\mathsf{RealAnalytic}^{\uparrow}$, $\mathsf{RealSine}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealArctangent}^{\uparrow}}$ *row.*

The classifier compares accepted arctangent packets only through $X, S, R, D, E, T, Q, H, C, P, N$. It has no coordinate for a host arctangent function, quotient real equality, analytic continuation, selected infinite sum, countable-choice schedule, unrestricted trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealArctangentUp.RealArctangentTasteGate single carrier alignment`

Theorem 6220.2 (RealArctangent NameCert obligations)**.** *For every accepted* $\mathsf{RealArctangent}^{\uparrow}$ *carrier $A = (X, S, R, D, E, T, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealArctangent}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; stream exposure through S over the* $\mathsf{StreamName}^{\uparrow}$ *finite-window route; regular readback through R; dyadic tolerance accounting through D; endpoint sealing through E and Q; analytic and trigonometric dependency transport through T; componentwise* hsame *stability through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Proof. Project the accepted carrier. The only visible input, stream, regularity, tolerance, endpoint, dependency, classifier, transport, replay, provenance, and naming rows are $X, S, R, D, E, T, Q, H, C, P, N$.

The stream obligation is discharged by the finite windows in S together with the regular readback R. The dyadic ledger D records the bounded-window estimates and alternating-remainder comparisons needed before the endpoint row is available.

Use the dependency row T to route the analytic and trigonometric material through $\mathsf{RealAnalytic}^{\uparrow}$ and $\mathsf{RealSine}^{\uparrow}$. This row is a displayed BEDC dependency route, not a host inverse-transcendental primitive.

Finally E, Q, H, C, P, N seal, classify, transport, replay, source, and name exactly the same rows. Since no carrier coordinate stores a host arctangent, quotient real equality, analytic-continuation datum, selected infinite sum, countable-choice schedule, trichotomy oracle, or ambient completeness theorem, none of those objects is exported by the local NameCert surface. □

Theorem 6220.3 (RealArctangent stream dependency route)**.** *Every public read of an accepted* $\mathsf{RealArctangent}^{\uparrow}$ *packet factors through the concrete route*

$$\mathsf{RealAnalytic}^{\uparrow}, \quad \mathsf{RealSine}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before an arctangent endpoint is consumed. Consequently the packet names arctangent by alternating Cauchy-stream data, regular rational readback, dyadic tolerance accounting, and real endpoint sealing, not by a host inverse tangent or an ambient analytic library.

Proof. Start from the carrier of Definition 6220.1. The bounded real input X and the stream row S expose the arctangent partial sums only as finite $\mathsf{StreamName}^{\uparrow}$ windows.

The readback and tolerance steps are R and D. These rows place the partial sums inside the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ surfaces before any endpoint classifier may be inspected.

The analytic dependency row T ties the local alternating stream to $\mathsf{RealAnalytic}^{\uparrow}$ and the trigonometric route already isolated by $\mathsf{RealSine}^{\uparrow}$. It supplies a dependency handoff over existing siblings rather than a primitive host arctangent.

The endpoint rows E, Q and structural rows H, C, P, N then preserve and name the same route. Thus every public arctangent read factors through the displayed analytic, sine, stream, regular, dyadic, and real rows before the value is consumed. □

Falsifiable prediction: Every $\mathsf{RealArctangent}^{\uparrow}$ public read factors through a bounded RealUp input row, alternating arctangent StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealAnalytic and RealSine dependency transport row, a RealUp endpoint seal, endpoint classifier, componentwise hsame transport, displayed continuation, package provenance, and local naming.

Independence witness: real-analytic, real-sine, real-exponential, real-logarithm, streamname, regseqrat, dyadicratcore, real: $\mathsf{RealArctangent}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the alternating arctangent Cauchy stream, regular rational readback, dyadic tolerance ledger, analytic and trigonometric dependency transport, endpoint classifier, Real seal, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealArctangent}^{\uparrow}}$.

Constructive story: A $\mathsf{RealArctangent}^{\uparrow}$ packet is generated from a bounded RealUp input, alternating arctangent StreamName windows, RegSeqRat regular readback, a DyadicRatCore tolerance ledger, a RealAnalytic and RealSine dependency route, a RealUp endpoint seal, endpoint classifier, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealArctangent}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6220.1, Definition 6220.2, and Definition 6220.3 seed the finite arctangent Cauchy-stream route through existing real, analytic, trigonometric, stream, regularity, and dyadic-tolerance surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealArctangent}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host arctangent functions, quotient real equality, analytic continuation, selected infinite sums, countable choice, unrestricted trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, alternating stream exposure, regular readback, dyadic tolerance accounting, analytic and trigonometric dependency transport, endpoint classifier stability, and TasteGate field faithfulness for BEDC.Derived.RealArctangentUp.

Chapter 6221

A Concrete Naming Certificate for $\mathsf{CompletionDenseRange}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley uniform spaces, the $\mathsf{CompletionDenseRange}^{\uparrow}$ packet records the finite dense-subsource extension interface for L10 Real and Completion consumers. It sits after the extension-uniqueness surface of chapter 397, the functorial uniform-completion handoff of chapter 1892, the Cauchy-completion reflection boundary of chapter 3376, the finite stream window route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names dense-range extension as displayed BEDC data; it does not introduce quotient completion equality, selected limits, ambient complete objects, host equality of completed points, or countable-choice representatives.

Definition 6221.1 (CompletionDenseRange carrier)**.** *A* $\mathsf{CompletionDenseRange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, D, E, U, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source carrier row, naming the metric or uniform source whose completion-facing reads are being served.*
2. *D is the dense-subsource witness, recording finite evidence that the inspected subsurface is dense for the source requests consumed by the packet.*
3. *E is the completion-extension row, carrying the displayed extension action from the dense-subsource data into the completion-facing target.*
4. *U is the uniqueness-on-dense-source row, comparing two extension reads only after their common action on D has been displayed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect source, dense-subsource, and extension data at the requested tolerance.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the same finite windows.*
7. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that bounds the finite window and readback comparisons.*
8. *H records componentwise* hsame *transport for the source, dense-subsource, extension, uniqueness, window, readback, tolerance, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a dense-source request through S, D, E, U, W, R, Q.*

10. *P is the* Pkg *provenance over* $\mathsf{CompletionDenseRange}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}$ $\mathsf{CauchyCompletionReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionDenseRange}^{\uparrow}}$ *row.*

The carrier exports only this finite dense-range route. It has no coordinate for quotient completion equality, selected representatives, selected limits, host equality of completed values, ambient complete objects, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompletionDenseRangeUp.CompletionDenseRangeTasteGate single carrier alignment`

Theorem 6221.2 (CompletionDenseRange NameCert obligations)**.** *For an accepted* $\mathsf{CompletionDenseRange}^{\uparrow}$ *carrier $G = (S, D, E, U, W, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionDenseRange}^{\uparrow}}$ *surface consists exactly of source admission, dense-subsource admission, completion-extension admission, uniqueness-on-dense-source admission, StreamName finite-window admission, RegSeqRat readback, DyadicRatCore tolerance admission, componentwise transport, displayed replay, provenance, and local naming for the rows $S, D, E, U, W, R, Q, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.CompletionDenseRangeUp.CompletionDenseRangeCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 6221.1. The analytic rows are S, D, E, U, W, R, Q, and the structural rows are H, C, P, N.

The dense-window coverage comes first. A completion-facing request reads the source carrier S and the dense-subsource witness D before the extension row E or uniqueness row U can be inspected.

The finite observation rows then bind the extension to BEDC-readable data. The row W supplies StreamName windows, R repacks those windows as regular rational readback, and Q gives the dyadic tolerance budget used by both the extension and uniqueness comparisons.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no quotient completion equality, selected representative, selected limit, host equality, ambient completion object, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6221.3 (CompletionDenseRange extension)**.** *Every extension read from an accepted* $\mathsf{CompletionDenseRange}^{\uparrow}$ *packet factors through the finite route*

$$S, D \longmapsto E \longmapsto W, R, Q \longmapsto H, C, P, N.$$

Thus a Real or Completion consumer receives extension data only after the dense-subsource witness, StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance budget are visible.

Proof. Start with the obligation surface of Definition 6221.2. It exposes S and D before any completion-extension row is available.

The extension row E is therefore tied to the displayed dense-subsource witness. A consumer that reaches E must also carry the finite StreamName windows W, the regular rational readback R, and the dyadic tolerance row Q that make the extension readable.

The structural rows do not create a second extension. They only transport, replay, source, and name the same route, so the accepted extension read factors through $S, D, E, W, R, Q, H, C, P, N$. □

Theorem 6221.4 (CompletionDenseRange nonescape)**.** *Every uniqueness or completion-facing read from an accepted* $\mathsf{CompletionDenseRange}^{\uparrow}$ *packet is exhausted by*

$$S, D, E, U, W, R, Q, H, C, P, N.$$

In particular, the packet cannot export quotient completion equality, a selected representative, a selected limit, host equality of completed points, an ambient complete object, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Use the extension theorem. By Definition 6221.3, extension reads already pass through the source, dense-subsource witness, finite windows, regular readback, and dyadic tolerance budget.

The uniqueness row U is read on the same route. It compares accepted extension rows only after their common dense-source action has been displayed through D, so it is uniqueness on the dense source rather than quotient equality of completed points.

It remains to exclude escape data. The carrier inventory has no coordinate for quotient completion equality, selected representatives, selected limits, host equality, ambient complete objects, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness, and H, C, P, N preserve only the displayed rows. □

Falsifiable prediction: If a Real or Completion consumer reads a dense-range extension without first displaying the source carrier, dense-subsource witness, StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance row, it is not a $\mathsf{CompletionDenseRange}^{\uparrow}$ packet.

Independence witness: completionuniversalproperty, uniformcompletionfunctor, cauchy-completion-reflection, streamname, regseqrat, dyadicratcore, real: $\mathsf{CompletionDenseRange}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source, dense-subsource, extension, uniqueness, finite-window, readback, tolerance, transport, replay, provenance, and local naming rows in one finite dense-range route.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionDenseRange}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionDenseRange}^{\uparrow}$ packet is generated from source rows, dense-subsource witness rows, completion-extension rows, uniqueness-on-dense-source rows, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionDenseRange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6221.1, Definition 6221.2, Definition 6221.3, and Definition 6221.4 seed the finite dense-range extension route from dense source data to completion-facing reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionDenseRange}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CompletionDenseRangeUp`

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, selected limits, host equality, countable choice, ambient completion, $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-window coverage, completion-extension replay, uniqueness-on-dense-source exactness, StreamName window replay, RegSeqRat readback, DyadicRatCore tolerance control, transport preservation, and ledger refusal for BEDC.Derived.CompletionDenseRangeUp.

Chapter 6222

A Concrete Naming Certificate for $\mathsf{HadamardFinitePart}^{\uparrow}$

Following Hadamard's finite-part treatment of singular integrals and the constructive integration discipline of Bishop and Bridges, the $\mathsf{HadamardFinitePart}^{\uparrow}$ packet records a finite cutoff-and-subtraction certificate over the L10 Real and Completion surface. It sits after the Darboux and Riemann integration rows of chapter 1460 and chapter 1526, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the bounded-variation control route of chapter 398. The packet names only the finite singular window, the displayed subtraction row, rational readback, and Real seal handoff; it is not a measure completion, a principal-value host limit, a quotient-function construction, a selected limiting process, or an ambient real-completeness theorem.

Definition 6222.1 (Hadamard finite-part carrier)**.** *A* $\mathsf{HadamardFinitePart}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, S, K, A, B, R, D, E, V, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval-source row, including the endpoint seals and the named singular location or finite singular subwindow.*
2. *S is the singular-kernel row, recording the local pole order or displayed asymptotic term to be subtracted.*
3. *K is the cutoff row, a finite family of excluded neighborhoods and retained compact subintervals.*
4. *A is the subtraction row, displaying the finite counterterm or polynomial singular part removed on the retained windows.*
5. *B is the Darboux or Riemann integration handoff row for the cutoff integrand on the retained finite partition.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the cutoff-and-subtracted values.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the cutoff width, subtraction budget, rational readback, and Real seal comparison.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, public only after K, A, B, R, D have been displayed.*
9. *V is the* $\mathsf{BoundedVariation}^{\uparrow}$ *or variation-control row used to justify that the retained window remains a finite integration object.*

10. *H stores componentwise* hsame *transport for $I, S, K, A, B, R, D, E, V$.*
11. *C stores displayed* Cont *replay from a finite-part request through cutoff selection, subtraction, integration handoff, rational readback, tolerance comparison, and Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{HadamardFinitePart}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{HadamardFinitePart}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. No coordinate stores an ambient principal-value limit, measure completion, quotient function, chosen limiting sequence, host distribution object, or a proof that $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 (definition) `BEDC.Derived.HadamardFinitePartUp.HadamardFinitePartUp`
Lean4 ✓ `BEDC.Derived.HadamardFinitePartUp.HadamardFinitePartTasteGate single carrier alignment`

Theorem 6222.2 (Hadamard finite-part NameCert obligations)**.** *For every accepted* $\mathsf{HadamardFinitePart}^{\uparrow}$ *carrier $F = (I, S, K, A, B, R, D, E, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HadamardFinitePart}^{\uparrow}}$ *surface consists exactly of interval-source admission, singular-kernel exposure, finite cutoff visibility, subtraction-row exposure, Darboux or Riemann handoff, regular rational readback, dyadic tolerance accounting, Real seal routing, bounded-variation control, componentwise transport, displayed replay, package provenance, and local naming. A finite-part read is accepted only after the cutoff row K, subtraction row A, integration handoff B, readback row R, and tolerance ledger D are all displayed.*

Proof. Project the carrier of Definition 6222.1. The interval row I and singular-kernel row S identify the singular site before any finite-part value can be read.

The cutoff and subtraction rows are then exposed. The row K records the retained windows, while A records the displayed singular term removed on those windows. The integration row B is therefore a Darboux or Riemann handoff for a finite cutoff object rather than an ambient singular integral.

Next R, D, E, V provide regular rational readback, tolerance accounting, the terminal Real seal, and bounded-variation control. Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of these rows contains a principal-value host limit, measure completion, quotient function, selected limiting sequence, distribution object, or ambient real-completeness proof, the listed rows exhaust the local obligations. □

Theorem 6222.3 (Hadamard finite-part cutoff nonescape)**.** *Every* $\mathsf{HadamardFinitePart}^{\uparrow}$ *consumer that reads an accepted carrier must factor its singular request through the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{DarbouxIntegral}^{\uparrow} \text{ or } \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the displayed rows $I, S, K, A, B, R, D, E, V, H, C, P, N$. In particular, deleting K or A leaves no public finite-part read.

Proof. Begin with the NameCert obligations of Definition 6222.2. They place the finite cutoff K and subtraction row A before the integration handoff and before any rational readback is available.

The Darboux or Riemann row B can then be read only as the cutoff-and-subtracted integral surface. The rows R and D translate that surface into regular rational and dyadic tolerance data before the seal E is public.

The structural rows H, C, P, N preserve exactly that order. Without K the retained finite window is absent; without A the singular counterterm is absent. In either case the carrier has no coordinate from which a finite-part value can be exported. □

Theorem 6222.4 (Hadamard finite-part Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{HadamardFinitePart}^{\uparrow}$ *packet reaches the Real seal* E *only after the displayed cutoff row, subtraction row, integration handoff, regular rational readback, dyadic tolerance ledger, and bounded-variation control row have been consumed. The handoff supplies a finite singular-read certificate, not a measure completion, host principal-value limit, quotient-function equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. By Definition 6222.1, the only Real-facing output coordinate is E. The coordinate E occurs after the cutoff, subtraction, integration, readback, tolerance, and variation-control rows in the displayed carrier.

Apply Definition 6222.3. Any consumer of E must first traverse K, A, B, R, D, V together with the structural rows. Therefore the Real seal is a terminal read of the finite certificate and not a host analytic limit. □

Falsifiable prediction: Every accepted $\mathsf{HadamardFinitePart}^{\uparrow}$ singular read is refuted if a Real seal is cited without the displayed cutoff row, subtraction row, Darboux or Riemann handoff, RegSeqRat readback, DyadicRatCore tolerance ledger, and bounded-variation control row.

Independence witness: darboux-integral, riemann-integral, regseqrat, dyadicratcore, real, bounded-variation: none is bijective to $\mathsf{HadamardFinitePart}^{\uparrow}$ because this packet jointly carries a singular-window row, cutoff row, subtraction row, integration handoff, rational readback, tolerance ledger, Real seal, variation-control row, transport, replay, provenance, and local naming as one finite-part certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardFinitePart}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HadamardFinitePart}^{\uparrow}$ packet is generated from a Real interval source, singular-kernel row, finite cutoff row, subtraction row, Darboux or Riemann integration handoff, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, bounded-variation control, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HadamardFinitePart}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6222.1, Definition 6222.2, Definition 6222.3, and Definition 6222.4 seed the finite cutoff-and-subtraction route for Hadamard finite-part singular reads over the L10 Real and Completion surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HadamardFinitePart}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, principal-value host limits, quotient functions, selected limits, host distributions, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval-source admission, singular-kernel exposure, cutoff visibility, subtraction-row exposure, Darboux or Riemann handoff, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal routing, bounded-variation control, transport, replay, provenance, and local naming for BEDC.Derived.HadamardFinitePartUp.

Chapter 6223

A Concrete Naming Certificate for $\mathsf{RegulatedMeshModulus}^{\uparrow}$

Following Riemann and Darboux, a regulated function is useful for constructive integration only when a finite mesh request can be read before any integral value is sealed. The $\mathsf{RegulatedMeshModulus}^{\uparrow}$ packet records that mesh-control surface between the regulated-function source of chapter 1906, the finite partition mesh of chapter 3496, the tagged partition observations of chapter 4296, and the integration-facing handoff of chapter 1960. It names a finite route for mesh-controlled tagged sums; it is not a host uniform-continuity theorem, an arbitrary refinement principle, a selected limiting integral, or an ambient completeness claim.

Definition 6223.1 (Regulated mesh modulus carrier)**.** *A* $\mathsf{RegulatedMeshModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, G, T, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row whose left and right local reads are the only function data available to the packet.*
2. *G is the* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *mesh-control row, assigning each displayed oscillation request a finite partition mesh bound for the same regulated source.*
3. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *observation row, reading tagged partition samples only at partitions whose mesh has passed through G.*
4. *I is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff row, available only after F, G, T have been displayed.*
5. *H records componentwise* hsame *transport for F, G, T, I.*
6. *C records displayed* Cont *replay from regulated reads through mesh bounds, tagged partition observations, the integration handoff, and the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{RegulatedMeshModulus}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedMeshModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through F, G, T, I, H, C, P, N. It has no coordinate for host uniform continuity, arbitrary refinement choice, quotient equality of tagged sums, selected integral values, countable choice, open-cover compactness, or ambient real completeness.

Lean4 ✓ BEDC.Derived.RegulatedMeshModulusUp.RegulatedMeshModulusTasteGate single carrier alignment

Theorem 6223.2 (Regulated mesh modulus obligations)**.** *For every accepted* $\mathsf{RegulatedMeshModulus}^{\uparrow}$ *carrier*

$$M = (F, G, T, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedMeshModulus}^{\uparrow}}$ *surface consists exactly of carrier admission through* M*, regulated-function exposure through* F*, finite mesh-control exposure through* G*, tagged partition observation through* T*, Riemann-facing handoff through* I*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*. No obligation exports a host uniform-continuity modulus, arbitrary partition refinement, quotient equality of sums, a selected integral, countable choice, compactness, or ambient completeness.*

Proof. Project the carrier of Definition 6223.1. The analytic rows are precisely the regulated source, the finite partition mesh, the tagged partition observations, and the Riemann handoff.

A mesh request is answered by G before tagged samples are inspected. Thus the row T can read only partitions whose mesh-control route has already been displayed for the same regulated source F.

The handoff row I is downstream of F, G, T. The structural rows H, C, P, N transport, replay, source, and name that same finite packet; they do not add any of the excluded host principles. □

Theorem 6223.3 (Regulated mesh modulus Riemann handoff)**.** *Every* $\mathsf{RiemannIntegrable}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegulatedMeshModulus}^{\uparrow}$ *carrier factors through the finite route*

$$F, G, T \longmapsto I, H, C, P, N.$$

The consumer first reads the regulated-function source, then the finite partition mesh bound, then the tagged real partition observations, and only then receives the integration-facing handoff. The route exports mesh-controlled tagged-sum data, not a selected integral value, host refinement theorem, quotient equality of sums, countable choice, compactness, or ambient real completeness.

Proof. Begin with a Riemann-facing consumer of M. By the carrier definition, the consumer can inspect the regulated source only through F and can request partition control only through the mesh row G.

The tagged row T then supplies observations attached to that mesh. Because T is downstream of G, the consumer cannot replace the mesh-control step by an arbitrary refinement or by a host limiting argument.

Finally the handoff row I is sealed by H, C, P, N as a local NameCert route. Since no selected integral, quotient, choice, compactness, or ambient-completeness coordinate occurs in M, the Riemann-facing output is exactly the displayed finite handoff. □

Falsifiable prediction: A $\mathsf{RegulatedMeshModulus}^{\uparrow}$ consumer that reads $\mathsf{RiemannIntegrable}^{\uparrow}$ before displaying F, G, T, or that exports selected integrals, quotient equality of sums, arbitrary refinement choice, compactness, countable choice, or ambient completeness, refutes the carrier of Definition 6223.1.

Independence witness: Nearest siblings: regulated-function, finite-partition-mesh, tagged-real-partition, and riemann-integrable. $\mathsf{RegulatedMeshModulus}^{\uparrow}$ is not bijective to any one sibling because it jointly carries regulated-function source data, finite mesh control, tagged partition observations, Riemann-facing handoff, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedMeshModulus}^{\uparrow}}$.

Constructive story: A RegulatedMeshModulus$^{\uparrow}$ packet is generated from a RegulatedFunction source row, a FinitePartitionMesh mesh-control row, a TaggedRealPartition observation row, a RiemannIntegrable handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegulatedMeshModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6223.1, Definition 6223.2, and Definition 6223.3 seed the finite regulated-function mesh-control route before Riemann-facing handoff reads.

Formal verification: FormalStatus(NameCert$_{\text{RegulatedMeshModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host uniform continuity, arbitrary refinement choice, quotient equality of tagged sums, selected integral values, countable choice, compactness, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-function exposure, mesh-control exactness, tagged partition observation, Riemann-facing handoff ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedMeshModulusUp.

Chapter 6224

A Concrete Naming Certificate for $\mathsf{Epigraph}^{\uparrow}$

Following Rockafellar's convex-analysis terminology, the $\mathsf{Epigraph}^{\uparrow}$ packet names the epigraph of a displayed extended-real-valued map as finite BEDC rows. It is read through domain points, function-value observations, lower-bound comparisons, and package provenance rather than through a host subset of a product space. The packet supplies the finite epigraph interface consumed by the lower-semicontinuity route of chapter 1536, and its value and comparison rows terminate at the real-name boundary of chapter 38.

Definition 6224.1 (Epigraph carrier)**.** *An* $\mathsf{Epigraph}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, V, L, O, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain-point row naming the source object and the inspected point.*
2. *V is the function-value row, read through the relevant displayed value carrier and sealed at the* $\mathsf{Real}^{\uparrow}$ *boundary when a real comparison is requested.*
3. *L is the lower-bound row naming the candidate ordinate for the epigraph inspection.*
4. *O is the comparison row recording that the displayed lower bound is below the displayed value row.*
5. *H stores componentwise* hsame *transport for the domain point, value, lower bound, comparison, replay, provenance, and local naming rows.*
6. *C stores displayed* Cont *replay from an epigraph query through D, V, L, O, H.*
7. *P is the* Pkg *provenance over* $\mathsf{Epigraph}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *dependency rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Epigraph}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. No coordinate stores a host graph, a powerset of a product, quotient equality of functions, a selected minimizing point, ambient real completeness, or an external lower-semicontinuity theorem.

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphCarrier rows exposed`

↪ variant `BEDC.Derived.EpigraphUp.EpigraphCarrierRowTransportSurface`

Theorem 6224.2 (Epigraph NameCert obligations)**.** *For every accepted* $\mathsf{Epigraph}^{\uparrow}$ *carrier* $E = (D, V, L, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Epigraph}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, classifier comparison through the domain-point, value, lower-bound, and comparison rows, componentwise transport through* H*, lower-set exposure through the comparison row* O*, and ledger exactness through* C, P, N*. A consumer may inspect epigraph membership only after the domain point, function value, lower bound, and comparison rows are displayed, and the packet exports no host subset, graph quotient, selected minimizer, ambient completeness theorem, or hidden function-space equality.*

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphNamecertObligations`
↪variant `BEDC.Derived.EpigraphUp.EpigraphCarrier namecert obligations`

Proof. Project the carrier of Definition 6224.1. The only mathematical rows before the structural data are D, V, L, O, so carrier admission and classifier comparison must read the domain point, value, lower bound, and comparison directly.

The lower-set clause is exactly the comparison row O. Transport by H preserves that comparison componentwise, while C replays the same displayed route from an epigraph query to the visible rows.

The provenance and local naming rows P, N source and name this finite packet. Since no carrier coordinate contains a host subset, graph quotient, selected minimizer, completeness theorem, or function-space equality, the listed rows exhaust the NameCert obligations. □

Theorem 6224.3 (Epigraph lower-semicontinuity handoff)**.** *Every* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumer that reads open-sublevel or closed-superlevel obligations through an accepted* $\mathsf{Epigraph}^{\uparrow}$ *packet receives only the finite route*

$$D, V, L, O \longmapsto H, C, P, N.$$

The handoff supplies the epigraph row consumed by the lower-semicontinuity certificate: a displayed domain point, a displayed value row, a lower-bound row, a comparison row, componentwise transport, replay, provenance, and local naming. It does not supply host open sets, a quotient graph, arbitrary function extensionality, selected witnesses, or ambient completeness of $\mathsf{Real}^{\uparrow}$*. The comparison row* O *is the finite lower-set surface consumed by chapter 1536, and its value comparison terminates at the real-name boundary of chapter 38.*

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphLowerSemicontinuousHandoff`

Proof. Use Definition 6224.2. It forces every epigraph membership read to expose D, V, L, O before the structural rows may replay or source the answer.

Now pass to the $\mathsf{LowerSemicontinuous}^{\uparrow}$ consumer. The open-sublevel and closed-superlevel obligations read the epigraph-facing comparison as the finite row O, together with the value and lower-bound rows that make the comparison meaningful at the real-name boundary.

The structural rows H, C, P, N preserve and name that route only. Because the carrier has no host topology, quotient graph, arbitrary function-extensional equality, selected witness coordinate, or ambient completeness field, the lower-semicontinuity consumer receives exactly the displayed epigraph packet. □

Definition 6224.4 (Epigraph classifier stability)**.** *For an accepted* $\mathsf{Epigraph}^{\uparrow}$ *carrier* $E = (D, V, L, O, H, C, P, N)$*, classifier stability is the requirement that every repeated epigraph-membership read compares the same domain-point row* D*, value row* V*, lower-bound row* L*, and comparison row* O*, transported*

only through H and replayed only through C. The stable classifier is therefore the finite row inventory governed by Definition 6224.2; it is not a host topology, quotient graph, arbitrary function equality, selected minimizer, or ambient completeness claim.

Lean4 (definition) `BEDC.Derived.EpigraphUp.EpigraphClassifierStability`

Theorem 6224.5 (Epigraph lower-set transport)**.** *Every lower-set read exported by an accepted* $\mathsf{Epigraph}^{\uparrow}$ *packet preserves the rows D, V, L, O, H, C, P, N before a* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumer may inspect it. In particular, the comparison row O can be transported only together with the displayed domain point, value row, lower-bound row, componentwise transport, replay, provenance, and local naming rows required by Definition 6224.2.*

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphLowerSetTransport`

Proof. Project the carrier of Definition 6224.1. The lower-set information appears only as the comparison row O attached to D, V, L.

Apply Definition 6224.2. Its lower-set exposure clause keeps O inside the local $\mathsf{NameCert}_{\mathsf{Epigraph}^{\uparrow}}$ surface, while H transports that comparison componentwise and C replays the same route.

The provenance and naming rows P, N source the transported packet. Since no host subset, quotient graph, arbitrary function equality, selected minimizer, or completeness coordinate is present, lower-set transport cannot leave the displayed rows. □

Theorem 6224.6 (Epigraph ledger exactness)**.** *For every accepted* $\mathsf{Epigraph}^{\uparrow}$ *carrier $E = (D, V, L, O, H, C, P, N)$, the ledger rows C, P, N are exact for the classifier of Definition 6224.4: they replay, source, and name only the displayed domain-point, value, lower-bound, comparison, and transport rows. Together with Definition 6224.2, these rows close the obligation surface without asserting host topology, quotient graph equality, arbitrary function extensionality, selected minimizers, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphLedgerExactness`

Proof. Read the classifier stability definition. It allows repeated reads only through D, V, L, O, H, C, P, N.

Use Definition 6224.2. The NameCert surface already identifies C as replay, P as provenance, and N as local naming for the displayed carrier rows.

Therefore the ledger is exact by exhaustion of carrier coordinates. No additional row can name host topology, quotient graph equality, arbitrary function extensionality, selected minimizers, or ambient completeness, so the obligation surface remains finite. □

Theorem 6224.7 (Epigraph scoped kernel dependencies)**.** *Every* $\mathsf{Epigraph}^{\uparrow}$ *consumer route factors through the displayed domain-point rows, function-value observation rows, lower-bound comparison rows,* $\mathsf{Real}^{\uparrow}$ *boundary rows,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of Definition 6224.1. The route exports no host subset of a product, function extensionality principle, selected minimizer, or ambient real-completeness principle.*

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphScopedKernelDependencies`

Proof. Start with the carrier in Definition 6224.1. Its analytic rows are exactly D, V, L, O, with V and O reaching the $\mathsf{Real}^{\uparrow}$ boundary only through displayed value and lower-bound comparisons.

Apply Definition 6224.3 to pass any lower-semicontinuity consumer through the same displayed value and comparison route. Then use Definition 6224.4 and Definition 6224.5 to keep repeated reads and transported lower-set reads on D, V, L, O, H, C, P, N.

Finally apply Definition 6224.6. The replay, provenance, and naming rows are exact for the displayed carrier, so no additional coordinate can supply a host product subset, function extensionality, selected minimizer, or ambient completeness principle. □

Theorem 6224.8 (Epigraph mature crosslink)**.** *The comparison row O of an accepted* $\mathsf{Epigraph}^{\uparrow}$ *packet is the lower-set comparison row consumed by both the lower-semicontinuity route of chapter 1536 and convex-analysis sibling routes such as chapter 208. Any such consumer must read O together with the displayed domain point D, value row V, lower-bound row L, componentwise transport H, replay C, provenance P, and local naming N before interpreting a lower-set or convex-level comparison.*

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphMatureCrosslink`

Proof. Start with Definition 6224.7. It keeps every epigraph consumer on the displayed rows D, V, L, O, H, C, P, N and refuses host subsets, function extensionality, selected minimizers, and ambient real completeness.

For lower-semicontinuity, apply Definition 6224.3. The open-sublevel and closed-superlevel reads receive the comparison row O only with its domain, value, and lower-bound rows still present.

For convex-analysis consumers, the same row is read as a finite lower-set comparison before any convex-level route can inspect it. The convex sibling therefore receives a displayed comparison surface, not a host epigraph, quotient graph, selected minimizer, or external convexity theorem. □

Theorem 6224.9 (Epigraph mature consumer completeness)**.** *Every lower-semicontinuity, convex-level, and lower-set consumer of an accepted* $\mathsf{Epigraph}^{\uparrow}$ *packet receives exactly the rows*

$$D, V, L, O, H, C, P, N$$

through the carrier of Definition 6224.1, the lower-semicontinuity handoff of Definition 6224.3, the lower-set transport of Definition 6224.5, the ledger exactness of Definition 6224.6, and the mature crosslink of Definition 6224.8. No consumer receives a host epigraph subset, quotient graph, selected minimizer, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, or function-extensional equality outside those rows.*

Lean4 ✓ `BEDC.Derived.EpigraphUp.EpigraphMatureConsumerCompleteness`

Proof. The carrier displays only D, V, L, O, H, C, P, N. By Definition 6224.2, every epigraph read must expose the domain point, function value, lower bound, comparison, transport, replay, provenance, and local naming rows before a consumer can inspect membership.

For lower-semicontinuity consumers, Definition 6224.3 routes the open-sublevel and closed-superlevel read through the same value and comparison rows. For lower-set consumers, Definition 6224.5 keeps the comparison row O attached to D, V, L, H, C, P, N.

Convex-level consumers use the crosslink of Definition 6224.8. Ledger exactness from Definition 6224.6 then says that replay, provenance, and local naming source only this displayed packet. The listed consumers therefore receive exactly the carrier rows and none of the excluded host objects. □

Falsifiable prediction: An accepted $\mathsf{Epigraph}^{\uparrow}$ read is refuted if the comparison row O is preserved while the displayed domain point D, value row V, and lower-bound row L are removed.

Independence witness: lowersemicontinuous, real: neither sibling is bijective with $\mathsf{Epigraph}^{\uparrow}$ because this packet jointly carries a domain-point row, function-value row, lower-bound row, comparison row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{Epigraph}^{\uparrow}}$**.**

Constructive story: An $\mathsf{Epigraph}^{\uparrow}$ packet is generated from a domain-point row, a function-value row, a lower-bound row, a comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Epigraph}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 6224.1, Definition 6224.2, Definition 6224.3, Definition 6224.4, Definition 6224.5, Definition 6224.6, Definition 6224.7, and Definition 6224.9 close the finite epigraph dependency scope and expose the lower-semicontinuity, convex-level, and lower-set consumer routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Epigraph}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Not claimed: This chapter does not close host epigraph topology, quotient graphs, arbitrary function extensionality, selected minimizers, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: No further paper-side closure remains; Lean verification and bridge checking remain separate.

Chapter 6225

A Concrete Naming Certificate for $\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}$

The $\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}$ packet realizes the practice-level audit taxonomy of section 9462.12 as finite NameCert data. It is distinct from the positive-discovery classifier of chapter 6202: that chapter accepts a positive interpretability discovery only after classifier novelty and net-information accounting are displayed, while this packet classifies the practice event that changed the audit surface itself. It sits beside the classifier novelty witness of chapter 6138, the discovery pipeline calculus of chapter 5914, and the effective replacement ledger of chapter 568.

Definition 6225.1 (Positive interpretability classifier practice carrier)**.** *A* $\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (E_0, E_1, J, T, L, Q, D, B, H, C, R, N)$$

with the following displayed rows:

1. E_0 *is the before-practice explanation-state row, including the classifier label then used by the interpretability report.*
2. E_1 *is the after-practice explanation-state row, including the classifier label after the practice change.*
3. J *is the* $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ *row exposing a common-source comparison and the before/after classifier disagreement.*
4. T *is the practice-taxonomy row, distinguishing feature event, classifier event, certificate event, ledger event, verification event, optimization lineage, discovery lineage, and positive discovery lineage.*
5. L *is the effective replacement ledger row recording which practice row is used by downstream reports rather than merely named.*
6. Q *is the public cost row, recording the audit cost of changing the practice classifier and the public rows needed to reproduce the classification.*
7. D *is the debt row separating classifier debt, ledger debt, semantic debt, verification debt, intervention debt, and generalization debt.*
8. B *is the benefit row recording the exposed coverage, prediction, transfer, intervention, verification, or unification gain.*

9. *H stores componentwise* hsame *transport for $E_0, E_1, J, T, L, Q, D, B$.*
10. *C stores displayed* Cont *replay through before/after classifier comparison, practice-taxonomy selection, ledger lookup, public-cost accounting, debt exposure, and benefit exposure.*
11. *R is the* Pkg *provenance over* PositiveInterpretabilityClassifierPractice$^{\uparrow}$, PositiveInterpretabilityClassifier$^{\uparrow}$, ClassifierNoveltyWitness$^{\uparrow}$, DiscoveryPipelineCalculus$^{\uparrow}$, EffectiveReplacementLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{PositiveInterpretabilityClassifierPractice}^{\uparrow}}$ *row.*

The carrier has no coordinate for a prose-only practice shift, a positive-discovery verdict without before/after classifier disagreement, a hidden cost convention, a ledger row with no downstream use, or a classifier-practice claim without public debt and benefit rows.

Theorem 6225.2 (Positive interpretability classifier practice NameCert obligations)**.** *For every accepted* PositiveInterpretabilityClassifierPractice$^{\uparrow}$ *carrier $P = (E_0, E_1, J, T, L, Q, D, B, H, C, R, N)$, the local* NameCert$_{\text{PositiveInterpretabilityClassifierPractice}^{\uparrow}}$ *surface consists exactly of before-state admission, after-state admission, classifier-novelty witness, practice-taxonomy exposure, effective replacement ledger, public cost row, debt row, benefit row, componentwise transport, displayed replay, package provenance, and local naming. A practice-level classifier shift is accepted only when J displays before/after classifier disagreement and Q, L, D, B display the public cost and ledger rows used by the report.*

Proof. Project the carrier of Definition 6225.1. The rows E_0, E_1, J expose the before state, after state, and common-source classifier disagreement.

Next read the practice rows. The taxonomy row T says which practice event is being classified, while L records downstream use and Q, D, B record public cost, debt, and benefit.

Finally H, C, R, N transport, replay, source, and name the same packet. Since no other coordinate can supply a hidden practice shift, hidden cost convention, ledger-only completion, or positive-discovery verdict, the listed rows are exactly the local obligations. □

Theorem 6225.3 (Practice classifier separation from positive discovery)**.** *An accepted* PositiveInterpretabilityClassifi *packet classifies the practice event that changes the interpretability audit surface; it does not by itself classify the result as* PositiveInterpretabilityClassifier$^{\uparrow}$. *A downstream positive-discovery read must separately supply the positive classifier's net-information rows and cannot replace them by the practice-taxonomy row T.*

Proof. Use Definition 6225.2. The practice packet carries T as an event-kind row and records before/after classifier disagreement through J.

The positive-discovery packet of chapter 6202 requires its own cost-protocol and net-information rows. The practice row T is not one of those rows, and the carrier here has no coordinate that asserts positive net information.

Thus the practice classifier can record a classifier-practice shift without accepting a positive-discovery verdict. Any downstream positive claim must pass through the separate positive classifier surface. □

Theorem 6225.4 (Practice classifier public-cost ledger nonescape)**.** *Every public* PositiveInterpretabilityClassifierPra *read factors through the before/after classifier disagreement row J, the practice-taxonomy row T, the effective replacement ledger L, the public cost row Q, and the debt and benefit rows D, B. If any one of J, T, L, Q, D, B is absent, the practice-level classifier shift is not public.*

Proof. Begin with the carrier definition. The only rows that expose the practice shift are J and T, and the only rows that expose public cost and use are L, Q, D, B.

Apply the NameCert obligations. They force any accepted practice read to consume all six rows before replay, provenance, and local naming can certify the packet.

The structural rows H, C, R, N preserve the same route and do not add missing classifier, cost, ledger, debt, or benefit data. Therefore deleting any one of J, T, L, Q, D, B prevents the read from being public. □

Falsifiable prediction: An accepted $\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}$ packet is refuted by a pair of before/after explanation states whose classifier labels agree, or by a report that hides the public cost row, effective replacement ledger, debt row, or benefit row used to classify the practice event.

Independence witness: positive-interpretability-classifier, classifier-novelty-witness, discovery-pipeline-calculus, effective-replacement-ledger: none is bijective to $\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}$ because this packet jointly carries before/after explanation states, a practice-taxonomy row, classifier disagreement, public cost, downstream ledger use, debt and benefit rows, transport, replay, provenance, and local naming as a practice-level classifier.

The Lean follow-up must provide $\mathsf{Nontrivial\ PositiveInterpretabilityClassifierPractice}^{\uparrow}$ and $\mathsf{FieldFaithful\ PositiveInte}$ instances before checked markers for $\mathsf{BEDC.Derived.PositiveInterpretabilityClassifierPracticeUp}$ are cited. Those instances must preserve $E_0, E_1, J, T, L, Q, D, B, H, C, R, N$ as distinct fields, so before/after classifier disagreement, public cost, ledger use, debt, benefit, and practice taxonomy cannot collapse into a one-row carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}$ packet is generated from before and after explanation states, a classifier novelty witness, a practice-taxonomy row, an effective replacement ledger, public cost, debt and benefit rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6225.1, Definition 6225.2, Definition 6225.3, and Definition 6225.4 seed the finite practice-level classifier for interpretability audit shifts.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveInterpretabilityClassifierPractice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the positive interpretability discovery classifier, global interpretability quality, hidden semantic truth, prose-only practice shifts, uncounted costs, undisplayed debts, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked before and after state admission, classifier-disagreement exposure, practice-taxonomy exposure, public cost, effective replacement ledger, debt and benefit rows, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for $\mathsf{BEDC.Derived.PositiveInterpretabilityClassifierPracticeUp}$.

Chapter 6226

A Concrete Naming Certificate for $\mathsf{CauchyModulusCompleteness}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completion, the $\mathsf{CauchyModulusCompleteness}^{\uparrow}$ packet records the finite handoff from an explicit Cauchy modulus to a completion-facing Real seal. It sits after the effective completion route of chapter 2026, the convergence-modulus ledger of chapter 2074, the criterion/modulus comparison of chapter 3343, the real Cauchy criterion of chapter 1590, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite NameCert route for modulus-controlled completion consumers; it is not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$ and it does not create quotient streams, selected limits, countable choice, trichotomy, or host real equality.

Definition 6226.1 (CauchyModulusCompleteness carrier)**.** *A* $\mathsf{CauchyModulusCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (M, E, K, W, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row, recording the finite modulus request and the threshold data accepted by the completion-facing read.*
2. *E is the* $\mathsf{EffectiveCompletion}^{\uparrow}$ *row, exposing the effective completion handoff through which the modulus data reaches a Real-facing consumer.*
3. *K is the* $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$ *or* $\mathsf{RealCauchyCriterion}^{\uparrow}$ *row, binding the same modulus request to a finite Cauchy-criterion read.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by M, E, K before any readback or Real seal is inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and consumed by the completion route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic scales, split radii, slack, and comparison witnesses shared by M, W, R.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reached only after M, E, K, W, R, D have been displayed.*

8. *H records componentwise* hsame *transport for modulus, effective completion, criterion, window, readback, tolerance, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$M, E, K \longmapsto W, D \longmapsto R \longmapsto L.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusCompleteness}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{EffectiveCompletion}^{\uparrow}$, $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$, $\mathsf{RealCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, K, W, R, D, L, H, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyModulusCompletenessUp.TasteGate.CauchyModulusCompletenessTasteGate`
`single carrier alignment`

Theorem 6226.2 (CauchyModulusCompleteness NameCert obligations)**.** *For every accepted* CauchyModulusComp *carrier*

$$X = (M, E, K, W, R, D, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusCompleteness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Cauchy modulus, effective completion, criterion, finite-window, regular readback, tolerance, real-seal, transport, replay, provenance, and local naming rows;*

2. *modulus visibility, requiring every completion-facing request to expose M before any finite window, readback, or Real seal is consumed;*

3. *criterion and completion compatibility, requiring E and K to bind the same modulus request, finite windows, regular readback, dyadic tolerance data, and terminal Real seal;*

4. *window-readback-tolerance exactness, requiring every read used by L to pass through the displayed* $\mathsf{StreamName}^{\uparrow}$ *row W,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*

5. *structural non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed route and to export no ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream, selected limit, countable-choice schedule, trichotomy branch, host real equality, Lean verification credential, or bridge credential.*

No Cauchy modulus completeness obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6226.1. The accepted packet displays exactly the Cauchy modulus, effective completion, criterion, finite-window, readback, tolerance, Real seal, and structural rows.

The modulus-visibility clause is read from M. Since W, R, D, L occur downstream of the displayed modulus route, a completion-facing consumer cannot inspect stream data, rational readback, dyadic tolerance, or a Real seal before the modulus request is visible.

The compatibility and exactness clauses are read from E, K, W, R, D, L. The effective completion row E and the criterion row K bind the same request to finite windows W, regular readback R, and dyadic tolerance data D before the terminal seal L is reached.

The structural clause is exhausted by H, C, P, N. These rows only transport, replay, source, and name the displayed route, and the carrier has no coordinate for the excluded completeness, quotient, selection, choice, trichotomy, host-equality, verification, or bridge data. □

Theorem 6226.3 (CauchyModulusCompleteness Real seal handoff)**.** *For every accepted* CauchyModulusCompleten *carrier*

$$X = (M, E, K, W, R, D, L, H, C, P, N),$$

every completion-facing consumer must pass through the displayed route

$$M, E, K \longmapsto W, D \longmapsto R \longmapsto L$$

with transport, replay, provenance, and local naming supplied only by H, C, P, N before reading the terminal $\mathsf{Real}^{\uparrow}$ *seal. The consumer receives no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream equality, selected limit, countable-choice schedule, trichotomy branch, or host real equality.*

Proof. Fix a completion-facing consumer of X. The only terminal Real-facing coordinate is L, so any allowed read of a Real seal must reach that row through the displayed carrier route.

Read the dependencies of L. The seal is downstream of the finite-window row W, the dyadic tolerance row D, and the regular readback row R.

The source of those rows is fixed by M, E, K. The modulus row M exposes the Cauchy-modulus request, E carries the effective completion handoff, and K records the criterion route binding the same request to the same finite data.

The structural rows add no analytic data. Componentwise transport through H preserves the displayed coordinates, replay through C preserves the route order, and P, N only source and name the same packet.

Since no excluded object appears as a carrier coordinate, the consumer cannot obtain ambient Real completeness, quotient stream equality, a selected limit, countable choice, trichotomy, or host real equality. Thus every completion-facing consumer passes through the displayed modulus, window, readback, tolerance, and Real-seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusCompleteness}^{\uparrow}$ packet is generated from a CauchyModulus row, an EffectiveCompletion row, a CauchyCriterionEquivalence or RealCauchyCriterion row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6226.1, Definition 6226.2, and Definition 6226.3 seed the finite modulus-controlled completion handoff from CauchyModulus data to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus visibility, completion and criterion compatibility, window-readback-tolerance exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusCompletenessUp.

Chapter 6227

A Concrete Naming Certificate for $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$

Following Specker's bounded monotone sequence construction and Bishop–Bridges constructive analysis, the $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$ packet names the finite boundary between bounded monotone rational stream data and any later located-supremum or completion-facing claim. It is read next to the Specker obstruction surface of chapter 3516, the stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet records monotone bounded window data and the refusal rows that keep that data from becoming a located supremum or ambient completeness principle.

Definition 6227.1 (Specker monotone boundary carrier)**.** *A* $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, W, D, R, B, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ *source row naming the nonlocated-supremum obstruction inherited from the bounded monotone Specker stream.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the finite rational windows inspected by the boundary packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and bound ledger read from those windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data visible at the scheduled windows.*
5. *B is the monotone bounded stream ledger recording displayed order, bound, and window-comparison data before any supremum-facing row is considered.*
6. *L is the refusal row separating the displayed stream data from a located supremum, a selected limit, and any ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*
7. *H stores componentwise* hsame *transport for S, W, D, R, B, L.*
8. *C stores displayed* Cont *replay from source and schedule rows through dyadic bounds, regular readback, monotone bounded evidence, and the refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$, $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SpeckerMonotoneBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, R, B, L, H, C, P, N$. It has no coordinate for a located supremum, selected limit, quotient stream equality, trichotomy, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SpeckerMonotoneBoundaryUp.SpeckerMonotoneBoundaryTasteGate single carrier alignment`

Theorem 6227.2 (Specker monotone boundary NameCert obligations)**.** *For every accepted* SpeckerMonotoneBoun *carrier*

$$M = (S, W, D, R, B, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SpeckerMonotoneBoundary}^{\uparrow}}$ *surface consists exactly of source admission through S, finite schedule selection through W, dyadic tolerance and bound accounting through D, regular rational readback through R, bounded monotone ledger admission through B, supremum-and-completeness refusal through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6227.1. The analytic rows are precisely the Specker boundary source, stream schedule, dyadic ledger, regular rational readback, bounded monotone ledger, and refusal row.

The structural rows H, C, P, N transport, replay, source, and name those same coordinates. Since the carrier contains no further analytic field, the listed rows exhaust the local NameCert obligations.

The excluded principles would require extra public coordinates. A located supremum, selected limiting real, quotient stream equality, trichotomy branch, countable-choice selector, or ambient completeness theorem is therefore not part of the accepted packet. □

Theorem 6227.3 (Specker monotone boundary nonescape)**.** *Every consumer of an accepted* $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$ *carrier receives only the finite rows $S, W, D, R, B, L, H, C, P, N$. Consequently bounded monotone rational stream data may be passed to* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*-facing readers only through the displayed schedule, tolerance ledger, regular readback, bounded monotone ledger, and refusal row; it exports no located supremum, selected limit, trichotomy, quotient stream equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use Definition 6227.2 to identify the complete public surface of the accepted packet. Every analytic read passes through S, W, D, R, B, L before the structural rows can name or replay it.

The Specker source row records the obstruction surface, while W, D, R, B expose only finite stream windows, dyadic bounds, regular rational readbacks, and monotone bounded comparison data. These rows do not contain a selector for a supremum or a quotient equality on streams.

Finally read the refusal row L. It is the only completion-facing boundary coordinate, and it records separation from located supremum and ambient Real completeness rather than supplying them. Transport, replay, provenance, and naming preserve that finite route, so none of the excluded principles can escape from the packet. □

Falsifiable prediction: Every $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$ consumer that treats bounded monotone rational stream data as a located supremum or as ambient $\mathsf{Real}^{\uparrow}$ completeness without displaying $S, W, D, R, B, L, H, C, P, N$ refutes Definition 6227.1.

Independence witness: Nearest siblings: specker-sequence-boundary, streamname, regseqrat, dyadicratcore, and real. $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$ is not bijective to any listed sibling because it

jointly carries the Specker obstruction source, finite stream schedule, dyadic bound ledger, regular rational readback, bounded monotone ledger, refusal row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SpeckerMonotoneBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{SpeckerMonotoneBoundary}^{\uparrow}$ packet is generated from a SpeckerSequenceBoundary source row, a StreamName schedule, a DyadicRatCore tolerance and bound ledger, a RegSeqRat readback row, a bounded monotone stream ledger, a located-supremum and Real-completeness refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpeckerMonotoneBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6227.1, Definition 6227.2, and Definition 6227.3 seed the finite boundary between bounded monotone rational stream data and completion-facing claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpeckerMonotoneBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim located supremum construction, selected limits, trichotomy, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, monotone bounded readback, nonescape, classifier transport, displayed replay, provenance, and local naming for BEDC.Derived.SpeckerMonotoneBoundaryUp.

Chapter 6228

A Concrete Naming Certificate for $\mathsf{UniformIntegrability}^{\uparrow}$

Following Dunford and Schwartz, the $\mathsf{UniformIntegrability}^{\uparrow}$ packet records the finite tail-control surface that sits between dominated convergence and Vitali convergence. It reads the measure and integral rows used by chapter 2340, exposes a family-indexed tail cutoff and uniform tail-bound ledger, and then supplies the uniform-integrability row consumed by chapter 5167. The packet is a finite BEDC carrier for tail budgets; it is not measure-theoretic choice, full dominated convergence, ambient integration completeness, quotient almost-everywhere equality, or a selected representative theorem.

Definition 6228.1 (Uniform integrability carrier)**.** *A* $\mathsf{UniformIntegrability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, I, F, T, B, H, C, P, N)$$

with the following displayed rows:

1. M *is the* $\mathsf{Measure}^{\uparrow}$ *source row for the displayed measurable-domain and measurable-set requests.*
2. I *is the* $\mathsf{Integral}^{\uparrow}$ *readback row through which tail integrals and budget comparisons are inspected.*
3. F *is the finite family row naming the integrands whose tails are being controlled.*
4. T *is the tail-cutoff row, assigning each displayed tolerance request a finite cutoff window.*
5. B *is the uniform tail-bound row, recording the shared bound read after* M, I, F, T *have been exposed.*
6. H *records componentwise* hsame *transport for* M, I, F, T, B *and the local structural rows.*
7. C *records displayed* Cont *replay from a tail-budget request through the cutoff and bound rows.*
8. P *is the* Pkg *provenance over* $\mathsf{UniformIntegrability}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{DominatedConvergence}^{\uparrow}$, $\mathsf{VitaliConvergence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{UniformIntegrability}^{\uparrow}}$ *row.*

The carrier has no coordinate for countable choice of representatives, ambient measure completion, full dominated convergence, global integration completeness, quotient almost-everywhere equality, or a detached Vitali theorem.

Lean4 ✓ `BEDC.Derived.UniformIntegrabilityUp.UniformIntegrabilityTasteGate single carrier alignment`

Theorem 6228.2 (Uniform integrability NameCert obligations)**.** *For every accepted* $\mathsf{UniformIntegrability}^{\uparrow}$ *carrier* $U = (M, I, F, T, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformIntegrability}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure row, integral row, displayed family row, tail-cutoff row, uniform tail-bound row, transport row, replay row, provenance row, and local naming row. The cutoff and bound obligations are read only through* T *and* B *after* M, I, F *have been displayed.*

Proof. Project the carrier of Definition 6228.1. The analytic rows are exactly M, I, F, T, B, and the structural rows are exactly H, C, P, N.

Tail control is the ordered read through T and B. The cutoff row answers the displayed tolerance request, and the uniform bound row records the shared tail estimate after the same measure, integral, and family rows have already been exposed.

The structural rows preserve the same packet. Componentwise transport, replay, provenance, and local naming do not add a selected representative, measure completion, host domination theorem, or integration-completeness coordinate. Hence the listed rows exhaust the local NameCert surface. □

Theorem 6228.3 (Uniform integrability Vitali consumption)**.** *Every* $\mathsf{VitaliConvergence}^{\uparrow}$ *consumer of a* $\mathsf{UniformIntegrability}^{\uparrow}$ *packet reads the uniform-integrability budget through the finite route*

$$M \longmapsto I \longmapsto F \longmapsto T \longmapsto B \longmapsto H, C, P, N.$$

When a dominated-convergence sibling route is present, chapter 2340 may supply the displayed majorant-side evidence, but the Vitali-facing handoff of chapter 5167 still consumes only the tail-cutoff and uniform tail-bound rows listed in Definition 6228.1.

Proof. Start with a Vitali-facing read. By Definition 6228.1, the only family-level analytic rows are M, I, F, T, B.

The budget visible to $\mathsf{VitaliConvergence}^{\uparrow}$ is the tail route $T \longmapsto B$. It records finite cutoffs and a shared tail-bound ledger, not a host theorem about all measurable functions.

If a dominated-convergence handoff is also used, it is sibling evidence attached through the displayed measure, integral, and family rows. It does not replace the uniform-integrability row by full dominated convergence.

The structural rows H, C, P, N transport and replay the same finite route. Since the carrier lacks measure-theoretic choice, ambient integration completeness, quotient almost-everywhere equality, and selected representatives, the Vitali consumer cannot read any of those objects from this packet. □

Falsifiable prediction: Any $\mathsf{VitaliConvergence}^{\uparrow}$ read that claims a uniform-integrability budget while bypassing the displayed Measure, Integral, family, tail-cutoff, uniform tail-bound, hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 6228.1.

Independence witness: dominated-convergence, vitali-convergence, measure, integral: $\mathsf{UniformIntegrability}^{\uparrow}$ is not bijective to any listed sibling because it stores the finite tail-cutoff and uniform tail-bound rows that dominated convergence may imply and Vitali convergence consumes, without storing full dominated convergence or the Vitali conclusion.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformIntegrability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformIntegrability}^{\uparrow}$ packet is generated from displayed Measure, Integral, integrand-family, tail-cutoff, uniform tail-bound, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6228.1, Definition 6228.2, and Definition 6228.3 seed the finite tail-budget interface between dominated convergence and Vitali convergence.

Formal verification: FormalStatus(NameCert$_{\text{UniformIntegrability}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim measure-theoretic choice, full dominated convergence, ambient integration completeness, quotient almost-everywhere equality, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-cutoff visibility, uniform tail-bound exactness, dominated-convergence sibling routing, Vitali consumption routing, structural transport, replay, provenance, and nonescape for BEDC.Derived.UniformIntegrabilityUp.

Chapter 6229

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailBall}^{\uparrow}$

Following Bishop and Bridges' regular Cauchy completion route, the $\mathsf{RegularCauchyTailBall}^{\uparrow}$ packet concretizes the finite tail-ball direction of chapter 9238. It sits on the dyadic tolerance surface of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet records a selected tail threshold, a displayed ball radius, a finite observation window, and a Real-facing seal row; it does not assert ambient completeness, quotient streams, selected host limits, countable choice, or host equality of real names.

Definition 6229.1 (Regular Cauchy tail-ball carrier)**.** *A* $\mathsf{RegularCauchyTailBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, S, D, Q, W, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened at the tail threshold.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the selected tail radius with the requested precision.*
4. *Q is the tail-threshold row naming the finite index after which the regular Cauchy source is read inside the ball.*
5. *W is the tail-ball witness row, recording the displayed center, radius, and finite window selected by Q.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, S, D, Q, W have been displayed.*
7. *H records componentwise* hsame *transport for the analytic rows and the local structural rows.*
8. *C records displayed* Cont *replay from a Real-completion request through the threshold, window, dyadic ledger, and seal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBall}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected host limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, or host equality of real names.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailBallUp.RegularCauchyTailBallTasteGate single carrier alignment`

Theorem 6229.2 (Regular Cauchy tail-ball NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailBall}^{\uparrow}$ *carrier* $T = (R, S, D, Q, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBall}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular rational source, finite stream window, dyadic tolerance ledger, tail threshold, tail-ball witness, Real seal, componentwise transport, displayed replay, provenance, and local naming rows.*

Proof. Project the carrier of Definition 6229.1. The visible analytic rows are R, S, D, Q, W, E, and the structural rows are H, C, P, N.

The tail-ball obligation is the ordered read through Q and W. The threshold row fixes the finite tail, and the witness row records the center, radius, and finite window within that tail.

The dyadic and Real-facing rows are downstream. The ledger D supplies the displayed tolerance comparison, and the seal E is consumed only after the regular rational source and stream window have been exposed.

Transport, replay, provenance, and naming preserve the same finite route. Since the carrier lacks quotient streams, selected limits, countable choice, host equality, and ambient completeness, the listed rows exhaust the local surface. □

Theorem 6229.3 (Regular Cauchy tail-ball Real-completion route)**.** *Every Real-completion consumer that reads a* $\mathsf{RegularCauchyTailBall}^{\uparrow}$ *packet must pass through*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by $R, S, D, Q, W, E, H, C, P, N$*. Thus the tail-ball route turns the finite regular Cauchy tail idea of chapter 9238 into a concrete NameCert packet available to* $\mathsf{Real}^{\uparrow}$ *consumers without exporting quotient streams or ambient completeness.*

Proof. Begin with the accepted carrier $T = (R, S, D, Q, W, E, H, C, P, N)$. The regular rational source R and finite window schedule S are the only source rows available to the packet.

The threshold and ball data are Q and W. They select a finite tail and a displayed ball witness before any Real-facing seal can be read.

The dyadic ledger D and terminal seal E form the completion-facing handoff. A consumer reads dyadic tolerance data before reaching the $\mathsf{Real}^{\uparrow}$ boundary, so it receives a finite tail-ball certificate rather than a quotient completion.

Finally H, C, P, N transport, replay, source, and name the same route. Because the excluded objects are absent from the carrier, the Real-completion consumer cannot extract ambient completeness, quotient streams, selected host limits, countable choice, or host equality from the packet. □

Falsifiable prediction: A Real-completion consumer that claims a $\mathsf{RegularCauchyTailBall}^{\uparrow}$ read while omitting the displayed RegSeqRat, StreamName, DyadicRatCore, tail-threshold, tail-ball, RealUp seal, hsame, Cont, Pkg, or NameCert rows refutes the carrier of Definition 6229.1.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyTailBall}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores a regular rational source, finite tail

threshold, tail-ball witness, dyadic tolerance ledger, stream window, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBall}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyTailBall}^{\uparrow}$ packet is generated from a RegSeqRat source, StreamName finite window, DyadicRatCore tolerance ledger, tail threshold, tail-ball witness, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailBall}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6229.1, Definition 6229.2, and Definition 6229.3 seed the finite tail-ball route from regular Cauchy data to the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailBall}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient completeness, quotient streams, selected host limits, countable choice, host equality of real names, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold visibility, tail-ball witness exactness, dyadic tolerance readback, Real seal handoff, transport, replay, provenance, and nonescape for BEDC.Derived.RegularCauchyTailBallUp.

Chapter 6230

A Concrete Naming Certificate for $\mathsf{LocatedIntervalSupremum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedIntervalSupremum}^{\uparrow}$ packet records the finite interval-restricted route by which a located supremum read becomes available over a displayed real interval. It sits over the upper-bound and lower-approximation surface of chapter 1427, the retained-branch discipline of chapter 1711, the bounded interval completion boundary of chapter 5836, the dyadic tolerance ledger of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names constructive interval supremum data as finite rows; it does not assert general $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, trichotomy, countable choice, quotient real equality, or a selected host supremum.

Definition 6230.1 (Located interval supremum carrier)**.** *A* $\mathsf{LocatedIntervalSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (J, U, A, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the located interval source row. It records the displayed endpoints, interval membership requests, and interval-local locatedness data consumed before any supremum-facing read is accepted.*
2. *U is the upper-bound ledger. It records that the candidate Real-facing row bounds the interval-local family through displayed endpoint, membership, and tolerance checks.*
3. *A is the lower-approximation ledger. For each accepted precision request it displays an interval-local approximation row that lies below the bound surface and is read through the same precision route.*
4. *B is the bisection and refinement row. It records retained subintervals, branch decisions, and diameter or tolerance refinements supplied by the located interval bisection surface.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened at the indices and tolerances displayed by J, U, A, B.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows and dyadic tolerance data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, consumed only after the interval source, upper-bound ledger, lower-approximation ledger, refinement row, finite windows, and regular readback have been displayed.*

8. *H records componentwise* hsame *transport for $J, U, A, B, W, R, E, C, P, N$.*
9. *C records displayed* Cont *replay for interval-supremum requests through the finite route*

$$J, U, A, B \longmapsto W, R \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalSupremum}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalSupremum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $J, U, A, B, W, R, E, H, C, P, N$. It has no coordinate for a selected host supremum, quotient real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalSupremumUp.TasteGate.LocatedIntervalSupremumTasteGate single carrier alignment`

Theorem 6230.2 (Located interval supremum NameCert obligations)**.** *For every accepted* LocatedIntervalSupremum *carrier $I = (J, U, A, B, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalSupremum}^{\uparrow}}$ *surface is exhausted by the following finite obligations:*

1. *carrier admission for the located interval source, upper-bound ledger, lower-approximation ledger, bisection and refinement row, finite StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *upper-bound exposure, requiring every supremum-facing bound read to display J and U before E can be consumed;*
3. *lower-approximation cofinality, requiring each accepted precision request to receive an approximation row in A through the same interval and window route;*
4. *bisection-window exactness, requiring the retained subinterval and refinement data in B to determine the windows opened in W;*
5. *readback and seal handoff, requiring each Real-facing read to pass through W, R, E after the interval source, bound, approximation, and bisection rows have been displayed;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No obligation exports a selected host supremum, quotient real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalSupremumUp.LocatedIntervalSupremumTasteGate single carrier alignment`

Proof. Project the carrier of Definition 6230.1. The projection exposes exactly the located interval source J, the upper-bound ledger U, the lower-approximation ledger A, the bisection and refinement row B, the finite observation rows W, R, the terminal seal E, and the structural rows H, C, P, N.

The upper and lower supremum faces are row-local. A bound read must use J and U, while a precision request for lower approximation must use A over the same interval source. Since both faces are tied to B, the retained branch and refinement data determine which finite windows are opened.

The Real-facing handoff is then forced through W, R, E. The StreamName row supplies only the displayed finite windows, the RegSeqRat row supplies the regular rational readback attached to those windows, and the Real seal is downstream of that readback.

Finally the structural rows transport, replay, source, and name the same finite route. Because the carrier contains no row for a selected host supremum, quotient equality, choice schedule, trichotomy decision, open-cover subcover, or ambient completeness theorem, the listed obligations exhaust the local NameCert surface. □

Theorem 6230.3 (Located interval supremum Real seal route)**.** *Every Real-facing supremum read exported by an accepted* $\mathsf{LocatedIntervalSupremum}^{\uparrow}$ *carrier*

$$I = (J, U, A, B, W, R, E, H, C, P, N)$$

factors through the finite route

$$J, U, A, B \longmapsto W, R \longmapsto E, H, C, P, N.$$

The read first displays the located interval source, the upper-bound ledger, the lower-approximation ledger, and the retained bisection or refinement row; it then opens finite StreamName windows, reads them through RegSeqRat, and only then consumes the terminal Real seal. The route exports no selected host supremum, quotient real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier rows named in Definition 6230.1. A Real-facing supremum read has no access to the seal E until the interval source J, upper-bound ledger U, lower-approximation ledger A, and bisection row B have been displayed.

The finite readback route is fixed by those rows. The bisection and approximation ledgers determine the requested finite windows W, and the regular rational readback R is attached to those same windows before the seal can be consumed.

Transport and replay do not create a new supremum source. The rows H and C move and replay only the displayed coordinates, while P and N record provenance and local naming for the same packet.

Thus every exported Real-facing observation factors through $J, U, A, B, W, R, E, H, C, P, N$. Since no coordinate of the packet carries a host supremum selector, quotient equality, choice, trichotomy, open-cover compactness, or ambient completeness, none of those principles is exported by the route. □

Falsifiable prediction: Every $\mathsf{LocatedIntervalSupremum}^{\uparrow}$ Real-facing read factors through one located interval source row, one upper-bound ledger, one lower-approximation ledger, one bisection and refinement row, one StreamName window row, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: Nearest siblings: locatedsupremum, located-interval-bisection, bounded-complete-real-interval, dyadicratcore, streamname, regseqrat, and real. $\mathsf{LocatedIntervalSupremum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries interval source data, upper-bound exposure, lower-approximation cofinality, bisection-window exactness, readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalSupremum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedIntervalSupremum}^{\uparrow}$ packet is generated from a located interval source, an upper-bound ledger, a lower-approximation ledger, a bisection and refinement row, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{LocatedIntervalSupremum}\uparrow}$, seed)

Scope closed: Definition 6230.1, Definition 6230.2, and Definition 6230.3 seed the finite interval-supremum route over located interval, bound, approximation, bisection, readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedIntervalSupremum}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general Real$^{\uparrow}$ completeness, selected host suprema, quotient real equality, countable choice, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-bound exposure, lower-approximation cofinality, bisection-window exactness, RegSeqRat handoff, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalSupremumUp.

Chapter 6231

A Concrete Naming Certificate for $\mathsf{EulerMethodFiniteStep}^{\uparrow}$

Following Euler and the constructive numerical ODE tradition, the $\mathsf{EulerMethodFiniteStep}^{\uparrow}$ packet records the finite forward-step certificate by which a displayed ordinary differential equation is read through a bounded mesh, a visible initial state, and finitely many endpoint updates. It sits after the ODE source of chapter 193, the continuous-map row of chapter 130, the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, and the terminal real-name surface of chapter 38. The certificate names a bounded numerical flow segment; it does not assert exact solution existence, global continuation, convergence as the mesh tends to zero, or ambient real completeness.

Definition 6231.1 (Euler finite-step carrier)**.** *An* $\mathsf{EulerMethodFiniteStep}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (O, F, T, X, D, H, C, P, N)$$

with the following rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *local time-state row, naming the initial state, finite time window, and state-cell boundary.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *vector-field read available on the same displayed window.*
3. *T is the finite step ledger, recording the ordered time nodes, step widths, and endpoint budget.*
4. *X is the finite state-readback ledger, recording each displayed Euler update from the previous state and the vector-field row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic row for step widths, local products, and endpoint error budgets.*
6. *H records componentwise* hsame *transport for the ODE, vector-field, step, state, dyadic, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$O, F, T, D \longmapsto X \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{EulerMethodFiniteStep}^{\uparrow}$*,* $\mathsf{Ode}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{EulerMethodFiniteStep}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their displayed transports. It has no coordinate for a host solution curve, selected limiting path, quotient equality of functions, countable-choice schedule, or an exact ODE solution.

Lean4 ✓ `BEDC.Derived.EulerMethodFiniteStepUp.EulerMethodFiniteStepTasteGate single carrier alignment`

Theorem 6231.2 (Euler finite-step NameCert obligations)**.** *For every accepted* $\mathsf{EulerMethodFiniteStep}^{\uparrow}$ *carrier* $E = (O, F, T, X, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EulerMethodFiniteStep}^{\uparrow}}$ *surface consists of the following five obligation rows:*

1. *carrier admission for the displayed* $\mathsf{Ode}^{\uparrow}$ *source* O *and* $\mathsf{ContinuousMap}^{\uparrow}$ *vector-field row* F*;*
2. *finite step-budget admission through* T*, including node order, step widths, and endpoint range;*
3. *update-readback exposure through* X*, with each update read from the previous state,* F*, and the matching step-width row;*
4. *dyadic arithmetic and tolerance accounting through* D*, stable under componentwise* hsame *transport* H *and displayed* Cont *replay* C*;*
5. Pkg *provenance and local naming through* P, N*, including the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumer faces reached only after the finite step ledger is visible.*

No local obligation may read exact ODE solution existence, convergence beyond the displayed finite step budget, global continuation, quotient path equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only analytic source rows are the ODE row O, vector-field row F, finite step ledger T, update ledger X, and dyadic arithmetic row D.

The step ledger fixes the finite budget before any state readback is exposed. Each update in X is therefore a displayed read from the previous state, the vector-field row, and the matching dyadic step-width data.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a host solution curve, limiting path, global continuation, choice schedule, or ambient completeness theorem, the five rows listed in the statement exhaust the NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{EulerMethodFiniteStep}^{\uparrow}$ consumer that reads an endpoint update without the displayed ODE row, continuous-map vector-field row, finite step ledger, dyadic arithmetic row, and structural hsame, Cont, Pkg, and NameCert rows refutes the packet surface.

Independence witness: ode, continuousmap, dyadicratcore, streamname, real: none is bijective to $\mathsf{EulerMethodFiniteStep}^{\uparrow}$ because this packet binds the local ODE source, vector-field read, finite step budget, update ledger, dyadic arithmetic, transport, replay, provenance, and local naming rows into one finite method certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{EulerMethodFiniteStep}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EulerMethodFiniteStep}^{\uparrow}$ packet is generated from an Ode local source row, a ContinuousMap vector-field row, a finite step ledger, finite update readbacks, DyadicRatCore arithmetic, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EulerMethodFiniteStep}^{\uparrow}}$, seed)

Scope closed: Definition 6231.1 and Definition 6231.2 seed the finite forward-Euler step route over ODE, continuous-map, dyadic, stream-name, real-readback, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{EulerMethodFiniteStep}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim exact ODE solution existence, convergence beyond the displayed finite step budget, global continuation, selected limiting paths, quotient function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, step-budget visibility, update-readback exposure, dyadic arithmetic stability, transport, replay, provenance, and local naming for BEDC.Derived.EulerMethodFiniteStepUp.

Chapter 6232

A Concrete Naming Certificate for $\mathsf{RegularCauchySaturation}^{\uparrow}$

The $\mathsf{RegularCauchySaturation}^{\uparrow}$ packet realizes the real-completion vision route of chapter 9238 and section 9238.1 as a finite tail-budget closure surface. It binds the dyadic tolerance ledger of chapter 291, the finite window naming discipline of chapter 126, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the equality boundary of chapter 1820. The packet names a saturation route for finite tail windows; it does not assert full real completeness, selected limits, quotient representatives, countable choice, or a global metric completion theorem.

Definition 6232.1 (Regular Cauchy saturation carrier)**.** *A* $\mathsf{RegularCauchySaturation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, D, E, Q, H, C, P, N)$$

with the following rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window row, naming the inspected regular Cauchy stages and the requested precision window.*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested rational radius, tail comparison budget, and diagonal readback arithmetic.*
4. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* W, R, D *have been displayed.*
5. Q *is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *boundary row, recording equality only through the displayed tail-window and tolerance route.*
6. H *records componentwise* hsame *transport for the window, readback, tolerance, real-seal, setoid-boundary, replay, provenance, and naming rows.*
7. C *records displayed* Cont *replay through*

$$W, R, D, Q \longmapsto E \longmapsto H, P, N.$$

8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchySaturation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySaturation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, R, D, E, Q, H, C, P, N$. It has no coordinate for a selected limit, quotient stream representative, countable-choice schedule, ambient completeness theorem, or host equality of real names.

Theorem 6232.2 (Regular Cauchy saturation NameCert obligations)**.** *For every accepted* RegularCauchySaturation *carrier $S = (W, R, D, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySaturation}^{\uparrow}}$ *surface consists exactly of finite tail-window admission through W, regular-rational readback through R, dyadic tolerance accounting through D, terminal real-seal exposure through E, Cauchy-equivalence boundary routing through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No local obligation may read full* $\mathsf{Real}^{\uparrow}$ *completeness, a selected limit representative, quotient stream equality, countable choice, metric-completion universality, or host real equality.*

Proof. Project the accepted carrier. The completion-facing data are exactly the tail-window row W, regular-rational readback row R, dyadic tolerance row D, terminal real-seal row E, and setoid-boundary row Q.

The finite tail-window row comes first. It fixes the stages and precision request before the regular rational readback and dyadic comparison can be inspected.

The equality boundary is then only a displayed Cauchy-equivalence route over the same rows. Componentwise transport, continuation replay, provenance, and local naming preserve this finite surface and do not add a selected limit, quotient representative, choice schedule, universal completion object, or ambient completeness theorem. □

Falsifiable prediction: A $\mathsf{RegularCauchySaturation}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ rows refutes the packet surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy-equivalence-setoid: none is bijective to $\mathsf{RegularCauchySaturation}^{\uparrow}$ because this packet jointly carries finite tail windows, regular-rational readback, dyadic tolerance, terminal Real seal, Cauchy-equivalence boundary, transport, replay, provenance, and local naming rows.

The Lean TasteGate follow-up for $\mathsf{RegularCauchySaturation}^{\uparrow}$ must include explicit Nontrivial RegularCauchySatura and FieldFaithful $\mathsf{RegularCauchySaturation}^{\uparrow}$ instances, with field faithfulness preserving the order $W, R, D, E, Q, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySaturation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySaturation}^{\uparrow}$ packet is generated from StreamName finite tail windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal row, a CauchyEquivalenceSetoid boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySaturation}^{\uparrow}}$, seed)

Scope closed: Definition 6232.1 and Definition 6232.2 seed the finite tail-budget route from regular Cauchy windows to the terminal Real seal and Cauchy-equivalence boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySaturation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim full real completeness, selected limit representatives, quotient stream equality, countable choice, metric-completion universality, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked tail-window admission, regular-rational readback, dyadic tolerance accounting, terminal Real seal routing, Cauchy-equivalence boundary exposure, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySaturationUp.

Chapter 6233

A Concrete Naming Certificate for $\mathsf{MarkovReal}^{\uparrow}$

Following Markov and Kushner on constructive recursive real analysis, the $\mathsf{MarkovReal}^{\uparrow}$ packet records a Markov-school effective real inspection boundary as finite BEDC data. It is read beside the effective source rows of chapter 336, the Markov-sensitive refusal row of chapter 1666, the constructive trichotomy boundary of chapter 6149, the regular-rational readback of chapter 301, the stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet exposes the finite rows through which a Markov-school inspection may be replayed, while keeping Markov's principle, real trichotomy, stream quotients, selected representatives, countable choice, and ambient completeness outside the BEDC kernel.

Definition 6233.1 (MarkovReal carrier)**.** *A* $\mathsf{MarkovReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (C, B, A, S, R, D, E, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{ComputableReal}^{\uparrow}$ *source row naming the effective real presentation whose finite observations are being inspected.*
2. *B is the* $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ *inspection/refusal row that bounds any use of negative evidence.*
3. *A is the apartness-or-trichotomy-boundary row supplied by* $\mathsf{ConstructiveRealTrichotomyBoundary}^{\uparrow}$ *for displayed comparison evidence and refusal.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window through which the inspection reads the effective source.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed by the window.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the endpoint and margin rows used by the readback.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the effective source, boundary, window, readback, and tolerance rows have been displayed.*
8. *H records componentwise* hsame *transport for the effective source, Markov boundary, trichotomy boundary, stream window, regular readback, dyadic ledger, real seal, replay, provenance, and local naming row.*

9. *K records displayed* Cont *replay from a Markov-school inspection request through C, B, A, S, R, D, E.*
10. *P records* Pkg *provenance over* $\mathsf{MarkovReal}^{\uparrow}$, $\mathsf{ComputableReal}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, ConstructiveRealTrich $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for Markov's principle as an imported axiom, constructive real trichotomy, quotient stream equality, selected representatives, countable choice, selected limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.MarkovRealUp.MarkovRealTasteGate single carrier alignment`

Theorem 6233.2 (MarkovReal NameCert obligations)**.** *For every accepted* $\mathsf{MarkovReal}^{\uparrow}$ *carrier*

$$M = (C, B, A, S, R, D, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MarkovReal}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for the displayed effective source, Markov boundary, trichotomy boundary, finite window, readback, tolerance ledger, real seal, transport, replay, provenance, and local name;*
2. *effective-window exposure, requiring every public observation of C to pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *row S;*
3. *Markov-boundary non-escape, requiring every use of negative evidence to cite B rather than a global Markov rule;*
4. *apartness/refusal compatibility, requiring every comparison-facing inspection to pass through the displayed row A;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring each inspected rational value to be exposed through R before any real-facing conclusion is public;*
6. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring the seal E to consume only the displayed readback and tolerance rows;*
7. *componentwise transport through H;*
8. *displayed continuation replay through K;*
9. *package provenance through P;*
10. *local naming through N.*

No Markov-real naming obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6233.1. The tuple displays the effective source, the two boundary rows, the finite window, the regular-rational readback, the dyadic tolerance ledger, and the real seal before it lists transport, replay, provenance, and local naming.

The effective-window and readback obligations follow from the positions of S and R. A consumer cannot inspect the effective source C without first naming a finite stream window S, and the rational data read from that window is public only through the regular-sequence row R and the dyadic ledger D.

The Markov-boundary and apartness/refusal obligations are the boundary rows B and A. They record the finite evidence or refusal that an inspection may cite, but they do not add Markov's principle or trichotomy as ambient rules.

The remaining rows are componentwise. Transport is exactly H, replay is exactly K, provenance is exactly P, and the local public name is exactly N. Since the carrier contains no additional coordinate, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{MarkovReal}^\uparrow}$ surface. □

Theorem 6233.3 (MarkovReal RegSeqRat handoff)**.** *Every* $\mathsf{Real}^\uparrow$*-facing* $\mathsf{MarkovReal}^\uparrow$ *read factors through the displayed route*

$$\mathsf{ComputableReal}^\uparrow \to \mathsf{MarkovPrincipleBoundary}^\uparrow \to \mathsf{StreamName}^\uparrow \to \mathsf{RegSeqRat}^\uparrow \to \mathsf{DyadicRatCore}^\uparrow \to \mathsf{Real}^\uparrow$$

before any inspection conclusion is public. In particular, the $\mathsf{MarkovReal}^\uparrow$ *packet exposes no direct path from an effective real source to a real-facing Markov conclusion that bypasses the boundary, finite window, regular-rational readback, dyadic tolerance ledger, and real seal.*

Proof. Let $M = (C, B, A, S, R, D, E, H, K, P, N)$ be an accepted carrier. The source row C names the effective real presentation, while B bounds the Markov-sensitive inspection that may be performed on it.

Any actual observation must next pass through the finite window S. The read values are not public as a completed real object; they are exposed through the regular-rational row R and the dyadic tolerance ledger D.

Only after those rows have been displayed may the real seal E be cited. Transport H and replay K preserve the same route componentwise, while P and N repackage it as the public NameCert surface. Thus every Real-facing read factors through the stated chain before it can support an inspection conclusion. □

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovReal}^\uparrow}$.

Constructive story: A $\mathsf{MarkovReal}^\uparrow$ packet is generated from a ComputableReal source row, a MarkovPrincipleBoundary inspection/refusal row, an apartness-or-trichotomy-boundary row, a finite StreamName window, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MarkovReal}^\uparrow}$, seed)

Scope closed: Definition 6233.1, Definition 6233.2, and Definition 6233.3 seed the finite Markov-school effective real inspection boundary over L10 Real and Completion rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MarkovReal}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim imported Markov's principle, constructive real trichotomy, quotient stream equality, selected representatives, countable choice, ambient $\mathsf{Real}^\uparrow$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, effective-window exposure, Markov-boundary non-escape, apartness/refusal compatibility, RegSeqRat handoff, Real-seal non-escape, componentwise transport, replay, provenance, and local naming for the same finite packet.

Chapter 6234

A Concrete Naming Certificate for $\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}$

Following Arzela-Ascoli and Bishop–Bridges, the $\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}$ packet records the finite BEDC route that turns a compact metric source and an equicontinuous family of continuous maps into one displayed uniform budget for the whole family. It sits over the compact finite-net surface of chapter 129, the map carrier of chapter 130, the family surface of chapter 413, the precision consumer of chapter 369, the finite-window row of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite-net modulus route; it does not claim open-cover compactness, a selected global modulus outside the carrier, or a choice principle over the family.

Definition 6234.1 (Compact equicontinuous family modulus carrier)**.** *A* $\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{E} = (X, F, M, U, W, R, S, H, C, P, N)$$

with the following visible rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including its finite-net schedules and tolerance coverage data.*
2. *F is the* $\mathsf{EquicontinuousFamily}^{\uparrow}$ *row, displaying the common pointwise budget for the family over the compact source.*
3. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family-member row used when a particular displayed map is inspected.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row that receives the compact-family budget.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the source and target observations are scheduled.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational precision histories attached to the windows.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the finite-net, family, map, window, and readback rows have been displayed.*
8. *H records componentwise* hsame *transport for $X, F, M, U, W, R, S, C, P, N$.*
9. *C records displayed* Cont *replay of the same finite-net route for downstream consumers.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EquicontinuousFamily}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. There is no coordinate for open-cover compactness, host function-space compactness, selected subnet, quotient equality of maps, or a modulus chosen outside the finite packet.

Lean4 (definition) `BEDC.Derived.CompactEquicontinuousFamilyModulusUp.TasteGate.CompactEquicontinuousFamily`
Lean4 ✓ `BEDC.Derived.CompactEquicontinuousFamilyModulusUp.TasteGate.CompactEquicontinuousFamilyModulus`
`single carrier alignment`

Theorem 6234.2 (Compact equicontinuous family modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}$ *carrier*

$$\mathcal{E} = (X, F, M, U, W, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through X, equicontinuous-family admission through F, displayed family-member inspection through M, uniform-budget output through U, finite-window and regular-rational readback through W, R, terminal Real sealing through S, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6234.1. Its visible coordinates list exactly the compact source, equicontinuity family, inspected continuous map, uniform-modulus output, finite windows, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

The compact and family clauses are read through X and F. The finite-net schedule belongs to the compact metric row, while the common family budget belongs to the equicontinuity row; neither clause exposes an open cover, a selected subnet, or a host function-space object.

The output and seal clauses are then read through M, U, W, R, S and preserved by H, C, P, N. Since no other coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 6234.3 (Compact equicontinuous family uniform budget route)**.** *Every uniform-budget consumer of an accepted* $\mathsf{CompactEquicontinuousFamilyModulus}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{EquicontinuousFamily}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{UniformModul}$$

Concretely, the compact finite-net row X and the family row F are public before any member row M or output row U is read, and the terminal seal S is public only after the window and readback rows W, R have been replayed.

Proof. Start with the carrier row $\mathcal{E} = (X, F, M, U, W, R, S, H, C, P, N)$. The source-side information is exactly X, and the common family budget is exactly F.

A consumer inspecting a displayed family member then reads M over the same compact source and family budget. The finite-window row W schedules the visible source and target observations, while R supplies the regular rational readback for the precision history used by the output row.

Finally U packages the uniform budget and S seals the Real-facing read. The rows H, C, P, N transport, replay, source, and name the same route, so no open-cover compactness theorem, selected global modulus, quotient map equality, or choice-selected family element can replace the displayed finite-net route. □

Theorem 6234.4 (Compact equicontinuous family finite-net nonescape)**.** *The* CompactEquicontinuousFamilyModul *packet exports no modulus data outside the compact finite-net, equicontinuity-family, continuous-map, finite-window, regular-rational, and Real-seal rows*

$$X, F, M, W, R, S.$$

Every downstream UniformModulus$^{\uparrow}$ *read is therefore a finite BEDC read over those rows together with* H, C, P, N*, not a host Arzela–Ascoli compactness argument, an open-cover proof, a selected subnet, or an external modulus selector.*

Proof. Use Definition 6234.2 to identify the carrier surface. The only rows that can supply the budget are X, F, M, W, R, S together with the structural rows H, C, P, N.

Apply Definition 6234.3. It orders the compact source, family budget, inspected map, finite windows, readback, output, and seal before any downstream consumer can read a uniform modulus.

Because the carrier of Definition 6234.1 contains no host compactness, selected subnet, quotient equality, or external selector coordinate, the finite-net route is nonescaping. □

Falsifiable prediction: Every accepted CompactEquicontinuousFamilyModulus$^{\uparrow}$ budget read factors through one CompactMetric$^{\uparrow}$ source row, one EquicontinuousFamily$^{\uparrow}$ family row, one ContinuousMap$^{\uparrow}$ member row, one StreamName$^{\uparrow}$ finite-window row, one RegSeqRat$^{\uparrow}$ readback row, one UniformModulus$^{\uparrow}$ output row, one terminal Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, continuousmap, equicontinuityfamily, uniformmodulus, streamname, regseqrat, real: CompactEquicontinuousFamilyModulus$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite-net data, equicontinuity-family data, inspected map data, precision windows, rational readback, uniform output, Real sealing, transport, replay, provenance, and local NameCert rows as one packet.

Closure status for NameCert$_{\text{CompactEquicontinuousFamilyModulus}^{\uparrow}}$.

Constructive story: A CompactEquicontinuousFamilyModulus$^{\uparrow}$ packet is generated from a CompactMetricUp finite-net source, an EquicontinuousFamilyUp common-budget row, a ContinuousMapUp inspected-member row, StreamNameUp windows, RegSeqRatUp readback, a UniformModulusUp output row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactEquicontinuousFamilyModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6234.1, Definition 6234.2, and Definition 6234.3 seed the compact-family uniform-budget route over finite-net, family, map, window, readback, output, and seal rows.

Formal verification: FormalStatus(NameCert$_{\text{CompactEquicontinuousFamilyModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host function-space compactness, selected subnets, quotient map equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, family-budget stability, member inspection, window and readback exactness, uniform-output exactness, Real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 6235

A Concrete Naming Certificate for $\mathsf{CWComplex}^{\uparrow}$

Following Whitehead and Hatcher, the $\mathsf{CWComplex}^{\uparrow}$ packet records the finite cell-attachment surface used by algebraic-topology and homology consumers before any quotient-space, weak-topology, or homotopy-extension theorem is imported. It sits after the open-neighbourhood interface of chapter 88, the finite face inventory of chapter 238, the boundary and cycle consumer of chapter 98, and the finite subcover discipline of chapter 60. The chapter names cellular strata, attaching maps, boundary incidence, and homology handoff as displayed BHist data rather than as an ambient topological construction.

Definition 6235.1 (CW-complex carrier)**.** *A* $\mathsf{CWComplex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (T, K, E, A, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, naming the open-neighbourhood interface on which cells are inspected.*
2. *K is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *comparison row for finite face-style reads and cellular approximation consumers.*
3. *E is the finite cell inventory, with each displayed cell carrying a dimension, a name, and an incidence window.*
4. *A is the attaching ledger, recording the finite boundary route by which an n-cell reads the lower-dimensional skeleton.*
5. *B is the cellular boundary ledger, listing incidence coefficients only through displayed attaching data.*
6. *C is the* $\mathsf{Compact}^{\uparrow}$ *inspection row for finite subcomplex and compact-closure reads.*
7. *H records componentwise* hsame *transport for topology, simplicial comparison, cell inventory, attaching, boundary, compact inspection, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from T, K, E, A, B, C, H to cellular and homology-facing consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{CWComplex}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CWComplex}^\uparrow}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host quotient topology, arbitrary weak topology, selected characteristic maps, infinite cellular chains, global homotopy extension, or completed homology computation.

Lean4 ✓ `BEDC.Derived.CWComplexUp.CWComplexTasteGate single carrier alignment`

Theorem 6235.2 (CW-complex NameCert obligations)**.** *For an accepted* $\mathsf{CWComplex}^\uparrow$ *carrier* $X = (T, K, E, A, B, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CWComplex}^\uparrow}$ *surface consists exactly of the finite carrier admission, cell-inventory coverage, attaching-ledger replay, cellular-boundary exposure, compact finite-subcomplex inspection, componentwise transport, displayed replay, provenance, and local naming obligations recorded by* $T, K, E, A, B, C, H, R, P, N$*. A consumer cannot replace these rows by quotient-space semantics, weak-topology closure, selected characteristic maps, arbitrary infinite cellular chains, host homotopy extension, or an ambient homology computation.*

Proof. Project the carrier of Definition 6235.1. The topology and comparison rows are T, K, the cellular data are E, A, B, the compact inspection row is C, and the structural rows are H, R, P, N.

Cell-inventory coverage is read from E. Each cell has a displayed dimension and incidence window before an attaching route is considered, so the packet never starts from an unbounded class of cells.

The attaching and boundary obligations are then read from A and B. The boundary ledger can inspect only the lower-skeleton data named by the attaching ledger, while compact finite-subcomplex reads pass through C.

Finally H and R transport and replay the same rows, and P, N source and name them. Since no coordinate stores quotient topology, weak topology, selected characteristic maps, infinite cellular chains, homotopy extension, or completed homology, those endpoints are outside the certificate. □

Theorem 6235.3 (CW-complex cellular-boundary handoff)**.** *Every* $\mathsf{Homology}^\uparrow$ *consumer of an accepted* $\mathsf{CWComplex}^\uparrow$ *packet reaches cellular boundary data only through the finite route*

$$\mathsf{Topology}^\uparrow,\ \mathsf{SimplicialComplex}^\uparrow,\ E, A, B, C \longmapsto \mathsf{Homology}^\uparrow.$$

The handoff exposes the topological source, simplicial comparison surface, finite cell inventory, attaching ledger, cellular boundary ledger, compact finite-subcomplex inspection, componentwise transport, replay, provenance, and local naming rows. It does not export quotient-space equality, a weak-topology oracle, selected characteristic maps, unrestricted cellular chains, host homotopy extension, or computed homology groups.

Proof. Begin with the NameCert obligations of Definition 6235.2. They force the consumer to read the topology row T, the simplicial comparison row K, and the finite cell inventory E before boundary data is available.

Next use the attaching ledger A. A cellular boundary read through B is valid only after the lower-skeleton route named by A is displayed, and compact finite-subcomplex inspection remains the separate row C.

The structural rows H, R, P, N repack this route for homology-facing consumers. Therefore the $\mathsf{Homology}^\uparrow$ handoff is exactly the displayed finite cellular boundary route and cannot import quotient spaces, weak topology, selected characteristic maps, unrestricted chain complexes, host homotopy extension, or completed homology. □

Falsifiable prediction: A $\mathsf{Homology}^{\uparrow}$ consumer using $\mathsf{CWComplex}^{\uparrow}$ must display the topology source, simplicial comparison row, finite cell inventory, attaching ledger, cellular boundary ledger, compact finite-subcomplex inspection, componentwise hsame transport, Cont replay, Pkg provenance, and local naming rows.

Independence witness: topology, simplicialcomplex, homology, and compact are non-bijective siblings: none alone carries the complete cellular inventory, attaching ledger, boundary handoff, compact inspection, transport, replay, provenance, and local NameCert surface exposed by $\mathsf{CWComplex}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{CWComplex}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CWComplex}^{\uparrow}$ packet is generated from a Topology row, SimplicialComplex comparison row, finite cell inventory, attaching ledger, cellular boundary ledger, Compact finite-subcomplex inspection, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CWComplex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6235.1, Definition 6235.2, Definition 6235.3, the falsifiable prediction, and the independence witness seed the finite CW-complex carrier and its cellular boundary handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CWComplex}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-space semantics, weak topology, selected characteristic maps, infinite cellular chain complexes, homotopy extension, or completed homology computations.

Upgrade path: Obligation closure requires checked carrier admission, cell-inventory coverage, attaching-ledger replay, cellular-boundary exposure, compact finite-subcomplex inspection, transport preservation, provenance exhaustion, and local naming for BEDC.Derived.CWComplexUp.

Chapter 6236

A Concrete Naming Certificate for $\mathsf{HermitePolynomial}^{\uparrow}$

Following Hermite and the standard orthogonal-polynomial tradition, the $\mathsf{HermitePolynomial}^{\uparrow}$ packet names the finite Gaussian-weight recurrence surface for the displayed family H_n without importing an ambient L^2 space, quotient polynomial ring, or completed measure theory. It sits after the polynomial carrier of chapter 50, the orthogonal-polynomial surface of chapter 2264, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the sibling recurrence packets of chapter 3480 and chapter 6128.

Definition 6236.1 (Hermite polynomial carrier)**.** *A* $\mathsf{HermitePolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (d, H_0, H_1, R, O, W, Q, E, T, C, P, N)$$

with the following displayed rows:

1. *d is the finite degree-window row.*
2. *H_0 and H_1 are the seed* $\mathsf{Poly}^{\uparrow}$ *rows for the inspected Hermite family.*
3. *R is the finite recurrence ledger for $H_{n+1} = 2xH_n - 2nH_{n-1}$, including the displayed coefficient and polynomial-equality rows for each accepted step.*
4. *O is the* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *handoff row for the Gaussian-weight moment ledger and finite orthogonality reads.*
5. *W is the finite Gaussian-weight window row, recording the bounded moment and evaluation requests through which no completed measure space is exposed.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for inspected coefficients, moment approximants, and evaluations.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for recurrence coefficients, Gaussian-window reads, and evaluation results.*
8. *T records componentwise* hsame *transport for the displayed rows.*
9. *C records displayed* Cont *replay of recurrence, Gaussian-window, readback, and orthogonality requests.*
10. *P is the* Pkg *provenance over* $\mathsf{HermitePolynomial}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{OrthogonalPolynomial}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HermitePolynomial}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host Gaussian measure, completed L^2 space, quotient polynomial equality, selected infinite basis, or analytic spectral theorem.

Lean4 ✓ `BEDC.Derived.HermitePolynomialUp.HermitePolynomialTasteGate single carrier alignment`

Theorem 6236.2 (Hermite polynomial NameCert obligations)**.** *For every accepted* $\mathsf{HermitePolynomial}^{\uparrow}$ *carrier $G = (d, H_0, H_1, R, O, W, Q, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HermitePolynomial}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *the* $\mathsf{Poly}^{\uparrow}$ *source row displaying the degree window, seed polynomials, recurrence coefficients, and polynomial-equality checks;*
2. *the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row sealing every inspected coefficient, finite Gaussian-window moment, and evaluation request;*
3. *the* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *handoff row recording orthogonality only through displayed recurrence and finite Gaussian-weight window data;*
4. *the recurrence-stability row, requiring* hsame *transport and displayed* Cont *replay to preserve the same Hermite seed and step ledgers;*
5. *the* Pkg *and* NameCert *row naming the packet while exporting no host measure, quotient equality, infinite basis selector, or completed function space.*

No Hermite-polynomial obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 6236.1. The rows d, H_0, H_1, R display the only polynomial source, so every recurrence and coefficient request is a finite $\mathsf{Poly}^{\uparrow}$ ledger read.

The Gaussian-weight side is exposed by O, W, Q, E. The orthogonal-polynomial handoff O can be read only together with the finite window row W, the regular rational readback row Q, and the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Finally T, C, P, N preserve, replay, source, and name the same finite packet. Since no row stores a host Gaussian measure, completed L^2 space, quotient polynomial equality, selected infinite basis, or analytic spectral theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6236.3 (Hermite polynomial recurrence stability)**.** *Every accepted* $\mathsf{HermitePolynomial}^{\uparrow}$ *recurrence read factors through*

$$d, H_0, H_1 \longmapsto R \longmapsto O, W, Q, E \longmapsto T, C, P, N.$$

Under componentwise hsame *transport and displayed* Cont *replay, the same finite seed rows, recurrence coefficients, Gaussian-weight windows, readback rows, Real seals, provenance, and local naming remain visible. The packet therefore cannot infer a host Gaussian measure, completed L^2 equality, selected infinite Hermite basis, or analytic spectral theorem from recurrence data alone.*

Proof. Start with the recurrence ledger. The degree row and the two seed rows determine the inspected recurrence window, and R displays each accepted step of $H_{n+1} = 2xH_n - 2nH_{n-1}$ as a polynomial-row equality.

Next read the orthogonality and value-facing rows. The handoff through O is tied to the finite Gaussian-weight windows W, the regular readback Q, and the terminal Real seal E, so orthogonality remains a displayed finite ledger rather than a host measure-space claim.

The transport and replay rows T, C preserve exactly those coordinates, while P, N record provenance and local naming. No carrier coordinate supplies the excluded host or infinite data, so recurrence stability is confined to the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{HermitePolynomial}^{\uparrow}$ read factors through PolynomialUp seeds and recurrence rows, RealUp and RegSeqRat readback, an OrthogonalPolynomialUp handoff, finite Gaussian-weight windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: polynomial, real, regseqrat, dyadicratcore, orthogonal-polynomial, chebyshev-polynomial, legendre-polynomial: $\mathsf{HermitePolynomial}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Hermite seeds, recurrence coefficients, Gaussian-weight windows, orthogonality handoff, readback, Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HermitePolynomial}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HermitePolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6236.1, Definition 6236.2, and Definition 6236.3 seed the finite Hermite recurrence and Gaussian-weight orthogonality certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HermitePolynomial}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Gaussian measures, completed function spaces, quotient polynomial equality, selected infinite Hermite bases, analytic spectral theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, recurrence exactness, finite Gaussian-window readback, OrthogonalPolynomial handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HermitePolynomialU

Constructive story: A $\mathsf{HermitePolynomial}^{\uparrow}$ packet is generated from a degree window, two seed PolynomialUp rows, a finite Hermite recurrence ledger, an OrthogonalPolynomialUp handoff, finite Gaussian-weight windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6237

A Concrete Naming Certificate for $\mathsf{HyperbolicMobiusInvariant}^{\uparrow}$

The $\mathsf{HyperbolicMobiusInvariant}^{\uparrow}$ packet realizes the boundary-fixed disk-transport reading of chapter 9463 as finite Mobius-invariant rows. It sits after the disk carrier of chapter 377, the metric route of chapter 3474, the Poincare disk metric packet of chapter 6209, the hyperbolic cross-ratio packet of chapter 3948, and the boundary-fixed transport route of chapter 3500. The packet names invariant preservation for displayed disk and boundary rows; it is not a completed hyperbolic plane, a quotient ideal boundary, a global automorphism group, or a physical observer law.

Definition 6237.1 (Hyperbolic Mobius invariant carrier)**.** *A* $\mathsf{HyperbolicMobiusInvariant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (U, M, D, X, B, A, R, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *row for the source and target disk observations.*
2. *M is the disk-map row recording the Mobius-style transport on displayed disk coordinates.*
3. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *or* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row consumed after the disk observations and transport have been exposed.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *comparison row for boundary or near-boundary quadruple reads.*
5. *B is the boundary-fixed row, recording which visible boundary source is preserved by the transport.*
6. *A is the invariant audit row stating that the metric or cross-ratio read is preserved only through the displayed disk-map, boundary, and comparison rows.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row attached to metric and cross-ratio readback.*
8. *H records componentwise* hsame *transport for the displayed rows.*
9. *C records displayed* Cont *replay of disk-coordinate, map, metric, cross-ratio, boundary, audit, Real-seal, provenance, and local-name reads.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicMobiusInvariant}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicMobiusInvariant}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed disk, quotient boundary, host automorphism group, selected geodesic, global compactification, or physical spacetime invariant.

Theorem 6237.2 (Hyperbolic Mobius invariant NameCert obligations)**.** *For every accepted* HyperbolicMobiusInvari *carrier* $I = (U, M, D, X, B, A, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicMobiusInvariant}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, displayed Mobius-transport admission, hyperbolic metric readback, cross-ratio comparison, boundary-fixed preservation, invariant-audit exactness, Real sealing, componentwise transport, displayed replay, provenance, and local naming. The invariant row* A *may be consumed only after* U, M, D, X, B *have been displayed, and it exports no completed hyperbolic plane, quotient boundary, host automorphism group, global compactification, or physical observer law.*

Proof. Project the carrier of Definition 6237.1. The disk data U and transport row M are the only source rows from which the invariant route can begin.

The metric and cross-ratio reads are downstream. Rows D and X expose the finite comparison surfaces, while B records the boundary-fixed source preserved by the displayed transport.

The audit row A can therefore certify only preservation along that visible route. Rows R, H, C, P, N seal, transport, replay, source, and name the same packet, and no excluded host geometry or physical law is present in the carrier. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicMobiusInvariant}^{\uparrow}$ consumer must display UnitDisk coordinates, Mobius-style disk transport, HyperbolicMetricUp or PoincareDiskMetricUp metric reads, HyperbolicCrossRatioUp comparison, boundary-fixed preservation, invariant audit, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before reading invariant preservation.

Independence witness: unitdisk, hyperbolicmetric, poincare-disk-metric, hyperbolic-cross-ratio, poincare-boundary-fixed-transport: no listed sibling is bijective to $\mathsf{HyperbolicMobiusInvariant}^{\uparrow}$ because this packet jointly carries disk coordinates, Mobius-style transport, metric readback, cross-ratio comparison, boundary-fixed preservation, invariant audit, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicMobiusInvariant}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicMobiusInvariant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6237.1 and Definition 6237.2 seed the finite Mobius-invariant disk-transport route over UnitDisk, hyperbolic metric, cross-ratio, boundary-fixed, Real-seal, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicMobiusInvariant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic planes, quotient ideal boundaries, global automorphism groups, selected geodesics, physical observer laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-coordinate admission, Mobius-transport admission, metric and cross-ratio exactness, boundary-fixed preservation, invariant audit nonescape, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicMobiusInvariantUp.

Constructive story: A $\mathsf{HyperbolicMobiusInvariant}^{\uparrow}$ packet is generated from UnitDisk coordinates, displayed Mobius-style disk transport, PoincareDiskMetric or HyperbolicMetric reads, HyperbolicCrossRatio comparison, boundary-fixed preservation, an invariant audit row, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6238

A Concrete Naming Certificate for $\mathsf{CauchyMeshStability}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{CauchyMeshStability}^{\uparrow}$ packet records the finite mesh-refinement stability surface used before a regular rational name is sealed as a real. It sits over the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names mesh refinement as displayed BEDC data; it is not a quotient of Cauchy streams, a selected completion point, countable choice for refinements, or an ambient completeness theorem.

Definition 6238.1 (Cauchy mesh stability carrier)**.** *A* $\mathsf{CauchyMeshStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the mesh-source row, naming the finite refinement schedule whose entries are inspected by the packet.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the bounded stream observations read at the displayed mesh levels.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, supplying the dyadic comparison budget used to test whether two displayed mesh reads are stable at the requested precision.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the accepted window and tolerance data as a regular rational name.*
5. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, W, D, R have been displayed.*
6. *H records componentwise* hsame *transport for the mesh source, finite windows, dyadic tolerances, regular rational readback, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a mesh-refinement request through M, W, D, R and then to E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyMeshStability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyMeshStability}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $M, W, D, R, E, H, C, P, N$. There is no coordinate for an infinite refinement selector, quotient stream equality, selected real value, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyMeshStabilityUp.CauchyMeshStabilityTasteGate single carrier alignment`

Theorem 6238.2 (Cauchy mesh stability NameCert obligations)**.** *For every accepted* $\mathsf{CauchyMeshStability}^{\uparrow}$ *carrier* $S = (M, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyMeshStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the mesh source, finite stream window, dyadic tolerance row, regular rational readback row, real seal handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6238.1. The analytic rows are exactly M, W, D, R, E, and the structural rows are exactly H, C, P, N.

The mesh source M supplies the refinement schedule before any stream entry is consumed. The finite window W then exposes only the bounded observations attached to that schedule, while the dyadic row D supplies the precision budget used to compare those observations.

The regular rational readback R is downstream of M, W, D, and the real seal E is downstream of R. Rows H, C, P, N transport, replay, source, and name only that finite route, so the listed rows exhaust the local NameCert obligations. □

Theorem 6238.3 (Cauchy mesh stability Real-completion handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyMeshStability}^{\uparrow}$ *carrier factors through the finite route*

$$M, W, D \longmapsto R \longmapsto E, H, C, P, N.$$

The consumer first reads the mesh source, then the finite stream window and dyadic tolerance budget, then the regular rational readback, and only then receives the real-name seal. The route exports mesh-stable readback data, not quotient Cauchy-stream equality, a selected completion point, countable choice for refinements, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with a Real or Completion consumer of S. The carrier exposes the mesh source only through M, and every bounded observation is read through the finite window W attached to that same source.

The dyadic tolerance row D is the only precision coordinate available for stability comparisons. Thus a consumer cannot replace the displayed mesh comparison by an arbitrary refinement theorem or an external selector.

The regular rational row R repacks the accepted mesh-window and tolerance data before the real seal E can be read. The structural rows H, C, P, N preserve that route without adding quotient equality, selected limits, countable choice, or ambient completeness, so the handoff factors through the displayed packet. □

Falsifiable prediction: A $\mathsf{CauchyMeshStability}^{\uparrow}$ consumer that reads a $\mathsf{Real}^{\uparrow}$ seal without first displaying mesh-source data, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, transport, replay, provenance, and local naming is not reading the carrier of Definition 6238.1.

Independence witness: dyadicratcore, streamname, regseqrat, real: none alone is bijective with $\mathsf{CauchyMeshStability}^{\uparrow}$ because the packet jointly carries mesh-source data, finite stream windows, dyadic tolerance comparisons, regular rational readback, Real seal handoff, componentwise transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMeshStability}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{CauchyMeshStability}^{\uparrow}$ packet is generated from a mesh-source row, StreamName finite windows, DyadicRatCore tolerance comparisons, RegSeqRat readback, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyMeshStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6238.1, Definition 6238.2, and Definition 6238.3 seed the finite mesh-refinement stability route from displayed stream windows to Real-facing completion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyMeshStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient Cauchy-stream equality, selected completion points, countable choice for refinements, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, mesh-source exposure, finite stream-window stability, dyadic tolerance exactness, regular rational readback, Real-seal handoff ordering, transport, replay, provenance, and local naming for BEDC.Derived.CauchyMeshStabilityUp.

Chapter 6239

A Concrete Naming Certificate for $\mathsf{CauchyCompletionPushout}^{\uparrow}$

Following Bishop–Bridges constructive completion and Mac Lane pushout terminology, the CauchyCompletionPusho packet records the finite gluing surface for two completion legs over a shared dense source. It sits between the unit-and-bind schedule of chapter 378, the extension uniqueness route of chapter 397, the metric completion carrier of chapter 1506, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names completion gluing without quotienting Cauchy names, selecting representatives, invoking countable choice, or importing ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6239.1 (Cauchy completion pushout carrier)**.** *A* $\mathsf{CauchyCompletionPushout}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, L, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the shared source row, naming the common metric or Cauchy source and the finite requests on which both completion legs are compared.*
2. *L is the left completion leg row, carrying the displayed dense entry, finite Cauchy windows, and completion-facing readback for the left side.*
3. *R is the right completion leg row, carrying the analogous displayed dense entry, finite Cauchy windows, and completion-facing readback for the right side.*
4. *Q is the compatibility-square row, recording that the two legs agree on the shared source through displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any terminal seal is read.*
5. *E is the endpoint seal row, exposing the* $\mathsf{Real}^{\uparrow}$ *or completion-facing endpoint reached after S, L, R, Q have been displayed.*
6. *H records componentwise* hsame *transport for S, L, R, Q, E and for the structural rows.*
7. *C records displayed* Cont *replay from a shared source request through the two completion legs, the compatibility square, and the endpoint seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionPushout}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CompletionUniversalProper $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionPushout}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, a selected pushout representative, countable choice of approximants, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionPushoutUp.CauchyCompletionPushoutTasteGate single carrier alignment`

Theorem 6239.2 (Cauchy completion pushout NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionPushout}$ *carrier* $X = (S, L, R, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionPushout}^{\uparrow}}$ *surface consists exactly of shared-source admission, left completion-leg admission, right completion-leg admission, compatibility-square admission, endpoint-seal admission, componentwise transport, displayed replay, provenance, and local naming for the rows* $S, L, R, Q, E, H, C, P, N$*.*

Proof. Project the carrier of Definition 6239.1. The analytic rows are S, L, R, Q, E, and the structural rows are H, C, P, N.

The shared source row is read first. The left and right completion legs are then inspected against the same finite source request, using the finite-window and regular-readback routes already named by the StreamName and RegSeqRat siblings.

The compatibility square Q is available only after both legs have been displayed over S. The endpoint seal E is downstream of that square, so a Real or Completion consumer cannot bypass the compatibility row.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no quotient equality, selected representative, countable-choice schedule, host equality, or ambient completeness row appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 6239.3 (Cauchy completion pushout nonescape)**.** *Every public read from an accepted* $\mathsf{CauchyCompletionPushout}^{\uparrow}$ *packet factors through*

$$S, L, R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus completion functoriality and Real seal consumers receive a displayed gluing route, not quotient completion equality, selected pushout representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 6239.2. They expose the source row and both completion legs before the compatibility square is readable.

The endpoint seal is read only after the square. A consumer that reaches E has therefore already consumed the shared-source row, the left and right leg rows, and the square witnessing their agreement on the source.

The structural rows preserve this same order and add no analytic coordinate. Hence every public read factors through the displayed route and cannot export any of the excluded host-side or quotient data. □

Falsifiable prediction: A $\mathsf{CauchyCompletionPushout}^{\uparrow}$ consumer that reads a terminal $\mathsf{Real}^{\uparrow}$ or completion seal without first displaying one shared source row, two completion legs, one compatibility square, transport, replay, provenance, and local naming is not reading the carrier of Definition 6239.1.

Independence witness: cauchycompletionmonad, completionuniversalproperty, metriccompletion, streamname, regseqrat, real: none is bijective to $\mathsf{CauchyCompletionPushout}^{\uparrow}$ because the

packet jointly carries a shared source, two completion legs, a compatibility square, endpoint seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionPushout}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionPushout}^{\uparrow}$ packet is generated from a shared source row, left and right completion-leg rows, a compatibility-square row, an endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionPushout}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6239.1, Definition 6239.2, and Definition 6239.3 seed the finite completion-gluing route over a shared source.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionPushout}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, countable choice, host equality of completed points, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-leg compatibility, endpoint seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionPushoutUp.

Chapter 6240

A Concrete Naming Certificate for $\mathsf{LocatedLowerBound}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedLowerBound}^{\uparrow}$ packet isolates the finite lower-bound witness that located infimum and compact-minimum arguments may inspect before any ambient completeness or selected minimum principle is available. It is the order-dual reusable face to the $\mathsf{LocatedUpperBound}^{\uparrow}$ packet of chapter 3396, feeds the infimum route of chapter 1452, and keeps its readback tied to the located-real, regular-rational, and real-name surfaces of **??**, chapter 301, and chapter 38. The chapter names lower-bound data as a finite NameCert carrier, not as Real completeness, trichotomy, quotient cuts, selected extrema, or a host order oracle.

Definition 6240.1 (Located lower-bound carrier)**.** *A* $\mathsf{LocatedLowerBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, L, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *F is the located source row, read through the* $\mathsf{LocatedReal}^{\uparrow}$ *surface and its displayed comparison windows;*
2. *L is the lower-bound comparison ledger, recording the finite rows that place the proposed lower surface below each inspected source value;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule that fixes the finite precision windows in which source and lower-bound comparisons are inspected;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that repacks the scheduled comparison observations as regular rational data;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, L, W, R have been displayed;*
6. *H records componentwise* hsame *transport for the located source, lower-bound ledger, window schedule, regular readback, Real seal, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *routes for lower-bound reads, regular-rational handoff, Real-seal readback, and downstream located-infimum replay;*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedLowerBound}^{\uparrow}$, $\mathsf{LocatedUpperBound}^{\uparrow}$, $\mathsf{LocatedInfimum}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedLowerBound}^{\uparrow}}$ *row.*

The carrier has no row for Real completeness, trichotomy, quotient-cut equality, a selected minimum, an arbitrary infimum operator, countable choice, or host-level order evaluation.

Lean4 (definition) `BEDC.Derived.LocatedLowerBoundUp`

Theorem 6240.2 (Located lower-bound NameCert obligations)**.** *For every accepted* $\mathsf{LocatedLowerBound}^{\uparrow}$ *carrier* $B = (F, L, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedLowerBound}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, source exposure through* F*, lower-bound comparison exactness through* L*, finite request-window compatibility through* W*, regular-rational readback through* R*, terminal Real-seal routing through* E*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.LocatedLowerBoundUp.LocatedLowerBoundCarrier namecert obligations`

Proof. Project the carrier of Definition 6240.1. The analytic rows are precisely F, L, W, R, E, and the structural rows are precisely H, C, P, N.

Carrier admission and source exposure read F before any comparison is consumed. Lower-bound comparison exactness then reads only the displayed entries of L inside the request schedule fixed by W.

The regular-rational and Real-facing obligations are downstream from that schedule. The row R repacks the inspected comparisons, and E seals the Real-facing read only after F, L, W, R have been exposed.

The remaining rows preserve the same packet. The transports in H, replays in C, provenance in P, and local name N add no completeness principle, trichotomy row, quotient-cut equality, selected extremum, or host order evaluator. □

Theorem 6240.3 (Located lower-bound Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedLowerBound}^{\uparrow}$ *carrier receives the finite route*

$$F, L, W, R, E, H, C, P, N.$$

The consumer must read the located source row, the lower-bound comparison ledger, the request schedule, and the regular-rational readback before the terminal Real seal is available. The route is stable under the displayed hsame *and* Cont *rows, and it exports no Real completeness, trichotomy, quotient cut, selected minimum, arbitrary infimum operator, countable choice, or host order evaluation.*

Proof. Start with an accepted carrier $B = (F, L, W, R, E, H, C, P, N)$. By Definition 6240.2, any Real-facing read must first expose the located source, lower-bound ledger, finite request window, and regular readback rows.

The terminal row E is therefore downstream from F, L, W, R. A consumer that has not read those rows has no coordinate from which to obtain a Real-facing lower-bound certificate.

Transport and replay do not enlarge the route. The rows H and C preserve the displayed packet through componentwise sameness and continuation replay, while P, N source and name the same finite data.

Thus the Real-seal route is exactly $F, L, W, R, E, H, C, P, N$, with the listed excluded principles absent from the carrier. □

Lean4 ✓ `BEDC.Derived.LocatedLowerBoundUp.LocatedLowerBoundRealSealRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedLowerBound}^{\uparrow}}$**.**

Constructive story: A LocatedLowerBound$^{\uparrow}$ packet is generated from a located source row, a lower-bound comparison ledger, a StreamName request schedule, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedLowerBound}\uparrow}$, seed)

Scope closed: Definition 6240.1, Definition 6240.2, and Definition 6240.3 seed the reusable lower-bound face for located infimum and compact-minimum consumers over the L10 Real route.

Formal verification: FormalStatus(NameCert$_{\text{LocatedLowerBound}\uparrow}$, encodedDef)

Lean target: `BEDC.Derived.LocatedLowerBoundUp`

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, quotient-cut equality, selected extrema, arbitrary infima, countable choice, host order evaluation, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, lower-bound comparison exactness, request-window compatibility, regular readback, Real-seal routing, transport, replay, provenance, and local naming for the displayed packet.

Chapter 6241

A Concrete Naming Certificate for $\mathsf{ClassifierNoveltyLedger}^{\uparrow}$

The $\mathsf{ClassifierNoveltyLedger}^{\uparrow}$ packet realizes the classifier-shift audit surface of section 9462.9 as finite BEDC certificate data. It sits beside the positive-discovery classifier of chapter 6202, the classifier novelty witness of chapter 6138, the practice-level classifier of chapter 6225, the discovery pipeline calculus of chapter 5914, and the effective replacement ledger of chapter 568. The packet records before and after classifier profiles as a ledgered finite object, rather than as a prose score or a marker-only label change.

Definition 6241.1 (Classifier novelty ledger carrier)**.** *A* $\mathsf{ClassifierNoveltyLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, A, S, J, D, U, Q, H, C, P, N)$$

with the following displayed rows:

1. *B is the before-profile row, naming the source scope, classifier relation, stability mode, ledger status, and seal claim before the inspected shift.*
2. *A is the after-profile row, naming the corresponding source scope, classifier relation, stability mode, ledger status, and seal claim after the inspected shift.*
3. *S is the shared-source row, proving that B and A are compared over the same displayed behavior or source family.*
4. *J is the classifier-novelty witness row, exposing the before and after classifier disagreement inside the shared source scope.*
5. *D is the debt row, separating classifier debt, semantic debt, ledger debt, verification debt, intervention debt, and generalization debt.*
6. *U is the downstream-use row, recording which report, certificate, or consumer reads the after profile rather than merely naming it.*
7. *Q is the public audit row, recording the finite evidence needed to replay the disagreement, debt accounting, and downstream use.*
8. *H records componentwise* hsame *transport for B, A, S, J, D, U, Q and for the structural rows.*
9. *C records displayed* Cont *replay from the shared source through the before profile, after profile, novelty witness, debt row, downstream use, and audit row.*

10. *P is the* Pkg *provenance over* ClassifierNoveltyLedger$^{\uparrow}$, PositiveInterpretabilityClassifier$^{\uparrow}$, ClassifierNoveltyWitness$^{\uparrow}$, PositiveInterpretabilityClassifierPractice$^{\uparrow}$, DiscoveryPipelineCalculus$^{\uparrow}$, EffectiveReplacementLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassifierNoveltyLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a marker-only classifier change, a detached score, a prose-only novelty claim, a hidden source switch, or a positive-discovery verdict without displayed classifier disagreement and ledger rows.

Theorem 6241.2 (Classifier novelty ledger NameCert obligations)**.** *For every accepted* ClassifierNoveltyLedger$^{\uparrow}$ *carrier $L = (B, A, S, J, D, U, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClassifierNoveltyLedger}^{\uparrow}}$ *surface consists exactly of before-profile admission, after-profile admission, shared-source admission, classifier-novelty witness admission, debt-row admission, downstream-use admission, public-audit admission, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6241.1. The profile rows are B, A, the comparison rows are S, J, the ledger rows are D, U, Q, and the structural rows are H, C, P, N.

The shared-source row is read before classifier disagreement. Thus the novelty witness cannot be manufactured by changing the source family or observation protocol.

The debt, downstream-use, and public-audit rows are read next. They record why the classifier shift matters to a consumer and which finite evidence replays the disagreement.

Finally H, C, P, N transport, replay, source, and name the same packet. Since marker-only labels, detached scores, hidden source switches, prose-only novelty claims, and positive-discovery verdicts have no carrier coordinate, the listed rows are exactly the local obligations. □

Theorem 6241.3 (Classifier novelty ledger rejects marker-only shifts)**.** *An accepted* ClassifierNoveltyLedger$^{\uparrow}$ *packet cannot be obtained by changing only an external marker attached to an unchanged classifier profile. If B and A agree on shared source, classifier relation, stability mode, ledger status, debt row, downstream use, and public audit row, then the packet has no classifier-novelty witness row J.*

Proof. Read the obligation surface of Definition 6241.2. The novelty witness J is a displayed classifier-disagreement row over the shared source S.

If the before and after profiles agree on the classifier relation and the supporting rows D, U, Q, then a marker change is outside the carrier inventory. It is not a row that J can read.

The structural rows preserve the displayed coordinates and do not create a new disagreement. Hence an external marker change alone cannot satisfy the novelty ledger. □

Theorem 6241.4 (Classifier novelty ledger handoff)**.** *Every downstream read from an accepted* ClassifierNoveltyLedger$^{\uparrow}$ *packet factors through*

$$B, A, S \longmapsto J \longmapsto D, U, Q \longmapsto H, C, P, N.$$

The consumer receives before and after classifier-profile disagreement as finite certificate data, not a detached theorem-DNA score or an unledgered interpretability label.

Proof. Start from the carrier. The before and after profiles and the shared source must be visible before J can certify classifier disagreement.

The rows D, U, Q then bind the disagreement to debt accounting, downstream use, and replayable audit evidence. Without those rows, the classifier shift has no public ledger surface.

Transport, replay, provenance, and local naming preserve that route. Therefore every downstream read factors through the displayed finite packet and cannot replace it by a detached score or unledgered label. □

Falsifiable prediction: A report that changes only a classifier marker while preserving the same source scope, classifier relation, stability mode, debt row, downstream-use row, and public audit row cannot satisfy the $\mathsf{ClassifierNoveltyLedger}^{\uparrow}$ carrier of Definition 6241.1.

Independence witness: positive-interpretability-classifier, classifier-novelty-witness, positive-interpretability-classifier-practice, discovery-pipeline-calculus, effective-replacement-ledger: none is bijective to $\mathsf{ClassifierNoveltyLedger}^{\uparrow}$ because the packet jointly carries before and after profiles, shared-source comparison, classifier disagreement, debt, downstream-use, public-audit, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierNoveltyLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassifierNoveltyLedger}^{\uparrow}$ packet is generated from before and after classifier profiles, a shared-source row, a classifier-novelty witness, debt and downstream-use rows, a public audit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClassifierNoveltyLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6241.1, Definition 6241.2, Definition 6241.3, and Definition 6241.4 seed the finite before and after classifier-profile ledger for NDNA-style novelty audits.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClassifierNoveltyLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim positive-discovery status, global interpretability quality, detached theorem-DNA scoring, prose-only novelty, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked before and after profile admission, shared-source comparison, classifier-disagreement exposure, debt and downstream-use rows, public-audit replay, transport, provenance, and local naming for BEDC.Derived.ClassifierNoveltyLedgerUp.

Chapter 6242

A Concrete Naming Certificate for $\mathsf{OsgoodModulus}^{\uparrow}$

Following Osgood and Bishop–Bridges constructive ODE uniqueness, the $\mathsf{OsgoodModulus}^{\uparrow}$ packet records the finite modulus-divergence surface consumed by uniqueness criteria before an ODE solution comparison may reach a Real-facing seal. It sits beside the continuous-map carrier of chapter 130, the ODE row of chapter 193, the Osgood uniqueness route of chapter 5199, the Osgood criterion route of chapter 6159, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite divergence ledger for uniqueness consumers; it is not a host improper-integral theorem, a Lipschitz constant, a contraction ratio, a selected solution representative, or quotient equality of solution traces.

Definition 6242.1 (OsgoodModulus carrier)**.** *An* $\mathsf{OsgoodModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, V, A, T, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *source row, recording the time-state window and the uniqueness request that will consume the modulus data.*
2. *V is the* $\mathsf{ContinuousMap}^{\uparrow}$ *vector-field row on the same ODE window, read as displayed continuity rather than as a host function.*
3. *A is the modulus schedule row, listing positive* $\mathsf{RegSeqRat}^{\uparrow}$ *radius names, monotone comparison bounds, and the admissible near-zero window.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording dyadic scales, split radii, slack, and comparison witnesses used by the schedule.*
5. *Q is the finite divergence ledger, recording reciprocal-modulus budget rows and lower-window checks rather than a host improper integral.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the radius, budget, and solution-distance traces inspected by downstream consumers.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after O, V, A, T, Q, R have been displayed.*
8. *H records componentwise* hsame *transport for ODE, continuous-map, schedule, tolerance, divergence, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$O, V \longmapsto A, T, Q \longmapsto R \longmapsto L.$$

10. *P is the* Pkg *provenance over* $\mathsf{OsgoodModulus}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OsgoodModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, V, A, T, Q, R, L, H, C, P, N$. It has no coordinate for a Lipschitz constant, contraction ratio, selected solution representative, host integral theorem, quotient equality of curves, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.OsgoodModulusUp.OsgoodModulusTasteGate single carrier alignment`

Theorem 6242.2 (OsgoodModulus NameCert obligations)**.** *For every accepted* $\mathsf{OsgoodModulus}^{\uparrow}$ *carrier*

$$M = (O, V, A, T, Q, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OsgoodModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed ODE source, continuous vector-field, modulus schedule, dyadic tolerance, divergence ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *ODE and continuity visibility, requiring O and V to be public before any modulus or divergence budget is read;*
3. *schedule exactness, requiring A to display only positive* $\mathsf{RegSeqRat}^{\uparrow}$ *radius names, monotone comparison bounds, and the near-zero window used by the uniqueness consumer;*
4. *tolerance exactness, requiring T to record every dyadic scale, split radius, slack, and comparison witness used by the displayed schedule;*
5. *divergence-ledger exactness, requiring Q to store finite reciprocal-modulus budget rows and lower-window checks, not a host improper integral;*
6. *readback and seal nonescape, requiring R, L, H, C, P, N to read, seal, transport, replay, source, and name only the displayed route.*

No Osgood modulus obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6242.1. The accepted packet displays exactly the ODE source, continuous vector-field, modulus schedule, dyadic tolerance, divergence ledger, regular readback, Real seal, and structural rows.

The source and continuity clauses are read from O, V. A uniqueness-facing consumer therefore sees the ODE window and continuous vector-field row before it may inspect a modulus schedule or divergence budget.

The schedule and tolerance clauses are read from A, T. The schedule exposes positive regular-rational radius names, monotone comparison bounds, and the near-zero window, while the dyadic row records the scales and slack used by those comparisons.

The divergence and readback clauses are read from Q, R, L. The ledger Q stores finite reciprocal-modulus budget checks, R reads the radius and solution-distance traces, and L seals the Real-facing boundary only after the displayed route is present. The structural rows H, C, P, N transport, replay, source, and name that same route, so the carrier has no place to store the excluded host or choice data. □

Theorem 6242.3 (OsgoodModulus divergence handoff)**.** *Every uniqueness or criterion consumer of an accepted* $\mathsf{OsgoodModulus}^{\uparrow}$ *carrier must pass through*

$$\mathsf{Ode}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ Q \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by Definition 6242.1. The consumer receives a finite divergence ledger and tolerance schedule for Osgood comparison, not a Lipschitz constant, contraction certificate, selected solution curve, host improper-integral theorem, or quotient equality of solution traces.

Proof. Begin with a uniqueness-facing consumer of M. The only source row is O, and the only vector-field row is V, so the consumer is confined to the displayed ODE window and continuous-map readback.

Next read the modulus rows. The row A supplies the regular-rational radius schedule, T supplies the dyadic tolerance arithmetic, and Q supplies only finite reciprocal-modulus budget checks.

Finally read R, L, H, C, P, N. These rows provide regular readback, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming for the same route. Since no other coordinate is present, the handoff cannot export the excluded Lipschitz, contraction, selection, host-integral, quotient, choice, completeness, verification, or bridge data. □

Theorem 6242.4 (OsgoodModulus reciprocal-budget divergence row)**.** *For every accepted* $\mathsf{OsgoodModulus}^{\uparrow}$ *carrier*

$$M = (O, V, A, T, Q, R, L, H, C, P, N),$$

every Osgood uniqueness consumer reads the finite reciprocal-modulus budget row Q only after the ODE source row O, continuous vector-field row V, positive $\mathsf{RegSeqRat}^{\uparrow}$ *radius schedule A, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row T are displayed, and before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R and* $\mathsf{Real}^{\uparrow}$ *seal L are exported. The row Q is therefore consumed as finite divergence data internal to the displayed packet, not as a host improper integral or as external completeness, choice, selection, contraction, Lipschitz, or quotient-curve data.*

Proof. Project the accepted carrier through Definition 6242.1. Its displayed coordinates put O, V, A, T, Q, R, L in the only route available to a uniqueness consumer, with H, C, P, N transporting, replaying, sourcing, and naming the same packet.

Apply Definition 6242.2 to identify the exact rows. The source and continuity clauses expose O, V, the schedule and tolerance clauses expose A, T, and the divergence-ledger clause identifies Q as finite reciprocal-modulus budget data rather than a host improper integral.

Apply Definition 6242.3 for the consumer order. The handoff sends the consumer through the displayed ODE and continuous-map rows, then through the regular-rational schedule, dyadic tolerance arithmetic, and Q, before any readback or Real-facing seal is exported. Since the carrier has no coordinate for the excluded host or choice data, the reciprocal-budget row cannot export a Lipschitz constant, contraction ratio, selected solution representative, quotient curve equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{OsgoodModulus}^{\uparrow}$ uniqueness read that reaches $\mathsf{RegSeqRat}^{\uparrow}$ distance readback or a $\mathsf{Real}^{\uparrow}$ seal displays one $\mathsf{Ode}^{\uparrow}$ source row, one $\mathsf{ContinuousMap}^{\uparrow}$ vector-field row, one modulus schedule, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one finite divergence ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: ode, continuousmap, osgood-uniqueness, osgood-criterion, regseqrat, dyadicratcore, real: no listed sibling supplies the joint finite packet containing an ODE source,

continuous vector-field row, positive regular-rational radius schedule, dyadic tolerance row, divergence ledger, regular readback, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{OsgoodModulus}\uparrow}$.

Constructive story: An $\mathsf{OsgoodModulus}^{\uparrow}$ packet is generated from an OdeUp source row, a ContinuousMapUp vector-field row, a RegSeqRatUp radius schedule, a DyadicRatCoreUp tolerance row, a finite divergence ledger, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OsgoodModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6242.1, Definition 6242.2, Definition 6242.3, and Definition 6242.4 seed the finite Osgood modulus route from displayed ODE and ContinuousMap rows through regular-rational radius schedules, dyadic tolerance arithmetic, divergence ledgers, readback, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OsgoodModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, Lipschitz uniqueness, Banach contraction, selected solution representatives, quotient equality of curves, countable choice, host improper-integral theorems, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, ODE-window visibility, continuous-map readback, modulus schedule exactness, dyadic tolerance exactness, divergence-ledger exactness, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.OsgoodModulusUp.

Chapter 6243

A Concrete Naming Certificate for $\mathsf{TheoremDnaScore}^{\uparrow}$

The $\mathsf{TheoremDnaScore}^{\uparrow}$ packet realizes the neural theorem-DNA scoring surface of section 9462.9 as finite NameCert data. It sits beside the proof trace normal form of chapter 5157, the tensor product carrier of chapter 87, the black-box decomposition certificate of chapter 6100, the audit gate boundary of chapter 526, the certificate audit gate of chapter 1002, the discovery pipeline calculus of chapter 5914, and the positive interpretability classifier of chapter 6202. The packet names a finite scoring carrier for source, feature, circuit, classifier, stability, intervention, ledger, and seal rows; it is not a neural oracle, a hidden tensor explanation, or an unledgered taste judgment.

Definition 6243.1 (TheoremDnaScore carrier)**.** *A* $\mathsf{TheoremDnaScore}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, G, F, U, K, A, I, L, E, W, H, C, P, N)$$

with the following displayed rows:

1. *B is the behavior or theorem-like target row whose explanation is being scored.*
2. *G is the role-complete theorem-DNA source row, displaying source, feature, circuit, classifier, stability, intervention, ledger, and seal loci.*
3. *F is the feature row, including tensor direction, probe, sparse-latent, attention, residual-stream, or proof-feature evidence visible to the score.*
4. *U is the circuit row, recording the causal or proof-route structure that the feature row claims to explain.*
5. *K is the classifier row induced by B, G, F, U, with its declared boundary and comparison relation.*
6. *A is the stability row, recording perturbation, representation, transfer, or proof-normalization stability over the classifier boundary.*
7. *I is the intervention row, including ablation, activation transfer, proof-route edit, failed-variant, off-target, or counterfactual evidence.*
8. *L is the ledger row, recording residue, failed loci, debt, and audit boundary for the score.*
9. *E is the seal row, declaring the score scope, critical-locus coverage, hardening state, and not-claimed boundary.*

10. *W is the weight and score row, recording nonnegative locus weights, displayed costs, certified gain, and the finite comparison verdict.*
11. *H records componentwise* hsame *transport for behavior, genome, feature, circuit, classifier, stability, intervention, ledger, seal, score, replay, provenance, and local naming rows.*
12. *C records displayed* Cont *replay from the source behavior through loci, classifier, stability, intervention, ledger, seal, and score rows.*
13. *P is the* Pkg *provenance over* $\mathsf{TheoremDnaScore}^{\uparrow}$, BHist, *tensor-feature packets, proof-trace packets, audit-gate packets,* hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{TheoremDnaScore}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, G, F, U, K, A, I, L, E, W, H, C, P, N$. It has no coordinate for hidden model knowledge, unobserved circuit causality, natural-language substitution for anchors, unlabeled debt, unscoped taste, Lean verification, or bridge checking.

Theorem 6243.2 (TheoremDnaScore NameCert obligations)**.** *For every accepted* $\mathsf{TheoremDnaScore}^{\uparrow}$ *carrier*

$$S = (B, G, F, U, K, A, I, L, E, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TheoremDnaScore}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed behavior, theorem-DNA loci, feature, circuit, classifier, stability, intervention, ledger, seal, score, transport, replay, provenance, and local naming rows;*
2. *role completeness, requiring G to display source, feature, circuit, classifier, stability, intervention, ledger, and seal loci before W may score the packet;*
3. *classifier faithfulness, requiring K to be induced by the displayed behavior, feature, and circuit rows and to expose its boundary before stability or intervention evidence is counted;*
4. *stability and intervention exactness, requiring A, I to name the perturbations, transfers, edits, failures, off-target effects, and counterfactuals that support the score;*
5. *ledger and seal exactness, requiring L, E to record residue, debt, critical-locus coverage, scope, hardening state, and not-claimed boundary;*
6. *score nonescape, requiring W, H, C, P, N to score, transport, replay, source, and name only the displayed route.*

No theorem-DNA score obligation is stored outside these rows.

Proof. Project the carrier of Definition 6243.1. The accepted packet displays exactly the behavior, role-complete theorem-DNA row, feature, circuit, classifier, stability, intervention, ledger, seal, score, and structural rows.

Role completeness is read from G. Because G displays source, feature, circuit, classifier, stability, intervention, ledger, and seal loci before W is read, a score cannot be certified from a single feature label, isolated circuit diagram, classifier-only relation, or narrative seal.

Classifier faithfulness is read from B, F, U, K. The classifier row is tied to the displayed behavior and explanatory rows, so the stability and intervention rows can only support the declared boundary.

The remaining obligations are read from $A, I, L, E, W, H, C, P, N$. Stability and intervention evidence is ledgered before the seal and score are consumed, and the structural rows only transport, replay, source, and name the same route. Since the carrier has no coordinate for hidden model

knowledge, unobserved causality, unanchored language, unlabeled debt, or unscoped taste, the listed rows exhaust the NameCert surface. □

Theorem 6243.3 (TheoremDnaScore critical-locus refusal)**.** *If an accepted* $\mathsf{TheoremDnaScore}^{\uparrow}$ *scoring request omits a critical source, feature, circuit, classifier, stability, intervention, ledger, or seal locus, then the local* $\mathsf{NameCert}_{\mathsf{TheoremDnaScore}^{\uparrow}}$ *refuses certification. A certified score may be read only after the omitted locus is supplied as a displayed row and replayed through* H, C, P, N*.*

Proof. Use Definition 6243.2. Role completeness requires all eight loci to be visible before the score row W is read.

If a critical locus is absent, the corresponding row in G is not displayed. The score row therefore lacks one of the rows required for carrier admission and role completeness.

The structural rows cannot repair the gap. Transport, replay, provenance, and local naming preserve displayed rows; they do not create missing source, feature, circuit, classifier, stability, intervention, ledger, or seal content. Hence certification is refused until the missing locus is supplied and replayed through the finite packet. □

Falsifiable prediction: Any $\mathsf{TheoremDnaScore}^{\uparrow}$ packet missing a critical source, feature, circuit, classifier, stability, intervention, ledger, or seal locus fails local certification before the score row can be read.

Independence witness: proof-trace-normal-form, tensor-namecert, black-box-ledger, auditgateboundary, certificateauditgate: $\mathsf{TheoremDnaScore}^{\uparrow}$ is not bijective to any listed sibling because proof-trace-normal-form supplies proof-route shape without neural loci, tensor-namecert supplies feature carriers without score weights, black-box-ledger records residue without critical-locus scoring, auditgateboundary supplies refusal boundary without theorem-DNA weights, and certificateauditgate supplies admission discipline without the role-complete score row.

Closure status for $\mathsf{NameCert}_{\mathsf{TheoremDnaScore}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TheoremDnaScore}^{\uparrow}$ packet is generated from a behavior or theorem-like target, role-complete theorem-DNA loci, feature, circuit, classifier, stability, intervention, ledger, seal, score, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row. The Lean follow-up BEDC.Derived.TheoremDnaScoreUp.TasteGate must provide Nontrivial and FieldFaithful instances before TasteGate admission is claimed.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TheoremDnaScore}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6243.1, Definition 6243.2, and Definition 6243.3 seed the finite theorem-DNA scoring route over role-complete loci, classifier faithfulness, stability, intervention, ledger, seal, score, and nonescape rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TheoremDnaScore}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, neural circuit truth, hidden-model explanation, positive discovery, unscoped taste, or classifier novelty beyond the displayed score carrier.

Upgrade path: Obligation closure requires checked carrier admission, role completeness, classifier faithfulness, stability and intervention exactness, ledger and seal exactness, score nonescape, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.TheoremDnaScoreUp.TasteGate.

Chapter 6244

A Concrete Naming Certificate for $\mathsf{NoetherNormalization}^{\uparrow}$

Following Noether normalization in commutative algebra, the $\mathsf{NoetherNormalization}^{\uparrow}$ packet records the finite row surface by which an affine algebra is displayed as integral over a polynomial coordinate subalgebra. It sits after the polynomial and affine-variety carriers of chapter 50 and chapter 154, the algebraic source rows of chapter 43, chapter 46, and chapter 45, and the reduction ledger supplied by chapter 2197. The packet names only displayed coordinate rows, monic dependence witnesses, finite module-spanning ledgers, transport, replay, provenance, and a local certificate; it does not construct quotient rings, select bases, assert dimension equality, or import a host algebraic-geometry category.

Definition 6244.1 (Noether normalization carrier)**.** *A* $\mathsf{NoetherNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (F, R, P, A, G, C, I, M, H, Q, K)$$

with the following displayed rows:

1. *F is the* $\mathsf{Field}^{\uparrow}$ *source row over which the affine coordinate algebra is read.*
2. *R is the* $\mathsf{Ring}^{\uparrow}$ *row naming the accepted finitely generated algebra surface.*
3. *P is the* $\mathsf{Poly}^{\uparrow}$ *coordinate row, including the displayed finite list of polynomial coordinates used for the independent subalgebra.*
4. *A is the* $\mathsf{AffineVar}^{\uparrow}$ *source row whose coordinate data is consumed by R and P.*
5. *G is the* $\mathsf{GroebnerBasis}^{\uparrow}$ *reduction ledger used only as a finite dependency anchor for displayed polynomial reduction checks.*
6. *C is the coordinate-change ledger. It records the chosen finite coordinate rows and the replay order by which the polynomial subalgebra is presented before any dependence row is consumed.*
7. *I is the finite integral-dependence ledger. For each displayed algebra generator it records a monic polynomial equation over the coordinate subalgebra and the BEDC continuation path that reads its coefficients.*
8. *M is the* $\mathsf{Module}^{\uparrow}$ *finite-spanning ledger, recording the displayed list of module words read from the integral-dependence rows.*

9. *H records componentwise* hsame *transport for field, ring, polynomial, affine-variety, reduction, coordinate-change, integral-dependence, module-spanning, replay, provenance, and local naming rows.*

10. *Q records displayed* Cont *replay from an affine algebra request through $F, R, P, A, G, C, I, M, H$ and only then to provenance and naming.*

11. *K is the* Pkg *provenance together with the local* $\mathsf{NameCert}_{\mathsf{NoetherNormalization}^{\uparrow}}$ *row.*

Accepted carriers are compared only through these rows. There is no coordinate for a quotient-ring construction, selected basis, external transcendence basis, dimension theorem, or ambient algebraic-geometry category.

Lean4 ✓ `BEDC.Derived.NoetherNormalizationUp.NoetherNormalizationTasteGate single carrier alignment`

Theorem 6244.2 (Noether normalization NameCert obligations)**.** *For every accepted* $\mathsf{NoetherNormalization}^{\uparrow}$ *carrier $N = (F, R, P, A, G, C, I, M, H, Q, K)$, the local* $\mathsf{NameCert}_{\mathsf{NoetherNormalization}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{Field}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{AffineVar}^{\uparrow}$, $\mathsf{GroebnerBasis}^{\uparrow}$, *coordinate-change, integral-dependence, finite* $\mathsf{Module}^{\uparrow}$*-spanning, transport, replay, provenance, and local naming rows.*

Proof. Project the carrier of Definition 6244.1. The algebraic source rows are F, R, P, A, G, the normalization rows are C, I, M, and the structural rows are H, Q, K.

The coordinate-change row C is read before any dependence row, so the polynomial coordinate subalgebra is a displayed BEDC dependency rather than a quotient construction. The integral-dependence row I records only monic equations for the displayed generators over that coordinate surface.

The module-spanning row M is downstream of I and supplies finite words produced from those monic equations. Transport, replay, provenance, and local naming do not add quotient rings, selected bases, dimension statements, or host categories, so the listed rows exhaust the NameCert obligations. □

Theorem 6244.3 (Noether normalization finite integral-dependence route)**.** *Every accepted finite integral-dependence read exported by a* $\mathsf{NoetherNormalization}^{\uparrow}$ *carrier factors through the displayed route*

$$F, R, P, A, G, C \longmapsto I \longmapsto H, Q, K.$$

The read first exposes the field, ring, polynomial-coordinate, affine-variety, and reduction rows, then the finite coordinate-change ledger, and only then the monic dependence equations. It exports no quotient-ring carrier, selected basis, or external algebraic closure.

Proof. Start with an accepted dependence read. Carrier admission exposes the source algebra only through the rows F, R, P, A and the finite reduction ledger G.

The coordinate-change row C fixes the displayed polynomial coordinate surface before the dependence ledger can be inspected. Hence the coefficients of each monic equation are read from the shown coordinate rows, not from an ambient quotient presentation.

The integral-dependence row I then supplies the monic equations, and H, Q, K preserve that finite route under transport, replay, provenance, and naming. No extra coordinate can introduce selected bases, quotient rings, or host closure data. □

Theorem 6244.4 (Noether normalization finite module stability)**.** *Let $N = (F, R, P, A, G, C, I, M, H, Q, K)$ and $N' = (F', R', P', A', G', C', I', M', H', Q', K')$ be accepted* $\mathsf{NoetherNormalization}^{\uparrow}$ *carriers whose*

source, coordinate-change, and integral-dependence rows are related componentwise by hsame*. Then their finite* Module$^{\uparrow}$*-spanning ledgers classify the same normalization boundary: a consumer reading M may be transported to M' through the same displayed dependence route, and no independent basis-selection row is required.*

Proof. The componentwise hsame hypotheses identify the accepted field, ring, polynomial, affine-variety, reduction, coordinate-change, and integral-dependence rows of the two packets. Transport by H and H' therefore aligns the monic equations used to produce the finite module words.

The module ledgers M and M' are downstream of those equations. Their spanning reads are replayed through Q and Q' from the same displayed dependence route, so a consumer sees the same finite normalization boundary after transport.

Since the carrier has no basis-selection coordinate, the stability claim cannot depend on choosing a free basis or a quotient-ring presentation. It depends only on the displayed integral-dependence and module-spanning rows. □

Falsifiable prediction: Every accepted NoetherNormalization$^{\uparrow}$ consumer that reads integral dependence or finite module spanning must first display Field$^{\uparrow}$, Ring$^{\uparrow}$, Poly$^{\uparrow}$, AffineVar$^{\uparrow}$, GroebnerBasis$^{\uparrow}$, coordinate-change, transport, replay, provenance, and local NameCert rows.

Independence witness: polynomial, affinevar, ring, module, field, groebnerbasis: NoetherNormalization$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries coordinate-change rows, monic dependence witnesses, finite module-spanning ledgers, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{NoetherNormalization}^{\uparrow}}$.

Constructive story: A NoetherNormalization$^{\uparrow}$ packet is generated from FieldUp, RingUp, PolynomialUp, AffineVarUp, GroebnerBasisUp, coordinate-change, monic integral-dependence, finite ModuleUp-spanning, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{NoetherNormalization}^{\uparrow}}$, seed)

Scope closed: Definition 6244.1, Definition 6244.2, Definition 6244.3, and Definition 6244.4 seed the finite normalization route from displayed affine coordinate data to integral-dependence and module-spanning ledgers.

Formal verification: FormalStatus(NameCert$_{\text{NoetherNormalization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient rings, selected bases, dimension equality, transcendence-basis existence, host algebraic geometry, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coordinate-change exposure, finite integral-dependence exactness, finite module-spanning stability, transport, replay, provenance, and local naming for BEDC.Derived.NoetherNormalizatio

Chapter 6245

A Concrete Naming Certificate for $\mathsf{CoxeterGroup}^{\uparrow}$

Following Coxeter's presentation of reflection groups and Bourbaki's treatment of Coxeter systems, the $\mathsf{CoxeterGroup}^{\uparrow}$ packet records a group generated by involutive simple generators with finite braid-relation rows. It sits between the algebraic group surface of chapter 41, the root-reflection ledger of chapter 144, and the Weyl-group consumer of chapter 145. The packet names the displayed Coxeter matrix, finite alternating-word ledgers, relation witnesses, word-reduction obligations, transport, replay, provenance, and local naming surface; it does not assert a host quotient group, a complete word-problem solver, or a classification of finite reflection groups.

Definition 6245.1 (CoxeterGroup carrier)**.** *A* $\mathsf{CoxeterGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, M, W, R, N, H, Q, P, L)$$

with the following displayed rows:

1. *S is the finite simple-generator row, with each generator tagged by an involution witness read through the* $\mathsf{Group}^{\uparrow}$ *operation surface.*
2. *M is the Coxeter matrix row. It records $m_{s,s} = 1$ and, for distinct displayed generators s, t, a finite braid length $m_{s,t}$ or an obstruction row stating that no finite braid row is exposed.*
3. *W is the finite signed-word carrier generated from S by empty word, singleton generator word, and concatenation.*
4. *R is the relation ledger. It contains involution rows $ss \rightsquigarrow e$ and, whenever M exposes a finite value $m_{s,t}$, the two alternating words of length $m_{s,t}$ with a classified relation witness between them.*
5. *N is the word-reduction obligation row. It records the local cancellation and braid-step routes that any public normal-form or reduction consumer must read before claiming a reduced endpoint.*
6. *H records componentwise* hsame *transport for S, M, W, R, N, Q, P, L.*
7. *Q records displayed* Cont *replay for generator insertion, concatenation, involution cancellation, braid transport, and reduction-step replay.*
8. *P is the* Pkg *provenance over* $\mathsf{CoxeterGroup}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{RootSystem}^{\uparrow}$, $\mathsf{WeylGroup}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{CoxeterGroup}^\uparrow}$ *row.*
The classifier compares Coxeter packets only through $S, M, W, R, N, H, Q, P, L$. It does not compare ambient presentations by host equality and does not identify the packet with a Weyl group unless the Weyl consumer supplies the root-action rows separately.

Lean4 ✓ `BEDC.Derived.CoxeterGroupUp.CoxeterGroupTasteGate single carrier alignment`

Theorem 6245.2 (CoxeterGroup word-reduction obligation)**.** *Every public word-reduction read from an accepted* $\mathsf{CoxeterGroup}^\uparrow$ *packet must factor through the displayed relation ledger R and reduction obligation row N. A finite generator word in W alone is only a carried word endpoint; it is not a reduced representative, a normal form, or a word-problem decision procedure until the involution, braid, and replay rows named by R, N, Q have been read.*

Proof. Project the carrier of Definition 6245.1. The row W supplies finite words generated from the simple-generator row S, but it records only construction of words by empty word, singleton generator, and concatenation.

Reduction information enters through R and N. The relation ledger R gives the involution rows and finite braid rows selected by the Coxeter matrix M, while N records the obligation that a consumer must use those rows as the public reduction surface.

The replay row Q then transports each cancellation or braid step through displayed Cont data, and the transport row H keeps the endpoints classified under hsame. Thus a public reduced-word claim is downstream of R, N, Q, H, not a property of the bare word carrier W. □

Theorem 6245.3 (CoxeterGroup NameCert obligations)**.** *A* $\mathsf{NameCert}_{\mathsf{CoxeterGroup}^\uparrow}$ *obligation surface consists exactly of the finite simple-generator carrier, the Coxeter matrix row, the word carrier, the involution and braid relation ledger, the word-reduction obligation row, componentwise transport, continuation replay, provenance, and local naming rows. The surface may be consumed by* $\mathsf{WeylGroup}^\uparrow$ *only after the* $\mathsf{RootSystem}^\uparrow$ *reflection and Cartan rows supply the root-action interpretation of the same relation ledger.*

Proof. Read the rows $S, M, W, R, N, H, Q, P, L$ from the carrier. These rows provide the whole Coxeter packet: generators, relation parameters, finite word construction, relation witnesses, reduction-facing obligations, classifier transport, replay, provenance, and the local certificate name.

The $\mathsf{Group}^\uparrow$ dependency supplies the operation, unit, inverse, and classifier rows needed to read generator words as group-facing histories. The Coxeter packet itself adds the matrix and braid ledger, but it does not add root actions or a finite-reflection representation.

For a Weyl consumer, the root-action interpretation must be supplied separately through the $\mathsf{RootSystem}^\uparrow$ reflection and Cartan ledger rows. Only after those rows are read can chapter 145 consume the Coxeter relation ledger as a root-action ledger, so the Coxeter certificate remains a distinct dependency surface. □

Falsifiable prediction: A $\mathsf{CoxeterGroup}^\uparrow$ consumer that exports a reduced word or Weyl action from W without reading R, N, Q refutes the carrier surface.

Independence witness: group, rootsystem, weylgroup, braidgroup: the group packet lacks the Coxeter matrix and braid ledger; the root-system packet has reflections and Cartan rows but no word carrier; the Weyl-group packet consumes root-action rows beyond the Coxeter relation carrier; the braid-group packet records Artin braid words without the involution relation $ss \rightsquigarrow e$.

Closure status for $\mathsf{NameCert}_{\mathsf{CoxeterGroup}^\uparrow}$.

Constructive story: A CoxeterGroup$^{\uparrow}$ packet is generated from a finite simple-generator row, Coxeter matrix row, finite word carrier, involution and braid relation ledger, word-reduction obligation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CoxeterGroup}\uparrow}$, seed)

Scope closed: Definition 6245.1, Definition 6245.2, and Definition 6245.3 seed the finite generator, Coxeter-matrix, word-carrier, relation-ledger, reduction-obligation, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{CoxeterGroup}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a host quotient presentation, a complete word-problem decision procedure, finite reflection-group classification, or Weyl-group root-action soundness.

Upgrade path: Obligation closure requires checked generator, matrix, word-carrier, involution, braid, reduction-obligation, transport, replay, provenance, and local naming rows for BEDC.Derived.CoxeterGroupUp.

Chapter 6246

A Concrete Naming Certificate for $\mathsf{LipschitzCompletionExtension}^{\uparrow}$

Following Bishop and Bridges on metric completion and Lipschitz extension, the $\mathsf{LipschitzCompletionExtension}^{\uparrow}$ packet records the finite route by which a displayed Lipschitz map on a dense source row is handed to a completion target. It sits after the completion carrier of chapter 95, the complete-metric boundary of chapter 128, the finite window surface of chapter 126, and the regular rational readback of chapter 301. The packet is a completion-frontier NameCert surface; it is not a host extension theorem, a selected limit operation, quotient equality of completed points, countable choice, or ambient completeness imported from outside the displayed target seal.

Definition 6246.1 (Lipschitz completion extension carrier)**.** *A* $\mathsf{LipschitzCompletionExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (D, M, L, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense source row, naming the source carrier, dense observation interface, and the finite source points on which the map is already displayed.*
2. *M is the metric row, recording source and target distance readbacks, tolerance windows, and the metric comparison rows consumed by the extension route.*
3. *L is the Lipschitz modulus row, listing the rational modulus bound, its tolerance rescalings, and the finite checks that transport source closeness into target closeness.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, exposing the finite source windows and target windows inspected by the route.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source stream, target stream, distance budget, and modulus-scaled tolerance requests.*
6. *E is the completion target seal, recording that the target-side Cauchy row is admitted only through the displayed completion boundary.*
7. *H records componentwise* hsame *transport for the dense source, metric, modulus, stream-window, regular-rational, completion-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$D, M, L \longmapsto S, Q \longmapsto E.$$

9. *P is the* Pkg *provenance over* LipschitzCompletionExtension$^{\uparrow}$, Completion$^{\uparrow}$, CompleteMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{LipschitzCompletionExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, L, S, Q, E, H, C, P, N$. It has no coordinate for a host extension operator, selected target limit, quotient equality of completed points, countable choice, global completeness of an ambient space, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.LipschitzCompletionExtensionUp.LipschitzCompletionExtensionTasteGate`
`single carrier alignment`

Theorem 6246.2 (Lipschitz completion extension NameCert obligations)**.** *For every accepted* LipschitzCompletionExtension$^{\uparrow}$ *carrier*

$$X = (D, M, L, S, Q, E, H, C, P, N),$$

the local NameCert$_{\text{LipschitzCompletionExtension}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dense source row, metric row, Lipschitz modulus row, StreamName windows, RegSeqRat readback, completion target seal, transport, replay, provenance, and local naming rows;*
2. *Lipschitz-modulus transport, requiring the rational bound and tolerance rescalings in L to be read before any target closeness claim is exported;*
3. *dense-window handoff, requiring each source observation used by the extension request to pass through the finite D, S, Q route;*
4. *completion target sealing, requiring the target-side Cauchy row to enter through E after the displayed windows and regular rational readback are visible;*
5. *nonescape from selected limits or host completeness, requiring H, C, P, N to transport, replay, source, and name only the rows D, M, L, S, Q, E.*

No Lipschitz completion extension obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6246.1. The accepted packet displays the dense source, metric comparison, Lipschitz modulus, finite windows, regular rational readback, completion seal, and structural rows.

The modulus clause is read from L together with the metric row M. A target closeness request must therefore cite the displayed rational Lipschitz bound and the tolerance rescalings before it can reach a target-side Cauchy claim.

The dense-window handoff is read from D, S, Q. The source observations are first exposed as dense rows, then inspected through finite StreamName windows, and then repacked as regular rational readback at the displayed tolerance.

The completion seal is read from E. The structural rows H, C, P, N transport, replay, source, and name the same route, so the carrier contains no field where a selected limit, quotient equality, countable-choice schedule, host extension operator, or ambient completeness theorem could enter. □

Theorem 6246.3 (Lipschitz completion extension Cauchy handoff)**.** *Let $X = (D, M, L, S, Q, E, H, C, P, N)$ be an accepted* LipschitzCompletionExtension$^{\uparrow}$ *carrier. Every Cauchy source stream routed through*

the displayed Lipschitz modulus yields a completion-target Cauchy row only through the finite route

$$D, M, L \longmapsto S, Q \longmapsto E, H, C, P, N.$$

The handoff supplies target Cauchy evidence for completion consumers without exporting a selected limit, quotient equality of completed points, countable choice, a host extension operator, or ambient completeness beyond the displayed completion target seal.

Proof. Start with a Cauchy source stream accepted by the dense source row. The stream is visible to the carrier only through D and the finite windows S, so every source tolerance request is confined to the displayed dense-window route.

The metric row M and Lipschitz modulus row L rescale the source tolerance into the target tolerance. This step uses only the stored rational bound and its finite checks, not a host continuity theorem or a selected target value.

The row Q reads the source and target windows as regular rational traces, and E admits the target-side Cauchy row through the completion boundary. Finally H, C, P, N preserve the same route as transport, replay, provenance, and local naming data. Since no other coordinate is present, any completion-target Cauchy handoff must pass through exactly these rows. □

Falsifiable prediction: Every accepted $\mathsf{LipschitzCompletionExtension}^{\uparrow}$ handoff from a dense source stream to a completion-target Cauchy row displays one dense source row, one metric row, one Lipschitz modulus row, one $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one completion target seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: completion, completemetric, streamname, regseqrat: no listed sibling supplies the joint finite packet containing dense source rows, metric comparison rows, Lipschitz modulus transport, finite source and target windows, regular rational readback, completion target sealing, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzCompletionExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzCompletionExtension}^{\uparrow}$ packet is generated from dense source rows, metric comparison rows, Lipschitz modulus rows, StreamName windows, RegSeqRat readback, completion target seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzCompletionExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6246.1, Definition 6246.2, and Definition 6246.3 seed the finite route from dense-source Lipschitz data to completion-target Cauchy evidence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzCompletionExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host Lipschitz extension theorems, selected target limits, quotient equality of completed points, countable choice, or ambient completeness outside the displayed completion target seal.

Upgrade path: Obligation closure requires checked carrier admission, Lipschitz-modulus transport, dense-window handoff, completion target sealing, Cauchy handoff replay, nonescape from selected limits or host completeness, transport, replay, provenance, and local naming for BEDC.Derived.LipschitzCompletionExtensionUp.

Chapter 6247

A Concrete Naming Certificate for OrdinalAnalysis$^{\uparrow}$

Following Gentzen and proof-theoretic ordinal analysis, the OrdinalAnalysis$^{\uparrow}$ packet records the finite ordinal-notation and descent-budget surface that a proof-normalization consumer may read before it reaches the MetaCIC normalization frontier. It sits beside the decidability boundary of chapter 749, the normalization frontier of chapter 892, the natural-deduction proof-tree surface of chapter 3756, the first-order syntax carrier of chapter 197, and the lambda-calculus proof-term boundary of chapter 200. The packet names only notation, descent, trace, consumer, refusal, transport, replay, provenance, and local naming rows; it does not assert global normalization, a host proof ordinal, or an unrestricted consistency theorem.

Definition 6247.1 (Ordinal analysis carrier)**.** *An* OrdinalAnalysis$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, B, C, U, L, H, R, P, N)$$

with the following displayed rows:

1. *A is the ordinal-notation row, read as a finite notation code and comparison window rather than as a completed host ordinal.*
2. *B is the descent-budget row, recording the finite measure used by a cut-elimination or normalization trace.*
3. *C is the cut-elimination trace row, displaying the local reduction or cut-reduction steps whose budget is being consumed.*
4. *U is the normalization-consumer row, naming the* MetaCICNormalizationFrontier$^{\uparrow}$*,* NaturalDeduction$^{\uparrow}$*,* FirstOrder$^{\uparrow}$*, or* LambdaCalc$^{\uparrow}$ *reader that may inspect the trace.*
5. *L is the refusal ledger, recording absent global-normalization, host-ordinal, subject-reduction, confluence, and consistency coordinates.*
6. *H records componentwise* hsame *transport for the notation, budget, trace, consumer, refusal, replay, provenance, and local naming rows.*
7. *R records displayed* Cont *replay from ordinal notation and descent budget through the trace into the named consumer boundary.*
8. *P is the* Pkg *provenance over* OrdinalAnalysis$^{\uparrow}$*,* MetaCICDecidableBoundary$^{\uparrow}$*,* MetaCICNormalizationFrontier$^{\uparrow}$*,* NaturalDeduction$^{\uparrow}$*,* FirstOrder$^{\uparrow}$*,* LambdaCalc$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{OrdinalAnalysis}^{\uparrow}}$ *row.*
The carrier has no coordinate for an ambient well-order theorem, a completed proof ordinal, a host consistency proof, a blanket cut-elimination theorem, or global MetaCIC normalization.

Theorem 6247.2 (Ordinal analysis NameCert obligations)**.** *For every accepted* $\mathsf{OrdinalAnalysis}^{\uparrow}$ *carrier* $O = (A, B, C, U, L, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OrdinalAnalysis}^{\uparrow}}$ *surface consists exactly of carrier admission for ordinal notation, descent budget, cut-elimination trace, normalization consumer, refusal ledger, transport, replay, provenance, and local naming; descent exactness requiring the trace row C to consume only the displayed budget B over the notation row A; consumer compatibility requiring every* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$*,* $\mathsf{NaturalDeduction}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{LambdaCalc}^{\uparrow}$ *read to pass through U; and nonescape excluding host proof ordinals, global normalization, unchecked subject reduction, unchecked confluence, and external consistency claims.*

Proof. Project the carrier of Definition 6247.1. The displayed rows are exactly $A, B, C, U, L, H, R, P, N$, so the local certificate has no source outside this finite packet.

Descent exactness is read from A, B, C. The notation row supplies the comparison window, the budget row supplies the finite descent measure, and the trace row records only the reduction steps charged to that budget.

Consumer compatibility is read from U, R, P, N. Replay and provenance make the named MetaCIC, natural-deduction, first-order, and lambda-calculus readers consume the displayed route rather than a detached host proof.

Finally, the refusal ledger L and the absence of further carrier coordinates exclude ambient proof ordinals, unrestricted normalization, subject reduction, confluence, and consistency claims. Thus the listed rows exhaust the NameCert obligations. □

Lean4 ✓ `BEDC.Derived.OrdinalAnalysisUp.OrdinalAnalysisCarrier namecert obligations`

Theorem 6247.3 (Cut-elimination budget boundary)**.** *Every cut-elimination or normalization-facing read of an accepted* $\mathsf{OrdinalAnalysis}^{\uparrow}$ *carrier must expose the route*

$$A, B, C, U, L, H, R, P, N$$

before it can be consumed by $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$*,* $\mathsf{NaturalDeduction}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or* $\mathsf{LambdaCalc}^{\uparrow}$*. The budget row B is a finite BEDC descent ledger attached to the notation row A and trace row C; it is not a host proof ordinal and does not by itself close global normalization.*

Proof. Read the analytic rows first. The notation row A and descent-budget row B precede the trace row C, so any cut-elimination consumer receives a finite charged trace rather than an unbounded ordinal argument.

Next read the consumer row U. It records which sibling boundary is allowed to inspect the trace: the MetaCIC decidability and normalization frontiers, the natural-deduction proof-tree packet, the first-order syntax carrier, or the lambda-calculus proof-term carrier.

The support rows H, R, P, N transport, replay, source, and name the same route. Since L records the refused readings and no carrier coordinate supplies a completed proof ordinal or global normalization theorem, the budget remains a boundary object for downstream consumers. □

Falsifiable prediction: A packet claiming $\mathsf{OrdinalAnalysis}^{\uparrow}$ acceptance while omitting ordinal notation, descent budget, cut-elimination trace, normalization consumer, refusal ledger, transport, replay, provenance, or local NameCert rows fails local certification before any MetaCIC normalization-frontier read can begin.

Independence witness: metacicnormalizationfrontier, metacicdecidableboundary, natural-deduction, firstorder, lambdacalc: $\mathsf{OrdinalAnalysis}^{\uparrow}$ is not bijective to any listed sibling because it carries an ordinal-notation row, a descent-budget row, a cut-elimination trace row, a named normalization-consumer row, and a refusal ledger as one finite packet. The MetaCIC frontier chapters carry bounded normalization and decidability surfaces without a proof-theoretic descent ledger; NaturalDeductionUp carries proof trees without ordinal notation; FirstOrderUp carries syntax and deduction endpoints; LambdaCalcUp carries term reduction rows without the displayed ordinal-analysis budget.

Closure status for $\mathsf{NameCert}_{\mathsf{OrdinalAnalysis}^{\uparrow}}$.

Constructive story: An $\mathsf{OrdinalAnalysis}^{\uparrow}$ packet is generated from ordinal notation, descent budget, cut-elimination trace, normalization-consumer, refusal-ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OrdinalAnalysis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6247.1, Definition 6247.2, and Definition 6247.3 seed the finite proof-theoretic descent route consumed by MetaCIC and proof-calculus boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OrdinalAnalysis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global normalization, host proof ordinals, unrestricted cut elimination, subject reduction, confluence, or consistency for $\mathsf{OrdinalAnalysis}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, descent-budget exactness, cut-elimination trace replay, normalization-consumer compatibility, refusal-ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.OrdinalAnalysisUp.

Chapter 6248

A Concrete Naming Certificate for $\mathsf{CartanMatrix}^{\uparrow}$

Following Bourbaki and Humphreys, the $\mathsf{CartanMatrix}^{\uparrow}$ packet records the finite integer matrix row that sits between root-system pairings and Weyl or Coxeter consumers. It is read after the root-system surface of chapter 144, the Weyl-group boundary of chapter 145, the Coxeter-group relation surface of chapter 6245, the finite matrix rows of chapter 49, and the integer endpoint rows of chapter 31. The packet names the Cartan-pairing table as finite NameCert data; it does not import Lie-algebra classification, root-string completeness, ambient vector-space equality, or a host crystallographic oracle.

Definition 6248.1 (Cartan matrix carrier)**.** *A* $\mathsf{CartanMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, A, D, O, S, R, W, C, H, K, P, N)$$

with the following displayed rows:

1. *I is the finite index row, naming the simple-root positions whose pairings are recorded.*
2. *A is the integer matrix-entry row, read through* $\mathsf{Mat}^{\uparrow}$ *and* $\mathsf{Int}^{\uparrow}$*, with an entry a_{ij} for every displayed pair of indices.*
3. *D is the diagonal-two row, recording $a_{ii} \sim_{\mathsf{Int}^{\uparrow}} 2$ for each displayed index i.*
4. *O is the nonpositive off-diagonal row, recording the inspected integer sign evidence for a_{ij} when i and j are distinct.*
5. *S is the symmetrizability or finite-type sign row exposed by the carrier when such a row is claimed by the root-system source.*
6. *R is the* $\mathsf{RootSystem}^{\uparrow}$ *pairing provenance row, tying each a_{ij} to the displayed coroot-pairing or reflection-pairing read.*
7. *W is the* $\mathsf{WeylGroup}^{\uparrow}$ *and* $\mathsf{CoxeterGroup}^{\uparrow}$ *consumer row, recording exactly which reflection or braid reads may consume I, A, D, O, S, R.*
8. *C records componentwise* hsame *transport for the index, entry, diagonal, off-diagonal, sign, pairing, consumer, replay, provenance, and naming rows.*
9. *H records displayed* Cont *replay for matrix-entry lookup, diagonal readback, off-diagonal sign readback, root-system pairing transport, and Weyl or Coxeter consumer handoff.*

10. *K is the package-local replay ledger that keeps every row of A attached to the same index row I.*
11. *P is the* Pkg *provenance over* $\mathsf{CartanMatrix}^{\uparrow}$, $\mathsf{RootSystem}^{\uparrow}$, $\mathsf{WeylGroup}^{\uparrow}$, $\mathsf{CoxeterGroup}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CartanMatrix}^{\uparrow}}$ *row.*

The classifier compares two Cartan-matrix packets only by these displayed rows and their transports. It carries no host matrix equality, no hidden root datum, and no classification of finite type beyond the row S explicitly supplied in the packet.

Lean4 ✓ `BEDC.Derived.CartanMatrixUp.CartanMatrixTasteGate single carrier alignment`

Theorem 6248.2 (Cartan matrix NameCert obligations)**.** *For every accepted* $\mathsf{CartanMatrix}^{\uparrow}$ *carrier $M = (I, A, D, O, S, R, W, C, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CartanMatrix}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index and integer matrix rows, diagonal-two exactness, off-diagonal sign exposure, the optional symmetrizability or finite-type sign row, root-system pairing provenance, Weyl and Coxeter consumer exposure, componentwise transport, displayed replay, package-local row coherence, provenance, and local naming.*

Proof. Project the carrier of Definition 6248.1. The rows I, A, D, O, S supply the finite matrix data, while R, W state how that data is sourced and consumed.

Carrier admission reads I and A through the finite matrix and integer surfaces. Diagonal exactness is the displayed row D, and off-diagonal sign exposure is the displayed row O.

The source and consumer boundaries are then forced by R and W. The row R ties entries to root-system pairings, while W records the only Weyl or Coxeter reads that may consume the displayed Cartan table.

Finally, C, H, K, P, N preserve and name the same packet. Transport, replay, package-local row coherence, provenance, and local naming add no hidden root datum, host matrix equality, finite-type classification theorem, or ambient Lie-algebra object. □

Theorem 6248.3 (Cartan matrix root-system consumer)**.** *Every* $\mathsf{RootSystem}^{\uparrow}$ *consumer that exports a Cartan row through* $\mathsf{CartanMatrix}^{\uparrow}$ *must first expose the finite index row I, the integer entry row A, the diagonal-two row D, the off-diagonal sign row O, and the root-system pairing provenance row R. The exported table cannot be replaced by a prose pairing convention, a host bilinear form, or an unindexed family of integers.*

Proof. Start from an accepted carrier $M = (I, A, D, O, S, R, W, C, H, K, P, N)$. The carrier lists the Cartan table as finite entries over the displayed index row, so no entry can be read without first reading I and A.

The Cartan-specific obligations are the diagonal and off-diagonal rows. The row D supplies the diagonal value, and O supplies the sign evidence for distinct indices.

The root-system origin of the table is not inferred from the matrix shape. It is the row R, which ties each entry to the displayed $\mathsf{RootSystem}^{\uparrow}$ pairing route.

Thus a root-system consumer receives a finite indexed table with visible integer entries and pairing provenance. The refused replacements are absent from the carrier and cannot be introduced by the transport or replay rows. □

Theorem 6248.4 (Cartan matrix Weyl-Coxeter boundary)**.** *Every* $\mathsf{WeylGroup}^{\uparrow}$ *or* $\mathsf{CoxeterGroup}^{\uparrow}$ *read of an accepted* $\mathsf{CartanMatrix}^{\uparrow}$ *packet factors through the same finite route*

$$I, A, D, O, S, R, W, C, H, K, P, N.$$

The consumer may use only the reflection-pairing, sign, and braid-facing rows recorded by R, S, W and preserved by C, H, K. It cannot read an unrecorded Coxeter matrix, a host reflection representation, a root-system classification theorem, or a detached Weyl action from the Cartan packet alone.

Proof. Read the consumer row W from Definition 6248.1. It is explicitly the boundary for Weyl and Coxeter consumers and is attached to the same I, A, D, O, S, R rows as the Cartan table.

The sign row S and pairing row R are the only rows that can feed reflection or braid-facing interpretations. If a consumer needs a Coxeter relation, it must obtain that relation through the displayed consumer route rather than by inventing a separate matrix.

The transport, replay, and package-local coherence rows C, H, K preserve the same indexed table under accepted comparisons. They do not add a representation space, a classification theorem, or an independent Weyl action.

Therefore the public Weyl-Coxeter boundary of the Cartan packet is exactly the finite route displayed above, with the listed external objects outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CartanMatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{CartanMatrix}^{\uparrow}$ packet is generated from a finite index row, integer matrix entries, diagonal-two rows, off-diagonal sign rows, an optional symmetrizability or finite-type sign row, RootSystem pairing provenance, Weyl and Coxeter consumer rows, componentwise hsame transport, displayed Cont replay, package-local row coherence, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CartanMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6248.1, Definition 6248.2, Definition 6248.3, and Definition 6248.4 seed the finite Cartan matrix carrier, root-system source, and Weyl-Coxeter consumer surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CartanMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, Lie-algebra classification, root-string completeness, a host root datum, ambient vector-space equality, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, diagonal exactness, off-diagonal sign exposure, root-system pairing provenance, Weyl-Coxeter consumer routing, transport, replay, package coherence, provenance, and local naming for BEDC.Derived.CartanMatrixUp.

Chapter 6249

A Concrete Naming Certificate for $\mathsf{ScopedExplanationLedger}^{\uparrow}$

The $\mathsf{ScopedExplanationLedger}^{\uparrow}$ packet realizes the scoped black-box certification principle of section 9462.19 as finite NameCert data. It records an explanation scope, the classifier rows valid inside that scope, the behavior ledger they cover, the global-ledger refusal row for uncovered behavior families, transport, replay, provenance, and local naming. The packet is an interpretability boundary: it certifies scoped explanation rows without pretending that a single classifier or natural-language summary eliminates global behavior residue.

The scoped ledger consumes relation rows from chapter 1089 and certificate compilation rows from chapter 473 before it records behavior-family residue. Those sibling surfaces supply the relation-site and compiled-certificate inputs that the scoped classifier reads; the ledger row keeps the uncovered behavior families visible instead of converting compilation into a global explanation claim.

Definition 6249.1 (Scoped explanation ledger carrier)**.** *A* $\mathsf{ScopedExplanationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (\Omega, B, E, Q, G, F, T, R, P, N)$$

with the following displayed rows:

1. *Ω is the explanation-scope row, naming the source domain, model state, admitted transformation family, and behavior being explained.*
2. *B is the behavior-family boundary row, separating the scoped behavior from behavior rows not covered by the packet.*
3. *E is the explanation-object row, containing the finite classifier, local NameCert, and scoped ledger entries used for the certified behavior.*
4. *Q is the scoped classifier row, recording exactly which comparisons or behavioral equivalences are valid inside Ω.*
5. *G is the global-ledger refusal row, recording that no global behavior-family ledger is exported unless a separate global carrier is supplied.*
6. *F is the failure and not-claimed row, listing uncovered behaviors, unverified transfers, semantic residue, and out-of-scope transformations.*
7. *T records componentwise* hsame *transport for $\Omega, B, E, Q, G, F, R, P, N$.*

8. *R records displayed* Cont *replay for scoped explanation reads, classifier reads, refusal reads, and downstream audit consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{ScopedExplanationLedger}^{\uparrow}$*, the scoped certification principle of section 9462.19,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ScopedExplanationLedger}^{\uparrow}}$ *row.*

The classifier compares packets only by the displayed scope, behavior boundary, explanation object, classifier, refusal, failure, transport, replay, provenance, and naming rows. It has no row that turns scoped resolution into global resolution.

Theorem 6249.2 (Scoped explanation ledger NameCert obligations)**.** *For every accepted* ScopedExplanationLedger *carrier $L = (\Omega, B, E, Q, G, F, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ScopedExplanationLedger}^{\uparrow}}$ *surface consists exactly of explanation-scope admission, behavior-boundary exposure, explanation-object exposure, scoped classifier exactness, global-ledger refusal, not-claimed residue, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6249.1. The rows Ω, B, E, Q state the scoped explanation and its classifier, while G, F state what is not exported.

The carrier admits a packet only when the scope and behavior boundary are displayed. The explanation object E and classifier row Q are therefore read inside that scope rather than as global model facts.

The refusal and residue rows are equally part of the certificate. The row G denies a global-ledger export, and F lists the behavior, transfer, semantic, and verification residue left outside the scoped claim.

Transport, replay, provenance, and naming preserve this same boundary. They do not create a global behavior-family ledger or a universal classifier, so the NameCert obligations are exactly the listed rows. □

Theorem 6249.3 (Scoped explanation ledger global nonescape)**.** *An accepted* $\mathsf{ScopedExplanationLedger}^{\uparrow}$ *packet never exports global black-box resolution from the scoped explanation row alone. Any consumer claiming global behavior coverage must read a separate global-ledger carrier; the rows $\Omega, B, E, Q, G, F, T, R, P, N$ only certify the scoped explanation and the explicit global-ledger refusal.*

Proof. Begin with the rows of Definition 6249.1. The explanation object E and classifier row Q are indexed by the scope row Ω and behavior boundary B.

The global-ledger row of this packet is a refusal row. It records that no global behavior-family ledger is exported from the scoped explanation.

The residue row F names the uncovered behavior, transfer, semantic, and verification residue. A consumer that ignores F has not consumed the certificate boundary of the packet.

Thus global behavior coverage is unavailable from this carrier. It requires a separate carrier whose rows actually display the covered behavior family and common global ledger. □

Theorem 6249.4 (Scoped explanation ledger cannot-claim dependency)**.** *The global-ledger refusal row G of an accepted* $\mathsf{ScopedExplanationLedger}^{\uparrow}$ *packet is consumed as refusal/export gating through chapter 1319. A consumer may export the scoped explanation rows Ω, B, E, Q only as scoped rows; any claim that removes the global-ledger refusal must present a separate global carrier and pass the cannot-claim export gate before it can be named as an exported target.*

Proof. Start with Definition 6249.3. The row G is not decorative metadata: it is the displayed refusal that blocks global behavior coverage from being read out of the scoped classifier.

The cannot-claim export gate supplies the sibling discipline for that refusal. Its registry, refusal, export-decision, target, audit, transport, continuation, provenance, and local naming rows force a refused claim to remain visible before any target export is named.

Transport the scoped explanation packet through T, R, P, N. These structural rows preserve the same refusal boundary, so a consumer can export the packet only as a scoped explanation ledger unless a separate global carrier discharges the refused coverage claim through the gate. □

Theorem 6249.5 (Scoped explanation ledger sibling independence)**.** *The* $\mathsf{ScopedExplanationLedger}^{\uparrow}$ *carrier is not bijective with any single classifier packet, relation packet, compiler packet, no-global-synchronization ledger, or machine-interface socket. Its public route requires the combined scope, behavior boundary, explanation object, scoped classifier, global-ledger refusal, residue, transport, replay, provenance, and local naming rows.*

Proof. A single classifier packet can supply a comparison row, but it lacks the explanation scope, behavior-family boundary, global-ledger refusal, and not-claimed residue required by Definition 6249.1.

A relation or compiler packet can expose relation or compilation rows, but those rows do not determine which behavior is certified inside which explanation scope.

A no-global-synchronization ledger or machine-interface socket can expose refusal or boundary rows, but it lacks the scoped explanation object and classifier exactness row.

Therefore none of those siblings is bijective with the scoped explanation ledger. The carrier is the combined finite route $\Omega, B, E, Q, G, F, T, R, P, N$. □

Falsifiable prediction: If a $\mathsf{ScopedExplanationLedger}^{\uparrow}$ packet is reduced to a single classifier row, then the global-ledger refusal row is lost.

Independence witness: layeredrelationsite, certificatecompiler, no_global_synchronization_ledger, machineinterfacesocket: the relation site supplies relation rows without the explanation-scope ledger; the certificate compiler supplies compilation rows without behavior-family residue; the no-global-synchronization ledger supplies refusal rows without scoped classifier exactness; the machine-interface socket supplies boundary access without the local explanation object. None is bijective with the combined scope, classifier, ledger, refusal, transport, replay, provenance, and NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{ScopedExplanationLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ScopedExplanationLedger}^{\uparrow}$ packet is generated from an explanation scope, behavior-family boundary, explanation object, scoped classifier, global-ledger refusal, not-claimed residue, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ScopedExplanationLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6249.1, Definition 6249.2, Definition 6249.3, Definition 6249.4, and Definition 6249.5 seed the scoped explanation, classifier, refusal, export-gating dependency, residue, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ScopedExplanationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, global black-box resolution, a universal classifier, global synchronization, open-domain behavior coverage, or a standard bridge.

Upgrade path: Obligation closure requires checked scope admission, behavior-boundary exposure, scoped classifier exactness, global-ledger refusal, residue, transport, replay, provenance, and local naming for BEDC.Derived.ScopedExplanationLedgerUp.

Chapter 6250

A Concrete Naming Certificate for $\mathsf{CompactCoverModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CompactCoverModulus}^{\uparrow}$ packet records the finite-cover modulus route that turns compact-source coverage and local continuity radii into a uniform-modulus handoff. It sits between the compact metric source of chapter 129, the continuous-map rows of chapter 130, the finite lower-bound fold of chapter 4096, and the uniform-modulus consumer of chapter 369. The packet names finite cover rows and lower-bound folds as BEDC histories; it does not choose an external modulus function, appeal to open-cover compactness, or import ambient real completeness.

Definition 6250.1 (Compact cover modulus carrier)**.** *A* $\mathsf{CompactCoverModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, C, L, F, R, H, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through* $\mathsf{CompactMetric}^{\uparrow}$*.*
2. *C is the finite cover row, displaying the compact finite subcover or* $\mathsf{ProbeBundle}$ *spine used by the modulus construction.*
3. *L is the local modulus list row, one positive-radius ledger for each displayed cover member and continuous-map observation.*
4. *F is the finite lower-bound fold row, recording the certified positive lower bound consumed by* $\mathsf{UniformModulus}^{\uparrow}$*.*
5. *R is the uniform radius row exported to the downstream uniform-modulus consumer.*
6. *H records componentwise* hsame *transport for the compact source, cover, local moduli, fold, radius, provenance, and local naming rows.*
7. *P is the* Pkg *provenance over* $\mathsf{CompactCoverModulus}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{ProbeBundle}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCoverModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for an external choice of cover, a host finite minimum, a pointwise-only modulus selector, quotient equality of metric points, or ambient compactness outside the displayed source row.

Lean4 ✓ `BEDC.Derived.CompactCoverModulusUp.TasteGate.CompactCoverModulusTasteGate single carrier alignment`

Theorem 6250.2 (Compact cover modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactCoverModulus}^{\uparrow}$ *carrier* $M = (K, C, L, F, R, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactCoverModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for compact metric source, finite cover, local modulus list, finite lower-bound fold, uniform radius, transport, provenance, and local naming; cover-source compatibility requiring* C *to be a cover of the displayed compact metric row* K*; fold exactness requiring* F *to read only the finite local-modulus list* L *over that cover; uniform-radius handoff requiring* R *to be exported only after the fold row is displayed; and nonescape excluding external cover choice, host finite minima, pointwise-only selector data, quotient point equality, and ambient completeness.*

Proof. Project the carrier of Definition 6250.1. The packet displays exactly K, C, L, F, R, H, P, N, so every local obligation must be read from these rows.

Cover-source compatibility is the route from K to C. The cover row is attached to the compact metric source row and cannot be interpreted over a detached source.

Fold exactness is the route from L to F and then to R. The finite lower-bound fold consumes only the displayed local modulus list, and the uniform radius is exported only after that fold is present.

The support rows H, P, N transport, source, and name the same carrier. Since no row stores external cover choice, a host finite minimum, a pointwise-only selector, quotient point equality, or ambient completeness, the listed obligations exhaust the NameCert surface. □

Theorem 6250.3 (Finite subcover handoff)**.** *Every compact-uniform-continuity consumer reading an accepted* $\mathsf{CompactCoverModulus}^{\uparrow}$ *carrier must pass through the ordered route*

$$K, C, L, F, R, H, P, N.$$

The finite cover row C *and local modulus list* L *are read before the finite lower-bound fold* F*, and the uniform radius row* R *is available only after that fold. Thus the consumer receives a concrete finite-cover modulus packet rather than a narrative compactness argument or an external uniform-modulus selector.*

Proof. Read the compact source row K and finite cover row C. These rows expose the source and the finite subcover or $\mathsf{ProbeBundle}$ spine used by the compact-uniform-continuity route.

Next read the local modulus list L. Each entry is attached to a displayed cover member and a continuous-map observation, so the list is finite before the fold begins.

Finally apply the fold and handoff rows F, R. Transport, provenance, and naming through H, P, N preserve this route, while the carrier excludes external selectors, host minima, quotient point equality, and ambient completeness. The downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer therefore reads the displayed finite-subcover handoff. □

Falsifiable prediction: A compact-uniform-continuity packet that claims $\mathsf{CompactCoverModulus}^{\uparrow}$ acceptance while omitting compact source, finite cover, local modulus list, finite lower-bound fold, uniform radius, transport, provenance, or local NameCert rows fails local certification before a $\mathsf{UniformModulus}^{\uparrow}$ consumer may read it.

Independence witness: compactmetric, continuousmap, finite-lower-bound-fold, uniformmodulus: $\mathsf{CompactCoverModulus}^{\uparrow}$ is not bijective to any listed sibling because it carries the compact source, finite cover, local modulus list, finite lower-bound fold, and uniform-radius handoff as

one packet. CompactMetricUp supplies the source without the continuous local modulus list; ContinuousMapUp supplies graph and local continuity rows without the finite compact cover; FiniteLowerBoundFoldUp supplies the fold without the source-cover handoff; UniformModulusUp consumes the radius without naming the finite cover that produced it.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCoverModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactCoverModulus}^{\uparrow}$ packet is generated from compact metric source, finite cover, local modulus list, finite lower-bound fold, uniform radius, componentwise hsame transport, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactCoverModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6250.1, Definition 6250.2, and Definition 6250.3 seed the finite-cover modulus handoff for compact uniform continuity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactCoverModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, external modulus choice, host finite minima, quotient point equality, or ambient completeness for $\mathsf{CompactCoverModulus}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, cover-source compatibility, local-modulus list admission, finite lower-bound fold exactness, uniform-radius handoff, transport, provenance, and local naming for BEDC.Derived.CompactCoverModulusUp.

Chapter 6251

A Concrete Naming Certificate for $\mathsf{RealReciprocal}^{\uparrow}$

Following Bishop and Bridges on constructive real arithmetic, the $\mathsf{RealReciprocal}^{\uparrow}$ packet names the guarded reciprocal surface for displayed nonzero-apart $\mathsf{Real}^{\uparrow}$ data. It sits after the real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance and lower-bound rows of chapter 291, the reciprocal-window budget of chapter 703, the guarded quotient route of chapter 1943, and the Heron consumer of chapter 3818. The chapter records reciprocal reads only under displayed apartness; it is not trichotomy, quotient real equality, a total inverse function, or ambient $\mathsf{Real}^{\uparrow}$ field completeness.

Definition 6251.1 (Real reciprocal carrier)**.** *A* $\mathsf{RealReciprocal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, A, B, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted* $\mathsf{Real}^{\uparrow}$ *source whose reciprocal is requested.*
2. *A is the nonzero-apartness row, recording the displayed lower-bound witness that keeps X away from the zero boundary.*
3. *B is the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row that selects the finite reciprocal-window budget for the source name and apartness witness.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the budgeted reciprocal route.*
5. *D is the* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *handoff row, exposing the same reciprocal as division of the unit regular name by the guarded source name.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the reciprocal candidate.*
7. *H records componentwise* hsame *transport for the source, apartness, budget, readback, division handoff, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for source inspection, apartness exposure, budget selection, regular readback, division handoff, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{RealReciprocal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{RegularCauchyDivision}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealReciprocal}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through $X, A, B, Q, D, E, H, C, P, N$ and has no coordinate for total inversion, trichotomy, quotient real equality, or an ambient field inverse.

Lean4 ✓ `BEDC.Derived.RealReciprocalUp.RealReciprocalTasteGate single carrier alignment`

Theorem 6251.2 (Real reciprocal NameCert obligations)**.** *For every accepted* $\mathsf{RealReciprocal}^{\uparrow}$ *carrier*

$$R = (X, A, B, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealReciprocal}^{\uparrow}}$ *surface consists exactly of source Real admission, nonzero-apartness exposure, finite Cauchy inverse budget selection,* $\mathsf{RegSeqRat}^{\uparrow}$ *reciprocal readback,* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the same finite packet.*

Lean4 ✓ `BEDC.Derived.RealReciprocalUp.RealReciprocalCarrier namecert obligation surface`

Proof. Project the carrier of Definition 6251.1. The rows $X, A, B, Q, D, E, H, C, P, N$ list all analytic and structural data available to an accepted reciprocal packet.

The analytic route is ordered. The apartness row A is exposed before the inverse budget B, the budget produces the regular rational readback Q, and the division handoff D identifies the same guarded reciprocal route before the terminal Real seal E is read.

The rows H, C, P, N then transport, replay, source, and name the displayed route. Since no additional coordinate is present, the local NameCert obligations are exhausted by the listed packet and cannot import total inversion, trichotomy, quotient real equality, or ambient field completeness. □

Theorem 6251.3 (Real reciprocal apartness-domain stability)**.** *Let* $R = (X, A, B, Q, D, E, H, C, P, N)$ *and* $R' = (X', A', B', Q', D', E', H', C', P', N')$ *be accepted* $\mathsf{RealReciprocal}^{\uparrow}$ *packets. If the displayed transport rows relate* X, A, B, Q, D, E *to* X', A', B', Q', D', E' *componentwise by* hsame*, then the reciprocal route for* R' *still exposes* A' *before any budget, readback, division handoff, or Real seal row is consumed. A route with no transported apartness row remains outside the reciprocal domain.*

Lean4 ✓ `BEDC.Derived.RealReciprocalUp.RealReciprocalCarrier apartness domain stability`

Proof. Start with the NameCert obligations for R. They place A before B, Q, D, E in the displayed reciprocal route.

Use the componentwise hsame rows to transport the source, apartness, budget, readback, handoff, and seal coordinates to R'. The transported route has the same row order because hsame changes only the displayed coordinate representatives, not the carrier inventory.

It follows that A' is still the first domain row for the reciprocal read. If the transported route omits A', then no row can justify the Cauchy inverse budget or the later Real seal, so the route remains a boundary attempt rather than an accepted reciprocal packet. □

Theorem 6251.4 (Real reciprocal regular-Cauchy handoff)**.** *Every accepted* $\mathsf{RealReciprocal}^{\uparrow}$ *read factors through*

$$X, A \longmapsto B \longmapsto Q \longmapsto D \longmapsto E.$$

The handoff reads the reciprocal candidate from $\mathsf{CauchyInverseBudget}^{\uparrow}$ *through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is public. It exports no host inverse function, no total reciprocal operation, no trichotomy principle, no quotient real equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.RealReciprocalUp.RealReciprocalCarrier regular cauchy handoff`

Proof. Apply Definition 6251.2. It exposes the source and apartness rows X, A before any reciprocal-window data is available.

Next read the Cauchy inverse budget row B. This row is the finite budget surface supplied by chapter 703; it selects only displayed windows and lower-bound data.

The regular rational handoff Q and guarded division row D are downstream of that budget. The division row agrees with the reciprocal route through chapter 1943, so the seal E receives a regular-Cauchy reciprocal packet rather than a host inverse.

Finally inspect the carrier inventory. Since the packet contains only $X, A, B, Q, D, E, H, C, P, N$, there is no coordinate for total reciprocal choice, trichotomy, quotient real equality, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{RealReciprocal}^{\uparrow}$ read exposes a nonzero-apartness row before the Cauchy inverse budget, RegSeqRat readback, RegularCauchyDivision handoff, and terminal Real seal.

Independence witness: real, regseqrat, dyadicratcore, cauchyinversebudget, regularcauchydivision: $\mathsf{RealReciprocal}^{\uparrow}$ is not bijective to any listed sibling because it binds a Real source, apartness-domain row, inverse budget, regular readback, guarded division handoff, Real seal, transport, replay, provenance, and local naming as one finite reciprocal packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealReciprocal}^{\uparrow}}$.

Constructive story: A $\mathsf{RealReciprocal}^{\uparrow}$ packet is generated from a displayed Real source, a nonzero-apartness row, a Cauchy inverse budget, RegSeqRat reciprocal readback, RegularCauchyDivision handoff, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealReciprocal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6251.1, Definition 6251.2, Definition 6251.3, and Definition 6251.4 seed the guarded reciprocal boundary over nonzero-apart Real data, finite Cauchy inverse budgets, RegSeqRat readback, guarded division handoff, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealReciprocal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total reciprocal choice, trichotomy, quotient real equality, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness-domain stability, finite inverse-budget readback, RegularCauchyDivision handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealReciprocalUp.

Lean4 (statement) `BEDC.Derived.RealReciprocalUp`

Chapter 6252

A Concrete Naming Certificate for $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$

Following Newton, Leibniz, and Bishop–Bridges constructive analysis, the $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$ packet records the finite derivative-integral handoff by which a displayed derivative window and a displayed Riemann integral row are read as one theorem-facing route. It sits after the derivative carrier of chapter 122, the Riemann-integral row of chapter 1526, the Darboux comparison surface of chapter 1880, the tagged-partition schedule of chapter 4296, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The certificate names only the displayed constructive route from derivative control to integral readback; it does not import a classical continuum theorem, select an antiderivative, identify quotient functions, or assert ambient completeness.

Definition 6252.1 (Fundamental theorem calculus carrier)**.** *A* $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, I, A, T, Q, S, G, R, H, C, P, N)$$

with the following rows:

1. *D is the* $\mathsf{Derivative}^{\uparrow}$ *window row, naming the displayed function, interval window, derivative witness, and local difference-quotient budget.*
2. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row through which the matching integral expression is inspected.*
3. *A is the* $\mathsf{DarbouxSum}^{\uparrow}$ *and refinement ledger, recording upper and lower comparison rows and the mesh refinement relation used by the integral readback.*
4. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row, exposing the ordered tags, cells, endpoint windows, and compatibility with the same interval read by D and I.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget for derivative windows, partition mesh, Darboux spread, integral readback, and endpoint comparison.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the endpoint values, derivative samples, tagged cells, and integral approximants.*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational sequences exposed by S.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the Real-facing derivative-integral conclusion.*

9. *H records componentwise* hsame *transport for derivative, integral, Darboux, tagged-partition, dyadic, stream, regular-rational, Real, replay, provenance, and naming rows.*
10. *C records displayed* Cont *replay of the finite route*

$$D, I, A, T, Q \longmapsto S \longmapsto G \longmapsto R \longmapsto \mathsf{NameCert}_{\mathsf{FundamentalTheoremCalculus}^{\uparrow}}.$$

11. *P is the* Pkg *provenance over* $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FundamentalTheoremCalculus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, I, A, T, Q, S, G, R, H, C, P, N$. It has no coordinate for ambient Real completeness, measure-theoretic integration, host function extensionality, selected antiderivatives, quotient equality of functions, or bridge checking.

Theorem 6252.2 (Fundamental theorem calculus NameCert obligations)**.** *For every accepted* $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$ *carrier*

$$F = (D, I, A, T, Q, S, G, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FundamentalTheoremCalculus}^{\uparrow}}$ *surface consists exactly of carrier admission for F, derivative-window exposure through D, Riemann-integral exposure through I, Darboux and refinement accountability through A, tagged-partition visibility through T, dyadic tolerance accounting through Q, StreamName window exposure through S, RegSeqRat readback through G, terminal Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.FundamentalTheoremCalculusUp.FundamentalTheoremCalculusTasteGate single carrier alignment`

Proof. Project the carrier of Definition 6252.1. The analytic rows D, I, A, T, Q are the only source of derivative control, integral inspection, Darboux comparison, tagged partition data, and tolerance budgets.

The readback rows are ordered. The finite StreamName row S exposes the visible endpoint, derivative, cell, and integral windows before G reads them as regular rational data and R seals the Real-facing conclusion.

The structural rows H, C, P, N transport, replay, source, and name exactly this displayed route. Since no carrier coordinate stores ambient Real completeness, measure-theoretic integration, host function extensionality, selected antiderivatives, quotient equality, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 6252.3 (Fundamental theorem calculus Riemann derivative route)**.** *Every accepted* $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$ *theorem read that hands a derivative window to a Riemann-integral conclusion factors through the finite route*

$$\mathsf{Derivative}^{\uparrow} \longmapsto \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{DarbouxSum}^{\uparrow} \longmapsto \mathsf{TaggedRealPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}$$

as instantiated by D, I, A, T, Q, S, G, R. The Real-facing conclusion receives derivative-window data, Riemann integral data, Darboux and refinement accountability, tagged partition visibility, dyadic tolerance budgets, finite stream windows, regular rational readback, terminal Real sealing,

componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row; it receives no ambient Real completeness theorem, measure-theoretic integration object, host function extensionality principle, selected antiderivative, quotient equality, or checked bridge.*

Proof. Start with the accepted carrier $F = (D, I, A, T, Q, S, G, R, H, C, P, N)$. The rows D and I display the derivative window and the matching Riemann-integral row before any theorem-facing conclusion is read.

Use the partition and comparison route next. The Darboux ledger A, tagged partition row T, and dyadic budget Q expose the finite mesh and tolerance data needed by the integral readback.

Finally pass through the completion-facing rows. The stream, regular-rational, and Real rows S, G, R are read in that order, and H, C, P, N preserve the same displayed path. Since the carrier has no coordinate for ambient completeness, measure-theoretic integration, host extensionality, selected antiderivatives, quotient equality, or bridge checking, the route is exhausted by the finite BEDC packet. □

Falsifiable prediction: Every $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$ theorem-facing read factors through one derivative-window row, one Riemann-integral row, one Darboux/refinement ledger, one tagged-partition row, one dyadic tolerance budget, one StreamName finite-window row, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: derivative, riemannintegral, darboux-sum, tagged-real-partition, dyadicratcore, streamname, regseqrat, real: $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the derivative window, integral row, Darboux comparison, tagged partition schedule, dyadic tolerance budget, finite observations, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FundamentalTheoremCalculus}^{\uparrow}}$.

Constructive story: A $\mathsf{FundamentalTheoremCalculus}^{\uparrow}$ packet is generated from a DerivativeUp window row, a RiemannIntegralUp row, a DarbouxSum refinement ledger, a TaggedRealPartition row, DyadicRatCore tolerance budgets, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FundamentalTheoremCalculus}^{\uparrow}}$, seed)

Scope closed: Definition 6252.1, Definition 6252.2, and Definition 6252.3 seed the finite derivative-integral route over derivative, Riemann-integral, Darboux, tagged-partition, dyadic, stream-name, regular rational, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FundamentalTheoremCalculus}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.FundamentalTheoremCalculusUp`

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, measure-theoretic integration, host function extensionality, selected antiderivatives, quotient equality, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-window exposure, Riemann-integral exposure, Darboux/refinement exactness, tagged-partition visibility, dyadic tolerance accounting, readback routing, Real sealing, provenance, and local naming for BEDC.Derived.FundamentalTheoremCalculusUp.

Chapter 6253

A Concrete Naming Certificate for $\mathsf{LocatedIntervalCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{LocatedIntervalCompletion}^{\uparrow}$ packet records the finite interval-completion surface where endpoint real names, dyadic tolerance requests, finite stream windows, regular rational readback, and Cauchy modulus rows are bound before any completion consumer reads a sealed interval point. It sits after the terminal real-name surface of chapter 38, the regular rational readback of chapter 301, the finite window route of chapter 126, the dyadic tolerance core of chapter 291, and the Cauchy route of chapter 3413. The packet names located interval completion data as finite rows; it does not quotient streams, select representatives, invoke countable choice, use trichotomy, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6253.1 (Located interval completion carrier)**.** *A* $\mathsf{LocatedIntervalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (E_0, E_1, D, W, Q, M, R, H, C, P, N)$$

with the following displayed rows:

1. *E_0 and E_1 are the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint rows. They are read as terminal real-name seals, not as host real representatives.*
2. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the interval-width budget, endpoint tolerance budget, and halving ledger used by completion reads.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened at the endpoint indices and tolerances displayed by E_0, E_1, D.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows and dyadic tolerance data.*
5. *M is the Cauchy modulus row. It records the finite schedule that makes the endpoint window reads Cauchy-compatible inside the located interval route.*
6. *R is the completion seal row, consumed only after the endpoint rows, dyadic tolerance row, StreamName windows, RegSeqRat readback, and Cauchy modulus row have been displayed.*
7. *H records componentwise* hsame *transport for E_0, E_1, D, W, Q, M, R.*
8. *C records displayed* Cont *replay for interval-completion requests through the finite route*

$$E_0, E_1, D \longmapsto W, Q, M \longmapsto R, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E_0, E_1, D, W, Q, M, R, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalCompletionUp.LocatedIntervalCompletionTasteGate single carrier alignment`

Theorem 6253.2 (Located interval completion NameCert obligations)**.** *For every accepted* LocatedIntervalComplet *carrier $L = (E_0, E_1, D, W, Q, M, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalCompletion}^{\uparrow}}$ *surface is exhausted by the following finite obligations:*

1. *endpoint admission for the two* $\mathsf{Real}^{\uparrow}$ *rows and their displayed interval order context;*
2. *dyadic tolerance admission for interval-width and endpoint-read budgets through D;*
3. *finite StreamName window exposure through W at the same endpoint and tolerance requests;*
4. *RegSeqRat readback through Q, attached to the displayed windows rather than to quotient streams;*
5. *Cauchy modulus compatibility through M, requiring the endpoint reads and the interval-width budget to share one finite schedule;*
6. *completion sealing through R, downstream of E_0, E_1, D, W, Q, M;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No obligation exports a selected representative, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6253.1. The projection exposes exactly the endpoint rows, dyadic tolerance row, finite windows, regular rational readback, Cauchy modulus, completion seal, and structural rows.

The endpoint and tolerance obligations are upstream of every completion read. A consumer cannot inspect R before E_0, E_1 and D determine the displayed interval and its finite precision request.

The window and readback obligations then follow the sibling routes of chapter 126 and chapter 301. The Cauchy modulus row M binds those finite reads to the same dyadic budget supplied by chapter 291.

The completion seal is therefore terminal only for this displayed route. Since H, C, P, N transport, replay, source, and name the same finite packet without adding a selector, quotient, choice schedule, trichotomy decision, host equality row, or ambient completeness theorem, the listed obligations exhaust the local NameCert surface. □

Theorem 6253.3 (Located interval completion Cauchy seal route)**.** *Every Cauchy-facing completion read exported by an accepted* $\mathsf{LocatedIntervalCompletion}^{\uparrow}$ *carrier*

$$L = (E_0, E_1, D, W, Q, M, R, H, C, P, N)$$

factors through the finite route

$$E_0, E_1, D \longmapsto W, Q, M \longmapsto R, H, C, P, N.$$

The read first displays the Real endpoint rows and dyadic tolerance budget; it then opens finite StreamName windows, reads them through RegSeqRat, checks the Cauchy modulus row, and only then consumes the completion seal. The route exports no selected limit, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the endpoint and tolerance rows named in Definition 6253.1. A Cauchy-facing read has no access to the completion seal until the two $\mathsf{Real}^{\uparrow}$ endpoint rows and the dyadic budget row have been displayed.

The finite observation route is fixed by those rows. The StreamName row supplies only the requested finite windows, the RegSeqRat row supplies the regular rational readback attached to those windows, and the Cauchy modulus row binds the readbacks to one completion schedule.

Transport and replay do not create a second completion source. The rows H and C move and replay only the displayed coordinates, while P and N record provenance and local naming for the same packet.

Thus every exported Cauchy-facing completion observation factors through $E_0, E_1, D, W, Q, M, R, H, C, P, N$. Since the carrier contains no coordinate for a selected limit, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness, none of those principles is exported by the route. □

Falsifiable prediction: Every $\mathsf{LocatedIntervalCompletion}^{\uparrow}$ Cauchy-facing read factors through two RealUp endpoint rows, one DyadicRatCore tolerance row, one StreamName window row, one RegSeqRat readback row, one Cauchy modulus row, one completion seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: Nearest siblings: real, regseqrat, streamname, dyadicratcore, and cauchy. $\mathsf{LocatedIntervalCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint Real seals, dyadic tolerance data, finite windows, regular rational readback, Cauchy modulus scheduling, completion sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalCompletion}^{\uparrow}$ packet is generated from RealUp endpoint rows, DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readback, Cauchy modulus rows, a completion seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedIntervalCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 6253.1, Definition 6253.2, and Definition 6253.3 seed the finite located interval completion route over endpoint, tolerance, window, readback, Cauchy modulus, seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedIntervalCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, dyadic tolerance exactness, StreamName window replay, RegSeqRat readback, Cauchy modulus compatibility, completion sealing, classifier transport, and local naming for BEDC.Derived.LocatedIntervalCompletionUp.

Chapter 6254

A Concrete Naming Certificate for $\mathsf{FiniteVariationLedger}^{\uparrow}$

Following Jordan, Rudin, and Folland, the $\mathsf{FiniteVariationLedger}^{\uparrow}$ packet records the finite partition-sum object used before any bounded-variation or Riemann–Stieltjes consumer takes a supremum over partitions. It isolates the reusable finite ledger read by chapter 398: interval rows, displayed partition rows, endpoint names, dyadic edge observations, finite sums, common refinements, transport, replay, provenance, and local naming. The displayed partition and variation-sum rows consumed by this ledger are sourced through chapter 398 and the partition route of chapter 6386. The packet is deliberately finite. It does not contain a host supremum over all partitions, a variation measure, a quotient function space, or ambient real completeness.

Definition 6254.1 (Finite variation ledger carrier)**.** *A* $\mathsf{FiniteVariationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, \Pi, X, D, V, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval row, read through* $\mathsf{RationalInterval}^{\uparrow}$ *or* $\mathsf{NestedInterval}^{\uparrow}$ *when the source supplies rational or nested endpoints.*
2. *Π is the displayed finite ordered partition of I, including endpoint order and adjacent-edge rows.*
3. *X records the endpoint rows, either as* $\mathsf{Real}^{\uparrow}$ *names or as* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational representatives consumed before a real seal is read.*
4. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations comparing the adjacent endpoint values on every displayed edge of Π.*
5. *V is the finite variation-sum ledger, obtained from exactly the edge observations displayed in D.*
6. *R records common-refinement rows comparing Π with another displayed finite partition and transporting endpoint and edge-observation rows to the refinement.*
7. *H records componentwise* hsame *transport for the interval, partition, endpoint, edge-observation, finite-sum, common-refinement, package, and naming rows.*
8. *C records displayed* Cont *replay from an interval request to partition endpoints, dyadic edge reads, finite-sum formation, refinement comparison, and consumer exposure.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteVariationLedger}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteVariationLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed interval row, finite partition, endpoint rows, edge observations, finite sum, common refinement, and visible transport, replay, package, and naming rows.

Lean4 ✓ `BEDC.Derived.FiniteVariationLedgerUp.FiniteVariationLedgerTasteGate single carrier alignment`

Theorem 6254.2 (Finite variation ledger NameCert obligations)**.** *For every accepted* $\mathsf{FiniteVariationLedger}^{\uparrow}$ *carrier* $L = (I, \Pi, X, D, V, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteVariationLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval and displayed finite partition, endpoint exposure through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$*, dyadic edge-observation exposure through* $\mathsf{DyadicRatCore}^{\uparrow}$*, finite variation-sum exactness, common-refinement routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6254.1. The rows I and Π supply the interval and finite partition data, while X, D, V supply the endpoint, dyadic edge, and finite sum rows.

The finite variation obligation is therefore local to the displayed partition. Each edge contribution is read from D, and the row V records the finite sum of precisely those edge observations.

The refinement and stability obligations are carried by R, H, C. A consumer may move to a common refinement only through the displayed refinement row, with endpoint and edge data transported by the recorded hsame and replayed by the recorded Cont routes.

Finally, P and N provide package provenance and the local NameCert row. No step introduces a supremum over all partitions, a measure-valued object, a quotient of functions, or ambient real completeness. □

Theorem 6254.3 (Finite variation ledger common-refinement route)**.** *Every common-refinement read of an accepted* $\mathsf{FiniteVariationLedger}^{\uparrow}$ *packet factors through the finite route*

$$I, \Pi, X, D, V, R, H, C, P, N.$$

The refined read may use only the displayed interval row, both displayed finite partitions, transported endpoint $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *names, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge observations, the finite variation-sum ledger, the common-refinement row, and the visible* hsame, Cont, Pkg, *and* NameCert *rows. It exports no host supremum over partitions, variation measure, quotient function, selected refinement outside R, or ambient real-completeness principle.*

Proof. Start from the common-refinement row R in Definition 6254.1. It is attached to the same interval, partition, endpoint, dyadic, and finite-sum rows as the original ledger.

Transport the endpoint and edge-observation rows along H, and replay the finite read order along C. The refined ledger therefore reuses the same finite BEDC rows rather than introducing a new partition family.

The package and naming rows P, N then repack the refined finite sum as the public consumer route. Since the carrier has no coordinate for a global supremum, variation measure, quotient function, selected external refinement, or completeness principle, none of those objects can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteVariationLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteVariationLedger}^{\uparrow}$ packet is generated from an interval row, a displayed finite partition, endpoint RealUp or RegSeqRatUp rows, DyadicRatCoreUp edge observations, a finite variation-sum ledger, a common-refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteVariationLedger}\uparrow}$, seed)

Scope closed: Definition 6254.1, Definition 6254.2, and Definition 6254.3 seed the reusable finite partition-sum ledger for BoundedVariationUp and Real-facing integration consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteVariationLedger}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host suprema over all partitions, variation measures, quotient functions, selected global refinements, ambient Real completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, dyadic edge observation, finite-sum exactness, common-refinement routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteVariationLedgerUp.

Chapter 6255

A Concrete Naming Certificate for $\mathsf{MetricCompletionMorphism}^{\uparrow}$

Following Bishop and Bridges on constructive metric completion, the $\mathsf{MetricCompletionMorphism}^{\uparrow}$ packet records the finite morphism surface by which a map between displayed metric-completion presentations preserves Cauchy data before any completed point or host map is read. It sits after the metric source of chapter 57, the complete-metric target of chapter 128, the completion-functor route of chapter 426, and the Cauchy-filter limit surface of chapter 1558. The packet names only finite completion-morphism rows; it does not assert quotient completion equality, choose representatives, import a host continuous map, use countable choice, or appeal to ambient completeness.

Definition 6255.1 (Metric completion morphism carrier)**.** *A* $\mathsf{MetricCompletionMorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, T, W, R, D, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric row, recording the* $\mathsf{Met}^{\uparrow}$ *carrier, distance readbacks, and the Cauchy source interface that the morphism may inspect.*
2. *T is the target completion row, recording the* $\mathsf{CompleteMetric}^{\uparrow}$ *and completion-functor data visible to target-side consumers.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite source windows and target windows inspected by the morphism.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for source distances, target distances, and modulus-scaled tolerance requests.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, naming the finite dyadic budgets used to compare source Cauchy windows with target Cauchy windows.*
6. *M is the modulus-preserving map row. It records the displayed map schedule and the finite checks that transport a source Cauchy tolerance into the target completion tolerance.*
7. *H records componentwise* hsame *transport for source metric, target completion, window, regular readback, dyadic tolerance, modulus-preserving map, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, T, M \longmapsto W, R, D \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* MetricCompletionMorphism$^{\uparrow}$, Met$^{\uparrow}$, CompleteMetric$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, CauchyFilterLimit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionMorphism}^{\uparrow}}$ *row.*

Accepted carriers are compared only through these rows. There is no carrier coordinate for quotient completions, chosen representatives, host maps, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MetricCompletionMorphismUp.MetricCompletionMorphismTasteGate single carrier alignment`

Theorem 6255.2 (Metric completion morphism NameCert obligations)**.** *For every accepted* MetricCompletionMorp *carrier $G = (S, T, W, R, D, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionMorphism}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the source metric row, target completion row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, modulus-preserving map row, transport, replay, provenance, and local naming rows;*
2. *source and target completion visibility, requiring S and T to be displayed before any completion-facing morphism read is exported;*
3. *Cauchy-window preservation, requiring W, R, D, M to show that finite source Cauchy windows are sent to target Cauchy windows at the recorded tolerance;*
4. *modulus-stability under classifier transport, requiring H and C to preserve the same modulus row rather than replacing it by a host continuity theorem;*
5. *ledger refusal of quotient completions, chosen representatives, host maps, countable choice, and ambient completeness.*

No metric-completion morphism obligation is stored outside these rows.

Proof. Project the carrier of Definition 6255.1. The source and target rows are S, T, the finite Cauchy-data rows are W, R, D, M, and the structural rows are H, C, P, N.

The visibility clause follows because a morphism read cannot reach M before both the source metric row and target completion row have been displayed. The Cauchy-window clause then reads W, R, D, M in order: finite windows, regular rational readback, dyadic tolerance, and the modulus-preserving map schedule.

Transport and replay preserve the same rows componentwise. Since the carrier has no field for quotient completions, selected representatives, host maps, countable-choice schedules, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.MetricCompletionMorphismUp.MetricCompletionMorphismCarrier namecert obligations`

Theorem 6255.3 (Metric completion morphism composition replay)**.** *Let $G = (S, T, W, R, D, M, H, C, P, N)$ and $G' = (T, U, W', R', D', M', H', C', P', N')$ be accepted* MetricCompletionMorphism$^{\uparrow}$ *carriers whose target row of G is the source row exposed to G' through componentwise* hsame*. Then their composition is replayed by concatenating the displayed finite routes through M and M':*

$$S, T, U \longmapsto W, R, D, M \longmapsto W', R', D', M' \longmapsto H, H', C, C', P, P', N, N'.$$

The replay preserves Cauchy windows and modulus budgets without adding quotient completion equality, chosen representatives, host maps, countable choice, or ambient completeness.

Proof. Start with the target-source agreement between the two carriers. Componentwise hsame identifies the completion row T exported by G with the row consumed by G', so the second morphism can read only the target completion data already displayed by the first route.

Apply the NameCert obligations of Definition 6255.2 to each carrier. The first route sends source Cauchy windows through W, R, D, M, and the second route sends the resulting target windows through W', R', D', M'.

Concatenate the replay rows C, C' and transport rows H, H'. Provenance and local naming preserve the same finite route, so the composite read has no opportunity to introduce a quotient completion, a chosen representative, a host map, a countable-choice schedule, or an ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{MetricCompletionMorphism}^{\uparrow}$ consumer that asks for a completion morphism must display the source metric row, target completion row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, modulus-preserving map row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before receiving any completion-facing output.

Independence witness: metric, completemetric, completionfunctor, cauchyfilterlimit: no listed sibling is bijective to $\mathsf{MetricCompletionMorphism}^{\uparrow}$ because the morphism packet jointly carries source metric data, target completion data, finite Cauchy windows, regular readbacks, dyadic tolerances, a modulus-preserving map row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionMorphism}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionMorphism}^{\uparrow}$ packet is generated from source MetricSpace data, target CompleteMetric and CompletionFunctor rows, CauchyFilterLimit-facing windows, StreamName observations, RegSeqRat readback, DyadicRatCore tolerance ledgers, a modulus-preserving map row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionMorphism}^{\uparrow}}$, seed)

Scope closed: Definition 6255.1, Definition 6255.2, and Definition 6255.3 seed the finite morphism route preserving metric-completion Cauchy data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionMorphism}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion equality, chosen representatives, host maps, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, source and target visibility, Cauchy-window preservation, modulus-stability under classifier transport, composition replay, ledger refusal, provenance, and local naming for BEDC.Derived.MetricCompletionMorphismUp.

Chapter 6256

A Concrete Naming Certificate for $\mathsf{LocatedIntervalUniformCauchy}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedIntervalUniformCauchy}^{\uparrow}$ packet records the finite uniform-Cauchy surface for located compact intervals. It reads located endpoints through **??** and chapter 394, interval containment through chapter 3986, finite observations through chapter 126, rational readback through chapter 301, dyadic tolerance through chapter 291, and terminal sealing through chapter 38. The packet names a compact-interval uniform-Cauchy route as finite certificate data; it is not a Heine–Borel theorem, an open-cover compactness theorem, a quotient completion, a selected limit, or a choice principle.

Definition 6256.1 (Located interval uniform Cauchy carrier)**.** *A* $\mathsf{LocatedIntervalUniformCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L, I, K, W, R, D, M, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row, carrying the lower and upper located real names used by the interval request.*
2. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row, exposing located containment and interval-membership data for the same endpoints.*
3. *K is the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *row, read only as a finite compact-interval certificate surface for this displayed interval.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the interval indices requested by L, I, K.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic mesh, refinement, and comparison budget used by uniform-Cauchy reads.*
7. *M is the uniform-Cauchy modulus row, requiring one dyadic tolerance budget to control all displayed interval windows accepted by W and R.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located endpoint, located interval, compact-interval, window, readback, tolerance, and uniform-Cauchy modulus rows have been displayed.*
9. *H records componentwise* hsame *transport for L, I, K, W, R, D, M, S.*

10. *C records displayed* Cont *replay through the finite route*

$$L, I, K \longmapsto W, R, D, M \longmapsto S, H, P, N.$$

11. *P is the* Pkg *provenance over* LocatedIntervalUniformCauchy$^{\uparrow}$, LocatedReal$^{\uparrow}$, LocatedInterval$^{\uparrow}$, BishopCompactInterval$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{LocatedIntervalUniformCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $L, I, K, W, R, D, M, S, H, C, P, N$. It has no coordinate for general Heine–Borel compactness, open-cover compactness, quotient completion equality, selected limits, countable choice, or host real equality.

Lean4 ✓ `BEDC.Derived.LocatedIntervalUniformCauchyUp.LocatedIntervalUniformCauchyTasteGate single carrier alignment`

Theorem 6256.2 (Located interval uniform Cauchy NameCert obligations)**.** *For every accepted* LocatedIntervalUniformCauchy$^{\uparrow}$ *carrier $U = (L, I, K, W, R, D, M, S, H, C, P, N)$, the local* NameCert$_{\text{LocatedIntervalUnifor}}$ *surface consists exactly of located-real endpoint admission, located-interval containment admission, compact-interval certificate admission, finite StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance exactness, uniform-Cauchy modulus admission, Real seal admission, componentwise transport, displayed replay, provenance, and local naming for the same displayed rows.*

Proof. Project the carrier of Definition 6256.1. The projection exposes the endpoint row, located interval row, compact-interval row, finite windows, rational readback, dyadic tolerance, uniform-Cauchy modulus, seal, and structural rows.

The endpoint and interval obligations are upstream of every uniform-Cauchy read. A consumer must first display L, I, K before it can ask for the finite windows W or the readback row R.

The dyadic tolerance row D and modulus row M then bind all accepted interval windows to one uniform request. The terminal seal S is downstream of those rows, while H, C, P, N transport, replay, source, and name the same packet.

Since the carrier has no coordinate for general compactness, quotient equality, selected limits, choice, or host real equality, the listed rows exhaust the local NameCert surface. □

Theorem 6256.3 (Located interval uniform Cauchy finite-net handoff)**.** *Every finite-net consumer of an accepted* LocatedIntervalUniformCauchy$^{\uparrow}$ *carrier factors through*

$$L, I, K \longmapsto W, R, D, M.$$

The compact-interval row K may hand off only the displayed located interval to the finite windows W, regular readback R, dyadic tolerance D, and uniform-Cauchy modulus M; it does not export an open-cover compactness theorem, a general Heine–Borel theorem, or a choice-selected net.

Proof. Start from the displayed carrier. The finite-net request has no source other than the located endpoint, located interval, and compact-interval rows L, I, K.

The window and readback rows are then read at the tolerances shown by D. The modulus row M records that the same dyadic budget controls the displayed interval windows, so the finite-net handoff is a local route through W, R, D, M.

The structural rows preserve the same route. Because no row stores an open cover, a selected finite subcover, or a hidden choice schedule, the handoff is exactly the displayed finite-net route. □

Theorem 6256.4 (Located interval uniform Cauchy Real seal)**.** *For every accepted* $\mathsf{LocatedIntervalUniformCauchy}^{\uparrow}$ *carrier* $U = (L, I, K, W, R, D, M, S, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S *can be consumed only after the located endpoint, located interval, compact-interval, finite-window, regular-readback, dyadic-tolerance, and uniform-Cauchy modulus rows have been displayed. The seal is therefore a local real-name endpoint for the packet, not a quotient completion, selected limit, ambient completeness theorem, or host real representative.*

Proof. Read the carrier projection. The seal row S appears after L, I, K, W, R, D, M, and the carrier lists no second real-facing coordinate.

Apply the NameCert obligation surface of Definition 6256.2. It forces window exposure, regular readback, dyadic tolerance exactness, and uniform-Cauchy modulus admission before the seal is public.

Finally use the non-escape content of the carrier: H, C, P, N only transport, replay, source, and name the same finite packet. Thus a consumer may read S only as the displayed terminal $\mathsf{Real}^{\uparrow}$ seal, not as any excluded completion, compactness, or choice object. □

Theorem 6256.5 (Located interval uniform Cauchy tail stability)**.** *For every accepted* $\mathsf{LocatedIntervalUniformCauch}$ *carrier* $U = (L, I, K, W, R, D, M, S, H, C, P, N)$*, replacing the displayed finite-net window* W *by a later cofinal tail window preserves the visible route through the located endpoint row* L*, located interval row* I*, compact interval row* K*, uniform-Cauchy modulus row* M*, StreamName windows, RegSeqRat readback* R*, terminal Real seal* S*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming* N*. The tail read does not introduce countable choice, a selected limit, open-cover compactness, or ambient Real completeness.*

Proof. Project the carrier of Definition 6256.1. The finite-net window, readback, tolerance, modulus, seal, and structural rows are all displayed as coordinates of the same packet.

Apply Definition 6256.3. The finite-net consumer reads only the route $L, I, K \longmapsto W, R, D, M$, so a later cofinal tail window can replace W only inside that displayed route and not by adding an external selector.

Next use Definition 6256.4. The terminal seal S is downstream of the located endpoint, located interval, compact-interval, finite-window, readback, tolerance, and modulus rows, so the tail read reaches the same Real-facing endpoint only after those rows remain visible.

The rows H, C, P, N then transport, replay, source, and name the same cofinal-tail route. Since the carrier contains no coordinate for countable choice, selected limits, open-cover compactness, or ambient Real completeness, the tail substitution preserves the visible certificate surface without importing any excluded principle. □

Falsifiable prediction: Every $\mathsf{LocatedIntervalUniformCauchy}^{\uparrow}$ read factors through located real endpoints, a located interval row, a compact interval row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a uniform-Cauchy modulus, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: Nearest siblings: locatedreal, locatedinterval, compactinterval, streamname, regseqrat, dyadicratcore, and real. $\mathsf{LocatedIntervalUniformCauchy}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located endpoints, interval containment, compact-interval admission, finite windows, rational readback, dyadic tolerance, uniform-Cauchy control, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalUniformCauchy}^{\uparrow}}$.

Constructive story: A LocatedIntervalUniformCauchy$^{\uparrow}$ packet is generated from LocatedReal endpoint rows, a LocatedInterval containment row, a CompactInterval certificate row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a uniform-Cauchy modulus row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedIntervalUniformCauchy}^{\uparrow}}$, seed)

Scope closed: Definition 6256.1, Definition 6256.2, Definition 6256.3, and Definition 6256.4 seed the finite compact-interval uniform-Cauchy route over located endpoints, interval containment, compact-interval admission, finite windows, readback, tolerance, modulus, seal, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{LocatedIntervalUniformCauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general Heine–Borel compactness, open-cover compactness, quotient completion, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located endpoint exactness, interval containment exactness, compact-interval admission, finite-window replay, RegSeqRat readback, dyadic tolerance exactness, uniform-Cauchy modulus exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalUniformCauchyUp.

Chapter 6257

A Concrete Naming Certificate for $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$ packet records the finite search basis through which a compact real interval exposes located endpoint refinements, dyadic tolerances, finite stream windows, regular rational readback, and a terminal real-name seal. It sits after the compact real interval surface of chapter 5553, the located refinement route of chapter 6199, the interval-completion route of chapter 6253, the dyadic tolerance core of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite interval-search data; it does not assert Heine–Borel compactness, selected subcovers, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6257.1 (Compact real interval search basis carrier)**.** *A* $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, L, F, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact real interval source row, read through* $\mathsf{CompactRealInterval}^{\uparrow}$ *with its displayed lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint seals.*
2. *L is the located endpoint refinement row, using the located interval refinement surface to expose endpoint brackets and radius data at requested precisions.*
3. *F is the finite search and cover-basis row. It lists the displayed interval cells, membership tests, cover probes, and retained cells available to a finite search consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the mesh budget, endpoint-read budget, and refinement depth used by L and F.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the endpoint and tolerance requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows and dyadic tolerance data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after the compact source, located refinement, finite search basis, dyadic tolerance, StreamName window, and RegSeqRat readback rows have been displayed.*
8. *H records componentwise* hsame *transport for K, L, F, D, W, R, E.*

9. *C records displayed* Cont *replay for search requests through the route*

$$K, L, F, D \longmapsto W, R \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$, $\mathsf{CompactRealInterval}^{\uparrow}$, LocatedIntervalRefinement $\mathsf{LocatedIntervalCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, L, F, D, W, R, E, H, C, P, N$. It has no coordinate for an open-cover theorem, a selected finite subcover, countable choice, quotient real equality, host endpoint equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompactRealIntervalSearchBasisUp.CompactRealIntervalSearchBasisTasteGate`
`single carrier alignment`

Theorem 6257.2 (Compact real interval search basis obligations)**.** *For every accepted* CompactRealIntervalSearchB *carrier $S = (K, L, F, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}}$ *surface is exhausted by the following finite obligations:*

1. *compact source admission for the* $\mathsf{CompactRealInterval}^{\uparrow}$ *row K and its displayed endpoint seals;*
2. *located refinement admission for the endpoint brackets and radius data in L;*
3. *finite search-basis admission for the cell list, probe list, and retained-cell ledger in F;*
4. *dyadic tolerance exactness for the mesh, endpoint-read, and refinement-depth budgets in D;*
5. *StreamName window exposure through W at the endpoint and tolerance requests named by K, L, D;*
6. *RegSeqRat readback through R, attached to the displayed windows rather than to quotient streams;*
7. *Real seal routing through E, downstream of K, L, F, D, W, R;*
8. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No obligation exports open-cover compactness, selected subcovers, countable choice, host endpoint equality, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6257.1. The projection exposes exactly the compact source, located refinement, finite search basis, dyadic tolerance, finite window, regular readback, real seal, transport, replay, provenance, and local naming rows.

The compact source and located refinement obligations are upstream of every search read. A consumer cannot inspect a retained search cell until K, L and the dyadic budget D determine the displayed interval bracket and precision request.

The finite search row then supplies the only cover-basis data available to the packet. StreamName and RegSeqRat rows read that data through finite windows and regular rational readback, while the Real seal is terminal only for this displayed route.

The support rows H, C, P, N transport, replay, source, and name the same packet. Since no row stores an open-cover theorem, selected subcover, choice schedule, quotient equality, host endpoint equality, or ambient completeness theorem, the listed obligations exhaust the local NameCert surface. □

Theorem 6257.3 (Compact real interval search finite cover route)**.** *Every finite-search consumer reading an accepted* $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$ *carrier factors through the ordered route*

$$K, L, F, D, W, R, E, H, C, P, N.$$

The consumer first displays the compact interval source and located endpoint refinement, then reads the finite search and cover-basis row against a dyadic tolerance budget, then opens StreamName windows, performs RegSeqRat readback, and only then reaches the $\mathsf{Real}^{\uparrow}$ *seal. The route exports finite cover-basis data, not an unrestricted open-cover compactness theorem or a choice-selected subcover.*

Proof. Begin with the source and refinement rows K, L. These rows expose the compact real interval and the located endpoint brackets used by the search basis.

Read the finite search row F together with the tolerance row D. The listed cells, probes, retained-cell ledger, mesh budget, endpoint-read budget, and refinement-depth budget are all finite rows of the same packet.

Next open the StreamName window W and read it through the RegSeqRat row R. The consumer reaches the Real seal E only after those finite observations have been displayed.

Finally transport and replay through H, C, P, N. These rows preserve the same route and do not add open-cover compactness, selected subcovers, countable choice, host equality, quotient equality, or ambient completeness. Thus every finite-search read factors through the stated route. □

Theorem 6257.4 (Compact real interval search Real seal nonescape)**.** *No accepted* CompactRealIntervalSearchBasis *carrier exposes a* $\mathsf{Real}^{\uparrow}$ *seal read that bypasses its located endpoint refinement, finite search basis, dyadic tolerance row, StreamName finite window, or RegSeqRat readback.*

Equivalently, every $\mathsf{Real}^{\uparrow}$*-facing observation of the packet is downstream of* K, L, F, D, W, R *and carries the displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}}$ *row.*

Proof. The seal coordinate in Definition 6257.1 is E. Its inputs are the compact source, located refinement, finite search basis, dyadic tolerance, finite window, and regular readback rows.

If a consumer asks for a Real-facing observation, Definition 6257.3 forces that observation through K, L, F, D, W, R before E is available.

The remaining rows H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for an alternate seal, hidden endpoint representative, selected subcover, choice schedule, or ambient completeness theorem, a bypass route is outside the accepted packet. □

Theorem 6257.5 (Compact real interval search basis NameCert surface)**.** *The public* CompactRealIntervalSearchBa *surface consists exactly of the carrier in Definition 6257.1, the obligation list in Definition 6257.2, the finite cover route in Definition 6257.3, and the Real seal nonescape boundary in Definition 6257.4.*

It is therefore a finite NameCert surface for compact real interval search data, not a proof of open-cover compactness, selected subcovers, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The carrier determines the coordinates available to the packet. The obligation theorem names the local NameCert checks for those coordinates and excludes additional compactness or choice data.

The finite cover route then fixes the consumer order from compact source and located refinement through search basis, tolerance, finite windows, readback, seal, transport, replay, provenance, and local naming.

The nonescape theorem closes the Real-facing boundary by ruling out any seal read that bypasses the displayed finite route. Combining these three surfaces gives exactly the advertised public NameCert surface. □

Falsifiable prediction: Every $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$ finite-search read factors through one compact real interval source row, one located endpoint refinement row, one finite search-basis row, one DyadicRatCore tolerance row, one StreamName window row, one RegSeqRat readback row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: Nearest siblings: compact-real-interval, located-interval-refinement, located-interval-completion, dyadicratcore, streamname, regseqrat, and real. $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact interval source data, located endpoint refinement, finite search and cover-basis rows, dyadic tolerance budgets, finite stream windows, regular rational readback, a real seal, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}$ packet is generated from compact real interval source rows, located endpoint refinement rows, finite search and cover-basis rows, DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6257.1, Definition 6257.2, Definition 6257.3, Definition 6257.4, and Definition 6257.5 seed the finite compact real interval search-basis route over source, refinement, cover basis, tolerance, window, readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalSearchBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, bridge checking, host endpoint equality, or quotient real equality.

Upgrade path: Obligation closure requires checked carrier admission, located refinement exactness, finite search-basis admission, dyadic tolerance exactness, StreamName window replay, RegSeqRat readback, Real seal nonescape, classifier transport, and local naming for BEDC.Derived.CompactRealIntervalSearchBasisUp.

Chapter 6258

A Concrete Naming Certificate for $\mathsf{CountablyBasedUniformity}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{CountablyBasedUniformity}^{\uparrow}$ packet records the standard countable-base interface for a uniform space as finite BEDC naming data. It sits after the entourage discipline of chapter 339, the Cauchy-filter consumer of chapter 333, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the Real seal of chapter 38. The packet gives completion consumers a countable basis route, not an arbitrary open-cover uniformity, quotient equality, countable-choice selector, or ambient completeness principle.

Definition 6258.1 (CountablyBasedUniformity carrier)**.** *A* $\mathsf{CountablyBasedUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (E, F, S, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row whose requests are read only through the displayed countable basis.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer row that receives Cauchy data from the basis rather than from an arbitrary open-cover surface.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row indexing the displayed countable basis requests.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling finite refinements between basis elements.*
6. *R is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row available only after E, F, S, Q, D have been replayed.*
7. *H records componentwise* hsame *transport for the uniform, filter, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$E, F \longmapsto S, Q, D \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{CountablyBasedUniformity}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CountablyBasedUniformity}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $E, F, S, Q, D, R, H, C, P, N$. It has no coordinate for arbitrary open-cover uniformity, quotient equality of uniform spaces, countable choice, selected Cauchy-filter limits, host Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CountablyBasedUniformityUp.CountablyBasedUniformityTasteGate single carrier alignment`

Theorem 6258.2 (CountablyBasedUniformity NameCert obligations)**.** *For every accepted* $\mathsf{CountablyBasedUniform}$ *carrier*

$$U = (E, F, S, Q, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CountablyBasedUniformity}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, countable basis coverage for the* $\mathsf{UniformSpace}^{\uparrow}$ *requests, finite refinement stability through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff through the generated basis, completion-consumer compatibility through the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route, and ledger nonescape from arbitrary open-cover uniformity, quotient equality, countable choice, selected limits, host Real equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 6258.1. The projection exposes exactly the uniform entourage row, Cauchy-filter consumer, stream-window basis index, regular rational readback, dyadic tolerance ledger, Real seal, and structural rows.

The countable-basis part is read through E, S, Q, D. The row S displays the finite windows for the basis, Q supplies the regular rational readback, and D records the finite refinement relation between basis elements before any completion-facing consumer can inspect the seal.

The filter and completion handoff then uses F and R. A Cauchy-filter request must pass through the generated basis before reaching the downstream Real seal, so the consumer receives a basis-indexed route rather than arbitrary open-cover data.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since none of the excluded principles occurs as a carrier coordinate, no NameCert obligation can export quotient equality, countable choice, selected limits, host equality, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CountablyBasedUniformity}^{\uparrow}$ completion consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row refutes the packet surface.

Independence witness: uniformspace, cauchyfilter, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{CountablyBasedUniformity}^{\uparrow}$ because this packet binds countable basis coverage, finite refinement stability, Cauchy-filter handoff, completion-consumer compatibility, transport, replay, provenance, and local naming as one L10 route.

Closure status for $\mathsf{NameCert}_{\mathsf{CountablyBasedUniformity}^{\uparrow}}$.

Constructive story: A $\mathsf{CountablyBasedUniformity}^{\uparrow}$ packet is generated from a UniformSpace entourage row, CauchyFilter consumer row, StreamName finite-window basis row, RegSeqRat readback row, DyadicRatCore finite-refinement ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountablyBasedUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6258.1 and Definition 6258.2 seed the countable-basis uniformity interface for Cauchy-filter and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountablyBasedUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover uniformity, quotient equality, selected limits, countable choice, host Real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, countable basis coverage, finite refinement stability, Cauchy-filter handoff, completion-consumer compatibility, transport, replay, provenance, local naming, and ledger nonescape for BEDC.Derived.CountablyBasedUniformityUp.

Chapter 6259

A Concrete Naming Certificate for $\mathsf{GaloisConnection}^{\uparrow}$

Following Birkhoff and Ore on Galois connections, the $\mathsf{GaloisConnection}^{\uparrow}$ packet records an order-theoretic adjunction between two displayed ordered carriers as finite NameCert data. It sits over the preorder substrate of chapter 52, the antisymmetric carrier discipline of chapter 53, the lattice consumers of chapter 55, and the order comparison surface of chapter 1378. The packet names monotone maps and the adjunction equivalence only through displayed rows; it does not import quotient posets, powerset closure, host implication, or choice-selected fixed points.

Definition 6259.1 (Galois connection carrier)**.** *A* $\mathsf{GaloisConnection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (P, Q, F, G, M, A, T, R, L, N)$$

with the following rows:

1. *P is the source preorder or poset carrier, read through the* $\mathsf{Preorder}^{\uparrow}$ *and* $\mathsf{Poset}^{\uparrow}$ *sibling surfaces.*
2. *Q is the target preorder or poset carrier, read through the same ordered-carrier discipline.*
3. *F is the displayed monotone map row from P to Q.*
4. *G is the displayed monotone map row from Q to P.*
5. *M records the two monotonicity ledgers: $x \leq_P x'$ implies $F(x) \leq_Q F(x')$, and $y \leq_Q y'$ implies $G(y) \leq_P G(y')$.*
6. *A records the adjunction inequality equivalence, namely that each displayed pair of histories satisfies $F(x) \leq_Q y$ exactly when $x \leq_P G(y)$ through the carried order rows.*
7. *T records componentwise* hsame *transport for $P, Q, F, G, M, A, R, L, N$.*
8. *R records displayed* Cont *replay for source-order reads, target-order reads, monotonicity reads, adjunction reads, and downstream closure or kernel consumers.*
9. *L is the* Pkg *provenance over* $\mathsf{GaloisConnection}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GaloisConnection}^{\uparrow}}$ *row.*

The classifier compares packets only by the displayed ordered carriers, the two map rows, the monotonicity ledger, the adjunction equivalence, structural transport, replay, provenance, and local

naming. It has no coordinate for an external order completion, quotient carrier, powerset universe, selected fixed point, or host-level implication principle.

Lean4 ✓ `BEDC.Derived.GaloisConnectionUp.GaloisConnectionTasteGate single carrier alignment`

Theorem 6259.2 (Galois connection NameCert obligations)**.** *For every accepted* $\mathsf{GaloisConnection}^{\uparrow}$ *carrier* $K = (P, Q, F, G, M, A, T, R, L, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GaloisConnection}^{\uparrow}}$ *surface consists exactly of carrier admission for the ordered source and target rows, monotone-map exposure for* F *and* G*, monotonicity ledger exposure through* M*, adjunction-equivalence exposure through* A*, componentwise transport through* T*, displayed replay through* R*, provenance through* L*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.GaloisConnectionUp.GaloisConnectionCarrier namecert obligations`

Proof. Project the carrier of Definition 6259.1. The rows P, Q supply the ordered carriers, while F, G supply only displayed map rows between those carriers.

The monotonicity ledger M is required before either map can be read as order preserving. The adjunction row A is required before a consumer may translate an inequality $F(x) \leq_Q y$ into $x \leq_P G(y)$ or conversely.

Transport, replay, provenance, and local naming preserve the same finite packet. Since the carrier has no quotient order, powerset universe, choice-selected fixed point, or host implication coordinate, the NameCert obligations are exactly the listed rows. □

Theorem 6259.3 (Galois connection closure operator)**.** *Let* $K = (P, Q, F, G, M, A, T, R, L, N)$ *be an accepted* $\mathsf{GaloisConnection}^{\uparrow}$ *carrier. Any closure-operator consumer on* P *may read the composite* $G \circ F$ *only through the displayed route*

$$P \longrightarrow F \longrightarrow Q \longrightarrow G \longrightarrow P$$

together with the monotonicity ledger M *and adjunction ledger* A*. The packet supplies the inflationary and monotone closure-facing boundary for that composite; it does not supply arbitrary suprema, a Moore-family representation, quotient fixed points, compactness, or a host powerset closure theorem.*

Proof. Start with the source row P and the map rows F, G. The composite $G \circ F$ is readable only by first applying the displayed F row and then the displayed G row.

Use the two monotonicity entries in M for the monotone part of the closure-facing boundary. A consumer cannot obtain monotonicity from the maps alone, because the maps are accepted as order maps only through M.

Use the adjunction row A for the inflationary direction. The equivalence specializes the inequality comparison so that the unit-style order read $x \leq_P G(F(x))$ is obtained from the displayed source and target order rows, not from host implication.

The structural rows T, R, L, N preserve this composite route. They do not add suprema, Moore-family data, quotient fixed points, compactness, or powerset closure, so the closure-operator consumer receives only the displayed finite boundary. □

Theorem 6259.4 (Galois connection kernel stability)**.** *For an accepted* $\mathsf{GaloisConnection}^{\uparrow}$ *carrier* $K = (P, Q, F, G, M, A, T, R, L, N)$*, any kernel or fixed-row consumer of the composite* $F \circ G$ *on* Q *must pass through the same two-map route, monotonicity ledger, and adjunction-equivalence ledger. The packet preserves the kernel-facing stability of the composite under* hsame *transport, but it does not identify the kernel with a chosen fixed-point set, a quotient lattice, or an interior operator unless a separate finite carrier supplies those rows.*

Proof. Read the target side first. A kernel-facing consumer begins with Q, then reaches the composite $F \circ G$ only through G followed by F.

The monotonicity ledger M transports order comparisons along both maps, and the adjunction ledger A records the inequality equivalence that controls the composite. These rows are part of the carrier and remain visible to the consumer.

Now apply componentwise transport through T and replay through R. If the ordered carriers, map rows, monotonicity rows, and adjunction rows are transported by hsame, the same finite kernel-facing boundary is replayed through L and named by N.

No coordinate of K contains a chosen fixed-point set, quotient lattice, or interior-operator carrier. Those structures can consume the Galois-connection packet, but they must bring their own finite carrier rows before they can be named. □

Falsifiable prediction: Deleting the adjunction row A leaves two monotone maps but no route that translates inequalities between P and Q.

Independence witness: preorder, poset, lattice, order: none is bijective to $\mathsf{GaloisConnection}^{\uparrow}$. The preorder and poset siblings supply ordered carriers without paired adjoint maps; the lattice sibling supplies meet/join consumers without the two-map adjunction row; the order sibling supplies comparison rows without the provenance, transport, replay, and local NameCert packet for $P, Q, F, G, M, A, T, R, L, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{GaloisConnection}^{\uparrow}}$.

Constructive story: A $\mathsf{GaloisConnection}^{\uparrow}$ packet is generated from two displayed ordered carrier rows, two monotone map rows, a monotonicity ledger, an adjunction-equivalence ledger, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaloisConnection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6259.1, Definition 6259.2, Definition 6259.3, and Definition 6259.4 seed the finite order-adjunction surface over displayed ordered carriers, monotone maps, adjunction equivalence, closure-facing consumers, kernel-facing consumers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaloisConnection}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.GaloisConnectionUp`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient order completion, arbitrary suprema, Moore-family representation, chosen fixed points, compactness, host powerset closure, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, monotonicity ledgers, adjunction-equivalence transport, closure-operator boundary, kernel-stability boundary, replay, provenance, and local naming for BEDC.Derived.GaloisConnectionUp.

Chapter 6260

A Concrete Naming Certificate for $\mathsf{StoneWeierstrassLattice}^{\uparrow}$

Following Stone and Weierstrass, the $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ packet records the finite lattice-subalgebra route by which compact real-valued approximation can be read without selecting external dense families or importing an ambient function-space completion. It sits beside the separating-algebra certificate of chapter 1919, the compact metric source of chapter 129, the continuous-name surface of chapter 59, the uniform-modulus handoff of chapter 369, and the real-name boundary of chapter 38. The chapter names only displayed compact metric rows, continuous real-valued rows, lattice operations, separation evidence, finite approximation budgets, transport, replay, provenance, and a local certificate.

Definition 6260.1 (Stone–Weierstrass lattice carrier)**.** *A* $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, F, A, S, B, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, including the named metric windows and finite compactness witnesses consumed by the approximation route.*
2. *F is the continuous real-valued function row, reading each inspected target through the continuous chapter interface and the same* $\mathsf{Real}^{\uparrow}$ *windows used by the rest of the packet.*
3. *A is the lattice subalgebra row. It displays constants, pointwise addition, pointwise multiplication, scalar multiplication, pointwise maximum, pointwise minimum, and the finite replay order by which these operations stay inside the named family.*
4. *S is the separating-family evidence. For each displayed pair of apart compact metric names it records a member of A and the finite real-window comparison that separates the pair.*
5. *B is the finite approximation budget. It records the rational tolerance, the compact metric finite-net or finite-cover row used for that tolerance, and the finite list of lattice-subalgebra expressions inspected before the consumer accepts an approximation.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal. Every value comparison, tolerance comparison, lattice operation output, and approximation error read passes through this row before it is exposed.*
7. *H records componentwise* hsame *transport for compact metric source, continuous target, lattice operations, separating-family evidence, finite budget, real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a compact real-valued approximation request through K, F, A, S, B, R, H and only then to provenance and naming.*
9. *P is the* Pkg *provenance tying the packet to* $\mathsf{StoneWeierstrassLattice}^{\uparrow}$, $\mathsf{StoneWeierstrass}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StoneWeierstrassLattice}^{\uparrow}}$ *row.*

Accepted carriers are compared only through these rows. There is no coordinate for classical choice, arbitrary function equality, measure completion, a selected dense sequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.StoneWeierstrassLatticeUp.StoneWeierstrassLatticeTasteGate single carrier alignment`

Theorem 6260.2 (Stone–Weierstrass lattice NameCert obligations)**.** *For every accepted* $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ *carrier*

$$L = (K, F, A, S, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StoneWeierstrassLattice}^{\uparrow}}$ *surface consists exactly of compact metric source admission, continuous real-valued target admission, lattice subalgebra operation visibility, separating-family evidence, finite approximation budget admission,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the rows of Definition 6260.1. The compact metric source is stored in K, while the inspected real-valued continuous target is stored in F.

The algebraic and lattice closure obligations are exactly the row A. The separating-family obligations are exactly the row S, and every accepted approximation request must pass through the finite budget row B.

The real-name boundary is fixed by R. Transport, replay, provenance, and naming are then supplied by H, C, P, N. Since the carrier has no other coordinates, the listed obligations exhaust the local certificate surface. □

Lean4 ✓ `BEDC.Derived.StoneWeierstrassLatticeUp.StoneWeierstrassLatticeNameCertObligations`

Theorem 6260.3 (Stone–Weierstrass lattice uniform approximation route)**.** *Every approximation-facing consumer of an accepted* $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ *carrier factors through the finite route*

$$K, F \longmapsto A, S \longmapsto B, R \longmapsto H, C, P, N.$$

Thus the consumer receives a compact metric source, a continuous real-valued target, displayed lattice-subalgebra operations, separating-family evidence, a finite approximation budget, a $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming; it receives no selected subsequence, open-ended function equality test, measure completion, or ambient completeness principle.*

Proof. Begin with an approximation-facing read of the accepted carrier. The request first reaches K and F, so the source and target are the displayed compact metric and continuous real-valued rows.

The request then reads lattice operations from A and separation data from S. These rows supply only finite expressions and finite real-window comparisons.

The finite budget row B selects the displayed tolerance and compact witness used by the consumer, while R seals every comparison through $\mathsf{Real}^{\uparrow}$. The structural rows H, C, P, N preserve the same route, so the excluded principles cannot be recovered from the packet. □

Theorem 6260.4 (Stone–Weierstrass lattice real-seal nonescape)**.** *In an accepted* $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ *carrier, every value read, lattice-operation output, separating comparison, tolerance comparison, and approximation-error claim reaches downstream consumers through the displayed* $\mathsf{Real}^{\uparrow}$ *seal row* R*. Consequently no downstream consumer can use the packet to claim classical choice, arbitrary function equality, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier route. Value reads and operation outputs are produced by F and A, but they are not exported until R records the corresponding real-name windows.

Separating comparisons and approximation-error claims are produced by S and B. Those rows also feed their real comparisons through R before replay reaches the public naming rows.

The remaining rows H, C, P, N transport and name only the already sealed route. Since no excluded principle is a coordinate of L, and no replay edge bypasses R, the real-seal boundary is nonescaping. □

Falsifiable prediction: Every accepted $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ approximation-facing read factors through compact metric rows, continuous real-valued target rows, displayed lattice-subalgebra operations, separating-family evidence, a finite approximation budget, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: stone-weierstrass, compactmetric, continuous, uniformmodulus, real: $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries lattice-subalgebra closure, separating-family evidence, compact metric approximation budgets, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{StoneWeierstrassLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{StoneWeierstrassLattice}^{\uparrow}$ packet is generated from compact metric source rows, continuous real-valued target rows, displayed lattice-subalgebra operations, separating-family evidence, finite approximation budgets, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StoneWeierstrassLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6260.1, Definition 6260.2, Definition 6260.3, and Definition 6260.4 seed the compact real-valued lattice approximation route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StoneWeierstrassLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical choice, arbitrary function equality, measure completion, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lattice-operation visibility, separating-family exactness, finite-budget routing, real-seal nonescape, and uniform approximation route proofs for BEDC.Derived.StoneWeierstrassLatticeUp.

Chapter 6261

A Concrete Naming Certificate for $\mathsf{PringsheimConvergence}^{\uparrow}$

Pringsheim and Bishop–Bridges constructive analysis treat convergence over two indices as an explicit route through finite rectangles, cofinal tails, and displayed regular readback, not as an ambient appeal to a completed double limit. The $\mathsf{PringsheimConvergence}^{\uparrow}$ packet records this route for positive rectangle partial sums after the two-parameter surface of chapter 460, the iterated handoff of chapter 1686, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It is a finite NameCert reconstruction of the Pringsheim route; it does not claim host double-series convergence, quotient equality of arrays, selected sums, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6261.1 (Pringsheim convergence carrier)**.** *A* $\mathsf{PringsheimConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, S, T, M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CauchyDoubleSequence}^{\uparrow}$ *source row. It records the two-parameter array and the finite rectangle requests from which Pringsheim reads are admitted.*
2. *S is the positive rectangle partial-sum row. It lists the displayed positive rectangular sums, successor-edge additions, and finite positivity witnesses visible to the packet.*
3. *T is the diagonal and cofinal tail-budget row. It binds each tolerance request to a diagonal entry point and to cofinal rectangle enlargements beyond that entry point.*
4. *M is the* $\mathsf{MooreOsgood}^{\uparrow}$ *handoff row. It records the iterated-limit route available when a consumer asks to compare the Pringsheim rectangle read with an iterated regular read.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It stores the finite rectangle windows, index bounds, and inspection order used by X, S, T, M.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It reads the same rectangle partial sums and cofinal tail budgets as a regular rational sequence before any endpoint seal is exported.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores dyadic tolerances, slack radii, denominator bounds, rectangle-side budgets, and accumulated arithmetic error.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is visible only after the source, positive rectangle sums, cofinal tail budget, Moore-Osgood handoff, StreamName windows, RegSeqRat readback, and DyadicRatCore ledger have been displayed.*
9. *H stores componentwise* hsame *transport for the source, rectangle sums, tail budget, handoff, windows, readback, tolerance ledger, real seal, continuation, provenance, and local naming row.*
10. *C stores displayed* Cont *replay from rectangle inspection to positive partial sums, from those sums to cofinal tail budgets, from the budgets to the Moore-Osgood and RegSeqRat handoffs, and from the handoffs to the real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{PringsheimConvergence}^{\uparrow}$, $\mathsf{CauchyDoubleSequence}^{\uparrow}$, $\mathsf{MooreOsgood}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PringsheimConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, T, M, W, R, D, E, H, C, P, N$. It has no coordinate for host double-series convergence, quotient equality of arrays, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Theorem 6261.2 (Pringsheim convergence NameCert obligations)**.** *For every accepted* $\mathsf{PringsheimConvergence}^{\uparrow}$ *carrier $K = (X, S, T, M, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PringsheimConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed CauchyDoubleSequence source, positive rectangle partial sums, diagonal and cofinal tail budget, Moore-Osgood handoff, StreamName windows, regular rational readback, dyadic tolerance ledger, real seal, transport, replay, provenance, and local naming row;*
2. *rectangle-window exactness, requiring every inspected two-index term and every positive rectangle partial sum to pass through X, S, W before a tail request is admitted;*
3. *cofinal-tail exactness, requiring T to display the diagonal entry point, rectangle enlargement rule, dyadic tolerance request, and cofinal threshold consumed by the Pringsheim route;*
4. *iterated-limit compatibility, requiring M to expose only the Moore-Osgood handoff already routed through the same windows and tail ledger;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring R to read the same positive rectangle sums and cofinal budgets before any* $\mathsf{Real}^{\uparrow}$ *seal is available;*
6. *real-seal nonescape, requiring E to remain downstream of X, S, T, M, W, R, D and to export no host double-series convergence, quotient array equality, selected infinite sum, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge datum;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No Pringsheim convergence obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.PringsheimConvergenceUp.TasteGate.PringsheimConvergenceTasteGate single carrier alignment`

Proof. Project the accepted packet $K = (X, S, T, M, W, R, D, E, H, C, P, N)$. The carrier definition exposes exactly the CauchyDoubleSequence source, positive rectangle partial sums, diagonal and cofinal tail budget, Moore-Osgood handoff, StreamName windows, regular readback, dyadic ledger, seal, and structural rows.

The rectangle data are read first. The source row X and window row W supply only displayed finite two-parameter windows, while S supplies only positive rectangle partial sums and their visible successor-edge additions.

The tail and handoff route then passes through T, M, R, D. The row T records the diagonal entry point and cofinal enlargement budget, M records the Moore-Osgood comparison surface, R performs the regular rational readback, and D stores the dyadic tolerances consumed by both handoffs.

Finally E, H, C, P, N seal, transport, replay, source, and name the same displayed route. Since no excluded analytic, quotient, choice, verification, or bridge object appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6261.3 (Pringsheim convergence iterated-limit route)**.** *Let $K = (X, S, T, M, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{PringsheimConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that compares the Pringsheim rectangle read with an iterated-limit read factors through*

$$X, S, W \longmapsto T, D \longmapsto M, R \longmapsto E, H, C, P, N.$$

Thus the comparison uses the displayed CauchyDoubleSequence source, positive rectangle partial sums, StreamName windows, diagonal and cofinal tail budgets, DyadicRatCore tolerance ledger, Moore-Osgood handoff, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local naming. It cannot be replaced by host double-series convergence, quotient equality of arrays, a selected infinite sum, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer comparing the Pringsheim rectangle read with an iterated-limit read. By Definition 6261.1, the only visible two-parameter source data are X and the finite windows W, and the only visible rectangle-sum data are the positive partial sums in S.

The comparison cannot reach an iterated route before the tail budget is displayed. The diagonal and cofinal row T names the finite entry point and allowed rectangle enlargements, while D accounts for the dyadic tolerances and accumulated arithmetic error.

The Moore-Osgood row M and regular readback row R then expose the comparison surface. Both rows read the same windows and budgets already displayed by X, S, T, W, D, so neither row can choose a separate array representative, limiting value, or external completeness principle.

The route reaches a real-facing consumer only through E and is preserved by H, C, P, N. Therefore every such comparison factors through the displayed packet route and has no coordinate for the excluded host, quotient, choice, or completeness data. □

Theorem 6261.4 (Pringsheim convergence real seal nonescape)**.** *In every accepted* $\mathsf{PringsheimConvergence}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *seal row E is downstream of the CauchyDoubleSequence source, positive rectangle partial sums, diagonal and cofinal tail budget, Moore-Osgood handoff, StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance ledger. Consequently a Real-facing consumer cannot obtain from the packet a host double-series convergence theorem, quotient equality of arrays, selected infinite sum, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Proof. Read the carrier order in Definition 6261.1. The seal row E is exposed only after X, S, T, M, W, R, D have supplied the source, positive rectangle sums, cofinal tail budget, iterated handoff, finite windows, regular readback, and dyadic tolerance data.

Apply Definition 6261.2. The real-seal nonescape clause binds E to that same displayed route, and the transport, replay, provenance, and local naming rows preserve the route without adding any new analytic coordinate.

Thus a Real-facing consumer receives only the sealed endpoint of the finite certificate. There is no row from which the consumer could read host double-series convergence, quotient array equality, a selected infinite sum, choice, ambient completeness, Lean verification, or bridge data. □

Falsifiable prediction: Every $\mathsf{PringsheimConvergence}^{\uparrow}$ Real-facing read factors through a CauchyDoubleSequence source, positive rectangle partial sums, StreamName windows, diagonal and cofinal tail budgets, a DyadicRatCore tolerance ledger, Moore-Osgood and RegSeqRat handoffs, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: cauchydoublesequence, moore-osgood, streamname, regseqrat, dyadicratcore, real: $\mathsf{PringsheimConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a two-parameter source, positive rectangle partial sums, cofinal tail budgets, iterated-limit handoff, regular readback, dyadic tolerance accounting, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PringsheimConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PringsheimConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6261.1, Definition 6261.2, Definition 6261.3, and Definition 6261.4 seed the finite constructive Pringsheim two-parameter convergence route from positive rectangle partial sums through cofinal tail budgets to RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PringsheimConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host double-series convergence, quotient equality of arrays, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rectangle-window exactness, cofinal-tail exactness, Moore-Osgood handoff compatibility, RegSeqRat readback, Real seal nonescape, and structural transport for BEDC.Derived.PringsheimConvergenceUp.

Constructive story: A $\mathsf{PringsheimConvergence}^{\uparrow}$ packet is generated from a CauchyDoubleSequence source, positive rectangle partial sums, a diagonal and cofinal tail-budget row, a Moore-Osgood handoff row, StreamName windows, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6262

A Concrete Naming Certificate for $\mathsf{OscillationRankFunction}^{\uparrow}$

Following Baire and Kechris, the $\mathsf{OscillationRankFunction}^{\uparrow}$ packet records the finite certificate surface by which a Baire-one name exposes a displayed oscillation-rank comparison at a named stage. It reads Baire-one value-window data from chapter 1604, local oscillation rows from chapter 3899, pointwise oscillation bounds from chapter 6136, pointwise-limit provenance from chapter 2314, and derivative-stage bookkeeping from chapter 2024. The packet names the finite rank-comparison ledger needed by downstream descriptive-analysis consumers; it is not a completed transfinite hierarchy and not a host quotient of function spaces.

Definition 6262.1 (Oscillation rank function carrier)**.** *An* $\mathsf{OscillationRankFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, O, B, L, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{BaireOneFunction}^{\uparrow}$ *source row, including the pointwise-limit ledger and value-window provenance of the named function.*
2. *O is the* $\mathsf{OscillationFunction}^{\uparrow}$ *row recording the local oscillation predicate whose threshold is being inspected.*
3. *B is the* $\mathsf{BairePointwiseOscillation}^{\uparrow}$ *bound row at the displayed source points and rational tolerance.*
4. *L is the* $\mathsf{PointwiseLimit}^{\uparrow}$ *lineage row that ties the approximant windows used by F and B to the same named source.*
5. *D is the finite* $\mathsf{CantorBendixson}^{\uparrow}$ *derivative-stage ledger used as the displayed rank stage, including the current derivative row and its predecessor window.*
6. *S is the rank-successor comparison row saying whether the named oscillation set survives to the displayed derivative stage.*
7. *Q is the rational threshold readback row for the oscillation bound and the displayed comparison tolerance.*
8. *H records componentwise* hsame *transport for the function source, oscillation predicate, pointwise bound, limit lineage, derivative stage, rank comparison, rational threshold, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Baire-one name and tolerance request through the oscillation windows, derivative-stage ledger, rank comparison, and downstream handoff surface.*
10. *P is the* Pkg *provenance over* $\mathsf{OscillationRankFunction}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{OscillationFunction}^{\uparrow}$, $\mathsf{BairePointwiseOscillation}^{\uparrow}$, $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{CantorBendixson}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{OscillationRankFunction}^{\uparrow}}$ *row.*

The carrier exports no completed transfinite hierarchy, no host function-space quotient, no arbitrary choice of ranks, and no ambient descriptive-set-theory theorem.

Lean4 (definition) `BEDC.Derived.OscillationRankFunctionUp.OscillationRankFunctionUp`

Theorem 6262.2 (Oscillation rank function NameCert obligations)**.** *For every accepted* $\mathsf{OscillationRankFunction}^{\uparrow}$ *carrier* $R = (F, O, B, L, D, S, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OscillationRankFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; Baire-one source compatibility for F; oscillation-threshold compatibility for O, B, Q; pointwise-limit lineage compatibility for L; finite derivative-stage admission for D; rank-successor comparison exactness for S; transport stability through H; continuation replay through C; provenance and local naming through P, N; and ledger refusal for completed transfinite hierarchies, host function-space quotients, arbitrary rank selectors, and ambient descriptive-set-theory theorems.*

Proof. Project the carrier of Definition 6262.1. The accepted packet exposes only the rows $F, O, B, L, D, S, Q, H, C$, so each local obligation must be read from those coordinates.

The source and oscillation obligations are the routes through F, O, B, Q. The Baire-one source fixes the value-window provenance, the oscillation row fixes the inspected predicate, the pointwise bound supplies the local comparison data, and the rational threshold readback fixes the displayed tolerance.

The rank-stage obligation is the route through L, D, S. The pointwise-limit lineage keeps the approximant windows attached to the same source, the Cantor–Bendixson row supplies only a displayed finite derivative stage, and the successor-comparison row records the survival test at that stage.

Transport and replay do not add coordinates. The rows H and C preserve and replay the same source, oscillation, lineage, stage, threshold, and comparison data, while P and N source and name the packet. Since no row stores a completed hierarchy, function-space quotient, arbitrary selector, or ambient theorem, the listed obligations exhaust the certificate. □

Theorem 6262.3 (Baire-one oscillation-rank handoff)**.** *Every Baire-one consumer row exported by an accepted* $\mathsf{OscillationRankFunction}^{\uparrow}$ *carrier factors through the displayed route*

$$F, O, B, L, D, S, Q \longmapsto H, C, P, N.$$

Thus a downstream consumer may read the named Baire-one function, the local oscillation predicate, the pointwise oscillation bound, the pointwise-limit lineage, the displayed Cantor–Bendixson derivative stage, and the finite rank comparison, but it receives no completed transfinite hierarchy, no host function-space quotient, no arbitrary choice of ranks, and no ambient descriptive-set-theory theorem.

Proof. Start with a consumer of the rank-comparison row. By carrier admission, the row S is available only after the Baire-one source F, oscillation row O, pointwise bound B, pointwise-limit lineage L, derivative-stage row D, and threshold readback Q have been displayed.

Replay the continuation row C. The request first opens the Baire-one value-window provenance, then reads the oscillation predicate and pointwise bound, then checks the finite derivative-stage ledger, and only then exposes the rank comparison.

The handoff is therefore a finite certificate route. Componentwise transport through H preserves the displayed coordinates, and P, N source and name only those coordinates. A downstream consumer cannot recover any excluded hierarchy, quotient, selector, or ambient theorem from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{OscillationRankFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OscillationRankFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6262.1, Definition 6262.2, and Definition 6262.3 seed the finite Baire-one oscillation-rank certificate from displayed oscillation windows and Cantor–Bendixson stage data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OscillationRankFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a completed transfinite hierarchy, host function-space quotient, arbitrary choice of ranks, ambient descriptive-set-theory theorems, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Baire-one source compatibility, oscillation-threshold compatibility, pointwise-limit lineage compatibility, derivative-stage admission, rank comparison exactness, transport, replay, provenance, and local naming for BEDC.Derived.OscillationRankFunctionUp.

Constructive story: An $\mathsf{OscillationRankFunction}^{\uparrow}$ packet is generated from BaireOneFunction, OscillationFunction, BairePointwiseOscillation, PointwiseLimit, CantorBendixson, RatUp, transport, continuation, provenance, and local NameCert rows.

Chapter 6263

A Concrete Naming Certificate for $\mathsf{CompactCoverNerve}^{\uparrow}$

Following Bishop–Bridges compactness and the finite nerve construction, the $\mathsf{CompactCoverNerve}^{\uparrow}$ packet records the finite cover-member and overlap ledger behind the compact-uniform-continuity proof route of chapter 9237. It reads compact metric finite-net data from chapter 129, continuous-map source rows from chapter 130, rational lower-bound folds from chapter 4096, finite-net minimum folds from chapter 619, and the downstream tolerance-only consumer from chapter 369. The packet names the finite nerve object and its rational-fold handoff; it does not assert open-cover compactness, an external Lebesgue number selector, or host quotient equality of metric points.

Definition 6263.1 (Compact cover nerve carrier)**.** *A* $\mathsf{CompactCoverNerve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (K, U, O, R, F, H, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the compact metric carrier, finite probe spine, and located coverage witnesses.*
2. *U is the* $\mathsf{ProbeBundle}$*-indexed cover-member ledger assigning each displayed probe to the compact source row and the local continuity radius it carries.*
3. *O is the overlap and nerve-incidence row recording which displayed cover members have certified nonempty overlap or certified adjacency in the finite nerve.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound readback row for the positive radius data attached to the cover members and overlap witnesses.*
5. *F is the* $\mathsf{FiniteNetMinimumFold}^{\uparrow}/\mathsf{UniformModulus}^{\uparrow}$ *handoff row, recording the finite fold that exports a tolerance-only uniform-radius ledger.*
6. *H records componentwise* hsame *transport for the compact source, cover-member ledger, overlap incidence, rational readback, fold handoff, provenance, and local naming rows.*
7. *P is the* Pkg *provenance over* $\mathsf{CompactCoverNerve}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{ProbeBundle}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCoverNerve}^{\uparrow}}$ *row.*

The carrier exports no external open-cover choice, no host nerve complex, no quotient equality of metric points, no arbitrary Lebesgue number, and no ambient compactness theorem beyond the displayed compact metric source row.

Theorem 6263.2 (Compact cover nerve NameCert obligations)**.** *For every accepted* $\mathsf{CompactCoverNerve}^{\uparrow}$ *carrier* $C = (K, U, O, R, F, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactCoverNerve}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; compact-source compatibility for* K, U*; finite cover-member admission for the* ProbeBundle *ledger* U*; overlap-incidence exactness for* O*; rational lower-bound readback for* R*; uniform-modulus handoff exactness for* F*; transport stability through* H*; provenance and local naming through* P, N*; and ledger refusal for external open-cover choice, host nerve complexes, quotient equality of points, arbitrary Lebesgue numbers, and ambient compactness theorems.*

Lean4 ✓ `BEDC.Derived.CompactCoverNerveUp.TasteGate.CompactCoverNerveTasteGate single carrier alignment`

Proof. Project the carrier of Definition 6263.1. The accepted packet exposes only K, U, O, R, F, H, P, N, so every local obligation must be read from these rows.

Compact-source compatibility and cover-member admission are the route through K and U. The compact metric row fixes the finite probe spine, and the cover-member ledger attaches each cover row to that same displayed source.

Overlap-incidence exactness is the route through O. The finite nerve records only displayed overlap or adjacency evidence among members of U, so it cannot introduce a host nerve complex detached from the packet.

The rational fold and uniform-modulus handoff are the route through R and F. The lower-bound readback consumes the displayed radius data, and the fold handoff exports only the tolerance-only radius row available to $\mathsf{UniformModulus}^{\uparrow}$ consumers.

Transport, provenance, and naming through H, P, N preserve the same coordinates. Since no row stores external cover choice, quotient point equality, arbitrary Lebesgue-number selection, or ambient compactness, the listed obligations exhaust the certificate. □

Theorem 6263.3 (Compact cover nerve uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row exported by an accepted* $\mathsf{CompactCoverNerve}^{\uparrow}$ *carrier factors through the displayed finite route*

$$K, U, O, R, F \longmapsto H, P, N.$$

The consumer receives compact metric finite-net data, cover-member rows, overlap incidence, rational lower-bound readback, and finite-fold handoff rows, but it receives no external open cover, no host nerve complex, no quotient equality of metric points, no arbitrary Lebesgue number, and no ambient compactness theorem.

Proof. Start with a uniform-modulus consumer of the fold handoff row F. Carrier admission makes F downstream of the compact source K, the cover-member ledger U, the overlap-incidence row O, and the rational readback row R.

Replay the finite route. The compact source supplies the finite probe spine, U attaches cover members and local radii to that spine, O records the finite incidence data, and R reads back the positive rational lower-bound data before F exports the uniform-radius handoff.

The structural rows do not widen the export surface. Transport through H preserves the same finite coordinates, while P, N source and name the packet. Thus every downstream $\mathsf{UniformModulus}^{\uparrow}$ read remains on the displayed cover-nerve route and cannot recover any excluded host object or selector. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCoverNerve}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactCoverNerve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6263.1, Definition 6263.2, and Definition 6263.3 seed the finite cover nerve from CompactMetric cover-member rows to rational-fold and UniformModulus handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactCoverNerve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close external open-cover choice, host nerve complexes, quotient equality of metric points, arbitrary Lebesgue numbers, ambient compactness theorems, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked compact-source compatibility, cover-member admission, overlap-incidence exactness, rational readback, uniform-modulus handoff, transport, provenance, and local naming for BEDC.Derived.CompactCoverNe

Constructive story: A $\mathsf{CompactCoverNerve}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ProbeBundle cover-member rows, finite overlap incidence, RatUp lower-bound readback, FiniteNetMinimumFold and UniformModulus handoff rows, transport, provenance, and local NameCert rows.

Chapter 6264

A Concrete Naming Certificate for $\mathsf{CompactUniformCauchy}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley compact-metric terminology, the $\mathsf{CompactUniformCauchy}^{\uparrow}$ packet records the finite route by which compact finite nets, uniform Cauchy tails, regular rational readback, dyadic tolerances, and the terminal $\mathsf{Real}^{\uparrow}$ seal are made into NameCert data. It sits after the compact metric source of chapter 129, the uniform Cauchy criterion of chapter 435, the uniform-limit handoff of chapter 463, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. It realizes the compact finite-net pressure of chapter 9237 without importing ambient real completeness.

Definition 6264.1 (CompactUniformCauchy carrier)**.** *An accepted* $\mathsf{CompactUniformCauchy}^{\uparrow}$ *carrier displays the finite* BHist *packet*

$$K = (K, F, W, R, D, U, E, H, C, P, N)$$

with the following visible coordinates:

1. *K is the compact metric source row, read as finite net data rather than as an open-cover compactness principle;*
2. *F is the family or stream of observed real-valued rows over the compact source;*
3. *W is the finite tail-window row, naming the indices and windows exposed to a uniform-Cauchy consumer;*
4. *R is the regular rational readback row through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*;*
5. *D is the dyadic tolerance row supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
6. *U is the uniform Cauchy tail row, recording one displayed tail bound for the whole compact finite net;*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row reached after the finite tail and tolerance readback;*
8. *H stores the componentwise* hsame *and* psame *transports for the compact, tail, tolerance, uniformity, seal, provenance, and naming rows;*
9. *C stores the finite* Cont *replay routes by which a consumer reads the compact net, uniform tail, regular readback, dyadic tolerance, and Real seal;*

10. *P records* Pkg *provenance over the cited compact, uniform-Cauchy, uniform-limit, stream, regular-rational, dyadic, and real-name surfaces;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchy}^{\uparrow}}$ *row.*

The carrier contains no hidden coordinate for an open-cover choice, quotient stream, selected limit, host real equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 (definition) `BEDC.Derived.CompactUniformCauchyUp.CompactUniformCauchyUp`

Theorem 6264.2 (CompactUniformCauchy NameCert obligations)**.** *For every accepted carrier Q displaying the packet $(K, F, W, R, D, U, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchy}^{\uparrow}}$ *surface consists of finite obligations for compact-net exposure, family-row exposure, uniform tail-window exactness, regular rational readback, dyadic tolerance exactness, Real seal nonescape, componentwise transport, route replay, package provenance, and local naming. Each obligation is read from the displayed coordinates $K, F, W, R, D, U, E, H, C, P, N$.*

Proof. Project the carrier coordinates. The compact row, family row, tail window, regular readback, dyadic tolerance, uniform tail, and Real seal are all explicit entries of the finite packet.

The transport and replay rows H and C determine how those entries move between certified presentations. They expose only componentwise sameness and displayed continuation routes, so a consumer cannot insert an open-cover choice, quotient stream, selected limit, or host equality proof.

The provenance and local naming rows P, N bind the packet to the cited sibling chapters. Repacking these rows gives exactly the stated finite NameCert obligation surface. □

Theorem 6264.3 (CompactUniformCauchy finite-net extraction)**.** *Every uniform-Cauchy read of an accepted* $\mathsf{CompactUniformCauchy}^{\uparrow}$ *carrier first extracts the compact finite-net source row K, then reads the family row F, the tail-window row W, the regular readback row R, the dyadic tolerance row D, and the uniform tail row U through H, C, P, N. The extraction exports finite net and tail data only; it does not export open-cover compactness, selected subcovers outside the displayed packet, countable choice, quotient point equality, or a host uniform modulus.*

Proof. Start with the compact source coordinate K. By definition it is the displayed compact-metric finite-net row, not an ambient compactness principle.

Next read the analytic rows F, W, R, D, U. These rows move from observed family data to finite tail windows, regular rational readback, dyadic tolerance, and one uniform tail bound over the displayed finite net.

Finally use H, C, P, N to transport, replay, source, and name that same route. Since no other coordinate is present, finite-net extraction is exhausted by the packet and cannot supply the excluded choice, quotient, subcover, equality, or host-modulus data. □

Theorem 6264.4 (CompactUniformCauchy Real seal nonescape)**.** *In every accepted* $\mathsf{CompactUniformCauchy}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *seal row E is reachable only after the compact finite-net row K, the family row F, the tail-window row W, the regular readback row R, the dyadic tolerance row D, and the uniform tail row U have been read through the displayed transport and replay rows. A downstream consumer may use E as the terminal seal of this finite route, but not as ambient Real completeness, a selected limit, host equality of completed reals, or a quotient-stream representative.*

Proof. Project the terminal row E from the carrier. It is named as the downstream Real seal coordinate and appears after the compact-net, family, tail-window, regular-readback, dyadic-tolerance, and uniform-tail coordinates.

The only routes to E are the displayed continuation routes in C transported by H and sourced by P, N. Those routes force the consumer to pass through K, F, W, R, D, U before the seal can be read.

Therefore the seal is a terminal row of the finite packet. It cannot be detached into a completeness theorem, selected limit, host real equality, or quotient-stream representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformCauchy}^{\uparrow}$ packet is generated from compact finite-net data, observed family rows, tail windows, regular rational readback, dyadic tolerances, uniform Cauchy tails, a terminal Real seal, componentwise transports, displayed continuation routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6264.1, Definition 6264.2, Definition 6264.3, and Definition 6264.4 record the finite carrier, NameCert obligations, finite-net extraction, and Real-seal nonescape rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim ambient Real completeness, quotient-stream completion, selected limits, open-cover compactness, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked NameCert obligation theorem for the compact-net, uniform-tail, regular-readback, dyadic-tolerance, and Real-seal rows.

Chapter 6265

A Concrete Naming Certificate for $\mathsf{CompleteRealModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CompleteRealModulus}^{\uparrow}$ packet records the finite modulus data by which a completion-facing real read is accepted without appealing to ambient completeness. It sits after the Cauchy-filter limit route of chapter 1558, the regular-rational sequence discipline of chapter 301, the stream-window naming surface of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. It also shares its modulus-facing boundary with chapter 1423: the point is not to add a new completion principle, but to name the displayed modulus route that lets completion consumers read a Real-facing limit through finite windows and tolerances.

Definition 6265.1 (CompleteRealModulus carrier)**.** *A* $\mathsf{CompleteRealModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, S, D, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *source row naming the Cauchy-filter data whose completion read is being inspected.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to expose the inspected stream segments.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the displayed dyadic budget for the read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row reached after the stream windows and dyadic tolerances are displayed.*
5. *Q is the complete-modulus row, recording the finite rule that sends each requested output tolerance to the displayed filter window, stream segment, and regular-rational comparison needed for the read.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is visible only after F, S, D, R, Q have supplied the displayed route.*
7. *H records componentwise* hsame *transport for the Cauchy-filter source, stream windows, dyadic tolerances, regular readback, modulus row, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-modulus request through $F, S, D, R, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CompleteRealModulus}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompleteRealModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, S, D, R, Q, E, H, C, P, N$. It has no coordinate for a selected limit, quotient filter, host equality of reals, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CompleteRealModulusUp.CompleteRealModulusTasteGate single carrier alignment`

Theorem 6265.2 (CompleteRealModulus NameCert obligations)**.** *For every accepted* $\mathsf{CompleteRealModulus}^{\uparrow}$ *carrier*

$$M = (F, S, D, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteRealModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for M, Cauchy-filter source exposure through F, stream-window exposure through S, dyadic tolerance exposure through D, regular-rational readback through R, complete-modulus accountability through Q, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6265.1. The analytic source is not an ambient completion object; it is the displayed Cauchy-filter row F together with finite stream windows S and dyadic tolerances D.

The readback rows are ordered. The regular-rational row R is reached only after the relevant stream windows and dyadic comparisons are present, and the modulus row Q records how each requested tolerance is answered by those displayed rows.

The Real-facing row E is terminal for this packet. It seals the displayed completion read after F, S, D, R, Q have been exposed, while H, C, P, N transport, replay, source, and name the same route.

Since no row stores a selected limit, quotient filter, host equality, countable choice schedule, or ambient completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6265.3 (CompleteRealModulus threshold seal route)**.** *Every Real-facing consumer of an accepted* $\mathsf{CompleteRealModulus}^{\uparrow}$ *packet must read a completion threshold through the finite route*

$$\mathsf{CauchyFilterLimit}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as instantiated by F, S, D, R, Q, E. In particular, the terminal seal is available only after the Cauchy-filter source, stream windows, dyadic tolerance row, regular-rational readback, complete-modulus row, componentwise transport, continuation replay, provenance, and local NameCert row have been displayed.

Proof. Start with an accepted carrier $M = (F, S, D, R, Q, E, H, C, P, N)$. The source row F names the Cauchy-filter limit request, so the consumer has no detached completion carrier to inspect.

The finite observation route then passes through S, D, R. Stream windows expose the inspected name segments, dyadic tolerances record the requested threshold, and regular-rational readback presents the comparison data in a form that can face the Real seal.

The complete-modulus row Q binds these observations to every requested output tolerance. The terminal row E can therefore be read only after the threshold route is displayed, and the structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming.

Thus a Real-facing completion consumer receives a finite threshold-seal packet, not a selected limit, quotient filter, host equality, countable choice principle, or ambient completeness claim. □

Falsifiable prediction: Every accepted $\mathsf{CompleteRealModulus}^{\uparrow}$ completion-threshold read factors through one CauchyFilterLimitUp source row, one StreamNameUp finite-window row, one DyadicRatCoreUp tolerance row, one RegSeqRatUp readback row, one complete-modulus row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: realcauchymodulus, cauchyfilterlimit, regseqrat, streamname, dyadicratcore, real: $\mathsf{CompleteRealModulus}^{\uparrow}$ is not bijective to any listed sibling because it packages the completion-threshold rule, source filter row, finite windows, dyadic tolerances, regular readback, terminal Real seal, transport, replay, provenance, and local NameCert as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteRealModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteRealModulus}^{\uparrow}$ packet is generated from a CauchyFilterLimitUp source row, StreamNameUp finite windows, DyadicRatCoreUp tolerances, RegSeqRatUp readback, a complete-modulus row, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteRealModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6265.1, Definition 6265.2, and Definition 6265.3 seed the finite completion-threshold route from Cauchy-filter source data to regular-rational readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteRealModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, quotient completion, selected limits, host equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-filter source exposure, stream-window exposure, dyadic tolerance exposure, regular-rational readback, modulus accountability, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompleteRealModulusUp.

Chapter 6266

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$ packet records the finite tail-filter basis generated by a regular Cauchy rational schedule before a completion consumer reads a $\mathsf{Real}^{\uparrow}$ seal. It sits after the regular rational sequence of chapter 301, the finite stream windows of chapter 126, the Cauchy filter-basis surface of chapter 1501, and the dyadic tolerance ledger of chapter 291. The packet names only displayed tail-filter basis rows; it does not assert quotient completion equality, selected limits, countable choice, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ equality.

Definition 6266.1 (Regular Cauchy tail-filter basis carrier)**.** *A* $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, W, B, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row. It records the regular rational schedule and the explicit tail bounds that generate the basis.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists the finite observation windows, requested indices, and inspection order used to read the schedule.*
3. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis row. It stores the finite family of tail neighborhoods generated from the regular Cauchy schedule.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records dyadic radii, denominator budgets, slack comparisons, and the tail-to-radius conversion used by the basis.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal row. It is visible only after R, W, B, D have displayed the regular schedule, finite windows, basis neighborhoods, and tolerance comparisons.*
6. *H records componentwise* hsame *transport for the source schedule, windows, basis, dyadic ledger, endpoint seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from regular Cauchy tail requests to finite filter-basis neighborhoods and then to the endpoint seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $R, W, B, D, E, H, C, P, N$. There is no carrier coordinate for quotient completion equality, a selected limiting real, countable choice, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ *equality.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFilterBasisUp.RegularCauchyTailFilterBasisTasteGate`
`single carrier alignment`

Theorem 6266.2 (Regular Cauchy tail-filter basis NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$ *carrier $T = (R, W, B, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular rational source, stream windows, Cauchy filter-basis row, dyadic tolerance ledger, endpoint seal, transport, replay, provenance, and local naming rows;*
2. *tail-window exactness, requiring every basis neighborhood to name the finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *tail request from which it was generated;*
3. *dyadic-radius exactness, requiring D to display the radius and slack comparison consumed by each tail neighborhood in B;*
4. *endpoint-seal nonescape, requiring E to remain downstream of R, W, B, D and to export no quotient completion equality, selected limiting real, countable-choice schedule, host completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *equality;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No regular Cauchy tail-filter basis obligation is stored outside these rows.

Proof. Project the accepted packet $T = (R, W, B, D, E, H, C, P, N)$. The carrier definition exposes exactly the regular rational source, finite windows, basis neighborhoods, dyadic ledger, endpoint seal, and structural rows.

The basis route starts with R and W. A tail neighborhood cannot be read until the regular Cauchy tail request and its finite observation window have both been displayed.

The dyadic comparison is then read through D. This row supplies the radius, denominator budget, and slack comparison used by the basis row B, so a filter-basis consumer receives a finite tail-to-radius certificate rather than a host completeness argument.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, host completeness, or ambient real equality, the listed rows exhaust the local NameCert surface. □

Theorem 6266.3 (Regular Cauchy tail-filter endpoint handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$ *carrier factors through*

$$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$$

Thus the endpoint seal is consumed only after the regular Cauchy schedule, finite windows, tail-filter basis neighborhoods, dyadic comparisons, transport, replay, provenance, and local naming have been displayed.

Proof. Begin with a completion-facing consumer of $T = (R, W, B, D, E, H, C, P, N)$. The only source rows available to the consumer are the regular Cauchy schedule R and the finite windows W.

The filter-basis handoff then passes through B and D. The row B records the tail neighborhoods generated by the schedule, while D records the dyadic radii and slack comparisons that make those neighborhoods usable by completion data.

The endpoint row E is downstream of this displayed basis route. The structural rows H, C, P, N preserve the same finite packet, so the consumer cannot replace the route by quotient completion equality, a selected limit, countable choice, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ equality. □

Falsifiable prediction: Every $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$ completion-facing read factors through a RegSeqRat source, StreamName windows, CauchyFilterBasis tail neighborhoods, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, cauchyfilterbasis, dyadicratcore, real: RegularCauchyTailFilterBas is not bijective to any listed sibling because it jointly carries regular Cauchy schedules, finite stream windows, generated tail-filter basis neighborhoods, dyadic tolerance comparisons, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6266.1, Definition 6266.2, and Definition 6266.3 seed the finite route from regular Cauchy schedules to tail-filter basis completion data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host completeness, ambient $\mathsf{Real}^{\uparrow}$ equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window exactness, dyadic-radius exactness, endpoint-seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailFilterBasisUp.

Constructive story: A $\mathsf{RegularCauchyTailFilterBasis}^{\uparrow}$ packet is generated from a RegSeqRat regular Cauchy schedule, StreamName windows, CauchyFilterBasis tail neighborhoods, a DyadicRatCore tolerance ledger, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6267

A Concrete Naming Certificate for $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$

Following Poincare disk geometry and Bishop–Bridges finite-data discipline, the $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ packet records boundary-preserving disk transport as displayed BEDC rows rather than as a host analytic automorphism of the disk. It concretizes the Poincare disk reading of section 9463.3 after the disk-coordinate surface of chapter 377, the disk metric packet of chapter 6209, the hyperbolic metric readback of chapter 3474, and the boundary-fixed transport surface of chapter 3500. The packet names only finite disk, boundary, metric, transport, provenance, and NameCert rows; it does not claim a completed disk, quotient ideal-boundary equality, selected boundary point, host Mobius action, or global compactification.

Definition 6267.1 (Poincare disk boundary transport carrier)**.** *A* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, B, M, T, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row, recording the finite source and target disk observations inspected by the transport.*
2. *B is the boundary row, recording the displayed boundary incidences and far-end labels preserved by the transport.*
3. *M is the metric-read row, sourced through* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *and* $\mathsf{HyperbolicMetric}^{\uparrow}$ *comparisons over the same disk observations.*
4. *T is the transport row, recording the finite disk movement, boundary-preservation check, and admissible source-target route.*
5. *F is the fixed-boundary compatibility row, comparing the transport with the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *surface when a consumer asks for boundary invariance.*
6. *H records componentwise* hsame *transport for disk coordinates, boundary rows, metric reads, disk transport, fixed-boundary compatibility, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route from disk observations to boundary-preserving transport and then to metric-facing consumers.*

8. *P is the* Pkg *provenance over* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $D, B, M, T, F, H, C, P, N$. There is no coordinate for a completed disk, quotient ideal-boundary equality, selected boundary point, host Mobius action, global compactification, Lean verification, or bridge data.

Lean4 ✓ `BEDC.Derived.PoincareDiskBoundaryTransportUp.PoincareDiskBoundaryTransportTasteGate`
`single carrier alignment`

Theorem 6267.2 (Poincare disk boundary transport NameCert obligations)**.** *For every accepted* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *carrier $G = (D, B, M, T, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PoincareDiskBoundaryTranspo}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for disk coordinates, boundary incidences, metric reads, disk transport, fixed-boundary compatibility, transport, replay, provenance, and local naming;*
2. *disk-boundary visibility, requiring every transport read to expose D and B before a boundary-preserving route is exported;*
3. *metric compatibility, requiring M to be sourced through the same displayed disk observations and boundary rows used by T;*
4. *fixed-boundary exactness, requiring F to compare the route with* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *without introducing a selected boundary point or host automorphism;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No Poincare disk boundary-transport obligation is stored outside these rows.

Proof. Project the accepted packet $G = (D, B, M, T, F, H, C, P, N)$. The carrier definition exposes disk coordinates, boundary incidences, metric reads, transport, fixed-boundary compatibility, and structural rows.

The boundary-preserving route starts with D and B. A transport row cannot be read as boundary-preserving until the finite disk observations and the displayed boundary incidences are both visible.

The metric and fixed-boundary checks then pass through M, T, F. The metric row reads the same disk data, the transport row records the admissible movement, and the fixed-boundary row compares that movement with the boundary-fixed transport surface.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since no carrier coordinate stores a completed disk, quotient ideal boundary, selected boundary point, host Mobius action, global compactification, Lean verification, or bridge data, the listed rows exhaust the local NameCert surface. □

Theorem 6267.3 (Poincare disk boundary transport nonescape)**.** *Every boundary-preserving disk-transport read from an accepted* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *packet factors through*

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{PoincareDiskMetric}^{\uparrow}, \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{PoincareBoundaryFixedTransport}^{\uparrow}, \mathsf{PoincareDiskPhaseTran}$$

Thus a consumer receives only finite disk, boundary, metric, transport, replay, provenance, and naming rows, not a completed disk, quotient ideal-boundary equality, selected boundary point, host Mobius action, or global compactification.

Proof. Start with the carrier rows of Definition 6267.1. The disk row D and boundary row B are the only source of visible boundary data.

The route reaches metric and transport consumers through M, T, F. These rows bind the metric read, disk movement, and fixed-boundary comparison to the same displayed source and boundary observations.

The structural rows H, C, P, N do not add a second geometric object. They preserve, replay, source, and name the displayed packet, so no completed disk, quotient ideal boundary, selected boundary point, host Mobius action, or global compactification can be exported from the accepted read. □

Falsifiable prediction: An accepted $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ read is refuted if a boundary-transport consumer obtains boundary preservation without displaying UnitDisk coordinates, boundary rows, PoincareDiskMetric and HyperbolicMetric reads, PoincareBoundaryFixedTransport compatibility, PoincareDiskPhaseTransport routing, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: unitdisk, poincare-disk-metric, hyperbolic-metric, poincare-boundary-fixed-transport, poincare-disk-phase-transport: no listed sibling is bijective to $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ because this packet jointly carries disk coordinates, boundary incidences, metric reads, boundary-preserving transport, fixed-boundary compatibility, replay, provenance, and local naming as one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6267.1, Definition 6267.2, and Definition 6267.3 seed the finite boundary-preserving Poincare disk transport route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed disks, quotient ideal-boundary equality, selected boundary points, host Mobius actions, global compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-coordinate admission, boundary visibility, metric compatibility, fixed-boundary exactness, transport preservation, replay, provenance, and local naming for BEDC.Derived.PoincareDiskBoundaryTransportUp.

Constructive story: A $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ packet is generated from UnitDisk coordinates, displayed boundary incidences, PoincareDiskMetric and HyperbolicMetric reads, boundary-preserving disk transport, PoincareBoundaryFixedTransport compatibility, PoincareDiskPhaseTransport routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6268

A Concrete Naming Certificate for $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$ packet records the finite Cauchy-window extraction that a constructive Real and Completion route may inspect before any compactness or limit principle is available. It sits over the dyadic tolerance surface of chapter 291, the finite schedule surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet extracts a displayed finite net row from a Cauchy window; it is not an open-cover compactness theorem, not a selected limit construction, and not a countable-choice schedule.

Definition 6268.1 (Finite Cauchy net extraction carrier)**.** *A* $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, W, Q, M, T, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the precision request and the dyadic comparison ledger used to judge the finite net.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming the observed stream positions available at that tolerance.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which the scheduled window is interpreted as regular rational Cauchy data.*
4. *M is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger recording that the chosen window is large enough for the displayed tolerance request.*
5. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row extracted from the displayed Cauchy window and indexed only by the entries named in W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff exposed only after D, W, Q, M, T have been displayed.*
7. *H records componentwise* hsame *transport for the dyadic tolerance, finite-window schedule, regular rational readback, modulus ledger, finite-net row, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite Cauchy-window request through D, W, Q, M, T, E, H and into a Real or Completion consumer.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyNetExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, Q, M, T, E, H, C, P, N$. It has no coordinate for open-cover compactness, a selected Cauchy limit, quotient stream equality, countable choice, host real equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.FiniteCauchyNetExtractionUp.FiniteCauchyNetExtractionTasteGate single carrier alignment`

Theorem 6268.2 (Finite Cauchy net extraction NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$ *carrier $F = (D, W, Q, M, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyNetExtraction}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite-window schedule readback, regular rational handoff, convergence-modulus ledger exactness, displayed finite-net extraction, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must read the displayed route*

$$D, W, Q, M \longmapsto T \longmapsto E \longmapsto H, C, P, N$$

before using a finite net as Cauchy-window evidence.

Proof. Project the carrier of Definition 6268.1. The dyadic row D supplies the tolerance request, and the finite schedule W supplies the only stream entries that may be inspected.

Read Q and M next. The regular rational row Q interprets the scheduled entries as Cauchy data, while the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ ledger M records that the displayed window is large enough for the request named by D.

The finite-net row T is then extracted from those displayed entries only. The Real seal E and the structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate supplies open-cover compactness, selected limits, quotient stream equality, countable choice, host real equality, or ambient Real completeness, none of those objects can occur in the local NameCert surface. □

Theorem 6268.3 (Finite Cauchy net extraction L10 route)**.** *Every L10 Real and Completion consumer of an accepted* $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$ *packet reads the extracted net only through the finite route*

$\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, P

The route exposes the dyadic tolerance, the scheduled Cauchy window, the regular rational readback, the convergence-modulus ledger, the finite-net row, the terminal Real seal, componentwise transport, replay, provenance, and local naming. It exports no open-cover compactness, selected limit, quotient stream equality, countable-choice schedule, host real equality, detached metric-completion row, or ambient Real completeness.

Proof. Apply Definition 6268.2. It fixes the only public route from the tolerance request through the scheduled window, regular rational readback, modulus ledger, finite-net row, and Real seal.

For a Real-facing consumer, the seal E is reached only after D, W, Q, M, T have already been displayed. Thus the consumer receives the finite net as an inspected Cauchy-window witness, not as a host-selected limit or quotient representative.

For a Completion-facing consumer, the same rows are replayed through H, C, P, N. The replay row can cite the displayed $\mathsf{TotallyBounded}^{\uparrow}$ net row and the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ ledger, but it cannot add an open-cover compactness proof, countable choice, detached metric-completion row, or ambient Real completeness, because those data are absent from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$ Real or Completion consumer factors through one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{RealModulusOfConvergence}^{\uparrow}$ ledger, one $\mathsf{TotallyBounded}^{\uparrow}$ finite-net row, one $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it may use finite Cauchy-window evidence.

Independence witness: dyadicratcore, streamname, regseqrat, real-modulus-of-convergence, totallybounded, real: $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately supply tolerance comparisons, finite schedules, rational readback, convergence ledgers, finite nets, and terminal Real sealing, while this packet binds them to the finite Cauchy-window extraction consumed by the L10 Real and Completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyNetExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyNetExtraction}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, a StreamName finite-window schedule, a RegSeqRat readback row, a RealModulusOfConvergence ledger, a TotallyBounded finite-net row, a Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCauchyNetExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6268.1, Definition 6268.2, and Definition 6268.3 seed the finite Cauchy-window extraction interface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCauchyNetExtraction}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FiniteCauchyNetExtractionUp.FiniteCauchyNetExtractionTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected limits, quotient stream equality, countable choice, host real equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window scheduling, RegSeqRat readback, convergence-modulus ledger exactness, finite-net extraction, Real seal handoff, structural transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.FiniteCauchyNetExtractionUp.

Chapter 6269

A Concrete Naming Certificate for PoincareRecurrence$^{\uparrow}$

Following Poincare's recurrence theorem and Bishop-style finite evidence, the PoincareRecurrence$^{\uparrow}$ packet records the displayed finite return-window route behind recurrence in a measure-preserving system. It sits after the finite routed-flow carrier of chapter 195, the invariant-measure surface of chapter 196, the normalized probability carrier of chapter 184, and the underlying measure packet of chapter 92. The packet names only a finite recurrence certificate; it is not a host infinite orbit theorem, not a selected recurrent point, not a sigma-completion principle, and not an ambient ergodic decomposition.

Definition 6269.1 (Poincare recurrence carrier)**.** *A* PoincareRecurrence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, E, P, M, A, W, T, H, C, Q, N)$$

with the following displayed rows:

1. *D is the* DynSystem$^{\uparrow}$ *finite routed-flow row, exposing the inspected step relation and orbit cells.*
2. *E is the* Ergodic$^{\uparrow}$ *invariant-measure or recurrence-facing row used only as finite classifier support.*
3. *P is the* ProbSpace$^{\uparrow}$ *normalization row for the total event and event classifier.*
4. *M is the* Measure$^{\uparrow}$ *measurable-set row naming the inspected positive-measure cell A.*
5. *A is the displayed source event whose nonzero measure is being tested for return.*
6. *W is the finite return-window row, listing the inspected nonzero times and their displayed inverse-image or forward-image cells.*
7. *T is the return-hit row asserting that the window contains a measured overlap between A and an allowed return of A.*
8. *H records componentwise* hsame *transport for the dynamic, invariant, probability, measure, event, window, return-hit, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the dynamic route, event classifier, finite window, and return-hit ledger.*
10. *Q is the* Pkg *provenance over* PoincareRecurrence$^{\uparrow}$, DynSystem$^{\uparrow}$, Ergodic$^{\uparrow}$, ProbSpace$^{\uparrow}$, Measure$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareRecurrence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eleven rows. It has no coordinate for a completed measure algebra, infinite orbit selector, countable recurrence schedule, host almost-everywhere predicate, or ergodic decomposition.

Lean4 ✓ `BEDC.Derived.PoincareRecurrenceUp.PoincareRecurrenceTasteGate single carrier alignment`

Theorem 6269.2 (Poincare recurrence NameCert obligations)**.** *For every accepted* $\mathsf{PoincareRecurrence}^{\uparrow}$ *carrier*

$$R = (D, E, P, M, A, W, T, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareRecurrence}^{\uparrow}}$ *surface consists exactly of finite routed dynamics, invariant-measure support, probability normalization, measurable-event exposure, finite return-window data, a displayed return-hit row, componentwise transport, displayed replay, package provenance, and local naming through the rows* $D, E, P, M, A, W, T, H, C, Q, N$.

Proof. Project the carrier of Definition 6269.1. The rows D, E, P, M, A expose the only dynamic, invariant, probability, measure, and source-event data visible to the packet.

Read the return evidence next. The row W gives the inspected finite return window, and T records the measured overlap that certifies a return within that displayed window.

Finally attach H, C, Q, N. Componentwise transport, continuation replay, provenance, and local naming preserve exactly the displayed rows, so the certificate cannot export an infinite orbit selector, a completed measure algebra, a countable recurrence schedule, or an ergodic decomposition. □

Theorem 6269.3 (Poincare recurrence return-window handoff)**.** *Every accepted* $\mathsf{PoincareRecurrence}^{\uparrow}$ *recurrence read factors through the route*

$$D \longmapsto E \longmapsto P \longmapsto M \longmapsto A \longmapsto W \longmapsto T \longmapsto H, C, Q, N$$

before a downstream consumer receives the return claim. Thus the handoff to later dynamic or probability formalization is a displayed finite system row, invariant-support row, probability normalization row, measurable source event, return-window ledger, return-hit witness, transport, replay, provenance, and local naming data.

Proof. Start with a consumer requesting recurrence data. The packet first exposes the finite dynamic row D, the invariant-support row E, and the normalized probability row P.

The measurable source event is then fixed by M and A. No return statement is available before these rows name the event whose positive measure is being inspected.

Only after that does the finite window W feed the return-hit row T. The structural rows H, C, Q, N preserve the same route for later consumers, so the handoff is a finite return-window certificate rather than a host recurrence theorem. □

Theorem 6269.4 (Poincare recurrence measure-preserving nonescape)**.** *Every accepted* $\mathsf{PoincareRecurrence}^{\uparrow}$ *measure-preserving read remains inside the finite carrier of Definition 6269.1. In particular, a consumer can read a recurrence claim only after displaying the* $\mathsf{DynSystem}^{\uparrow}$ *row,* $\mathsf{Ergodic}^{\uparrow}$ *invariant-support row,* $\mathsf{ProbSpace}^{\uparrow}$ *normalization row,* $\mathsf{Measure}^{\uparrow}$ *event row, finite return-window ledger, return-hit row, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. No accepted read may replace this route by a selected recurrent point, a completed invariant sigma-algebra, a countable-choice return schedule, a host almost-everywhere predicate, or an ambient ergodic decomposition.*

Proof. Let a consumer request a measure-preserving recurrence claim from an accepted carrier. Projection of Definition 6269.1 shows that the request first meets D, E, P, M, A and has no independent coordinate for a selected point or completed orbit.

The finite return-window row W is downstream from the displayed measurable source event, and the return-hit row T is downstream from that window. Hence the recurrence read is already tied to a finite inspected window and its measured overlap.

The remaining rows H, C, Q, N add no new analytic primitive. They transport equal displayed histories, replay the finite route, record package provenance, and attach the local name. Therefore every accepted measure-preserving read stays inside the finite recurrence certificate surface and cannot escape to the excluded host principles. □

Falsifiable prediction: If a recurrence-facing consumer preserves the $\mathsf{DynSystem}^{\uparrow}$ row but drops the $\mathsf{ProbSpace}^{\uparrow}$ normalization row, the $\mathsf{Measure}^{\uparrow}$ event row, or the finite return-window row, it is not reading a $\mathsf{PoincareRecurrence}^{\uparrow}$ packet.

Independence witness: dynsystem, ergodic, probspace, measure: no listed sibling is bijective to $\mathsf{PoincareRecurrence}^{\uparrow}$ because this packet jointly carries finite routed dynamics, invariant-support provenance, normalized probability, measurable source events, finite return windows, return-hit evidence, transport, replay, package sourcing, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareRecurrence}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareRecurrence}^{\uparrow}$ packet is generated from a finite DynSystem route, Ergodic invariant-support row, ProbSpace normalization row, Measure event row, source event, finite return-window ledger, return-hit witness, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareRecurrence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6269.1, Definition 6269.2, Definition 6269.3, and Definition 6269.4 seed the finite recurrence route through dynamics, invariant support, probability normalization, measurable events, return windows, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareRecurrence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host recurrence theorems, selected recurrent points, completed invariant sigma-algebras, countable-choice return schedules, almost-everywhere predicates, ergodic decompositions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dynamic routing, invariant-support stability, probability normalization, measurable-event exposure, return-window handoff, return-hit nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.PoincareRecurrenceUp.

Chapter 6270

A Concrete Naming Certificate for $\mathsf{GronwallBellman}^{\uparrow}$

Following Bellman's 1943 integral inequality and the standard Bishop–Bridges constructive analysis route, the $\mathsf{GronwallBellman}^{\uparrow}$ packet records the finite integral-comparison surface used before Picard, stability, or completion consumers read a real bound. It sits after the displayed Gronwall comparison of chapter 2034, the finite integration surface of chapter 1526, the regular-product route of chapter 1702, the rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite partition, kernel-bound, majorant, product/exponential budget, error-budget, readback, seal, transport, replay, provenance, and local naming rows.

Definition 6270.1 (Gronwall–Bellman carrier)**.** *A* $\mathsf{GronwallBellman}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, K, M, P, E, R, Z, H, C, Q, N)$$

with the following visible rows:

1. *I is the interval-partition row, recording the displayed time interval, finite ordered partition cells, endpoint names, and the tag or subinterval reads used by the integral comparison.*
2. *K is the kernel-bound row, displaying the nonnegative integral kernel or coefficient bound on each inspected cell and its finite comparison to the partition data in I.*
3. *M is the majorant row, storing the displayed initial bound and inhomogeneous comparison envelope whose reads are bounded through the Bellman route.*
4. *P is the finite product/exponential budget row, obtained from the kernel-bound row by a finite multiplication or exponential enclosure through* $\mathsf{RegularCauchyMultiplication}^{\uparrow}$ *and the dyadic budget rows already exposed to the Real route.*
5. *E is the error-budget row, recording the local slack by which cellwise Riemann sums, product enclosures, and majorant reads are kept inside the displayed tolerance.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the partition endpoints, kernel bounds, majorant samples, product/exponential budget, and error-budget witnesses.*
7. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row for the final Bellman bound after the finite partition and readback rows have been replayed.*

8. *H records componentwise* hsame *transport for the interval partition, kernel bound, majorant, product/exponential budget, error budget, readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the finite route*

$$I, K, M, P, E, R \longmapsto Z \longmapsto \mathsf{NameCert}_{\mathsf{GronwallBellman}^{\uparrow}}.$$

10. *Q is the* Pkg *provenance over* $\mathsf{GronwallBellman}^{\uparrow}$, $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, RegularCauchyMultiplicati $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GronwallBellman}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through these rows and their displayed transports. It has no coordinate for a host integral operator, selected limit, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or Lean-verified theorem.*

Lean4 ✓ `BEDC.Derived.GronwallBellmanUp.TasteGate.GronwallBellmanTasteGate single carrier alignment`

Theorem 6270.2 (Gronwall–Bellman NameCert obligations)**.** *For every accepted* $\mathsf{GronwallBellman}^{\uparrow}$ *carrier $G = (I, K, M, P, E, R, Z, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{GronwallBellman}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval partition, kernel bound, majorant, finite product/exponential budget, error budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. No obligation is discharged by a host integral, selected mesh limit, quotient stream equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or Lean verification.*

Proof. Project the accepted carrier of Definition 6270.1. The rows I, K, M, P, E, R, Z are the only analytic coordinates, and the structural rows H, C, Q, N only transport, replay, source, and name those coordinates.

The interval partition and kernel-bound rows determine the finite integral-comparison surface. The majorant row is read only over that same partition, while the product/exponential row records the finite enclosure produced from the kernel bounds.

The error-budget and regular-rational rows then bind the comparison to displayed observations. The real seal Z is exposed only after those finite rows have been replayed, so the local certificate cannot import a host integral, selected limit, quotient stream equality, trichotomy, ambient completeness theorem, or Lean verification. □

Theorem 6270.3 (Gronwall–Bellman finite partition handoff)**.** *Every accepted* $\mathsf{GronwallBellman}^{\uparrow}$ *carrier routes any integral-inequality read through the finite handoff*

$$\mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{GronwallBellman}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The read opens the interval partition I, kernel-bound row K, majorant row M, finite product/exponential budget P, and error-budget row E before the regular-rational readback R or real seal Z is available.

Proof. Begin with an accepted carrier G. The only integration-facing source is the finite partition row I, and the only coefficient source is the kernel-bound row K on that partition.

Read the majorant and product/exponential rows next. The majorant row M supplies the displayed comparison envelope, while P supplies the finite multiplicative or exponential enclosure needed for Bellman's bound.

The error row E and readback row R keep the handoff finite. Since Z is sealed only after I, K, M, P, E, R have been replayed, every integral-inequality consumer receives the stated route and cannot bypass it through host integration, selected mesh limits, quotient equality, trichotomy, or ambient completeness. □

Theorem 6270.4 (Gronwall–Bellman Real seal nonescape)**.** *For every accepted* $\mathsf{GronwallBellman}^{\uparrow}$ *carrier* $G = (I, K, M, P, E, R, Z, H, C, Q, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* Z *exposes only the Bellman bound obtained from the finite partition, kernel-bound, majorant, product/exponential, error-budget, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows. It exports no host integral value, selected limit, quotient stream equality, trichotomy branch, ambient* $\mathsf{Real}^{\uparrow}$ *completeness result, or Lean-checked bridge.*

Proof. Use Definition 6270.2 to identify the full local obligation surface. The seal row is listed there only as the terminal read of the finite carrier rows.

Use Definition 6270.3 to locate the route into Z. The handoff opens I, K, M, P, E, R before the real seal is available, so the seal cannot be an independent host integral or selected limit.

The structural rows H, C, Q, N preserve this same route under transport, replay, provenance, and local naming. Therefore a consumer of Z receives only the finite Bellman-bound packet and no quotient stream equality, trichotomy branch, ambient completeness theorem, or Lean-checked bridge. □

Falsifiable prediction: Every accepted $\mathsf{GronwallBellman}^{\uparrow}$ consumer that reads a real Bellman bound without the displayed interval partition, kernel-bound row, majorant row, finite product/exponential budget, error-budget row, RegSeqRat readback, transport, replay, provenance, and local NameCert rows refutes the packet surface.

Independence witness: gronwall-inequality, riemannintegral, regular-cauchy-multiplication, regseqrat, real: none is bijective to $\mathsf{GronwallBellman}^{\uparrow}$ because this packet binds finite partition data, kernel bounds, majorant reads, product/exponential budgets, error budgets, regular-rational readback, Real seal, transport, replay, provenance, and local naming into one integral-inequality certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{GronwallBellman}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GronwallBellman}^{\uparrow}$ packet is generated from one interval-partition row, one kernel-bound row, one majorant row, one finite product/exponential budget row, one error-budget row, one RegSeqRat readback row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GronwallBellman}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6270.1, Definition 6270.2, Definition 6270.3, and Definition 6270.4 seed the finite Bellman integral-inequality packet over partition, kernel-bound, majorant, product/exponential, error-budget, regular-rational, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GronwallBellman}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host integrals, selected limits, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite partition handoff, kernel-bound stability, product/exponential budget accounting, error-budget accounting, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.GronwallBellmanUp.

Chapter 6271

A Concrete Naming Certificate for $\mathsf{RealUniformCauchyProduct}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy products, the $\mathsf{RealUniformCauchyProduct}^{\uparrow}$ packet records the finite route by which two uniformly Cauchy real-window families expose a product family with the same uniform-tail discipline. It sits beside the shared-threshold criterion of chapter 435, the product-convergence route of chapter 3608, the regular product criterion of chapter 3672, and the endpoint-seal discipline of chapter 463. The chapter names only the finite product-stability certificate; it does not assert quotient sequence equality, selected product limits, countable choice, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6271.1 (Real uniform Cauchy product carrier)**.** *A* $\mathsf{RealUniformCauchyProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (F, G, M, W_F, W_G, D, U, K, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *F and G are the two real-window family rows whose values are read only through finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *endpoint displays.*
2. *M is the shared uniform threshold ledger assigning each product tolerance to one family-wide tail bound for both inputs.*
3. *W_F and W_G are the synchronized source-window rows exposed at the product request and the threshold selected by M.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget row, recording input tolerances, visible endpoint bounds, cross-error terms, and the output tolerance for the product window.*
5. *U is the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row certifying that the source comparisons beyond M are uniform in the displayed index.*
6. *K is the* $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$ *row that turns the synchronized source windows and dyadic product budget into a regular product read.*
7. *R is the* $\mathsf{CauchyProductConvergence}^{\uparrow}$ *route row for the resulting finite product-tail calculation.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the uniform tail, product budget, regular criterion, and product-convergence route have been displayed.*

9. *H records componentwise* hsame *transport for the source families, threshold ledger, synchronized windows, dyadic budget, uniform-tail row, product criterion, convergence route, seal row, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a product-stability request through $F, G, M, W_F, W_G, D, U, K, R, E, H, Q, N$*
11. *Q is the* Pkg *provenance over* $\mathsf{RealUniformCauchyProduct}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, RegularCauchyProductCriter CauchyProductConvergence$^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformCauchyProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows, their transports, replay routes, provenance, and local naming row.

Lean4 ✓ `BEDC.Derived.RealUniformCauchyProductUp.RealUniformCauchyProductTasteGate single carrier alignment`

Theorem 6271.2 (Real uniform Cauchy product NameCert obligations)**.** *For every accepted* $\mathsf{RealUniformCauchyProduct}^{\uparrow}$ *carrier $P = (F, G, M, W_F, W_G, D, U, K, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealUniformCauchyProduct}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two source families, shared threshold ledger, synchronized source windows, dyadic product budget, uniform-tail row, product criterion, product-convergence route, Real seal, transport, replay, provenance, and local naming;*
2. *uniform-threshold stability under componentwise* hsame *transport of F, G, M, W_F, W_G;*
3. *dyadic product-budget exactness through D, with all endpoint bounds and cross-error rows displayed before K is read;*
4. *uniform-tail compatibility between M, the synchronized source windows, and the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row U;*
5. *product-criterion routing through K and product-convergence routing through R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is exposed;*
6. *displayed* Cont *replay and* Pkg *provenance for the whole route;*
7. *refusal of any consumer that omits a source family, shared threshold, synchronized window, dyadic product budget, uniform-tail row, product criterion, convergence route, Real seal, transport row, replay row, provenance row, or local naming row.*

Lean4 ✓ `BEDC.Derived.RealUniformCauchyProductUp.RealUniformCauchyProductCarrier namecert obligations`

Proof. Project the carrier of Definition 6271.1. The projection exposes the two source families, shared threshold ledger, synchronized windows, dyadic product budget, uniform-tail row, product criterion, product-convergence route, Real seal, and support rows.

The uniform part is bound by M, W_F, W_G, U. A consumer can read the product family only after the same threshold has supplied both source comparisons, so the route is not pointwise-only.

The product part is bound by D, K, R. The dyadic row records the finite product budget, the regular criterion consumes that budget, and the convergence row records the product-tail calculation before any seal is available.

Finally E, H, C, Q, N seal, transport, replay, package, and name the same finite route. Since the carrier has no quotient-sequence, selected-limit, host-function-equality, choice, or ambient-completeness coordinate, the obligation list is exhaustive. □

Theorem 6271.3 (Real uniform Cauchy product ten-field package)**.** *The* $\mathsf{RealUniformCauchyProduct}^{\uparrow}$ *certificate instantiates the ten-field roadmap template as follows: traditional target, uniform Cauchy stability of products of real-window families; BEDC source, the displayed* BHist *route through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$, $\mathsf{CauchyProductConverger}$ *and* $\mathsf{Real}^{\uparrow}$*; carrier,* P*; classifier, componentwise comparison of the displayed rows; stability,* hsame *transport through* H*; ledger, the rows* M, W_F, W_G, D, U, K, R*; core theorem list, Definition 6271.2 and Definition 6271.4; exactness, exhaustion of the listed rows; standard bridge, none; status, paper seed certificate for* $\mathsf{NameCert}_{\mathsf{RealUniformCauchyProduct}^{\uparrow}}$.

Proof. Start with the carrier P of Definition 6271.1. Its source rows, threshold ledger, synchronized windows, dyadic budget, uniform-tail row, product criterion, convergence route, seal row, and support rows provide the listed BEDC source and carrier fields.

Apply Definition 6271.2. The theorem supplies the classifier, stability, ledger, routing, replay, provenance, and nonescape obligations, while the absence of a bridge row keeps the standard-bridge field empty.

Thus the ten fields form one citable seed certificate rather than a stronger analytic claim about completed real functions or selected product limits. □

Theorem 6271.4 (Real uniform Cauchy product seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RealUniformCauchyProduct}^{\uparrow}$ *carrier factors through the finite route*

$$F, G \longmapsto M, W_F, W_G \longmapsto D, U, K, R \longmapsto E, H, C, Q, N.$$

Thus a downstream Real or uniform-limit consumer first reads the two source families and the shared uniform threshold, then the synchronized windows, product budget, uniform-tail row, product criterion, and product-convergence route, and only then the terminal seal and local support rows. The route exports no quotient sequence equality, selected product limit, host function equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted packet $P = (F, G, M, W_F, W_G, D, U, K, R, E, H, C, Q, N)$. The only source-family coordinates are F and G, and the only shared threshold coordinate is M.

The synchronized windows W_F, W_G and the dyadic row D expose the finite data used by the product request. The uniform-tail row U and regular product criterion K then certify that these data are adequate for a uniform Cauchy product read.

The product-convergence row R precedes the Real seal E. The rows H, C, Q, N only transport, replay, package, and name the same route, so no second endpoint route can bypass the displayed product-tail calculation. □

Falsifiable prediction: Every accepted $\mathsf{RealUniformCauchyProduct}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting a source family, shared threshold ledger, synchronized source window, DyadicRatCore product-budget row, UniformCauchyCriterion row, RegularCauchyProductCriterion row, CauchyProductConvergence route, transport row, replay row, provenance row, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformCauchyProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformCauchyProduct}^{\uparrow}$ packet is generated from two real-window source families, a shared uniform threshold ledger, synchronized StreamName windows, a DyadicRatCore product budget, a UniformCauchyCriterion row, a RegularCauchyProductCriterion row, a CauchyProductConvergence route, a RealUp seal, componentwise transport, displayed continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealUniformCauchyProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6271.1, Definition 6271.2, Definition 6271.3, and Definition 6271.4 seed the finite uniform product-stability route from source families and shared thresholds to product budget, convergence routing, and Real seal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealUniformCauchyProduct}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient sequence equality, selected product limits, host function equality, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, uniform-threshold stability, synchronized-window admission, dyadic product-budget exactness, UniformCauchyCriterion compatibility, RegularCauchyProductCriterion routing, CauchyProductConvergence routing, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealUniformCauchyProductUp.

Chapter 6272

A Concrete Naming Certificate for $\mathsf{PeanoKernel}^{\uparrow}$

Following Peano and classical numerical analysis, the $\mathsf{PeanoKernel}^{\uparrow}$ packet isolates the finite-window data by which a quadrature-error functional is read without importing a host limiting theorem. It sits after the finite mesh carrier of chapter 3496, the tagged Riemann-sum window surface of chapter 4115, the Darboux comparison row of chapter 1880, the regular-rational readback of chapter 301, the stream-window naming route of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet names only a displayed finite interval source, a mesh, a finite annihilation ledger for test polynomials, a kernel row, a sum consumer, regular readback, stream windows, dyadic tolerance, transport, provenance, and local naming; it does not claim host quadrature convergence, selected mesh limits, quotient equality of functions, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6272.1 (Peano-kernel carrier)**.** *A* $\mathsf{PeanoKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, M, A, Q, S, R, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval-source row naming the two endpoint seals, the oriented finite window, and the real-valued functional being inspected.*
2. *M is the* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *row, either a finite dyadic mesh or a finite uniform mesh, with displayed mesh points and adjacent-cell incidence.*
3. *A is the test-polynomial annihilation ledger. It records the finite degree bound, the listed polynomial tests, and the zero-error verdict for those tests.*
4. *Q is the kernel row. It stores the signed finite-window weights or cellwise kernel values used by the quadrature-error read after I, M, A have been displayed.*
5. *S is the Riemann/Darboux sum consumer row, read through* $\mathsf{RiemannSumGauge}^{\uparrow}$ *or* $\mathsf{DarbouxSum}^{\uparrow}$ *data attached to the same mesh.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the displayed finite error value or bound as a regular rational name.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row recording the finite read windows through which consumers may request the error value.*

8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested precision, comparison slack, and cellwise error budget.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *error seal reached only after M, Q, S, R, W, D are public.*
10. *H records componentwise* hsame *transport for interval source, mesh, annihilation ledger, kernel row, sum consumer, readback, stream windows, dyadic tolerance, Real seal, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from every quadrature-error request through $I, M, A, Q, S, R, W, D, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{PeanoKernel}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PeanoKernel}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, M, A, Q, S, R, W, D, E, H, C, P, N$. It has no coordinate for an infinite refinement process, selected mesh limit, quotient equality of functions, measure completion, host convergence theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PeanoKernelUp.PeanoKernelTasteGate single carrier alignment`

Theorem 6272.2 (Peano-kernel NameCert obligations)**.** *For every accepted* $\mathsf{PeanoKernel}^{\uparrow}$ *carrier*

$$K = (I, M, A, Q, S, R, W, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PeanoKernel}^{\uparrow}}$ *surface consists exactly of carrier admission for K; Real interval-source exposure through I; finite dyadic or uniform mesh exposure through M; test-polynomial annihilation accountability through A; kernel-row compatibility through Q; Riemann/Darboux sum-consumer compatibility through S; regular-rational readback through R; stream-window read discipline through W; dyadic tolerance exactness through D; terminal Real error sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; local naming through N; and nonescape excluding host quadrature convergence, selected mesh limits, quotient function equality, measure completion, detached error representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6272.1. The interval, mesh, annihilation ledger, kernel row, and sum consumer are the analytic-facing coordinates I, M, A, Q, S.

The readback coordinates are ordered. A quadrature-error request first fixes the displayed mesh and polynomial-test ledger, then reads the kernel and sum rows, then exposes the regular rational row R through the stream window row W under the dyadic tolerance ledger D.

The terminal seal is E. It is downstream of the finite mesh, kernel, sum, readback, stream-window, and tolerance rows, so it exports a Real error name rather than a host convergence theorem.

Finally H, C, P, N transport, replay, source, and name exactly the same route. Since no carrier coordinate stores an infinite refinement process, selected mesh limit, quotient equality of functions, measure completion, detached error representative, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6272.3 (Peano-kernel error-functional route)**.** *Every quadrature-error read of an accepted* $\mathsf{PeanoKernel}^{\uparrow}$ *carrier factors through the displayed finite route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{FinitePartitionMesh}^{\uparrow} \longmapsto \mathsf{PeanoKernel}^{\uparrow} \longmapsto (\mathsf{RiemannSumGauge}^{\uparrow} \textit{ or } \mathsf{DarbouxSum}^{\uparrow}) \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

Equivalently, the read can inspect only the finite mesh row M, the kernel row Q, the sum row S, the regular readback row R, the stream-window row W, the dyadic tolerance ledger D, the Real error seal E, and the structural rows H, C, P, N after the interval source and annihilation ledger have been displayed.

Proof. Start with an accepted carrier $K = (I, M, A, Q, S, R, W, D, E, H, C, P, N)$ and a quadrature-error read. The only interval source is I, and the only mesh source is the displayed finite row M.

The annihilation ledger A binds the polynomial tests before the kernel is read. The row Q then provides the cellwise kernel or weight data, and S consumes it through the displayed Riemann or Darboux sum surface attached to the same mesh.

The read cannot leave the finite route after S. It reaches the regular-rational row R, the stream-window row W, and the dyadic tolerance ledger D before the terminal Real error seal E is exposed.

The rows H, C, P, N preserve that order under transport, replay, provenance, and local naming. Because the carrier contains no infinite refinement process, selected mesh limit, quotient function equality, measure completion, detached error representative, or ambient completeness coordinate, every accepted quadrature-error read factors through the stated finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PeanoKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{PeanoKernel}^{\uparrow}$ packet is generated from a RealUp interval source, a finite dyadic or uniform partition mesh, a test-polynomial annihilation ledger, a kernel row, a Riemann/Darboux sum consumer, RegSeqRatUp readback, StreamNameUp windows, a DyadicRatCoreUp tolerance ledger, a RealUp error seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PeanoKernel}^{\uparrow}}$, seed)

Scope closed: Definition 6272.1, Definition 6272.2, and Definition 6272.3 seed the finite quadrature-error route from interval source and finite mesh to kernel, sum, regular readback, stream windows, dyadic tolerance, and the Real error seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PeanoKernel}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host quadrature convergence, selected mesh limits, quotient function equality, measure completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exposure, finite mesh exposure, annihilation-ledger accountability, kernel-row compatibility, sum-consumer compatibility, regular readback, stream-window discipline, dyadic tolerance exactness, Real error sealing, transport, replay, provenance, and local naming for BEDC.Derived.PeanoKernelUp.

Chapter 6273

A Concrete Naming Certificate for BanachFixedPointIterationBudget$^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the BanachFixedPointIterationBudget$^{\uparrow}$ packet records the finite budget surface that sits between displayed contraction iteration and the fixed-point endpoint seal. It consumes the finite orbit ledger of chapter 2383, the contraction-map surface of chapter 1418, the complete-metric boundary of chapter 128, the regular Cauchy handoff of chapter 301, and the endpoint-facing Banach certificate of chapter 396. The packet names the tail budget a consumer must inspect before BanachFixedPoint$^{\uparrow}$ may read an endpoint.

Definition 6273.1 (Banach fixed-point iteration budget carrier)**.** *A* BanachFixedPointIterationBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, T, x_0, I, Q, R, K, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric source row, read through the carried metric and complete-metric surfaces before any orbit estimate is consumed.*
2. *T is the* ContractionMapping$^{\uparrow}$ *self-map row, including the graph-read and strict contraction-ratio ledger.*
3. *x_0 is the displayed initial-point row for the Picard orbit.*
4. *I is the finite Picard ledger supplied by* FixedPointIteration$^{\uparrow}$*, listing only the displayed iterates and adjacent-step reads.*
5. *Q is the contraction-ratio and tail-budget row, recording the finite residual threshold attached to the displayed Picard ledger.*
6. *R is the* RegSeqRat$^{\uparrow}$ *handoff row that receives the tail budget as regular Cauchy data.*
7. *K is the* CompleteMetric$^{\uparrow}$ *boundary row; it records the separate completion service that must be supplied before an endpoint-facing read.*
8. *H records componentwise* hsame *transport for the metric source, contraction map, initial point, Picard ledger, tail budget, RegSeqRat handoff, complete-metric boundary, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an endpoint request through X, T, x_0, I, Q, R, K, H.*

10. *P is the* Pkg *provenance over* BanachFixedPointIterationBudget$^{\uparrow}$, FixedPointIteration$^{\uparrow}$, ContractionMapping$^{\uparrow}$, CompleteMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{BanachFixedPointIterationBudget}^{\uparrow}}$ *row.*

The classifier compares packets only through $X, T, x_0, I, Q, R, K, H, C, P, N$. It has no coordinate for a selected fixed point, completed Picard endpoint, host fixed-point equality, quotient map equality, countable choice, or ambient completeness outside the displayed CompleteMetric$^{\uparrow}$ *boundary.*

Lean4 (definition) `BEDC.Derived.BanachFixedPointIterationBudgetUp.BanachFixedPointIterationBudgetUp`

Theorem 6273.2 (Banach fixed-point contracting-step budget)**.** *For every accepted* BanachFixedPointIterationBudg *carrier $B = (X, T, x_0, I, Q, R, K, H, C, P, N)$, each displayed Picard step in I shrinks the residual budget through the contraction row T and the ratio-tail ledger Q. A* BanachFixedPoint$^{\uparrow}$ *endpoint consumer may inspect only the finite route*

$$\text{ContractionMapping}^{\uparrow}, \quad \text{FixedPointIteration}^{\uparrow}, \quad \text{RegSeqRat}^{\uparrow}, \quad \text{CompleteMetric}^{\uparrow}$$

before reading the endpoint-facing seal. Thus the packet exposes the finite tail-modulus route and no selected endpoint, host fixed-point equality, quotient-map equality, countable-choice selector, or ambient completeness theorem.

Proof. Project the carrier rows. The Picard ledger I is finite, and every adjacent displayed step is read through the same metric source X, contraction graph T, and initial-point row x_0.

The contraction budget is the row Q. It stores the strict ratio and the residual threshold attached to the displayed ledger, so each later Picard read can only decrease the residual request along the finite ledger already present in I.

The completion-facing handoff is separate. The row R repacks the tail budget as a RegSeqRat$^{\uparrow}$ route, and the row K records the CompleteMetric$^{\uparrow}$ boundary that must be supplied before BanachFixedPoint$^{\uparrow}$ reads an endpoint.

Finally, H, C, P, N transport, replay, source, and name this same route. Since no carrier coordinate contains a selected endpoint, host fixed-point equality, quotient-map equality, choice selector, or ambient completeness theorem, none can be exported by the contracting-step budget packet. □

Closure status for NameCert$_{\text{BanachFixedPointIterationBudget}^{\uparrow}}$.

Constructive story: A BanachFixedPointIterationBudget$^{\uparrow}$ packet is generated from a metric source row, a ContractionMapping self-map row, an initial point, a finite Picard ledger, a contraction-ratio and tail-budget row, a RegSeqRat handoff, a CompleteMetric boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BanachFixedPointIterationBudget}^{\uparrow}}$, seed)

Scope closed: Definition 6273.1 and Definition 6273.2 seed the finite budget surface between Picard iteration and Banach endpoint sealing.

Formal verification: FormalStatus(NameCert$_{\text{BanachFixedPointIterationBudget}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.BanachFixedPointIterationBudgetUp.BanachFixedPointIterationBudgetUp`

Bridge status: none

Not claimed: This chapter does not close selected fixed points, completed Picard endpoints, host fixed-point equality, quotient-map equality, countable choice, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-step budget shrinkage, RegSeqRat tail handoff, complete-metric boundary discipline, transport, replay, provenance, and local naming for BEDC.Derived.BanachFixedPointIterationBu

Chapter 6274

A Concrete Naming Certificate for $\mathsf{CompactCauchyEquicontinuity}^{\uparrow}$

Following Heine–Cantor and Arzela–Ascoli constructive analysis, the $\mathsf{CompactCauchyEquicontinuity}^{\uparrow}$ packet records the finite Cauchy/equicontinuity route behind chapter 9237. It reads compact finite-net data from chapter 129, displayed map rows from chapter 130, regular tolerance readback from chapter 301, dyadic tolerance cells from chapter 291, and the terminal seal from chapter 38. The packet names the finite route used when a compact family has Cauchy-equicontinuity data before any $\mathsf{Real}^{\uparrow}$ consumer reads a completed value.

Definition 6274.1 (Compact Cauchy equicontinuity carrier)**.** *A* $\mathsf{CompactCauchyEquicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, M, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the finite-net centers, cover radii, and source metric observations used by the packet.*
2. *F is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, with each inspected member routed through a displayed graph and pointwise-modulus packet.*
3. *M is the pointwise family-modulus ledger, assigning only displayed center/tolerance requests to local source-radius rows.*
4. *W is the finite window row for the compact-net centers and inspected family members.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying positive dyadic requests, slack comparisons, and radius refinements.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the displayed Cauchy/equicontinuity window into regular rational tolerance data.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after K, F, M, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for compact source, family, pointwise modulus, windows, dyadic tolerance, regular readback, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for every compact-uniform-continuity consumer route through K, F, M, W, D, R, S, H.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactCauchyEquicontinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCauchyEquicontinuity}^{\uparrow}}$ *row.*

The classifier compares packets only through $K, F, M, W, D, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected subcovers, selected limiting functions, quotient stream equality, countable choice, host equicontinuity, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CompactCauchyEquicontinuityUp.CompactCauchyEquicontinuityUp`

Theorem 6274.2 (Compact Cauchy equicontinuity finite route)**.** *For every accepted* CompactCauchyEquicontinuity *carrier $E = (K, F, M, W, D, R, S, H, C, P, N)$, any compact-uniform-continuity consumer that requests a later Cauchy tolerance must first read the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the displayed rows K, F, M, W, D, R, S. The consumer receives a finite-net, pointwise-modulus, regular-tolerance, and real-seal handoff, and it receives no open-cover compactness, selected family limit, quotient stream equality, countable choice, host equicontinuity theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The compact source row K supplies only finite-net centers, cover radii, and source metric observations, while the family row F supplies only the displayed $\mathsf{ContinuousMap}^{\uparrow}$ members available to the packet.

The equicontinuity request is then forced through M, W, D. The row M records the local pointwise-radius ledger, W restricts the request to displayed finite windows, and D carries the dyadic tolerance and slack comparisons that refine the requested budget.

The Cauchy and Real-facing handoff is downstream. The row R repacks the displayed window and dyadic tolerance as a $\mathsf{RegSeqRat}^{\uparrow}$ readback, and S may be consumed only after that readback is present.

Finally, H, C, P, N transport, replay, source, and name the same route. Since no row stores open-cover compactness, a selected family limit, quotient stream equality, countable choice, host equicontinuity, or ambient real completeness, the finite route cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCauchyEquicontinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactCauchyEquicontinuity}^{\uparrow}$ packet is generated from a CompactMetricUp source row, finite ContinuousMapUp family rows, pointwise family-modulus rows, finite windows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactCauchyEquicontinuity}^{\uparrow}}$, seed)

Scope closed: Definition 6274.1 and Definition 6274.2 seed the compact Cauchy/equicontinuity route for compact-uniform-continuity consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactCauchyEquicontinuity}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.CompactCauchyEquicontinuityUp.CompactCauchyEquicontinuityUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, selected limiting functions, quotient stream equality, countable choice, host equicontinuity, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net route discipline, pointwise family-modulus routing, dyadic tolerance refinement, RegSeqRat readback, RealUp seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.CompactCauchyEquicontinuityUp.

Chapter 6275

A Concrete Naming Certificate for $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$ packet records the finite compact-indexed modulus extraction by which a uniformly Cauchy family over a compact metric source supplies one shared tail schedule for Real and Completion consumers. It sits over the compact metric surface of chapter 129, the compact uniform Cauchy route of chapter 6264, the Cauchy-modulus schedule of chapter 292, the finite stream-window surface of chapter 126, the regular rational readback surface of chapter 301, and the terminal Real seal of chapter 38. The packet is a NameCert carrier for a compact-indexed tail schedule; it is not an open-cover compactness theorem, not a selected limit construction, and not a host real equality principle.

Definition 6275.1 (Compact uniform Cauchy modulus carrier)**.** *A* $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, F, M, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact metric index space whose finite cover data may be inspected.*
2. *F is the* $\mathsf{UniformCauchy}^{\uparrow}$ *family row naming the uniformly Cauchy rational stream family over K.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *shared tail schedule chosen uniformly for the displayed compact source and family.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the stream positions read after the shared schedule in M.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the scheduled finite windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after K, F, M, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for compact source, family, modulus schedule, finite window, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-indexed precision request through K, F, M, S, Q, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformCauchy}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, M, S, Q, E, H, C, P, N$. It has no coordinate for a chosen compact cover, an extracted subnet, a selected limit, quotient stream equality, countable choice, host real equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.CompactUniformCauchyModulusUp.CompactUniformCauchyModulusTasteGate single carrier alignment`

Theorem 6275.2 (Compact uniform Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$ *carrier* $U = (K, F, M, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyM}}$ *surface consists exactly of carrier admission, compact metric source exposure, uniformly Cauchy family exposure, shared Cauchy-modulus extraction, finite stream-window exposure, regular rational readback, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must read the displayed route*

$$K, F \longmapsto M \longmapsto S, Q \longmapsto E \longmapsto H, C, P, N$$

before using a compact-indexed uniform tail schedule.

Proof. Project the carrier of Definition 6275.1. The compact source row K and the uniformly Cauchy family row F are the only analytic inputs to the shared schedule.

Read M next. The Cauchy-modulus row records one displayed tail schedule for the whole compact-indexed family, so a consumer cannot replace it by pointwise schedules detached from K and F.

The finite stream-window row S and the regular rational readback row Q then expose the scheduled finite observations. The Real seal E and structural rows H, C, P, N transport, replay, source, and name the same route. Since selected limits, quotient stream equality, countable choice, host real equality, chosen compact covers, and ambient Real completeness are absent from the carrier, none of those data can occur in the local NameCert surface. □

Theorem 6275.3 (Compact finite-net tail extraction)**.** *Let* $U = (K, F, M, S, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$ *carrier. Any finite-net or Real-and-Completion consumer that asks for a compact-indexed uniform tail must read $K, F, M, S, Q, E, H, C, P, N$ in the displayed order. The exported tail is therefore a finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback governed by one shared* $\mathsf{CauchyModulus}^{\uparrow}$ *row over the* $\mathsf{CompactMetric}^{\uparrow}$ *source, not a pointwise family of radii, selected subnet, host limit, quotient stream, countable-choice schedule, or ambient compactness theorem.*

Proof. Begin with the NameCert obligation theorem Definition 6275.2. It fixes the compact source, uniformly Cauchy family, shared schedule, finite window, rational readback, and Real seal as the whole public route.

A finite-net-facing consumer can inspect the compact source only through K and the family only through F. The shared schedule M must be read before any finite window S or readback row Q is available, so the tail cannot be assembled from detached pointwise radius schedules.

For a Real-and-Completion consumer, the seal row E is reached only after the same finite route has been displayed. The replay and provenance rows preserve that route and add no selected subnet, host limit, quotient stream, countable-choice schedule, or ambient compactness theorem. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$ Real or Completion consumer factors through one $\mathsf{CompactMetric}^{\uparrow}$ source row, one $\mathsf{UniformCauchy}^{\uparrow}$ family row, one shared $\mathsf{CauchyModulus}^{\uparrow}$ schedule, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it may use a compact-indexed uniform tail.

Independence witness: compactmetric, uniformcauchy, cauchymodulus, streamname, regseqrat, real: $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately supply compact sources, uniformly Cauchy families, modulus schedules, finite stream windows, rational readback, and terminal Real sealing, while this packet binds them to one compact-indexed uniform tail schedule.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformCauchyModulus}^{\uparrow}$ packet is generated from a CompactMetric source row, a UniformCauchy family row, a shared CauchyModulus schedule, a StreamName finite-window row, a RegSeqRat readback row, a Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6275.1, Definition 6275.2, and Definition 6275.3 seed the compact-indexed uniform Cauchy modulus interface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected limits, quotient stream equality, countable choice, host real equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, uniformly Cauchy family exposure, shared schedule exactness, finite-window readback, Real seal handoff, structural transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.CompactUniformCauchyModulusUp.

Chapter 6276

A Concrete Naming Certificate for MengerCoverCompactness$^{\uparrow}$

Following Menger and Bishop–Bridges constructive compactness, the MengerCoverCompactness$^{\uparrow}$ packet records finite cover-selection compactness as displayed NameCert data. It sits after the compact metric source of chapter 129, the finite-subcover criterion of FiniteSubcoverCriterion$^{\uparrow}$, the effective cover compactness surface of EffectiveCoverCompactness$^{\uparrow}$, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite cover requests and finite subcover witnesses; it does not choose an open-cover subfamily from a host theorem.

Definition 6276.1 (Menger cover compactness carrier)**.** *A* MengerCoverCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, R, B, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row read through* CompactMetric$^{\uparrow}$*.*
2. *R is a finite sequence of cover requests, each naming one inspected finite open-cover window and its tolerance budget.*
3. *B is the* ProbeBundle *finite-subcover ledger, recording for every request in R the selected finite probe rows, membership witnesses, and cover verification.*
4. *W is the* StreamName$^{\uparrow}$ *finite-window readback row used to inspect the cover requests and probe names.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the rational radii and comparison margins attached to the selected probes.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after K, R, B, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the compact metric source, cover requests, finite-subcover ledger, stream windows, regular-rational readback, Real seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each cover request through $K, R, B, W, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* MengerCoverCompactness$^{\uparrow}$, CompactMetric$^{\uparrow}$, FiniteSubcoverCriterion$^{\uparrow}$, EffectiveCoverCompactness$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MengerCoverCompactness}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, R, B, W, Q, E, H, C, P, N$. It contains no coordinate for countable choice, an arbitrary open-cover selector, quotient real equality, a host compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6276.2 (Menger cover compactness NameCert obligations)**.** *For every accepted* MengerCoverCompactnes *carrier $M = (K, R, B, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MengerCoverCompactness}^{\uparrow}}$ *surface consists exactly of compact metric source exposure through K; finite cover-request exposure through R;* ProbeBundle *finite-subcover verification through B; stream-window readback through W; regular-rational readback through Q; terminal Real sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.MengerCoverCompactnessUp.MengerCoverCompactnessCarrier namecert obligations`

Proof. Project the carrier of Definition 6276.1. The compact metric source, request list, and finite-subcover ledger are exactly K, R, B.

The readback rows W, Q, E are downstream of those finite cover rows. They expose the finite stream windows, rational radius data, and terminal real-name seal only after each selected subcover witness has been displayed.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route. Since the carrier has no row for countable choice, host open-cover selection, quotient real equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6276.3 (Menger cover compactness finite cover selection)**.** *Every finite cover-selection consumer of an accepted* $\mathsf{MengerCoverCompactness}^{\uparrow}$ *carrier must read the compact metric source K, then the finite request sequence R, then the* ProbeBundle *finite-subcover row B, before it can inspect the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback rows. The route factors through* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *and* $\mathsf{EffectiveCoverCompactness}^{\uparrow}$ *as finite certificate surfaces, not as a choice-selected open-cover theorem.*

Proof. Begin with an accepted carrier $M = (K, R, B, W, Q, E, H, C, P, N)$. The row K supplies the compact metric source, while R lists the only cover requests visible to the consumer.

For each request, B stores the finite probe rows and verification that they cover the inspected window. Thus the consumer receives finite subcover evidence before any stream, rational, or real readback row is exposed.

Finally W, Q, E, H, C, P, N read, transport, replay, source, and name that finite evidence. The route cannot introduce an arbitrary open-cover selector or countable-choice schedule, because no such coordinate occurs in the carrier. □

Theorem 6276.4 (Menger cover compactness Real-seal nonescape)**.** *No* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MengerCoverCompactness}^{\uparrow}$ *packet can bypass the displayed route*

$$\mathsf{CompactMetric}^{\uparrow},\ R,\ \mathsf{ProbeBundle},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The terminal Real seal E is public only after the compact metric source, finite cover requests, finite-subcover ledger, stream windows, and rational radius readback have all been displayed.

Proof. Read the finite cover-selection theorem Definition 6276.3. It places K, R, B before the stream, rational, and Real rows.

The terminal seal E is not an independent Real object. It is reached only through W and Q, which are themselves attached to the finite request and finite-subcover rows.

Consequently every accepted Real-facing read must pass through the displayed compactness packet and its structural rows H, C, P, N. The excluded host compactness, selected subcover, countable-choice, quotient-equality, and ambient-completeness claims are not exported. □

Falsifiable prediction: Every accepted $\mathsf{MengerCoverCompactness}^{\uparrow}$ Real or Completion consumer exposes the compact metric source, finite cover-request sequence, ProbeBundle finite-subcover row, stream windows, regular-rational readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before using finite cover-selection compactness.

Independence witness: compactmetric, finite-subcover-criterion, effective-cover-compactness, streamname, regseqrat, real: $\mathsf{MengerCoverCompactness}^{\uparrow}$ is not bijective to any listed sibling because this packet binds compact metric source rows, finite cover requests, finite ProbeBundle subcover witnesses, stream windows, rational readback, Real sealing, transport, replay, provenance, and local naming into one cover-selection certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MengerCoverCompactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MengerCoverCompactness}^{\uparrow}$ packet is generated from a CompactMetricUp source row, finite cover requests, ProbeBundle finite-subcover rows, StreamNameUp windows, RegSeqRatUp radius readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MengerCoverCompactness}^{\uparrow}}$, seed)

Scope closed: Definition 6276.1, Definition 6276.2, Definition 6276.3, and Definition 6276.4 seed the finite cover-selection NameCert route for compact metric Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MengerCoverCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, countable-choice subcover selection, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact metric source exposure, finite cover-request exposure, ProbeBundle finite-subcover verification, StreamName readback, RegSeqRat radius readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.MengerCoverCompactnessUp.

Chapter 6277

A Concrete Naming Certificate for $\mathsf{FiniteVolume}^{\uparrow}$

Following LeVeque and Eymard–Gallouet–Herbin, the $\mathsf{FiniteVolume}^{\uparrow}$ packet records conservative finite-mesh balance as BEDC-visible ledger data. It sits over the mesh cells of chapter 3496, the gauge and sum interfaces of chapter 4115 and chapter 1880, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the real-name seal of chapter 38, and the PDE relation surface of chapter 194. The packet names the finite conservation rows inspected by numerical PDE consumers; it does not import a host solution, mesh-limit convergence theorem, weak formulation quotient, solver trace, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6277.1 (Finite-volume carrier)**.** *A* $\mathsf{FiniteVolume}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (M, F, X, B, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *cell-mesh row, carrying finitely many control volumes with their displayed incidence names.*
2. *F is the face-incidence row, pairing each interior face with its two adjacent cells and each boundary face with its boundary tag.*
3. *X is the flux ledger, storing one oriented numerical flux entry for each displayed face incidence and the local stencil rows used to read it.*
4. *B is the boundary ledger, storing boundary flux, source, or trace data only along faces marked boundary by F.*
5. *S is the residual and conservation-balance row, recording for each cell the sum of incoming and outgoing face flux entries together with source and residual rows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the cellwise flux, source, residual, and balance windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare paired face contributions and displayed residual budgets.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, F, X, B, S, R, D have been displayed.*
9. *H records componentwise* hsame *transport for the mesh, incidence, flux, boundary, residual, regular readback, dyadic tolerance, Real seal, replay, provenance, and local naming rows.*

10. *C is the displayed* Cont *replay from a finite cell-balance request through $M, F, X, B, S, R, D, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteVolume}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteVolume}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host PDE solution, unrestricted mesh refinement limit, quotient weak solution, selected trace, hidden solver state, or ambient real completeness theorem.

Lean4 (definition) `BEDC.Derived.FiniteVolumeUp.FiniteVolumeUp`
Lean4 ✓ `BEDC.Derived.FiniteVolumeUp.FiniteVolumeTasteGate single carrier alignment`

Theorem 6277.2 (Finite-volume conservation balance)**.** *For every accepted* $\mathsf{FiniteVolume}^{\uparrow}$ *carrier*

$$V = (M, F, X, B, S, R, D, E, H, C, P, N),$$

the aggregate conservation read over any displayed finite set of cells cancels every interior face flux that is paired by the incidence row F. The visible aggregate balance consists only of boundary-ledger contributions from B, displayed source rows, residual rows from S, and the downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal data. It does not assert a host PDE solution, unrestricted convergence of a mesh family, selected weak trace, quotient equality of approximate solutions, or ambient completeness.*

Proof. Project the carrier of Definition 6277.1. The row F is the only source of face incidence, so every interior face visible to the packet appears with exactly the two adjacent cell orientations recorded by that row.

Read the oriented flux ledger X through the same incidence data. In a cellwise aggregate, the contribution of an interior face is inspected once from each adjacent cell with opposite orientation, so those two displayed ledger entries cancel as a pair. Boundary faces have no second adjacent cell row, hence they remain visible through the boundary ledger B.

The residual and conservation row S then records exactly what remains after the paired interior cancellations: boundary contributions, displayed source rows, and residual rows. The $\mathsf{RegSeqRat}^{\uparrow}$ readback R, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D, and $\mathsf{Real}^{\uparrow}$ seal E are downstream of this balance, while H, C, P, N transport, replay, source, and name the same finite route. No excluded host solution, mesh-limit, quotient, trace, or completeness coordinate is present in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteVolume}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteVolume}^{\uparrow}}$, seed)

Scope closed: Definition 6277.1 and Definition 6277.2 seed the conservative finite-volume packet over mesh cells, face incidence, flux ledgers, boundary rows, residual balances, RegSeqRat readback, dyadic tolerance, RealUp seals, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteVolume}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host PDE solutions, unrestricted mesh-limit convergence, quotient weak-solution equality, selected traces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked mesh admission, face-incidence pairing, flux-ledger transport, boundary-ledger routing, residual-balance exactness, regular readback, dyadic tolerance, Real-seal admission, replay, provenance, and local naming for BEDC.Derived.FiniteVolumeUp.

Constructive story: A $\mathsf{FiniteVolume}^{\uparrow}$ packet is generated from a FinitePartitionMeshUp cell mesh, face incidence rows, oriented flux ledgers, boundary ledgers, residual conservation balances, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6278

A Concrete Naming Certificate for $\mathsf{OrderedCauchyGroup}^{\uparrow}$

Following Bourbaki on ordered topological groups and Bishop-style completion, the $\mathsf{OrderedCauchyGroup}^{\uparrow}$ packet records the finite interface by which an ordered abelian group completion can be read without quotient representatives, countable choice, trichotomy, or an ambient completeness theorem. It sits after the algebraic source of chapter 42, the order surface of chapter 1378, the completion-routing functor of chapter 423, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the constructive order-compatible completion route needed by Phase Real and Completion consumers; it does not claim host quotient equality of Cauchy filters, selected representatives, decidable order, Archimedean completeness, or a public bridge.

Definition 6278.1 (Ordered Cauchy-group carrier)**.** *An* $\mathsf{OrderedCauchyGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, O, M, S, R, F, L, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbGroup}^{\uparrow}$ *source row, naming the group operation, inverse, neutral element, and finite algebraic laws through the accepted abelian-group packet.*
2. *O is the* $\mathsf{Order}^{\uparrow}$ *row on the same source, recording the displayed preorder or order comparisons available to the completion consumer.*
3. *M is the Cauchy-modulus ledger, assigning each requested comparison tolerance to a finite tail window and a group-difference bound.*
4. *S is the source-window row, exposing the finite Cauchy-name observations used by algebraic and order comparisons.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed comparison radii and rational error bounds.*
6. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *route row, carrying the source packet into a completion-facing object while preserving the visible modulus ledger.*
7. *L is the order-compatibility ledger. It records monotonicity of addition, sign reversal under inverse, and tolerance-stable comparison transport before any completed seal is public.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal row reached only after A, O, M, S, R, F, L have been displayed.*

9. *H records componentwise* hsame *transport for algebra, order, modulus, source windows, rational readback, completion route, order-compatibility ledger, seal, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from every ordered-completion request through $A, O, M, S, R, F, L, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{OrderedCauchyGroup}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{OrderedCauchyGroup}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, O, M, S, R, F, L, E, H, C, P, N$. It has no coordinate for a quotient completion, selected Cauchy representative, detached order relation on equivalence classes, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.OrderedCauchyGroupUp.OrderedCauchyGroupTasteGate single carrier alignment`

Theorem 6278.2 (Ordered Cauchy-group NameCert obligations)**.** *For every accepted* $\mathsf{OrderedCauchyGroup}^{\uparrow}$ *carrier*

$$G = (A, O, M, S, R, F, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OrderedCauchyGroup}^{\uparrow}}$ *surface consists exactly of carrier admission for G; abelian-group source exposure through A; order-source exposure through O; Cauchy-modulus exactness through M; finite source-window discipline through S; regular rational readback through R; completion-functor routing through F; order-compatibility accountability through L; terminal seal routing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; local naming through N; and nonescape excluding quotient completions, selected representatives, detached order relations, choice principles, trichotomy, and ambient completeness.*

Proof. Carrier admission is projection from Definition 6278.1. The algebraic and ordered source rows are A and O, and they are the only coordinates from which the consumer can read group operations or comparisons.

The completion-facing rows are ordered. A request first reads the finite modulus ledger M and the source windows S, then obtains rational comparison bounds through R, and only then enters the completion route F.

The order side is bound by L. It records the displayed compatibility of addition, inverse, and tolerance-stable comparison transport before the terminal seal E is exposed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no quotient-completion, selected-representative, detached-order, choice, trichotomy, or ambient-completeness coordinate, the listed obligations exhaust the local certificate surface. □

Theorem 6278.3 (Ordered Cauchy-group ten-field package)**.** *The* $\mathsf{OrderedCauchyGroup}^{\uparrow}$ *certificate instantiates the ten-field roadmap template as follows: traditional target, ordered abelian-group completion with order-compatible operations; BEDC source, the displayed* BHist *route through* $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*; carrier, G; classifier, componentwise comparison of the displayed rows; stability,* hsame *transport through H; ledger, M, S, R, F, L, E; core theorem list, Definition 6278.2 and Definition 6278.4; exactness, exhaustion of the listed rows; standard bridge, none; status, paper seed certificate for* $\mathsf{NameCert}_{\mathsf{OrderedCauchyGroup}^{\uparrow}}$.

Proof. Start with the carrier of Definition 6278.1. The rows A, O, M, S, R, F, L, E provide the source, completion route, order-compatibility ledger, and terminal seal fields.

Apply Definition 6278.2. It supplies classifier stability, ledger exactness, completion routing, order nonescape, replay, provenance, and local naming.

The absence of a bridge row keeps the standard-bridge field empty. The resulting package is therefore a seed certificate for the displayed constructive interface, not a stronger assertion about quotient completions or selected completed elements. □

Theorem 6278.4 (Ordered Cauchy-group order-compatible completion)**.** *Every completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{OrderedCauchyGroup}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{AbGroup}^{\uparrow}, \mathsf{Order}^{\uparrow} \longmapsto M, S, R \longmapsto \mathsf{CauchyCompletionFunctor}^{\uparrow} \longmapsto L \longmapsto E, H, C, P, N.$$

Thus a downstream Phase Real or Completion consumer first reads the abelian-group and order sources, then the Cauchy-modulus ledger, source windows, and regular rational comparison bounds, then the completion-functor route and order-compatibility ledger, and only then the terminal seal and structural rows. The route exports no quotient representative, detached completed order, countable-choice selector, trichotomy, Archimedean completeness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let $G = (A, O, M, S, R, F, L, E, H, C, P, N)$ be an accepted packet. The source rows A and O are the only algebra and order entry points, so every completion read begins with the displayed $\mathsf{AbGroup}^{\uparrow}$ and $\mathsf{Order}^{\uparrow}$ surfaces.

The finite Cauchy information is then forced through M, S, R. These rows provide the tail bounds, inspected source windows, and rational comparison budgets that the completion route can consume.

The row F carries that finite information into the $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ surface, and L records the compatibility of the order with completed addition, inverse, and tolerance-stable comparison transport. The terminal seal E is downstream of both rows.

The structural rows H, C, P, N only transport, replay, source, and name this same path. Since no other carrier coordinate stores a completed representative or a detached order relation, every accepted read factors through the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{OrderedCauchyGroup}^{\uparrow}$ consumer that reaches a completion-facing or $\mathsf{Real}^{\uparrow}$ seal while omitting the AbGroup source row, Order source row, Cauchy-modulus ledger, source-window row, RegSeqRat readback, CauchyCompletionFunctor route, order-compatibility ledger, transport row, replay row, provenance row, or local naming row refutes the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OrderedCauchyGroup}^{\uparrow}}$.

Constructive story: An $\mathsf{OrderedCauchyGroup}^{\uparrow}$ packet is generated from an AbGroupUp source row, an OrderUp source row, a Cauchy-modulus ledger, finite source windows, RegSeqRatUp readback, a CauchyCompletionFunctorUp route, an order-compatibility ledger, a RealUp or completion-facing seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OrderedCauchyGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6278.1, Definition 6278.2, Definition 6278.3, and Definition 6278.4 seed the finite order-compatible completion route from abelian-group and order sources through Cauchy windows, rational readback, completion routing, compatibility ledger, and terminal seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OrderedCauchyGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected Cauchy representatives, detached completed orders, countable choice, trichotomy, Archimedean completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, abelian-group exposure, order-source exposure, Cauchy-modulus exactness, source-window discipline, regular rational readback, completion-functor routing, order-compatibility accountability, terminal seal routing, transport, replay, provenance, and local naming for BEDC.Derived.OrderedCauchyGroupUp.

Chapter 6279

A Concrete Naming Certificate for $\mathsf{RealCompletionWitnessLedger}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RealCompletionWitnessLedger}^{\uparrow}$ packet records the finite witness rows by which StreamName observations, regular rational readback, dyadic tolerance, and a Real seal are read as completion data. It sits over the finite stream interface of chapter 126, the regular rational source of chapter 301, the dyadic tolerance ledger of chapter 291, the nested interval completeness route of chapter 6091, and the terminal real-name seal of chapter 38. The packet is a witness ledger for finite completion reads, not a quotient construction, selected limit, countable-choice schedule, or ambient completeness theorem.

Definition 6279.1 (Real completion witness ledger carrier)**.** *A* $\mathsf{RealCompletionWitnessLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, R, D, K, E, H, T, A, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, carrying the requested windows and the observed stream entries used by the completion read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row assembled from those same finite windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic comparison radii that certify compatibility of the window and readback data.*
4. *K is the nested-interval or Cauchy handoff row, displaying the finite bridge by which the regular readback is admitted as completion-facing data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after S, R, D, K.*
6. *H records componentwise* hsame *transport for the stream windows, regular readback, dyadic tolerance, handoff, Real seal, replay, provenance, and local naming rows.*
7. *T is the displayed* Cont *replay from a finite completion request through S, R, D, K, E, H, P, N.*
8. *A is the provenance and replay ledger, recording which finite windows and tolerance rows were inspected before the seal was consumed.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletionWitnessLedger}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NestedIntervalCompleteness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RealCompletionWitnessLedger}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, a host-selected representative, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RealCompletionWitnessLedgerUp.RealCompletionWitnessLedgerUp`

Theorem 6279.2 (Real completion witness ledger seal)**.** *Every completion-facing* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{RealCompletionWitnessLedger}^{\uparrow}$ *carrier factors through a finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{NestedIntervalCompleteness}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More explicitly, the seal E can be consumed only after the finite window row S, regular readback row R, dyadic tolerance row D, and nested-interval or Cauchy handoff row K have been displayed and transported componentwise. The packet exports no quotient stream equality, selected limit representative, countable-choice schedule, trichotomy, or ambient Real completeness.

Proof. Project the carrier of Definition 6279.1. The first visible data are the finite StreamName windows S and the regular rational readback R assembled from the same observations.

Read the dyadic tolerance row D and the completion handoff row K. These rows certify that the finite windows and regular readback are compatible before any completion-facing seal is available; the handoff may be nested-interval shaped or Cauchy shaped, but in either case it is displayed as a finite row.

The terminal Real seal E is downstream of S, R, D, K, and the rows H, T, A, P, N only transport, replay, source, and name that route. Since the carrier has no quotient, selected representative, choice, trichotomy, or host-completeness coordinate, every exported completion read is exactly the displayed finite witness-ledger seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionWitnessLedger}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCompletionWitnessLedger}^{\uparrow}}$, seed)

Scope closed: Definition 6279.1 and Definition 6279.2 seed the finite StreamName, RegSeqRat, DyadicRatCore, completion-handoff, RealUp seal, transport, replay, provenance, and local naming witness ledger.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCompletionWitnessLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, host-selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked StreamName window admission, RegSeqRat readback, DyadicRatCore tolerance, nested-interval or Cauchy handoff, Real-seal admission, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionWitnessLedgerUp.

Constructive story: A $\mathsf{RealCompletionWitnessLedger}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat regular readback, DyadicRatCore tolerance rows, a nested-interval or Cauchy handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, provenance rows, Pkg sourcing, and a local NameCert row.

Chapter 6280

A Concrete Naming Certificate for $\mathsf{RegularCauchyRealReflection}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers, the $\mathsf{RegularCauchyRealReflection}^{\uparrow}$ packet names the finite route by which a regular rational Cauchy sequence can be read as a Real-facing seal without importing quotient stream equality or host real equality. It sits after the regular rational source of chapter 301, the finite-window surface of chapter 126, the quotient-discipline boundary of chapter 1820, the dyadic tolerance core of chapter 291, and the terminal seal of chapter 38. The packet is a concrete L10 reflection route from classifier data to the public Real seal; it is not an assertion of ambient completeness, a selected representative theorem, or a host-limit construction.

Definition 6280.1 (RegularCauchyRealReflection carrier)**.** *A* $\mathsf{RegularCauchyRealReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, S, E, D, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row naming the regular rational Cauchy sequence whose Real-facing reflection is being inspected.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected prefixes, tail windows, and replay schedule for G.*
3. *E is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row recording exactly the displayed equivalence comparisons admitted for the regular sequence route.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-window row, with dyadic budgets aligned to the regular-Cauchy classifier comparisons named by E.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is visible only after G, S, E, D display the regular source, finite windows, admissible Cauchy-equivalence comparisons, and dyadic tolerance windows.*
6. *H records componentwise* hsame *transport for the regular source, stream windows, equivalence classifier, dyadic tolerance windows, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real-facing reflection request through G, S, E, D, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRealReflection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyRealReflection}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $G, S, E, D, R, H, C, P, N$. It has no coordinate for quotient stream equality, a selected representative of the equivalence class, a host real limit, ambient real equality, countable choice, or an external completeness theorem.

Lean4 ✓ `BEDC.Derived.RegularCauchyRealReflectionUp.RegularCauchyRealReflectionTasteGate single carrier alignment`

Theorem 6280.2 (RegularCauchyRealReflection NameCert obligations)**.** *For every accepted* RegularCauchyRealRe *carrier*

$$M = (G, S, E, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyRealReflection}^{\uparrow}}$ *surface consists exactly of carrier admission for M, regular-Cauchy classifier exposure through G and E, dyadic tolerance-window exactness through D, terminal* $\mathsf{Real}^{\uparrow}$ *seal reflection through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N. The certificate is stable under replay of the same displayed stream windows and tolerance budgets, and it never exports quotient stream equality or host real equality.*

Proof. Project the carrier of Definition 6280.1. The accepted source is the regular rational row G, and the only observable finite data for that source are the windows named by S.

The classifier rows are explicit. The Cauchy-equivalence row E records the admissible comparisons, while the dyadic tolerance row D records the exact tolerance windows used by those comparisons. No extra equality predicate is available outside these rows.

The Real-facing row R is therefore terminal for the displayed route. It can be read only after G, S, E, D have exposed the regular source, finite windows, classifier comparisons, and dyadic tolerances.

The remaining rows do not add analytic content. They transport the same data by H, replay the same route by C, record source accountability by P, and bind the local name by N. Since no row stores quotient stream equality, a selected representative, a host real limit, ambient real equality, countable choice, or external completeness, the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyRealReflection}^{\uparrow}$ reflection factors through one RegSeqRatUp source row, one StreamNameUp finite-window row, one CauchyEquivalenceSetoidUp classifier row, one DyadicRatCoreUp tolerance-window row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, cauchy-equivalence-setoid, dyadicratcore, real: $\mathsf{RegularCauchyRealReflection}^{\uparrow}$ is not bijective to any listed sibling because it packages the regular-Cauchy classifier, finite windows, dyadic tolerance windows, terminal Real seal, transport, replay, provenance, and local NameCert as one reflection certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRealReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRealReflection}^{\uparrow}$ packet is generated from a RegSeqRatUp source row, StreamNameUp finite windows, a CauchyEquivalenceSetoidUp classifier row, DyadicRatCoreUp tolerance windows, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyRealReflection}^{\uparrow}}$, seed)

Scope closed: Definition 6280.1 and Definition 6280.2 seed the finite reflection route from regular rational Cauchy classifier data to the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyRealReflection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, quotient equality, selected representatives, host limits, host real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-Cauchy classifier exposure, dyadic tolerance-window exactness, Real seal reflection, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.RegularCauchyR

Chapter 6281

A Concrete Naming Certificate for $\mathsf{InitialUniformity}^{\uparrow}$

Following Bourbaki on uniform structures and initial uniformities, the $\mathsf{InitialUniformity}^{\uparrow}$ packet names the finite pullback-uniformity route determined by a displayed map into a target uniform space. It sits after the Real-induced uniformity of chapter 1624, the abstract uniform entourage basis of chapter 2331, and the completion-facing handoff of chapter 3560. The packet records only source rows, target entourages, displayed maps, pulled-back entourage rows, transport, replay, provenance, and local naming; it is not an ambient topology, quotient uniformity, selected representative principle, open-cover compactness theorem, or countable-choice device.

Definition 6281.1 (InitialUniformity carrier)**.** *An* $\mathsf{InitialUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S, T, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source carrier row. It records the points or names on which the pulled-back uniformity is being inspected.*
2. *T is the target uniformity row. It exposes the finite target-entourage requests admitted by the target* $\mathsf{UniformSpace}^{\uparrow}$ *or by a basis packet such as* $\mathsf{UniformEntourageBasis}^{\uparrow}$*.*
3. *F is the displayed map row. It names the finite graph, readback, or continuation by which a source request is sent into the target carrier before an entourage is tested.*
4. *E is the pulled-back entourage row. Each entry records a target entourage from T together with the displayed source-pair request whose two F-images are tested against that target entourage.*
5. *H records componentwise* hsame *transport for S, T, F, E, C, P, N.*
6. *C records displayed* Cont *replay from a source-pair request through F and then through the target-entourage read in T.*
7. *P is the* Pkg *provenance over* $\mathsf{InitialUniformity}^{\uparrow}$*,* $\mathsf{UniformSpace}^{\uparrow}$*,* $\mathsf{UniformEntourageBasis}^{\uparrow}$*,* $\mathsf{UniformSpaceCompletio}$ $\mathsf{RealUniformStructure}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{InitialUniformity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, T, F, E, H, C, P, N. It has no coordinate for an ambient topology on S, a quotient uniformity, a selected representative family, a host continuity theorem, open-cover compactness, countable choice, or external completeness.

Theorem 6281.2 (InitialUniformity pullback entourage stability)**.** *Let $I = (S, T, F, E, H, C, P, N)$ be an accepted* $\mathsf{InitialUniformity}^{\uparrow}$ *carrier. If two displayed source-pair requests are componentwise* hsame *through H, and the target-entourage read is replayed through the displayed* Cont *route C, then the pulled-back entourage row E returns the same accepted pullback read. Thus pullback-entourage stability is internal to the displayed source row, target uniformity row, map row, pulled-back entourage row, transport row, and replay row.*

Proof. Project the carrier of Definition 6281.1. A pullback-entourage read begins with a source-pair request in S, sends both components through the displayed map row F, and then tests the resulting target pair against the target-entourage row T.

Use componentwise hsame transport in H on the source request, the two displayed map reads, and the target-entourage request. These transports preserve the visible coordinates of the packet, so the transported read still lands in the same target-entourage row.

Replay the transported request through C. Since C records only the route from source-pair data through F into T, the replay reaches the same pulled-back row E and cannot introduce an ambient topology, quotient uniformity, selected representative, or choice coordinate. □

Theorem 6281.3 (InitialUniformity NameCert obligations)**.** *For the carrier of Definition 6281.1, the local* $\mathsf{NameCert}_{\mathsf{InitialUniformity}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier exposure for $I = (S, T, F, E, H, C, P, N)$;*
2. *target-entourage exposure through the target uniformity row T;*
3. *map compatibility requiring every pulled-back request in E to read the displayed map row F before target-entourage testing;*
4. *pulled-back entourage stability under componentwise* hsame *transport and displayed* Cont *replay as in Definition 6281.2;*
5. *refusal of ambient topology on S, quotient uniformity, selected representatives, host continuity, open-cover compactness, countable choice, and external completion principles.*

Lean4 ✓ `BEDC.Derived.InitialUniformityUp.InitialUniformityCarrier namecert obligations`

Proof. Carrier exposure is the projection of the finite tuple $I = (S, T, F, E, H, C, P, N)$. The target-entourage exposure is the projection of T, and map compatibility is the requirement that every entry of E is read only after its two source components have been sent through F.

The stability obligation is exactly Definition 6281.2. It binds source-pair transport, target-entourage transport, and continuation replay to the same pulled-back entourage row.

The refusal obligation follows from the carrier inventory. No row stores an ambient topology, quotient uniformity, selected representative family, host continuity theorem, open-cover compactness proof, countable-choice selector, or external completion object, so the local certificate exports only the finite pullback-uniformity route. □

Falsifiable prediction: Every accepted $\mathsf{InitialUniformity}^{\uparrow}$ pullback-entourage read factors through one source row, one target uniformity row, one displayed map row, one pulled-back entourage row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real-uniform-structure, uniform-entourage-basis, uniform-space-completion: $\mathsf{InitialUniformity}^{\uparrow}$ is not bijective to any listed sibling because it packages the source carrier, target uniformity, displayed map, pulled-back entourage row, transport, replay, provenance, and local NameCert as one pullback-uniformity certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{InitialUniformity}^{\uparrow}}$.

Constructive story: An $\mathsf{InitialUniformity}^{\uparrow}$ packet is generated from a source carrier row, a target uniformity row, a displayed map row, pulled-back entourage rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InitialUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6281.1, Definition 6281.2, and Definition 6281.3 seed the finite pullback-uniformity boundary for target-entourage consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InitialUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient topology, quotient uniformity, selected representatives, host continuity, open-cover compactness, countable choice, external completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, target-entourage exposure, map compatibility, pulled-back entourage stability, transport, replay, provenance, local naming, and nonescape for $\mathsf{InitialUniformity}^{\uparrow}$.

Chapter 6282

A Concrete Naming Certificate for $\mathsf{UniformCompletionReflector}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and completion reflectors, the $\mathsf{UniformCompletionReflector}^{\uparrow}$ packet names the finite BEDC surface by which a displayed uniform source is sent to a completion target through certified countable names and regular Cauchy data. It sits after the quotient-discipline boundary of chapter 1820, the completion carrier of chapter 95, the uniform source of chapter 339, the uniform Cauchy filter route of chapter 5117, and the Real-facing uniform surface of chapter 1624. The packet is a NameCert interface for the reflector route; it is not a host quotient completion, not a choice-selected limit, and not an ambient real completeness theorem.

Definition 6282.1 (UniformCompletionReflector carrier)**.** *A* $\mathsf{UniformCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, W, Y, J, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the uniform source row, naming the uniform-space carrier, entourage basis, and separatedness boundary inspected by the reflector.*
2. *W is the Cauchy filter or finite-window row, recording the certified countable names, regular Cauchy windows, and tolerance comparisons admitted from X.*
3. *Y is the completion target row, displaying the completed uniform carrier only through the completion data certified by W.*
4. *J is the dense embedding row from X into Y, including the finite image windows and density witnesses visible to downstream consumers.*
5. *Q is the universal arrow row: every displayed uniformly continuous map from X into a complete separated target factors through the same Y, J surface by a unique displayed route.*
6. *H records componentwise* hsame *transport for the source, Cauchy window, target, dense embedding, universal arrow, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion-reflector request through X, W, Y, J, Q, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{UniformCompletionReflector}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformlyCauchyFilter}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, W, Y, J, Q, H, C, P, N$. It has no coordinate for quotient completion objects, selected Cauchy representatives, countable choice, a host limit operator, ambient equality on completed points, or an untracked universal map.

Lean4 ✓ `BEDC.Derived.UniformCompletionReflectorUp.UniformCompletionReflectorTasteGate single carrier alignment`

Theorem 6282.2 (UniformCompletionReflector NameCert obligations)**.** *For every accepted* UniformCompletionRef *carrier*

$$U = (X, W, Y, J, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCompletionReflector}^{\uparrow}}$ *surface consists exactly of uniform source admission through X, certified Cauchy-window readback through W, completion-target display through Y, dense embedding through J, universal arrow exactness through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N. The certificate therefore exposes the same finite route to completion consumers, Real-facing consumers, and countable-name consumers without exporting quotient completion equality or selected limits.*

Lean4 ✓ `BEDC.Derived.UniformCompletionReflectorUp.UniformCompletionReflectorNameCertObligations`

Proof. Project the carrier of Definition 6282.1. The source row X fixes the uniform object that can be inspected, while W records the only Cauchy filter or regular-window evidence available to the reflector.

The completion target and dense embedding rows are downstream of those inputs. Thus Y and J can be read only after the source and Cauchy-window rows have been displayed, and neither row carries a host quotient or selected representative.

The universal arrow row Q is part of the same packet. Any factorization read must use the displayed Y, J route and cannot replace it with an ambient completion object or a choice-selected limit.

Finally H, C, P, N transport, replay, source, and name the same rows componentwise. Since the carrier has no additional equality, selector, or host-limit coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 6282.3 (UniformCompletionReflector universal arrow)**.** *Every public universal-arrow read exported by an accepted* $\mathsf{UniformCompletionReflector}^{\uparrow}$ *carrier factors through the displayed source row X, Cauchy-window row W, completion target Y, dense embedding J, and universal row Q. A consumer may therefore replay the reflector property only as a finite route through H, C, P, N; it receives no host quotient completion, selected Cauchy representative, countable-choice selector, or ambient extension theorem outside the packet.*

Proof. Start from Definition 6282.2. It places the universal row Q after the uniform source, Cauchy-window, target, and dense-embedding rows.

The factorization route is consequently displayed. A consumer can inspect the uniformly continuous source map only through X and W, then read its extension through the public Y, J, Q rows.

Transport and replay preserve that order. The rows H, C, P, N move the same finite packet through classifier equivalence, replay the same route, record provenance, and bind the local name, so no endpoint can escape into an evidence-free completion or an untracked universal map. □

Falsifiable prediction: Any claimed $\mathsf{UniformCompletionReflector}^{\uparrow}$ universal-arrow read that reaches a completed target without the displayed uniform source row, Cauchy-window row, dense embedding row, and universal-arrow row refutes the carrier.

Independence witness: uniformspace, uniformly-cauchy-filter, cauchy-equivalence-setoid, completion, real-uniform-structure: $\mathsf{UniformCompletionReflector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source uniformity, Cauchy windows, a completion target, dense embedding, universal arrow, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCompletionReflector}^{\uparrow}$ packet is generated from a uniform source row, certified Cauchy-window row, completion target row, dense embedding row, universal-arrow row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6282.1, Definition 6282.2, and Definition 6282.3 seed the finite reflector route from uniform sources and Cauchy windows to completion targets and universal arrows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient uniform completion, quotient equality, selected representatives, countable choice, host limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-window readback, dense embedding exactness, universal-arrow exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.UniformCompletionReflectorU

Chapter 6283

A Concrete Naming Certificate for $\mathsf{RealCompletionAdjoint}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealCompletionAdjoint}^{\uparrow}$ packet records the finite universal-property surface by which regular rational Cauchy data enters the Real-facing completion seal and by which Real-facing maps are read back as regular-Cauchy extensions. It sits over the regular rational source of chapter 301, the Real seal of chapter 38, the finite reflection route of chapter 6280, and the adjacent Bishop completion-adjoint packet of chapter 6057. The certificate is a displayed adjoint boundary, not a quotient-completion theorem, selected-limit construction, or host equality principle.

Definition 6283.1 (Real completion adjoint carrier)**.** *A* $\mathsf{RealCompletionAdjoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, S, Q, R, E, U, X, K, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense-unit row naming the finite unit access from rational data into the completion-facing route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by every unit, reflection, and extension read.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy source row.*
4. *R is the* $\mathsf{RegularCauchyRealReflection}^{\uparrow}$ *row that exposes the route from Q and S to the Real-facing seal.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after D, S, Q, R have been projected.*
6. *U is the extension row recording the finite continuation by which a Real-facing target reads a regular-Cauchy source through the unit and reflection rows.*
7. *X is the uniqueness row: two displayed extensions agreeing on the dense-unit and regular-Cauchy source rows are identified only by componentwise certificate data.*
8. *K records local compatibility between the dense-unit row, the reflection row, the extension row, and the uniqueness row.*
9. *H records componentwise* hsame *transport for $D, S, Q, R, E, U, X, K, C, P, N$.*
10. *C records displayed* Cont *replay of the route*

$$D, S, Q \longmapsto R \longmapsto E \longmapsto U, X, K, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{RealCompletionAdjoint}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyRealReflection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionAdjoint}^{\uparrow}}$ *row.*

The accepted carrier is exactly the displayed packet A. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealCompletionAdjointUp.RealCompletionAdjointTasteGate single carrier alignment`

Theorem 6283.2 (Real completion adjoint NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionAdjoint}^{\uparrow}$ *carrier $A = (D, S, Q, R, E, U, X, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionAdjoint}^{\uparrow}}$ *obligations are exhausted by carrier admission for the dense unit, finite stream windows, regular-Cauchy source, Real reflection route, terminal Real seal, extension row, uniqueness row, local compatibility, transport, replay, provenance, and local naming rows. No obligation may call on quotient stream equality, a selected representative, host real equality, countable choice, trichotomy, open-cover compactness, ambient Real completeness, or an external adjunction theorem.*

Proof. Project the carrier of Definition 6283.1. The visible analytic rows are D, S, Q, R, E, U, X, K, and the visible structural rows are H, C, P, N.

Read the source side first. The dense-unit row D and finite windows S expose the rational access data, while Q supplies the regular-Cauchy source. The reflection row R is then the only route from that source to the terminal Real seal E.

Read the target side next. The extension row U consumes the same displayed unit and reflection route, and the uniqueness row X compares two such extensions only through componentwise displayed data. The compatibility row K records that the unit, reflection, extension, and uniqueness rows share the same finite source route.

Finally transport and replay by H and C, and bind provenance and naming by P, N. Since no excluded analytic coordinate appears in the carrier, the local certificate has no remaining place to import one. □

Theorem 6283.3 (Real completion adjoint reflection)**.** *Let $A = (D, S, Q, R, E, U, X, K, H, C, P, N)$ be an accepted* $\mathsf{RealCompletionAdjoint}^{\uparrow}$ *carrier. Every Real-facing read exported by A factors through the displayed finite route*

$$D, S, Q \longmapsto R \longmapsto E.$$

The extension row U and uniqueness row X may replay this route, but they cannot bypass the $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, or the* $\mathsf{RegularCauchyRealReflection}^{\uparrow}$ *reflection row.*

Proof. Start with the source projection. The carrier exposes the dense unit, finite windows, and regular-Cauchy source as D, S, Q, so any Real-facing read has an explicit finite source spine.

Apply the reflection row R. By construction it is the only row that turns the regular-Cauchy source and finite windows into a terminal $\mathsf{Real}^{\uparrow}$ seal. The seal row E is therefore downstream of D, S, Q, R.

Now inspect U and X. The extension row reads the same reflected source, and the uniqueness row compares extensions only after that read has occurred. Componentwise transport, replay, provenance, and local naming preserve this order, so no accepted route can jump directly to the Real seal. □

Theorem 6283.4 (Real completion adjoint uniqueness)**.** *Let* $A = (D, S, Q, R, E, U, X, K, H, C, P, N)$ *and* $A' = (D', S', Q', R', E', U', X', K', H', C', P', N')$ *be accepted* $\mathsf{RealCompletionAdjoint}^{\uparrow}$ *carriers. If the dense-unit, finite-window, regular-Cauchy source, reflection, Real seal, extension, compatibility, transport, replay, provenance, and local naming rows are componentwise* hsame*, then the uniqueness rows* X *and* X' *expose the same completion-adjoint comparison. The comparison is certificate-local and introduces no quotient stream equality, selected limit, host real equality, choice schedule, or ambient completeness row.*

Proof. Project both carriers and match the source rows. The componentwise hsame assumptions identify the dense unit, finite windows, regular-Cauchy source, reflection route, and Real seal as displayed certificate data.

Match the extension rows next. Since U and U' read the same reflected source route, their comparison is already constrained by the displayed rows D, S, Q, R, E and their primed counterparts.

The uniqueness rows X and X' therefore have only one local comparison surface: the componentwise certificate comparison replayed through K, H, C, P, N and K', H', C', P', N'. Because neither carrier contains an excluded analytic row, the uniqueness comparison remains internal to the NameCert packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionAdjoint}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionAdjoint}^{\uparrow}$ packet is generated from dense-unit access, finite StreamName windows, a RegSeqRat source, a RegularCauchyRealReflection route, a Real seal, extension and uniqueness rows, local compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCompletionAdjoint}^{\uparrow}}$, seed)

Scope closed: Definition 6283.1, Definition 6283.2, Definition 6283.3, and Definition 6283.4 seed the completion-adjoint packet over regular-Cauchy source data and the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCompletionAdjoint}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RealCompletionAdjointUp.RealCompletionAdjointTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected completed limits, host real equality, countable choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflection factorization, uniqueness comparison, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionAdjointUp.

Chapter 6284

A Concrete Naming Certificate for $\mathsf{UnifiedEpistemicObject}^{\uparrow}$

The $\mathsf{UnifiedEpistemicObject}^{\uparrow}$ packet realizes the unified closure pattern of section 9462.20 as finite NameCert data. It gathers generated material, classifier surface, certificate rows, ledger accounting, theorem-DNA roles, hardening profile, and scope seal into one auditable object. The packet sits beside the classifier-novelty ledger of chapter 6241, the scoped explanation ledger of chapter 6249, and the theorem-DNA score surface of chapter 6243; it does not claim positive discovery without a later TasteGate witness.

Definition 6284.1 (Unified epistemic object carrier)**.** *A* $\mathsf{UnifiedEpistemicObject}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (G, R, C, N, L, D, F, O, T, H, K, P, M)$$

with the following displayed rows:

1. *G is the generated-material row, covering observed material, proof traces, learned traces, theorem candidates, or intervention records.*
2. *R is the record row that fixes the local source scope and replayable material boundary.*
3. *C is the classifier row for the stated source scope.*
4. *N is the certificate row, carrying the local NameCert or Tensor NameCert data for C.*
5. *L is the ledger row recording residue from identification, compression, projection, thresholding, semantic assignment, verification, intervention, and scope refusal.*
6. *D is the theorem-DNA row recording role-complete loci for the object.*
7. *F is the hardening-profile row, recording which loci are hardened, which remain ledger-only, and which backend boundary is being used.*
8. *O is the scope-seal row, naming source scope, target scope, claim kind, not-claimed boundary, and closure route.*
9. *T is the classifier-nonescape row: every accepted classifier read must pass through G, R, C, N, L, D, F, O.*
10. *H records componentwise* hsame *transport for all rows.*
11. *K records displayed* Cont *replay from generated material through classifier, certificate, ledger, DNA, hardening, and seal rows.*

12. *P is the* Pkg *provenance over* $\mathsf{UnifiedEpistemicObject}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

13. *M is the local* $\mathsf{NameCert}_{\mathsf{UnifiedEpistemicObject}^{\uparrow}}$ *row.*

The accepted carrier has no coordinate for a bare classifier claim, an unledgered hardening claim, a positive-discovery verdict, a Nontrivial instance, a FieldFaithful instance, or a TasteGate result.

Theorem 6284.2 (Unified epistemic object NameCert obligations)**.** *For every accepted* $\mathsf{UnifiedEpistemicObject}^{\uparrow}$ *carrier* $U = (G, R, C, N, L, D, F, O, T, H, K, P, M)$*, the local* $\mathsf{NameCert}_{\mathsf{UnifiedEpistemicObject}^{\uparrow}}$ *obligations are exhausted by generated material, record scope, classifier, certificate, ledger, theorem-DNA, hardening-profile, scope-seal, classifier-nonescape, transport, replay, provenance, and local naming rows. In particular, the carrier does not certify positive discovery, Nontriviality, or FieldFaithfulness merely by packaging the rows.*

Proof. Project the carrier of Definition 6284.1. The material and record rows G, R determine the source boundary, and the classifier row C is readable only relative to that boundary.

Read the certificate and ledger rows next. The row N records the certificate surface for C, while L records the residue that prevents classifier assertions from escaping their declared accounting surface.

The theorem-DNA, hardening, and seal rows then place the object in its role, backend, and scope boundaries. The nonescape row T says that classifier reads must pass through all of these rows before any public claim can be exported.

The remaining structural rows H, K, P, M transport, replay, account for provenance, and name the same packet. None of them supplies a TasteGate verdict, Nontrivial instance, FieldFaithful instance, or positive-discovery result, so those obligations remain outside this carrier. □

Theorem 6284.3 (Unified epistemic object classifier nonescape)**.** *Let* $U = (G, R, C, N, L, D, F, O, T, H, K, P, M)$ *be an accepted* $\mathsf{UnifiedEpistemicObject}^{\uparrow}$ *carrier. Every classifier-facing read exported by* U *factors through*

$$G, R \longmapsto C \longmapsto N, L, D, F, O \longmapsto T, H, K, P, M.$$

Consequently a downstream consumer cannot read a bare classifier, unledgered verification claim, unsealed theorem-DNA packet, or positive-discovery verdict from the carrier.

Proof. Start with the generated-material and record rows. They fix the local source scope before a classifier can be read.

Apply the classifier and certificate rows. The classifier row C is named by N, and the ledger row L records residue from the relevant source and semantic operations.

Use the theorem-DNA, hardening-profile, and scope-seal rows. They bind role completeness, backend exposure, and public claim scope before any classifier-facing output may leave the packet.

Finally apply the classifier-nonescape row T and replay through H, K, P, M. Since the carrier has no row for a bare classifier, unledgered hardening claim, unsealed DNA packet, or TasteGate verdict, none of those objects can be exported by an accepted read. □

Falsifiable prediction: A downstream classifier report that reads a $\mathsf{UnifiedEpistemicObject}^{\uparrow}$ classifier without generated material, record scope, certificate, ledger, theorem-DNA, hardening profile, and scope seal refutes the classifier-nonescape row.

Independence witness: classifier-novelty-ledger, scoped-explanation-ledger, theorem-dna-score, hard-certificate-layer, audit-axis-separation: none is bijective to $\mathsf{UnifiedEpistemicObject}^{\uparrow}$ because

each sibling contributes only part of the generated-material, classifier, certificate, ledger, theorem-DNA, hardening-profile, scope-seal, nonescape, transport, replay, provenance, and local naming packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UnifiedEpistemicObject}^{\uparrow}}$.

Constructive story: A $\mathsf{UnifiedEpistemicObject}^{\uparrow}$ packet is generated from material, record, classifier, certificate, ledger, theorem-DNA, hardening-profile, scope-seal, classifier-nonescape, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UnifiedEpistemicObject}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6284.1, Definition 6284.2, and Definition 6284.3 seed the finite unified epistemic object packet without a discovery verdict.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UnifiedEpistemicObject}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close positive discovery, Nontriviality, FieldFaithfulness, TasteGate acceptance, Lean verification, bridge checking, or any classifier shift beyond the displayed carrier rows.

Upgrade path: Obligation closure requires checked carrier admission, classifier nonescape, ledger closure, theorem-DNA compatibility, hardening-profile accounting, scope-seal replay, and later TasteGate work for Nontrivial and FieldFaithful instances.

Chapter 6285

A Concrete Naming Certificate for $\mathsf{AlexanderSubbaseTheorem}^{\uparrow}$

Following Alexander and Kelley, the $\mathsf{AlexanderSubbaseTheorem}^{\uparrow}$ packet records a finite-subbase compactness route as BEDC naming data. It sits next to the compact metric finite-net surface of chapter 129, the finite-product compactness route of **??**, and the finite-subcover criterion of chapter 3503. The packet names only displayed subbase rows, finite obstruction ledgers, transport, replay, provenance, and local naming; it does not assert full choice-based compactness, arbitrary open-cover compactness, unrestricted Tychonoff compactness, quotient equality of covers, or a host subcover selector.

Definition 6285.1 (AlexanderSubbaseTheorem carrier)**.** *An* $\mathsf{AlexanderSubbaseTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, S, F, U, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the compactness-facing source row, read through the same finite-net discipline consumed by* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$*.*
2. *S is the subbase row, recording the named subbasic opens available to the packet.*
3. *F is the finite subbase obstruction ledger, listing the finite subfamilies inspected before a cover-facing conclusion is exposed.*
4. *U is the finite cover-read row obtained from the displayed subbase ledger rather than from an arbitrary open cover.*
5. *B is the compact-product boundary row that may hand the packet to finite* $\mathsf{TychonoffFiniteProduct}^{\uparrow}$ *consumers.*
6. *H records componentwise* hsame *transport for source, subbase, finite obstruction, finite cover, product-boundary, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the source row through subbase rows, finite obstruction checks, finite cover reads, product-boundary handoff, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{AlexanderSubbaseTheorem}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{TychonoffFiniteProduct}^{\uparrow}$*,* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AlexanderSubbaseTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, F, U, B, H, C, P, N$. It has no coordinate for a choice-selected ultrafilter, arbitrary open-cover compactness, unrestricted product compactness, quotient equality of cover families, or a host finite-subcover operation.

Theorem 6285.2 (AlexanderSubbaseTheorem NameCert obligations)**.** *For every accepted* AlexanderSubbaseTheor *carrier $A = (X, S, F, U, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlexanderSubbaseTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission, subbase exposure through S, finite obstruction exactness through F, finite cover-read exactness through U, finite product-boundary handoff through B, componentwise transport through H, displayed replay through C, provenance through P, local naming through N, and nonescape from full choice, arbitrary open-cover compactness, unrestricted Tychonoff compactness, quotient cover equality, and host subcover selection.*

Lean4 ✓ `BEDC.Derived.AlexanderSubbaseTheoremUp.AlexanderSubbaseTheoremCarrier namecert obligations`

Proof. Project the carrier of Definition 6285.1. The only compactness-facing source is X, the only subbase data are in S, and the only finite inspection rows are F and U.

The finite-product handoff is the displayed row B. It can be consumed by the finite product compactness route of **??**, but it does not add an unrestricted product theorem or a choice-selected product point.

Transport, replay, provenance, and local naming are exactly H, C, P, N. Since the carrier has no coordinate for full choice, arbitrary open-cover compactness, unrestricted Tychonoff compactness, quotient cover equality, or a host subcover selector, none of those objects can become a local NameCert obligation. □

Theorem 6285.3 (AlexanderSubbaseTheorem finite-subcover route)**.** *Every compactness-facing read from an accepted* $\mathsf{AlexanderSubbaseTheorem}^{\uparrow}$ *packet must display the source row X, the subbase row S, the finite obstruction ledger F, and the finite cover-read row U before any product-boundary handoff B or compactness consumer is exposed. The route factors through the finite-subcover criterion of chapter 3503, not through arbitrary open-cover compactness.*

Proof. Begin with the carrier in Definition 6285.1. Its compactness route is ordered by the displayed rows $X, S, F, U, B, H, C, P, N$.

Apply the finite-subcover criterion of chapter 3503. The cover-facing read therefore consumes a finite criterion row before a compactness consumer can inspect the result.

Use Definition 6285.2 for nonescape. The packet has no arbitrary open-cover row, no host subcover operation, and no full-choice coordinate, so the exported route is the displayed finite-subbase route through X, S, F, U and its structural rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{AlexanderSubbaseTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{AlexanderSubbaseTheorem}^{\uparrow}$ packet is generated from a compactness-facing source row, a displayed subbase row, a finite obstruction ledger, a finite cover-read row, a finite product-boundary handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AlexanderSubbaseTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 6285.1, Definition 6285.2, and Definition 6285.3 seed the finite-subbase compactness packet over compact metric, finite-product compactness, and finite-subcover criterion sibling rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AlexanderSubbaseTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full choice-based compactness, arbitrary open-cover compactness, unrestricted Tychonoff compactness, quotient equality of cover families, host finite-subcover selection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subbase exposure, finite obstruction exactness, finite cover-read exactness, finite product-boundary handoff, transport, replay, provenance, and local naming for BEDC.Derived.AlexanderSubbaseTheoremUp.

Chapter 6286

A Concrete Naming Certificate for $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$ packet records the finite uniform-Cauchy completion route by which regular rational names, finite windows, and dyadic tolerances are read before any Real or Completion consumer may inspect a completed endpoint. It sits beside the uniform-Cauchy packet of chapter 3618, the window and readback surfaces of chapter 126 and chapter 301, the tolerance core of chapter 291, the terminal Real seal of chapter 38, the Cauchy sequence space of chapter 406, and the theorem-level completion handoff of chapter 3484. The packet is a displayed NameCert interface for Bishop-style uniform Cauchy completion, not a quotient completion object, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 6286.1 (Bishop uniform-Cauchy completion carrier)**.** *A* $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, W, R, D, E, S, B, H, C, P, N)$$

with the following displayed rows:

1. *A is the uniform-Cauchy source row, naming the inspected uniform family, entourage request, and finite tail schedule admitted from the* $\mathsf{UniformCauchyCompletion}^{\uparrow}$ *surface.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row whose finite observations open the source and tail data.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that records the dyadic precision at which W and R are compared.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the source, window, readback, and tolerance rows have been displayed.*
6. *S is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff row recording how the same windowed readback is consumed by the space of Cauchy names.*
7. *B is the* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *handoff row recording the theorem-level completion route generated from the displayed uniform-Cauchy source.*
8. *H records componentwise* hsame *transport for $A, W, R, D, E, S, B, C, P, N$.*

9. *C records displayed* Cont *replay of the route from the source row through the window, readback, tolerance, Real seal, CauchySequenceSpace handoff, and BishopCompletionTheorem handoff rows.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$, $\mathsf{UniformCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{BishopCompletionTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient names, selected representatives, a limit selector, countable choice, host real equality, hidden completion points, or ambient Real completeness.

Theorem 6286.2 (Bishop uniform-Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$ *carrier* $U = (A, W, R, D, E, S, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyCompletion}^{\uparrow}}$ *surface consists exactly of the uniform-Cauchy source row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal row,* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff,* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion consumer of the packet must expose those rows before it may read a Real seal or completion-facing endpoint.*

Lean4 ✓ `BEDC.Derived.BishopUniformCauchyCompletionUp.BishopUniformCauchyCompletionCarrier namecert obligations`

Proof. Project the carrier of Definition 6286.1. The only analytic rows are A, W, R, D, E, S, B, and the only structural rows are H, C, P, N.

The source row A supplies the uniform-Cauchy request, but it is not itself a completed point. The finite window row W, readback row R, and dyadic tolerance row D are the displayed data that make the source inspectable.

The endpoint rows are downstream of those displays. The Real seal E, the CauchySequenceSpace handoff S, and the BishopCompletionTheorem handoff B can be read only after A, W, R, D have been projected.

Finally, H, C, P, N transport, replay, source, and name the same rows componentwise. Since the carrier contains no quotient, selector, choice schedule, host equality, or ambient completeness coordinate, the listed rows exhaust the local certificate. □

Theorem 6286.3 (Bishop uniform-Cauchy completion Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, *or* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *consumer read exported by an accepted* $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$ *carrier factors through the displayed finite route*

$$\mathsf{UniformCauchyCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}$$

before it reaches the Real seal row E, the CauchySequenceSpace handoff row S, or the BishopCompletionTheorem handoff row B. The route exports no quotient completion, selected limit, countable-choice schedule, host real equality, or ambient completeness witness.

Proof. Read the source side first. The accepted carrier displays A as the uniform-Cauchy source and then exposes it through the finite window, regular readback, and dyadic tolerance rows W, R, D.

The seal and completion rows are therefore not primitive endpoints. The row E is a Real-facing seal read after A, W, R, D, while S and B record the sibling CauchySequenceSpace and BishopCompletionTheorem handoffs over the same displayed data.

The structural rows H, C, P, N preserve that order under transport and replay. Thus every downstream read factors through the named finite route and cannot obtain any excluded completion mechanism from the packet. □

Falsifiable prediction: A claimed $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, or $\mathsf{BishopCompletionTheorem}^{\uparrow}$ without displaying the $\mathsf{UniformCauchyCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows refutes the carrier.

Independence witness: uniform-cauchy-completion, streamname, regseqrat, dyadicratcore, real, cauchysequencespace, bishop-completion-theorem: no listed sibling is bijective to $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$ because the packet jointly carries the uniform-Cauchy source, finite windows, regular readback, dyadic tolerance, Real seal, CauchySequenceSpace handoff, BishopCompletionTheorem handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$ packet is generated from a uniform-Cauchy source row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, Real seal rows, CauchySequenceSpace and BishopCompletionTheorem handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopUniformCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6286.1, Definition 6286.2, and Definition 6286.3 seed the finite Bishop uniform-Cauchy completion route from displayed source rows through windows, readbacks, tolerances, Real seal, CauchySequenceSpace handoff, and BishopCompletionTheorem handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{BishopUniformCauchyCompletion}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, source-window readback, dyadic tolerance exactness, Real seal nonescape, CauchySequenceSpace handoff, BishopCompletionTheorem handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopUniformCauchyCompletionUp.

Chapter 6287

A Concrete Naming Certificate for $\mathsf{PointedCompleteMetric}^{\uparrow}$

Following Bishop and Bridges on complete metric spaces with a chosen origin, the $\mathsf{PointedCompleteMetric}^{\uparrow}$ packet records a metric carrier, a completion service, and a base-pointed Cauchy request route as one finite BEDC NameCert surface. It sits next to the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, the $\mathsf{CompleteMetric}^{\uparrow}$ completion row of chapter 128, the $\mathsf{Real}^{\uparrow}$ distance seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ rational schedule of chapter 301, and the $\mathsf{StreamName}^{\uparrow}$ window ledger of chapter 126. The packet names the rooted complete-metric route without importing a selected host point, quotient equality on completed points, open-cover compactness, countable choice, or an ambient real-completeness theorem.

Definition 6287.1 (PointedCompleteMetric carrier)**.** *A* $\mathsf{PointedCompleteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, C, B, R, H, K, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *carrier row, including the metric distance, classifier, and local comparison data available to rooted Cauchy consumers.*
2. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-limit row, exposing the completion service only for regular Cauchy requests already displayed over M.*
3. *B is the base-point row, stored as named metric data over M rather than as a host point or as a point in a quotient completion.*
4. *R is the rooted Cauchy request row. It records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *rational tolerance reads that start at B and are sealed by the* $\mathsf{Real}^{\uparrow}$ *distance rows before the completion service C is inspected.*
5. *H records componentwise* hsame *transport for the metric carrier, completion row, base point, rooted Cauchy requests, provenance, replay, and local naming rows.*
6. *K records displayed* Cont *replay from a rooted Cauchy request through M, B, R, C, H and into the local certificate row.*
7. *N is the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetric}^{\uparrow}}$ *row for exactly this displayed packet.*

The classifier compares accepted packets only by transporting these seven rows together. It has no coordinate for a selected host point, a quotient-completion representative, a choice-selected limit, open-cover compactness, or ambient equality on real-valued distances.

Lean4 (definition) `BEDC.Derived.PointedCompleteMetricUp`

Theorem 6287.2 (PointedCompleteMetric NameCert obligations)**.** *For every accepted* $\mathsf{PointedCompleteMetric}^{\uparrow}$ *carrier* $P = (M, C, B, R, H, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Met}^{\uparrow}$ *row* M*, completion-service admission for* C*, base-point admission for* B*, rooted Cauchy request admission for* R*, componentwise transport through* H*, replay through* K*, and provenance with local naming through* N*. Each rooted request must display its* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance reads, and* $\mathsf{Real}^{\uparrow}$ *distance seals before the* $\mathsf{CompleteMetric}^{\uparrow}$ *row is available.*

Proof. Project the carrier of Definition 6287.1. The rows M, C, B, R, H, K, N are the only coordinates available to a downstream NameCert consumer.

The rooted request is not a separate completion object. It begins at the base-point row B, reads the stream windows and rational tolerance schedule inside R, and reaches the completion service only through the row C displayed over the same metric carrier M.

Transport and replay preserve the route componentwise. The row H moves the metric, completion, base-point, and rooted-request data together, while K replays the same displayed path for consumers. Since N records only provenance and local naming for that packet, no unlisted host point, representative selector, open-cover compactness principle, quotient equality, or ambient real-completeness theorem can enter the certificate. □

Theorem 6287.3 (PointedCompleteMetric completion anchor)**.** *Let* $P = (M, C, B, R, H, K, N)$ *be an accepted* $\mathsf{PointedCompleteMetric}^{\uparrow}$ *carrier. Every* $\mathsf{CompleteMetric}^{\uparrow}$ *completion read exported by* P *is anchored at the same* $\mathsf{Met}^{\uparrow}$ *carrier* M *and the same base-point row* B *used by the rooted Cauchy request row* R*. Thus a completion consumer may inspect* C *only after the route*

$$M, B, R \longmapsto C \longmapsto H, K, N$$

has been displayed.

Proof. Read M, B, R from the carrier first. The base point is a row over the metric carrier, and the rooted Cauchy request row is displayed over the same source.

The completion row is downstream of that route. By the carrier definition, C is the complete-metric service for requests already displayed over M, not a detached complete object. Therefore a consumer cannot inspect C before the metric carrier and rooted base-point request are visible.

Finally apply transport and replay. The rows H and K preserve the order M, B, R, C, and the naming row N records only that finite packet. The completion anchor is therefore the displayed rooted route, not a selected host endpoint or quotient representative. □

Theorem 6287.4 (PointedCompleteMetric rooted Cauchy route)**.** *Every rooted Cauchy consumer of an accepted* $\mathsf{PointedCompleteMetric}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow} \longmapsto M, B, R, C, H, K, N.$$

The route supplies the base-pointed completion handoff needed by downstream Cauchy and completion chapters, while refusing selected host points, selected subsequences, quotient real equality, choice, open-cover compactness, and an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with the rooted request row. It records the stream windows and regular rational tolerance reads over the displayed metric source and base point, so a consumer receives only finite observations before completion is considered.

Next use the real seal and completion row. The distance observations are sealed as $\mathsf{Real}^{\uparrow}$ data inside the same route, and the $\mathsf{CompleteMetric}^{\uparrow}$ row is available only after those observations have been displayed.

Transport, replay, provenance, and local naming do not add analytic content. They preserve and name the finite route through H, K, N. Hence every rooted Cauchy read factors through the displayed packet and cannot escape to selected host points, selected subsequences, quotient equality, choice, open-cover compactness, or ambient real completeness. □

Falsifiable prediction: A claimed $\mathsf{PointedCompleteMetric}^{\uparrow}$ consumer that reads a completed endpoint before displaying the metric carrier, base point, rooted Cauchy request, stream windows, regular rational tolerance reads, real distance seals, and complete-metric row refutes this carrier.

Independence witness: metricspace, completemetric, real, regseqrat, streamname: $\mathsf{PointedCompleteMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric carrier, completion row, base point, rooted Cauchy request, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{PointedCompleteMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedCompleteMetric}^{\uparrow}$ packet is generated from a MetricSpaceUp carrier row, a CompleteMetricUp Cauchy-limit row, a base-point row, a rooted Cauchy request row through StreamNameUp, RegSeqRatUp, and RealUp reads, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6287.1, Definition 6287.2, Definition 6287.3, and Definition 6287.4 seed the rooted complete-metric carrier and its Cauchy-to-completion handoff over the displayed finite rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, quotient completion equality, selected host endpoints, selected subsequences, countable choice, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, rooted Cauchy request admission, completion-anchor exactness, transport, replay, provenance, local naming, and downstream completion-consumer alignment for BEDC.Derived.PointedCompleteMetricUp.

Chapter 6288

A Concrete Naming Certificate for $\mathsf{CauchyContinuousFunction}^{\uparrow}$

Following Bishop and Bridges, constructive analysis treats a continuous function on real names through a displayed rule on regular Cauchy representatives together with the modulus data that preserves regularity. The $\mathsf{CauchyContinuousFunction}^{\uparrow}$ packet records that surface as finite BEDC data. It consumes the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the graph-and-modulus rows of chapter 130, and the tolerance-only handoff of chapter 369. The chapter names the map object used by Real and Completion consumers without adding host function equality, quotient representatives, selected limits, or ambient completeness to the carrier.

Definition 6288.1 (CauchyContinuousFunction carrier)**.** *A* $\mathsf{CauchyContinuousFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, M, U, J, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window source row for regular Cauchy real-name observations.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those source windows, including the regularity budget used by downstream image requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for source and target precision requests.*
4. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-and-local-modulus row; it records the displayed map rule only through finite source observations and target requests.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that turns each target tolerance into a displayed source tolerance when uniform control is supplied.*
6. *J is the image-name production row, read only after S, R, D, M, U have fixed the finite source and tolerance route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the produced regular Cauchy real name.*
8. *H records componentwise* hsame *transport for S, R, D, M, U, J, E and the structural rows.*
9. *C records displayed* Cont *replay forcing every consumer to read the packet in the order $S, R, D, M, U, J, E, H, P, N$*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyContinuousFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyContinuousFunction}^{\uparrow}}$ *row.*

The carrier classifies functions only by these displayed rows. It has no coordinate for host function extensionality, quotient equality of real names, a selected representative sequence, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6288.2 (CauchyContinuousFunction NameCert obligations)**.** *For every accepted* CauchyContinuousFunct *carrier*

$$F = (S, R, D, M, U, J, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyContinuousFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the StreamName source windows, RegSeqRat readback, DyadicRatCore tolerance ledger, ContinuousMap graph row, UniformModulus handoff, image-name row, Real seal, transport, replay, provenance, and local naming rows;*
2. *source-name exactness, requiring every map request to read the source only through S and R before any image-name row is available;*
3. *tolerance compatibility, requiring D to be the shared dyadic ledger consumed by the source readback, the continuous-map row, the uniform-modulus handoff, and the image-name production row;*
4. *continuity control, requiring M and U to answer each target precision request by a displayed source precision request before J may be read;*
5. *regular-image sealing, requiring J and E to expose only the produced regular Cauchy real name downstream of S, R, D, M, U;*
6. *componentwise transport, displayed replay, provenance, local naming, and nonescape for the same displayed route through H, C, P, N.*

No CauchyContinuousFunction obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6288.1. The accepted packet displays exactly the source windows S, regular readback R, dyadic ledger D, continuous-map row M, uniform-modulus handoff U, image-name row J, Real seal E, and structural rows H, C, P, N.

Source-name exactness reads the first two coordinates. A consumer opens the finite StreamName observations and then the RegSeqRat readback attached to those observations; the image-name side has no available row before this source route is fixed.

Tolerance compatibility and continuity control are the middle of the route. The DyadicRatCore ledger D supplies the common precision arithmetic, while M and U convert each requested target tolerance into a displayed source tolerance before the image-name row is admitted.

Regular-image sealing is terminal. The row J records only the produced regular Cauchy name generated from S, R, D, M, U, and E seals that name as a Real-facing datum only after those rows have been displayed.

Finally, H, C, P, N transport, replay, package, and name the same finite route. Since host function equality, quotient real-name equality, selected representatives, countable choice, ambient Real completeness, Lean verification, and bridge checking are absent from the carrier, no local obligation can export them. □

Falsifiable prediction: Every $\mathsf{CauchyContinuousFunction}^{\uparrow}$ read factors through one StreamName source-window row, one RegSeqRat readback row, one DyadicRatCore tolerance ledger, one ContinuousMap graph-and-local-modulus row, one UniformModulus handoff row, one image-name row,

one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, continuousmap, uniformmodulus: $\mathsf{CauchyContinuousFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the regular Cauchy source route, the displayed map row, the uniform precision handoff, and the produced real-name seal as one map object.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContinuousFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyContinuousFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6288.1 and Definition 6288.2 seed the finite map object over regular Cauchy real names through StreamName windows, RegSeqRat readback, DyadicRatCore tolerance arithmetic, ContinuousMap graph data, UniformModulus handoff, image-name production, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyContinuousFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient equality of real names, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-name exactness, tolerance compatibility, continuity control, regular-image sealing, transport, replay, provenance, and nonescape for BEDC.Derived.CauchyContinuousFunctionUp.

Constructive story: A $\mathsf{CauchyContinuousFunction}^{\uparrow}$ packet is generated from StreamName source windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a ContinuousMap graph row, a UniformModulus handoff, an image-name row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6289

A Concrete Naming Certificate for $\mathsf{RegularCauchyDensity}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers, the $\mathsf{RegularCauchyDensity}^{\uparrow}$ packet records the finite density route by which a dyadic rational approximation is read through regular Cauchy data before a terminal $\mathsf{Real}^{\uparrow}$ seal is exposed. It sits over the dyadic arithmetic of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the separable Real boundary of chapter 1809. The packet names a displayed approximation handoff for Real and Completion consumers; it is not a quotient equality of real names, a selected Cauchy representative, countable choice, trichotomy, a host density theorem, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6289.1 (RegularCauchyDensity carrier)**.** *A* $\mathsf{RegularCauchyDensity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, S, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row naming the dyadic rational candidate and the dyadic tolerance budget requested by the density read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected prefixes of the source real name at the precisions demanded by Q.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row reached from the finite windows.*
4. *A is the approximation row stating that Q is accepted only after the regular-rational comparison in R displays the requested dyadic tolerance.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after Q, S, R, A have been displayed.*
6. *H stores componentwise* hsame *transport for the dyadic candidate, stream windows, regular readback, approximation row, Real seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a density request through Q, S, R, A, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDensity}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDensity}^{\uparrow}}$ *row.*

The carrier stores only displayed finite rows. It has no coordinate for quotient equality of real names, selected representatives, countable choice, trichotomy, host density of rationals, or ambient completeness.

Theorem 6289.2 (RegularCauchyDensity NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDensity}^{\uparrow}$ *carrier*

$$D = (Q, S, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDensity}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic candidate, finite stream windows, regular-rational readback, approximation row, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming. The obligation surface also requires dyadic-budget compatibility between* Q *and* A*, window-readback exactness between* S *and* R*, seal nonescape through* E*, and absence of quotient real equality, selected representatives, countable choice, trichotomy, host density, and ambient completeness.*

Proof. Project the carrier of Definition 6289.1. The available analytic rows are Q, S, R, A, E, and the available structural rows are H, C, P, N.

The budget compatibility row reads Q before A. Thus an accepted density request cannot claim a dyadic approximation unless the requested dyadic tolerance is one of the displayed rows.

The readback part then runs through S and R. Finite stream windows expose the inspected prefixes, and the regular-rational row records the comparison data consumed by the approximation row.

Finally E seals the Real-facing output only after those rows have been displayed. The transport, replay, provenance, and naming rows preserve the same finite route, while the refused host objects are absent from the carrier inventory. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 6289.3 (RegularCauchyDensity dyadic approximation)**.** *Every Real-facing density read exported by an accepted* $\mathsf{RegularCauchyDensity}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as instantiated by Q, S, R, A, E*. In particular, the dyadic candidate and tolerance budget are read first, the finite stream windows and regular-rational comparison are displayed next, and the terminal Real seal is available only after the approximation row has consumed those data.*

Proof. Start with an exported density read and project the accepted carrier. The only dyadic candidate row is Q, so the read begins at the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ surface.

The finite observation route then passes through S and R. The stream row opens the inspected windows, and the regular-rational row supplies the comparison surface needed to judge the dyadic budget.

The approximation row A is downstream of these rows and upstream of the terminal seal E. Since the carrier has no direct edge from Q to E, a Real-facing consumer can receive the seal only through the displayed dyadic-window-readback route.

The rows H, C, P, N do not add another approximation source. They transport, replay, source, and name the same finite route, so every exported density read factors as claimed. □

Theorem 6289.4 (RegularCauchyDensity RegSeqRat handoff)**.** *An accepted* $\mathsf{RegularCauchyDensity}^{\uparrow}$ *carrier hands a dyadic approximation to the* $\mathsf{Real}^{\uparrow}$ *boundary only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*. No Real-facing consumer of the packet receives a quotient representative, a selected Cauchy stream, a countable-choice schedule, trichotomy, a host rational-density theorem, or an ambient Real-completeness principle.*

Proof. Apply the dyadic approximation theorem. It forces every Real-facing density read to pass through Q, S, R, A, E in that order, with R as the unique regular-rational readback coordinate.

It remains to inspect what the handoff can export. The carrier's structural rows H, C, P, N only preserve the same displayed rows under transport, replay, provenance, and local naming.

The refused objects are not coordinates of Definition 6289.1. Therefore the handoff exports a finite RegSeqRat-mediated approximation route and none of the listed host or quotient principles. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDensityRegSeqRatHandoff`

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyDensity}^{\uparrow}$ density read factors through one DyadicRatCoreUp candidate-and-budget row, one StreamNameUp finite-window row, one RegSeqRatUp regular-rational readback row, one approximation row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, real-separability: $\mathsf{RegularCauchyDensity}^{\uparrow}$ is not bijective to any listed sibling because it packages the dyadic approximation request, finite window opening, regular-rational readback, terminal Real seal, transport, replay, provenance, and local NameCert as one density certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDensity}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDensity}^{\uparrow}$ packet is generated from a DyadicRatCoreUp candidate-and-budget row, StreamNameUp finite windows, RegSeqRatUp regular-rational readback, an approximation row, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDensity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6289.1, Definition 6289.2, Definition 6289.3, and Definition 6289.4 seed the finite dyadic-density route from displayed dyadic budgets through regular-rational readback to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDensity}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyDensityUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, selected Cauchy representatives, countable choice, trichotomy, host rational-density theorems, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-budget compatibility, window-readback exactness, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.RegularCauchyDensityUp.

Chapter 6290

A Concrete Naming Certificate for $\mathsf{ChoquetCompleteSpace}^{\uparrow}$

Following Choquet and Oxtoby, the $\mathsf{ChoquetCompleteSpace}^{\uparrow}$ packet records the complete-space side of the Choquet and Baire route as finite BEDC NameCert rows. It sits beside the game interface of chapter 4077, the complete-metric route of chapter 128, the Baire surface of chapter 3535, the Baire-space prefix of chapter 334, the finite schedule discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a constructive complete-space object whose evidence is a nested-open play ledger, not a selected generic point, countable-choice sequence, quotient completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 6290.1 (Choquet-complete-space carrier)**.** *A* $\mathsf{ChoquetCompleteSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (G, M, L, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{ChoquetGame}^{\uparrow}$ *row naming the legal nested-open game requests and the finite play prefixes visible to the packet.*
2. *M is the complete metric and Baire route row, read through* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$, *and* $\mathsf{BaireSpace}^{\uparrow}$ *data before any terminal seal is available.*
3. *L is the nested-open play ledger, recording each inspected open request, successor open row, metric-ball refinement, inclusion check, player tag, and finite stability witness.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting the visible play prefixes, open rows, centers, radii, and requested tolerances.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational centers, radius budgets, and tolerance comparisons used by the nested-open route.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the Choquet game row, complete metric and Baire route, nested-open ledger, stream windows, and regular rational readback have been displayed.*
7. *H records componentwise* hsame *transport for Choquet-game rows, complete-metric and Baire route rows, nested-open play ledgers, finite windows, regular readbacks, Real seals, replay data, provenance, and local naming.*
8. *C records displayed* Cont *replay from a complete-space request to the same game, metric, Baire, ledger, window, readback, seal, transport, provenance, and naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{ChoquetCompleteSpace}^{\uparrow}$, $\mathsf{ChoquetGame}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, CompleteMetricBaireSu BaireSpace$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoquetCompleteSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected generic point, countable choice, quotient completion, global winning strategy, host intersection point, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.ChoquetCompleteSpaceUp.ChoquetCompleteSpaceTasteGate single carrier alignment`

Theorem 6290.2 (Choquet-complete-space NameCert obligations)**.** *For every accepted* $\mathsf{ChoquetCompleteSpace}^{\uparrow}$ *carrier* $Q = (G, M, L, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ChoquetCompleteSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, Choquet-game legality, complete-metric and Baire route exposure, nested-open ledger exactness, finite stream-window readback, regular rational tolerance readback, Real-seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $G, M, L, S, R, E, H, C, P, N$.

Proof. Project the accepted carrier of Definition 6290.1. The analytic rows are G, M, L, S, R, E, and the structural rows are H, C, P, N.

The game and completeness content is finite. The row G supplies the legal Choquet-game requests, while M supplies only the displayed complete-metric and Baire route data needed by those requests.

The nested-open content is stored in L and inspected through S and R. Thus each open request, successor row, metric-ball refinement, inclusion check, center, radius, and tolerance read is visible before any Real-facing seal is read.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded objects, the listed rows exhaust the local NameCert surface. □

Theorem 6290.3 (Choquet-complete-space nested-play stability)**.** *Let* $Q = (G, M, L, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ChoquetCompleteSpace}^{\uparrow}$ *carrier. Every finite nested-open play prefix recorded by* L *remains stable under the displayed* hsame *transport and* Cont *replay exactly when its Choquet-game row, complete-metric and Baire route row, stream windows, regular rational readback, and Real-seal handoff remain on the route*

$$G \longmapsto M \longmapsto L \longmapsto S \longmapsto R \longmapsto E.$$

The stability claim exports no selected generic point, countable choice, quotient completion, global winning strategy, host intersection point, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite play prefix displayed in L. Its predecessor and successor open rows, metric-ball refinements, inclusion checks, and player tags are carrier rows rather than predicates over a host topology.

Read the surrounding route through G and M. The Choquet-game row supplies legality of the finite play prefix, and the complete-metric and Baire row supplies the displayed ball and dense-open data used by that prefix.

The observable numerical data passes through S and R. The stream windows choose the finite centers, radii, open rows, and tolerances, while the regular rational row reads those values without adding a selected limit point.

Transport and replay stability are exactly the rows H and C, followed by provenance and local naming in P and N. The Real seal E is downstream from the same route, so a consumer cannot replace the packet by a choice sequence, quotient completion, host intersection, global strategy, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoquetCompleteSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoquetCompleteSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6290.1, Definition 6290.2, and Definition 6290.3 seed the Choquet-complete-space certificate over game rows, complete-metric and Baire route rows, nested-open ledgers, finite windows, rational readback, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoquetCompleteSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected generic points, countable choice, quotient completion, global winning strategies, host intersection points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Choquet-game legality, complete-metric and Baire route exposure, nested-open ledger exactness, finite-window readback, rational tolerance readback, real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.ChoquetCompleteSpaceUp.

Constructive story: A $\mathsf{ChoquetCompleteSpace}^{\uparrow}$ packet is generated from ChoquetGame rows, complete-metric and Baire route rows, nested-open play ledgers, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6291

A Concrete Naming Certificate for $\mathsf{SubstrateFlowInvariant}^{\uparrow}$

The $\mathsf{SubstrateFlowInvariant}^{\uparrow}$ packet realizes the cellular substrate reading of chapter 9390 as finite orbit-window invariant data. It sits beside the trust-substrate row of chapter 940, the orbit substrate of chapter 938, the classifier boundary of chapter 3810, the trace invariant of chapter 2360, and the local Rule 110 observation rows of chapter 6004. The chapter names a finite flow-invariant surface for cellular substrate evolution without importing an infinite orbit, internal induction over time, or a semantic conservation theorem outside the packet.

Definition 6291.1 (Substrate-flow-invariant carrier)**.** *A* $\mathsf{SubstrateFlowInvariant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (U, O, F, A, W, H, C, P, N)$$

with the following displayed rows:

1. *U is the cellular trust-substrate row naming the local update rule, manifest row, accepted alphabet, and substrate audit source.*
2. *O is the finite orbit-window row naming the inspected time interval, boundary convention, local stencils, and observed successor rows.*
3. *F is the flow-invariant ledger, recording the invariant tag, the row-window values before and after each displayed update, and the finite equality or monotone comparison witnessed at that window.*
4. *A is the audit-route row linking the local stencil observations, pattern-classifier rows, trace-invariant rows, and classifier-boundary rows used by F.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row selecting the finite orbit prefixes, stencil windows, classifier tags, and invariant checks visible to a consumer.*
6. *H records componentwise* hsame *transport for trust-substrate rows, orbit windows, invariant ledgers, audit routes, stream windows, replay data, provenance, and local naming.*
7. *C records displayed* Cont *replay from a substrate-flow request to the same trust-substrate, orbit-window, invariant-ledger, audit-route, stream-window, transport, provenance, and naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{SubstrateFlowInvariant}^{\uparrow}$, $\mathsf{CellularTrustSubstrate}^{\uparrow}$, $\mathsf{CellularOrbitSubstrate}^{\uparrow}$, $\mathsf{CellularSubstrateClassifierBoundary}^{\uparrow}$, $\mathsf{SubstrateTraceInvariant}^{\uparrow}$, $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{SubstrateFlowInvariant}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the finite local-rule, orbit-window, invariant-ledger, audit-route, stream-window, transport, replay, provenance, and naming rows. It has no coordinate for infinite orbits, internal induction over all time, semantic conservation laws, hidden classifier repair, or external cellular substrate trust.

Theorem 6291.2 (Substrate-flow-invariant NameCert obligations)**.** *For every accepted* $\mathsf{SubstrateFlowInvariant}^{\uparrow}$ *carrier* $I = (U, O, F, A, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SubstrateFlowInvariant}^{\uparrow}}$ *surface consists exactly of carrier admission, local-rule trust, finite orbit-window exposure, invariant-ledger exactness, audit-route coverage, stream-window readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $U, O, F, A, W, H, C, P, N$*.*

Proof. Project the carrier of Definition 6291.1. The substrate row U, orbit row O, invariant ledger F, audit route A, and stream window row W are the only data rows available before transport and replay.

The invariant check is finite. Each comparison in F is tied to an observed predecessor and successor window from O, and the relevant local stencil and classifier evidence is named by A.

The consumer sees those windows through W. Transport, replay, provenance, and local naming are then exactly the rows H, C, P, N, so the packet cannot substitute an infinite orbit, internal induction principle, semantic conservation theorem, hidden classifier repair, or external trust source for the displayed rows. □

Falsifiable prediction: A $\mathsf{SubstrateFlowInvariant}^{\uparrow}$ implementation should fail admission when a finite Rule 110 orbit-window update changes the displayed invariant tag while preserving the same trust-substrate and audit-route rows.

Independence witness: The packet is independent of any single cellular substrate sibling: it can cite chapter 940, chapter 938, chapter 2360, chapter 3810, and chapter 6004 while requiring only their finite row surfaces.

Theorem 6291.3 (Substrate-flow-invariant Lean interface)**.** *The Lean-facing surface for* $\mathsf{SubstrateFlowInvariant}^{\uparrow}$ *is expected to expose a nontrivial TasteGate over finite orbit-window invariant rows and FieldFaithful instances for the local-rule row, orbit-window row, invariant-ledger row, audit-route row, stream-window row, transport row, replay row, provenance row, and local NameCert row. The interface does not require an infinite orbit type or an induction principle over all time.*

Proof. Read the nine carrier rows of Definition 6291.1. A nontrivial TasteGate can distinguish at least one accepted finite invariant ledger from a ledger whose displayed before-and-after row values disagree on the same orbit window.

FieldFaithful evidence is rowwise. Each field named in the carrier has a finite projection whose equality is checked by the packet classifier, and no projection ranges over an infinite orbit or a semantic conservation predicate.

Thus the Lean interface is the row surface itself: nontriviality comes from finite disagreement of invariant ledgers, and faithfulness comes from the visible fields $U, O, F, A, W, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubstrateFlowInvariant}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubstrateFlowInvariant}^{\uparrow}}, \mathsf{seed})$
Scope closed: Definition 6291.1 and Definition 6291.2 seed the substrate-flow-invariant certificate over local-rule trust, finite orbit windows, invariant ledgers, audit routes, stream windows, transport, replay, provenance, and local naming.
Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubstrateFlowInvariant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim infinite orbit closure, internal induction over all time, semantic conservation outside finite rows, hidden classifier repair, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-rule trust, finite orbit-window exposure, invariant-ledger exactness, audit-route coverage, stream-window readback, transport, replay, provenance, nontrivial Taste-Gate evidence, and FieldFaithful row instances for BEDC.Derived.SubstrateFlowInvariantUp.

Constructive story: A SubstrateFlowInvariant$^{\uparrow}$ packet is generated from cellular trust-substrate rows, finite orbit windows, invariant ledgers, audit routes, StreamName windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6292

A Concrete Naming Certificate for $\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}$ packet records the finite-family form of equicontinuity used for located real intervals and regular Cauchy real-name maps. It sits after the Cauchy-continuous map object of chapter 6288, the located interval uniform-Cauchy route of chapter 6256, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance arithmetic of chapter 291, and the terminal real-name seal of chapter 38. The packet names the textbook finite-means equicontinuity handoff without importing host function equality, open-cover compactness, selected limits, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6292.1 (Bishop equicontinuity principle carrier)**.** *A* $\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, I, M, U, W, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite family row, listing the accepted family indices and the familywise consumer route without exposing a host function space.*
2. *I is the located interval source row, read through the displayed interval and located endpoint data used by the family.*
3. *M is the* $\mathsf{CauchyContinuousFunction}^{\uparrow}$ *row for each family member, recording the source-window, tolerance, graph, image-name, and real-seal route of the member.*
4. *U is the uniform-Cauchy handoff row supplied over the same located interval source; it records the common finite tolerance route consumed by the family.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for source and image observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic comparison budget used by the family and the common handoff.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, I, M, U, W, R, D have fixed the finite family route.*

9. *H records componentwise* hsame *transport for the family, interval, map, uniform-Cauchy, window, readback, tolerance, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through the finite route*

$$F, I, M, U \longmapsto W, R, D, S, H, P, N.$$

11. *P is the* Pkg *provenance over* BishopEquicontinuityPrinciple$^{\uparrow}$, CauchyContinuousFunction$^{\uparrow}$, LocatedIntervalUniform StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

12. *N is the local* NameCert$_{\text{BishopEquicontinuityPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host equality of functions, open-cover compactness, selected pointwise limits, quotient equality of real names, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6292.2 (Bishop equicontinuity principle NameCert obligations)**.** *For every accepted* BishopEquicontinuityPrinciple$^{\uparrow}$ *carrier*

$$E = (F, I, M, U, W, R, D, S, H, C, P, N),$$

the local NameCert$_{\text{BishopEquicontinuityPrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, finite family exposure through F, located interval exposure through I, CauchyContinuousFunction exposure through M, uniform-Cauchy handoff exposure through U, StreamName window exposure through W, RegSeqRat readback through R, DyadicRatCore tolerance accounting through D, Real sealing through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6292.1. The analytic rows are the finite family F, the located interval source I, the Cauchy-continuous member rows M, the uniform-Cauchy handoff U, and the window, readback, tolerance, and seal rows W, R, D, S.

The family and interval obligations are finite. The row F fixes the accepted family indices, while I fixes the located interval source on which every member row is read.

The map and handoff obligations are then read from M and U. Each member exposes only the CauchyContinuousFunction route, and the common handoff supplies the tolerance route that a downstream equicontinuity consumer may share.

Finally H, C, P, N transport, replay, source, and name exactly the displayed rows. Since the carrier has no coordinate for host function equality, open-cover compactness, selected limits, quotient real-name equality, choice, or ambient completeness, those objects cannot appear as local obligations. □

Theorem 6292.3 (Bishop equicontinuity principle uniform-Cauchy handoff)**.** *Every equicontinuity-facing consumer of an accepted* BishopEquicontinuityPrinciple$^{\uparrow}$ *carrier receives the finite handoff*

CauchyContinuousFunction$^{\uparrow}$, LocatedIntervalUniformCauchy$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$ $\vdash$

The consumer may read the finite family row, located interval source, CauchyContinuousFunction rows, common uniform-Cauchy handoff, finite windows, regular rational readback, dyadic tolerance budget, terminal Real seal, transport, replay, provenance, and local NameCert. It cannot bypass those rows by comparing host functions, selecting pointwise limits, importing open-cover compactness, or appealing to ambient completeness.

Proof. Apply Definition 6292.2. Any accepted consumer must open F, I, M, U, W, R, D, S before the structural rows H, C, P, N are available.

The common equicontinuity route is controlled by U over the same located interval row I. The finite family row F determines which member rows in M are being read, while W, R, D, S expose only finite windows, rational readback, dyadic tolerance, and the terminal real-name seal.

The displayed Cont replay preserves that order. Hence a downstream uniform-Cauchy or compact-interval consumer receives a finite BEDC handoff rather than an external function-space principle, selected limit argument, open-cover compactness theorem, quotient comparison, or Real completeness claim. □

Falsifiable prediction: Every accepted $\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}$ equicontinuity read factors through one finite family row, one located interval source row, CauchyContinuousFunction member rows, one uniform-Cauchy handoff row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchy-continuous-function, located-interval-uniform-cauchy, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries a finite family route, located interval source, Cauchy-continuous member rows, a common uniform-Cauchy handoff, finite windows, rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}$ packet is generated from a finite family row, located interval source, CauchyContinuousFunction member rows, a uniform-Cauchy handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6292.1, Definition 6292.2, and Definition 6292.3 seed the finite family equicontinuity route over located intervals, Cauchy-continuous map rows, uniform-Cauchy handoff, window readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopEquicontinuityPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host function equality, open-cover compactness, selected pointwise limits, quotient equality of real names, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite family exposure, located interval exposure, CauchyContinuousFunction member exposure, uniform-Cauchy handoff exactness, finite-window replay, RegSeqRat readback, dyadic tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopEquicontinuityPrincipleUp.

Chapter 6293

A Concrete Naming Certificate for CompactUniformOscillationWindow$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CompactUniformOscillationWindow$^{\uparrow}$ packet records the finite-net and finite oscillation-window route used by compact uniform continuity. It is the concrete landing for the vision of chapter 9237, sitting between the compact oscillation packet of chapter 3737 and the finite oscillation partition packet of chapter 3800. It also reads compact metric source data from chapter 129, continuous graph data from chapter 130, uniform-modulus data from chapter 369, finite windows from chapter 126, regular rational readback from chapter 301, dyadic tolerance from chapter 291, and terminal real-name sealing from chapter 38. The packet does not claim open-cover compactness, selected extrema, quotient function equality, unbounded partition search, or ambient completeness.

Definition 6293.1 (Compact uniform oscillation window carrier)**.** *A* CompactUniformOscillationWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, F, U, O, M, B, W, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net source row, read through the accepted* CompactMetric$^{\uparrow}$ *finite-net surface.*
2. *F is the continuous graph row, exposing the displayed* ContinuousMap$^{\uparrow}$ *observations consumed by the compact-uniform route.*
3. *U is the* UniformModulus$^{\uparrow}$ *ledger, recording tolerance requests and source-radius responses.*
4. *O is the* CompactUniformOscillation$^{\uparrow}$ *oscillation-bound row over the same compact source and graph rows.*
5. *M is the finite mesh row, listing the compact finite-net cells or interval cells used by the oscillation window.*
6. *B is the finite oscillation-window row supplied by* FiniteOscillationPartition$^{\uparrow}$*, recording the cell-wise bound and refinement readback.*
7. *W is the* StreamName$^{\uparrow}$ *finite-window row for source and target observations.*
8. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to those windows.*

9. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row shared by U, O, M, B, W, R.*
10. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the compact finite-net, graph, modulus, oscillation, mesh, window, readback, and tolerance rows have been displayed.*
11. *H records componentwise* hsame *transport for all analytic and structural rows.*
12. *C records displayed* Cont *replay through*

$$K, F, U, O, M, B, W, R, D, S \longmapsto H, P, N.$$

13. *P is the* Pkg *provenance over* $\mathsf{CompactUniformOscillationWindow}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactUniformOscillation}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformOscillationWindow}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, selected extrema, quotient equality of maps, unbounded partition search, choice-selected refinements, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6293.2 (Compact uniform oscillation window NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformOscillationWindow}^{\uparrow}$ *carrier*

$$Q = (K, F, U, O, M, B, W, R, D, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformOscillationWindow}^{\uparrow}}$ *surface consists exactly of compact finite-net exposure through K, continuous graph exposure through F, uniform-modulus accounting through U, compact oscillation-bound exposure through O, finite mesh exposure through M, finite oscillation-window exposure through B, StreamName window exposure through W, RegSeqRat readback through R, DyadicRatCore tolerance accounting through D, Real sealing through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6293.1. The compact-uniform rows are K, F, U, O, and the finite oscillation-window rows are M, B, W, R, D, S.

The compact source is finite at the point of consumption. The row K supplies finite-net data, F supplies the displayed continuous graph, and U records the tolerance-only modulus ledger used by the compact-uniform read.

The oscillation window is then read through O, M, B, W, R, D, S. The compact oscillation-bound row and finite mesh row determine which cellwise windows are visible, while the stream, rational, dyadic, and real rows provide the finite readback and terminal seal.

Finally H, C, P, N transport, replay, source, and name the same packet. Since none of the excluded compactness, selection, quotient, unbounded-search, or completeness principles is a carrier coordinate, no NameCert obligation can project one. □

Theorem 6293.3 (Compact uniform oscillation window modulus handoff)**.** *Every compact-uniform-continuity or integration-facing consumer of an accepted* $\mathsf{CompactUniformOscillationWindow}^{\uparrow}$ *packet receives a finite oscillation modulus through*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactUniformOscillation}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, Strea

The handoff reads compact finite nets, continuous graph observations, the tolerance-only modulus ledger, compact oscillation bounds, finite mesh cells, cellwise oscillation windows, finite stream windows, regular rational readback, dyadic tolerance, and terminal Real sealing before any structural replay is available.

Proof. Apply Definition 6293.2. A consumer must expose $K, F, U, O, M, B, W, R, D, S$ before it can use the transport, replay, provenance, or local naming rows.

The modulus handoff is finite because K and M fix the finite source and cell rows. The tolerance request is answered through U and D, while O and B record the compact oscillation and cellwise window bounds.

The readback remains certificate-local. The rows W, R, S expose finite observations, regular rational readback, and the terminal real-name seal, and H, C, P, N preserve that same route.

Thus the packet exports a finite oscillation modulus for compact-uniform readers. It does not export open-cover compactness, selected extrema, quotient function equality, unbounded partition search, choice-selected refinements, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformOscillationWindow}^{\uparrow}$ reader that claims a compact finite oscillation modulus while omitting one of the compact finite-net, continuous graph, uniform-modulus, compact oscillation-bound, finite mesh, cellwise window, StreamName, RegSeqRat, DyadicRatCore, Real seal, hsame transport, Cont replay, Pkg provenance, or local naming rows refutes the packet.

Independence witness: compact-uniform-oscillation, finite-oscillation-partition, compactmetric, continuousmap, uniformmodulus, streamname, regseqrat, dyadicratcore, real: $\mathsf{CompactUniformOscillationWindow}^{\uparrow}$ is not bijective with any listed sibling because it joins compact finite-net source data, continuous graph rows, uniform-modulus accounting, compact oscillation bounds, finite oscillation partitions, finite readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformOscillationWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformOscillationWindow}^{\uparrow}$ packet is generated from compact finite-net source data, ContinuousMap graph rows, a UniformModulus ledger, a CompactUniformOscillation bound row, a finite mesh row, a FiniteOscillationPartition window row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformOscillationWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6293.1, Definition 6293.2, and Definition 6293.3 seed the compact finite-net and finite oscillation-window route for compact-uniform-continuity and integration-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformOscillationWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected extrema, quotient function equality, unbounded partition search, choice-selected refinements, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous graph exposure, uniform-modulus accounting, compact oscillation-bound exposure, finite mesh exactness, finite oscillation-window accounting, finite readback, tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformOscillationWindowUp.

Chapter 6294

A Concrete Naming Certificate for $\mathsf{FiniteCoverModulusSelector}^{\uparrow}$

Following Bishop–Bridges finite-cover compactness, the $\mathsf{FiniteCoverModulusSelector}^{\uparrow}$ packet names the constructive selector sitting between displayed compact-cover data and a $\mathsf{UniformModulus}^{\uparrow}$ export. It reads the compact metric source of chapter 129, the displayed map rows of chapter 130, the output interface of chapter 369, and the positive finite-radius ledger of chapter 452. The packet records a finite-cover route to a modulus, not a selected subcover, host minimum, ambient compactness theorem, or hidden completeness principle.

Definition 6294.1 (Finite-cover modulus selector carrier)**.** *A* $\mathsf{FiniteCoverModulusSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, F, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-cover row, exposing the compact metric source, cover cells, and finite coverage ledger consumed by the selector.*
2. *F is the pointwise modulus row, assigning each displayed cover cell the local continuity data read from the* $\mathsf{ContinuousMap}^{\uparrow}$ *surface.*
3. *R is the rational lower-bound row, recording the positive comparison data obtained from the finite cover and pointwise radii.*
4. *L is the selector ledger, pairing the finite cover row with the pointwise modulus row and lower-bound row before any output is visible.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row produced by the displayed finite-cover route.*
6. *H records componentwise* hsame *transport for the compact cover, pointwise modulus, rational lower bound, selector ledger, output, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a target-tolerance request through K, F, R, L, U, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverModulusSelector}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverModulusSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, R, L, U, H, C, P, N$. It has no coordinate for a selected subcover, selected Lebesgue number, choice schedule, host minimum, sequence extraction, or ambient completeness.

Theorem 6294.2 (Finite-cover modulus selector NameCert obligations)**.** *For an accepted* FiniteCoverModulusSelec *carrier* $S = (K, F, R, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverModulusSelector}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the compact finite-cover row* K*, pointwise modulus row* F*, rational lower-bound row* R*, selector ledger* L*, output row* U*, and structural rows* H, C, P, N*;*
2. *source compatibility, requiring* K *and* F *to read the same compact metric source before the selector ledger is formed;*
3. *finite-cover accountability, requiring every output read to pass through the displayed finite cover in* K *and the pointwise modulus data in* F*;*
4. *rational lower-bound exactness, requiring* R *to be the positive finite-radius comparison row consumed by* L*;*
5. *output non-escape, requiring* U *to export only the displayed* $\mathsf{UniformModulus}^{\uparrow}$ *row and no selected subcover, host minimum, selected Lebesgue number, choice schedule, or ambient completeness.*

Proof. Project the carrier of Definition 6294.1. The rows $K, F, R, L, U, H, C, P, N$ are the only rows available to an accepted selector read.

The first two obligation rows bind carrier admission and source compatibility. The compact finite-cover row K and pointwise modulus row F must therefore share the same compact metric source before L can be read.

The next two rows force the finite-cover computation. The selector ledger L consumes the displayed finite cover, pointwise radii, and rational lower-bound row R rather than a host minimum or unrecorded cover choice.

Finally the output row U is downstream of that ledger. Componentwise transport, replay, provenance, and local naming preserve the same route, so the absent compactness and choice data have no carrier coordinate from which an accepted read could export them. □

Theorem 6294.3 (Finite-cover selector uniform output)**.** *Let* $S = (K, F, R, L, U, H, C, P, N)$ *be an accepted* $\mathsf{FiniteCoverModulusSelector}^{\uparrow}$ *carrier. Every* $\mathsf{UniformModulus}^{\uparrow}$ *output exported by* S *factors through the finite-cover selector route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{FiniteLebesgueNumber}^{\uparrow} \longmapsto \mathsf{FiniteCoverModulusSelector}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The exported read exposes the compact finite-cover row, pointwise modulus row, rational lower-bound row, selector ledger, transport, replay, provenance, and local naming. It exports no selected subcover, host minimum, selected Lebesgue number, choice schedule, or ambient completeness.

Proof. Start with the output coordinate U. By the carrier definition, U is not visible until the finite-cover row K, pointwise modulus row F, rational lower-bound row R, and selector ledger L have all been displayed.

Use the NameCert obligations of Definition 6294.2. They bind the source, finite-cover accountability, and lower-bound exactness needed by a compact-uniform-continuity consumer.

The route is then exactly the displayed BEDC path from compact metric and continuous-map data through the finite-radius ledger into the selector packet and the $\mathsf{UniformModulus}^{\uparrow}$ output. The structural rows H, C, P, N only transport, replay, source, and name that route.

Since selected subcovers, host minima, selected Lebesgue numbers, choice schedules, and ambient completeness do not occur among the carrier coordinates, no accepted output read can export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverModulusSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverModulusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6294.1, Definition 6294.2, and Definition 6294.3 seed the finite-cover selector route from compact finite-cover data and pointwise moduli to UniformModulus output.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverModulusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subcovers, host minima, selected Lebesgue numbers, choice schedules, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, finite-cover accountability, rational lower-bound exactness, output non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverModulusSele

Constructive story: A $\mathsf{FiniteCoverModulusSelector}^{\uparrow}$ packet is generated from compact finite-cover rows, pointwise modulus rows, rational lower-bound rows, a selector ledger, a UniformModulus output row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6295

A Concrete Naming Certificate for $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$

The $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$ packet realizes the ordered route of Definition 9462.553 as one finite NameCert carrier. It sits beside the kernel-inductive acceptance surface of chapter 915 and the audit-map family surface of chapter 807: those chapters name certificates and audit families, while this packet records the entire primitive-to-certified reading as one ordered carrier from generated distinction rows through the certified-object seal.

Falsifiable prediction: An accepted $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$ read is refuted if a CertifiedObject seal is exported without first displaying distinction, history, record, classifier, NameCert, ledger, transport, replay, provenance, and local naming rows.

Independence witness: namecert, auditmapfamily, machineinterfacesocket, groundcompilerauditmap, and certificategate: none is bijective to $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$ because only this packet records the ordered primitive-to-certified route as one carrier from generated distinction data through classifier, ledger, and certified-object seal.

Definition 6295.1 (Primitive-certified route carrier)**.** *A* $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, H_0, A, Q, N_0, L, Z, T, C, P, N)$$

with the following displayed rows:

1. *D is the generated distinction row, recording the primitive same-and-different boundary being certified.*
2. *H_0 is the history row, displaying the finite route by which the distinction entered the packet.*
3. *A is the record row, naming the generated record inspected by the classifier.*
4. *Q is the classifier row, assigning the record to the stable classifier surface consumed by the certificate.*
5. *N_0 is the inner* $\mathsf{NameCert}$ *row for the classified record.*
6. *L is the ledger row, recording the certificate-facing audit trail from D, H_0, A, Q, N_0.*
7. *Z is the CertifiedObject seal row exported only after the previous rows are displayed.*
8. *T records componentwise* hsame *transport for distinction, history, record, classifier, certificate, ledger, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through the ordered route $D, H_0, A, Q, N_0, L, Z, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimitiveCertifiedRoute}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the ordered rows $D, H_0, A, Q, N_0, L, Z, T, C, P, N$. It has no coordinate for a certified-object seal detached from the distinction, history, record, classifier, certificate, ledger, transport, replay, provenance, or local naming rows.

Theorem 6295.2 (Primitive-certified route NameCert obligations)**.** *For an accepted* $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$ *carrier $R = (D, H_0, A, Q, N_0, L, Z, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PrimitiveCertifiedRoute}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed distinction, history, record, classifier, certificate, ledger, seal, transport, replay, provenance, and local naming rows;*
2. *primitive order, requiring D, H_0, A to be read before the classifier row Q is available;*
3. *classifier certification, requiring Q and N_0 to certify the same record before the ledger row L is accepted;*
4. *ledger seal ordering, requiring Z to be downstream of L rather than a standalone certified-object export;*
5. *structural non-escape, requiring T, C, P, N to transport, replay, source, and name only the ordered route already displayed.*

Proof. Project the carrier of Definition 6295.1. The listed rows are the whole surface available to an accepted read.

The primitive order obligation forces a read through D, H_0, A before the classifier row Q can be consumed. Thus the classifier is attached to a displayed generated record rather than to an unnamed object.

Classifier certification then binds Q to the inner NameCert row N_0. The ledger row L records that certification before the certified-object seal Z can be exported.

Finally T, C, P, N only preserve this ordered route. Because the carrier has no detached seal coordinate, every accepted certified-object read remains inside the displayed primitive-to-certified packet. □

Theorem 6295.3 (Primitive-certified route classifier nonescape)**.** *Every classifier-facing read of an accepted* $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$ *packet factors through*

$$D, H_0, A, Q, N_0, L, Z, T, C, P, N.$$

In particular, the classifier row cannot export a CertifiedObject seal without the preceding distinction, history, record, NameCert, ledger, transport, replay, provenance, and local naming rows, and no sibling packet supplies a bijective replacement for that ordered route.

Proof. Start with the carrier row of Definition 6295.1. A classifier-facing read reaches Q only after the distinction, history, and record rows have been displayed.

Use the NameCert obligations of Definition 6295.2. They force certification through N_0, ledger recording through L, and seal export through Z in that order.

The structural rows T, C, P, N preserve the route but do not add a detached classifier or certified-object coordinate. The independence witness separates this packet from sibling NameCert,

audit-map, interface, compiler, and gate packets because none of them stores the same ordered primitive-to-certified carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrimitiveCertifiedRoute}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimitiveCertifiedRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6295.1, Definition 6295.2, and Definition 6295.3 seed the ordered primitive-to-certified route from distinction rows through classifier, NameCert, ledger, and certified-object seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimitiveCertifiedRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, a detached certified-object seal, or a bijective replacement by NameCert, AuditMapFamily, MachineInterfaceSocket, GroundCompilerAuditMap, or CertificateGate packets.

Upgrade path: Obligation closure requires checked carrier admission, primitive ordering, classifier certification, ledger seal ordering, structural non-escape, transport, replay, provenance, and local naming for BEDC.Derived.PrimitiveCertifiedRouteUp.

Constructive story: A $\mathsf{PrimitiveCertifiedRoute}^{\uparrow}$ packet is generated from distinction, history, record, classifier, NameCert, ledger, certified-object seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming rows.

Chapter 6296

A Concrete Naming Certificate for $\mathsf{FiniteDyadicRefinementBudget}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteDyadicRefinementBudget}^{\uparrow}$ packet records the finite mesh-budget surface used when a dyadic refinement is consumed by Real-facing and formal-ball consumers. It sits after the common-refinement route of chapter 1877, the formal-ball window of chapter 1510, the dyadic tolerance core of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite budget for mesh shrinkage and handoff; it does not assert open-cover compactness, selected limiting meshes, quotient equality of names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6296.1 (Finite dyadic refinement budget carrier)**.** *A* $\mathsf{FiniteDyadicRefinementBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, F, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicCoverRefinement}^{\uparrow}$ *common-refinement row whose source covers and restriction ledgers determine the dyadic cells being tightened.*
2. *F is the* $\mathsf{FormalBall}^{\uparrow}$ *center-radius window whose radius request consumes the mesh budget before any completion-facing read is available.*
3. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the dyadic mesh scale, its endpoint arithmetic, and the finite comparison rows used to say that the refined mesh is small enough for the requested radius.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window address at which the budget is read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback that turns the stream-window and dyadic ledger into a scheduled tolerance row.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read by Real-facing consumers after Q, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the refinement row, formal-ball window, dyadic ledger, stream address, regular rational readback, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the finite route*

$$D, F, Q, S, R, E \longmapsto H.$$

9. *P is the* Pkg *provenance over* FiniteDyadicRefinementBudget$^{\uparrow}$, DyadicCoverRefinement$^{\uparrow}$, FormalBall$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{FiniteDyadicRefinementBudget}^{\uparrow}}$ *row.*

The classifier of an accepted packet compares mesh-budget data only through these ten rows. It has no coordinate for open-cover compactness, selected subcovers, selected limiting meshes, quotient equality of streams or real names, countable choice, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FiniteDyadicRefinementBudgetUp.FiniteDyadicRefinementBudgetTasteGate`
`single carrier alignment`

Theorem 6296.2 (Finite dyadic refinement budget NameCert obligations)**.** *For every accepted* FiniteDyadicRefinementBudget$^{\uparrow}$ *carrier*

$$B = (D, F, Q, S, R, E, H, C, P, N),$$

the local NameCert$_{\text{FiniteDyadicRefinementBudget}^{\uparrow}}$ *surface consists exactly of the following six rows:*

1. *carrier admission for the displayed* DyadicCoverRefinement$^{\uparrow}$ *row,* FormalBall$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *ledger,* StreamName$^{\uparrow}$ *address,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *mesh-source exposure, requiring every budget request to name the common-refinement row D before it names a refined mesh;*
3. *formal-ball exposure, requiring the radius request in F to be visible before the budget is consumed by a completion-facing route;*
4. *dyadic scale exactness, requiring the mesh scale and endpoint comparisons to be read through Q;*
5. *regular-readback exactness, requiring the finite stream address S and regular rational row R to mediate the tolerance schedule before the real seal E is inspected;*
6. *classifier transport through componentwise* hsame, *displayed* Cont, Pkg *provenance, and local* NameCert *naming, with no escape to open-cover compactness, selected subcovers, selected limiting meshes, quotient equality, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these six rows.

Proof. Carrier admission is the projection of Definition 6296.1. The tuple displays the refinement row, formal-ball window, dyadic scale ledger, finite stream address, regular rational readback, real seal, and structural rows.

Mesh-source exposure is forced by D. The carrier has no detached mesh field; a refined mesh is read only as a budget attached to the common dyadic refinement route.

Formal-ball exposure is forced by F. The radius request that motivates the budget is part of the carrier, so a completion-facing consumer cannot read a budget before the formal-ball window has been displayed.

Dyadic scale exactness is the role of Q. Endpoint arithmetic, mesh scale comparison, and tolerance narrowing all remain in the dyadic ledger. The stream and regular rational rows S, R then mediate the scheduled tolerance before the terminal real seal E is available.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite route. Since the carrier contains no field for open-cover compactness, selected subcovers, selected limiting meshes, quotient equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking, the classifier cannot export such data. □

Theorem 6296.3 (Finite dyadic refinement budget mesh handoff)**.** *Let*

$$B = (D, F, Q, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteDyadicRefinementBudget}^{\uparrow}$ *carrier. Every consumer that receives a mesh-budget handoff from B factors through the displayed route*

$$\mathsf{DyadicCoverRefinement}^{\uparrow},\ \mathsf{FormalBall}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto D, F, Q, S, R, E, H,$$

Consequently the handoff exposes a finite common-refinement source, a formal-ball radius request, a dyadic mesh ledger, a finite stream address, a regular rational tolerance readback, a terminal real seal, transport, replay, provenance, and local naming.

Proof. Project the accepted carrier. The source of the mesh is D, and the consuming radius request is F; these are the only rows that connect the refinement route to formal-ball data.

Read the scale data next. The dyadic ledger Q supplies the mesh size and endpoint comparisons, while S records the finite window at which that budget is read.

The regular rational row R and real seal E are downstream of the finite window. Thus a Real-facing consumer sees the mesh budget only after the stream-window and scheduled-tolerance rows have already been displayed.

The remaining rows H, C, P, N preserve and name this route. Hence every mesh handoff factors through the finite packet and not through a detached compactness principle, selected mesh limit, quotient equality, choice schedule, or ambient real-completeness claim. □

Theorem 6296.4 (Finite dyadic refinement budget Real nonescape)**.** *Let $B = (D, F, Q, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{FiniteDyadicRefinementBudget}^{\uparrow}$ *carrier. A* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of B may inspect the terminal real seal E only after the rows D, F, Q, S, R have been displayed and replayed through H, C, P, N. In particular, the consumer cannot replace the finite budget route by open-cover compactness, a selected limiting mesh, quotient equality of names, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier rows preceding E. The refinement source D, formal-ball request F, dyadic ledger Q, stream address S, and regular rational readback R are all explicit coordinates of the packet.

The real seal is terminal in this route. It records the Real-facing tolerance read only after the finite dyadic and regular rational rows have been exposed.

Transport and replay do not add analytic content. The rows H, C, P, N preserve the displayed packet and name it locally. Because the carrier contains no coordinate for compactness, selected limiting meshes, quotient equality, choice, or ambient completeness, no Real-facing read can escape the finite budget surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDyadicRefinementBudget}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDyadicRefinementBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6296.1, Definition 6296.2, Definition 6296.3, and Definition 6296.4 seed the finite dyadic mesh-budget route through refinement, formal-ball, dyadic, stream, regular rational, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteDyadicRefinementBudget}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.FiniteDyadicRefinementBudgetUp.FiniteDyadicRefinementBudgetTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, Heine–Borel, selected subcovers, selected limiting meshes, quotient real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a checked BEDC.Derived.FiniteDyadicRefinementBudgetUp carrier, NameCert rows, mesh handoff, and Real nonescape theorem.

Constructive story: A FiniteDyadicRefinementBudget$^{\uparrow}$ packet is generated from a DyadicCoverRefinement source, a FormalBall radius request, a DyadicRatCore mesh ledger, StreamName finite windows, RegSeqRat tolerance readback, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6297

A Concrete Naming Certificate for $\mathsf{RealCauchyFilterBasis}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ packet records the finite filter-basis route by which regular rational sequence data, finite stream windows, and dyadic tolerance rows are read before a terminal $\mathsf{Real}^{\uparrow}$ seal is exposed. It sits between the Cauchy-filter surface of chapter 333, the finite window naming of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational handoff of chapter 301, and the real-name boundary of chapter 38. The packet names a finite basis for Real-facing completion reads; it is not a quotient-stream construction, a selected limit, a countable-choice principle, or an ambient completeness theorem.

Definition 6297.1 (Real Cauchy filter-basis carrier)**.** *A* $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, W, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *F is the basis row, recording the finite Cauchy-filter basic neighborhoods and their inclusion reads.*
2. *W is the finite tail-window row, recording the* $\mathsf{StreamName}^{\uparrow}$ *windows and requested indices used to inspect each basis neighborhood.*
3. *D is the dyadic tolerance row, recording the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, denominator budget, and slack comparison attached to each window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the accepted tail-window observations as regular rational sequence data.*
5. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after F, W, D, R have displayed the basis, windows, tolerances, and regular-sequence readback.*
6. *H stores componentwise* hsame *transport for the basis, tail-window, dyadic tolerance, readback, Real seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a Real-facing precision request through the basis row, finite windows, dyadic tolerance ledger, regular-sequence readback, and terminal seal.*
8. *P records* Pkg *provenance over* $\mathsf{RealCauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *data.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RealCauchyFilterBasis}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $F, W, D, R, Q, H, C, P, N$. There is no coordinate for quotient streams, selected representatives, selected limits, countable choice, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ *equality.*

Theorem 6297.2 (Real Cauchy filter-basis NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ *carrier $B = (F, W, D, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCauchyFilterBasis}^{\uparrow}}$ *surface consists exactly of carrier admission, basis-neighborhood exposure, finite tail-window exactness, dyadic-tolerance exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal descent, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row for the same finite packet. No local obligation is stored outside these rows.*

Proof. Project the accepted packet $B = (F, W, D, R, Q, H, C, P, N)$. The carrier definition exposes exactly the basis, window, tolerance, readback, seal, transport, replay, provenance, and naming rows.

The basis-facing obligations are F, W, D. A consumer must first read the basic neighborhood, then the finite stream window that inspects it, and then the dyadic radius and slack comparison attached to that window.

The completion-facing obligations are R, Q, H, C, P, N. They repack the displayed data as regular rational readback, seal it as a Real-facing row, transport and replay the same route, cite its provenance, and name it locally. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6297.3 (Real Cauchy filter-basis RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ *carrier factors through*

$$\mathsf{CauchyFilter}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

inside the displayed rows F, W, D, R. Thus the regular rational sequence readback is available only after the basis neighborhood, finite tail window, and dyadic tolerance ledger have been displayed.

Proof. Begin with a consumer asking for the regular rational readback row R. By the carrier definition, the only route to R passes through the basis row F, the window row W, and the dyadic tolerance row D.

The row F names the Cauchy-filter basic neighborhood. The row W records the finite stream window used to inspect the tail of that neighborhood, and D records the dyadic radius and comparison budget consumed by the read.

The row R then repacks exactly those displayed observations as $\mathsf{RegSeqRat}^{\uparrow}$ data. The route therefore has no coordinate for quotient streams, selected representatives, selected limits, countable choice, or host completeness. □

Theorem 6297.4 (Real Cauchy filter-basis completion ledger)**.** *For every accepted carrier $B = (F, W, D, R, Q, H, C, P, N)$, a completion-facing read consumes the finite ledger*

$$F, W, D, R, Q, H, C, P, N$$

in that order: basis neighborhood, tail window, dyadic tolerance, regular rational readback, Real seal, transport, replay, provenance, and local naming. The ledger exports no quotient-stream equality, chosen representative, selected limit, countable-choice schedule, host-completeness theorem, or ambient Real equality.

Proof. Read the displayed continuation row C. It routes a Real-facing precision request through F, W, D, R, Q before the structural rows are consumed.

The first four rows form the finite completion ledger. They display the basis neighborhood, the inspected window, the dyadic tolerance comparison, and the regular rational readback.

The row Q is downstream of that ledger, while H, P, N preserve, source, and name the same data. Because the excluded objects do not occur as carrier coordinates, the completion-facing read cannot export them. □

Theorem 6297.5 (Real Cauchy filter-basis Real seal)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ *packet is terminal for the displayed basis route: every public read of* Q *factors through* F, W, D, R *and then through* H, C, P, N*. Consequently the seal certifies only the finite Real-facing basis packet, not quotient completion equality, selected limits, countable choice, host completeness, or ambient equality of real names.*

Proof. Let a public consumer read the terminal row Q. The carrier definition places Q after the basis, window, dyadic, and regular readback rows, so the consumer must first expose F, W, D, R.

Componentwise transport H and replay C keep the public read on that same finite route. Provenance P and local naming N identify the packet without adding a completion principle.

Thus the terminal seal is a Real-facing row of the displayed carrier. It is not a quotient equality, selected limit, choice schedule, host-completeness theorem, or ambient equality proof. □

Falsifiable prediction: Every $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ Real-facing read factors through a CauchyFilter basis row, StreamName finite tail windows, a DyadicRatCore tolerance row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchyfilter, streamname, dyadicratcore, regseqrat, real: $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries basis neighborhoods, finite tail windows, dyadic tolerance comparisons, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyFilterBasis}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyFilterBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6297.1, Definition 6297.2, Definition 6297.3, Definition 6297.4, and Definition 6297.5 seed the finite route from Cauchy-filter basis rows to regular rational readback and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyFilterBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, selected limits, countable choice, host completeness, ambient $\mathsf{Real}^{\uparrow}$ equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window exactness, dyadic-tolerance exactness, RegSeqRat readback, Real seal descent, transport, replay, provenance, and local naming for BEDC.Derived.RealCauchyFilterBasisUp.

Constructive story: A $\mathsf{RealCauchyFilterBasis}^{\uparrow}$ packet is generated from a CauchyFilter basis row, finite StreamName tail windows, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6298

A Concrete Naming Certificate for $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$ packet records the finite pair interface by which a displayed metric source and its dense Cauchy-name completion route are read before any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer may inspect a seal. It sits beside the dyadic tolerance core of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the oscillation-bound route of chapter 448. The packet is a NameCert interface for the completion pair, not a quotient completion, selected representative, host limit, countable-choice schedule, or ambient completeness theorem.

Definition 6298.1 (Bishop Cauchy completion-pair carrier)**.** *A* $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, D, W, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the source metric row, naming the displayed points, distance evidence, and finite request surface of the pre-completion space.*
2. *D is the dense-embedding row, recording how source points are inserted into the completion route before any completed endpoint is inspected.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the Cauchy names attached to the source and embedded rows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy seal over the windows in W.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the comparison precision for W and R.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff, available only after M, D, W, R, T have been displayed.*
7. *H records componentwise* hsame *transport for the metric source, dense embedding, finite windows, regular-Cauchy seal, dyadic ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay of the route from M and D through W, R, T, E, H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyOscillation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionPair}^{\uparrow}}$ *row.*

The carrier stores no quotient class, selected limit, host equality proof, countable-choice schedule, hidden completion point, or ambient completeness witness.

Theorem 6298.2 (Bishop Cauchy completion-pair NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$ *carrier* $K = (M, D, W, R, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionPair}}$ *surface consists exactly of the following five obligation families:*

1. *carrier admission for the displayed metric source row* M*, dense-embedding row* D*,* $\mathsf{StreamName}^{\uparrow}$ *finite windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy seal* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T*, and* $\mathsf{Real}^{\uparrow}$ *seal handoff* E*;*
2. *dense-source routing, requiring every completion-facing read to pass from* M *through* D *before any window, readback, tolerance, or seal row is consumed;*
3. *regular-Cauchy exactness, requiring* W, R, T *to be read as one finite window-and-tolerance packet before* E *is public;*
4. *transport and replay stability for the same rows under componentwise* hsame *and displayed* Cont*;*
5. *provenance and local naming exhaustion through* P *and* N*, with no quotient completion, selected representative, host limit, countable choice, or ambient completeness row exported by the packet.*

Proof. Project the carrier of Definition 6298.1. Its analytic rows are exactly M, D, W, R, T, E, and its structural rows are exactly H, C, P, N.

The source route begins at M and D. A completion-facing consumer may inspect the metric source and its dense embedding, but neither row contains a completed endpoint or quotient representative.

The Cauchy-name route then opens the finite window W, regular readback R, and dyadic tolerance ledger T. These rows are the only data from which the Real seal handoff E can be reached.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for the refused host objects, the five listed obligation families exhaust the local NameCert surface. □

Theorem 6298.3 (Bishop Cauchy completion-pair routed seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$ *packet reads the terminal seal only through the finite route*

$$M \longmapsto D \longmapsto W \longmapsto R \longmapsto T \longmapsto E.$$

Equivalently, the source metric data, dense embedding, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy seal, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger must all be displayed before the* $\mathsf{Real}^{\uparrow}$ *seal handoff is public.*

Proof. The NameCert obligations of Definition 6298.2 order the carrier rows. Source admission exposes M, and dense-source routing forces the embedding row D to be read before the Cauchy-name rows are interpreted.

Regular-Cauchy exactness then ties W, R, T into one finite packet. The seal row E is downstream of that packet, so a consumer has no route to E that bypasses the displayed windows, readback, or tolerance ledger.

Transport, replay, provenance, and naming preserve the same route componentwise. Thus the exported seal is a finite completion-pair handoff rather than a quotient completion, selected representative, host limit, choice principle, or ambient completeness witness. □

Falsifiable prediction: A claimed $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ or a completion-facing seal without displaying M, D, W, R, T refutes the carrier.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchyoscillation: no listed sibling is bijective to $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$ because the packet jointly carries a source metric row, dense embedding, finite windows, regular-Cauchy seal, dyadic tolerance ledger, Real seal handoff, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionPair}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$ packet is generated from source metric data, a dense embedding row, StreamName finite windows, RegSeqRat regular-Cauchy seal, DyadicRatCore tolerance ledger, Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionPair}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6298.1, Definition 6298.2, and Definition 6298.3 seed the finite Bishop completion-pair route from metric source and dense embedding through windows, readback, tolerances, and Real seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionPair}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dense-source routing, regular-Cauchy exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyCompletionPairUp.

Chapter 6299

A Concrete Naming Certificate for JordanDecompositionBoundedVariation$^{\uparrow}$

Following Jordan's theorem for functions of bounded variation, the JordanDecompositionBoundedVariation$^{\uparrow}$ packet records the finite BEDC surface by which a bounded-variation real function is read as the difference of two increasing variation ledgers before any Riemann–Stieltjes or Real-facing consumer sees the result. It sits after the bounded-variation carrier of chapter 398, the finite partition-sum ledger of chapter 6254, the regular rational readback of chapter 301, the dyadic edge-observation route of chapter 291, and the terminal Real seal of chapter 38. The packet is a displayed Jordan split over finite partition rows; it does not introduce a host function quotient, a selected total-variation supremum, a measure-valued derivative, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 6299.1 (Jordan decomposition bounded-variation carrier)**.** *A* JordanDecompositionBoundedVariation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (B, L, P_+, P_-, M, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *B is the accepted* BoundedVariation$^{\uparrow}$ *source row.*
2. *L is the finite* FiniteVariationLedger$^{\uparrow}$ *partition-sum row attached to the same interval and endpoint data.*
3. *P_+ records the positive-edge accumulated ledger over the displayed partition.*
4. *P_- records the negative-edge accumulated ledger over the displayed partition.*
5. *M is the monotonicity witness row for the two accumulated ledgers on common refinements.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the endpoint and accumulated-value windows.*
7. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row for edge signs, absolute-value reads, and common-refinement comparisons.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after B, L, P_+, P_-, M, R, D have been displayed.*
9. *H records componentwise* hsame *transport for all source, split, readback, tolerance, Real-seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a bounded-variation request through finite partitions, signed edge ledgers, monotone accumulated rows, rational readback, dyadic tolerance, and terminal Real sealing.*

11. *Q is the* Pkg *provenance over* $\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{FiniteVariationLedger}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}}$ *row.*

Accepted packets are compared only through these displayed rows.

Theorem 6299.2 (Jordan decomposition bounded-variation NameCert obligations)**.** *For every accepted* $\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}$ *carrier* $J = (B, L, P_+, P_-, M, R, D, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}}$ *surface consists exactly of bounded-variation source admission, finite variation-ledger exposure, positive-edge and negative-edge accumulated ledgers, monotonicity on common refinements, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6299.1. The source and partition data are precisely B and L, and the two signed accumulated ledgers are P_+ and P_-.

The Jordan split is finite at every read. Edge signs and absolute-value comparisons are opened through D, accumulated over the displayed partition in P_+ and P_-, and checked on common refinements by M.

The readback and sealing rows are downstream. The row R exposes regular rational windows for endpoint and accumulated-value reads, and E seals only the Real-facing boundary reached from those finite rows.

Finally H, C, Q, N transport, replay, source, and name the same packet. Since no row stores a host function quotient, a selected global supremum, a measure derivative, countable choice, or ambient Real completeness, none of those objects is exported by the local NameCert surface. □

Theorem 6299.3 (Jordan decomposition bounded-variation consumer route)**.** *Every Riemann–Stieltjes, bounded-variation, or Real-facing consumer of an accepted* $\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}$ *packet must first read the route*

$$\mathsf{BoundedVariation}^{\uparrow},\ \mathsf{FiniteVariationLedger}^{\uparrow},\ P_+,\ P_-,\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto H, C, Q, N.$$

Thus the difference-of-increasing-functions handoff is exposed as signed finite variation ledgers over common refinements, not as a host-level decomposition of quotient functions or a selected supremum over all partitions.

Proof. Apply Definition 6299.2. A consumer cannot read the positive and negative accumulated ledgers until the bounded-variation source, finite partition ledger, edge signs, and common-refinement row have been displayed.

The handoff to analysis consumers then passes through the rational and Real boundary. The $\mathsf{RegSeqRat}^{\uparrow}$ row R records endpoint and accumulated-value windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ row D records the tolerance and edge-comparison ledger, and the $\mathsf{Real}^{\uparrow}$ row E seals only the displayed result.

The structural rows H, C, Q, N preserve that route for downstream Riemann–Stieltjes and bounded-variation readers. They add no host function extensionality, quotient-function equality, selected limiting partition, countable choice, or ambient Real-completeness coordinate. □

Theorem 6299.4 (Jordan decomposition signed ledger exposure)**.** *For every accepted* JordanDecompositionBounde*carrier* $J = (B, L, P_+, P_-, M, R, D, E, H, C, Q, N)$*, the positive accumulated ledger* P_+ *and negative accumulated ledger* P_- *are exposed only after the bounded-variation source row* B *and the finite variation-ledger row* L *have been displayed. A reader that asks for either signed accumulated component without first reading* B *and* L *has not reached the local* $\mathsf{NameCert}_{\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}}$ *surface.*

Proof. Project the carrier of Definition 6299.1. Its row order makes B the source admission and L the finite partition-sum ledger attached to the same interval and endpoint data.

The signed accumulated rows P_+ and P_- are downstream of those two rows. Apply the NameCert obligation surface of Definition 6299.2: positive and negative edge accumulation is one obligation, but it is exposed only together with bounded-variation source admission and finite variation-ledger exposure.

Thus a consumer that omits B or L can at most name an external signed decomposition. It cannot read the displayed BEDC Jordan packet, because the local certificate has not opened the finite ledger on which P_+ and P_- depend. □

Theorem 6299.5 (Jordan decomposition common-refinement monotonicity)**.** *For every accepted* $\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}$ *carrier* $J = (B, L, P_+, P_-, M, R, D, E, H, C, Q, N)$*, common-refinement monotonicity for the positive and negative accumulated ledgers is read through the displayed row* M *and transported componentwise by* H*. It is not a host theorem about all partitions, nor a selected supremum over a refinement family.*

Proof. The carrier of Definition 6299.1 assigns the common-refinement witness to the single row M. Therefore a monotonicity read has a finite source: the displayed accumulated ledgers and their stated common-refinement comparison row.

Transport is also rowwise. The componentwise hsame row H preserves the source, ledger, signed accumulated components, readback, tolerance, Real-seal, replay, provenance, and local naming rows without replacing them by a host partition family.

Consequently monotonicity reaches consumers only as the M row transported by H. No total-variation supremum, quotient function, or ambient completeness principle is added by this route. □

Theorem 6299.6 (Jordan decomposition Real seal nonescape)**.** *For every accepted* $\mathsf{JordanDecompositionBoundedVa}$ *carrier* $J = (B, L, P_+, P_-, M, R, D, E, H, C, Q, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is reached only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*. The seal exports no selected total-variation supremum, host function quotient, measure derivative, countable choice, or ambient Real completeness.*

Proof. The carrier separates rational readback, tolerance accounting, and Real sealing into the rows R, D, E. The row R reads endpoint and accumulated-value windows, while D accounts for edge signs, absolute-value reads, and common-refinement comparisons.

Apply the consumer route of Definition 6299.3. It sends Real-facing readers through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and only then $\mathsf{Real}^{\uparrow}$, so E is terminal rather than a new source of analytic data.

Since the rows before E are finite readback and tolerance rows, the terminal seal cannot introduce a selected supremum, a host quotient of functions, a measure derivative, countable choice, or ambient Real completeness. It records only the Real-facing boundary already supported by R and D. □

Falsifiable prediction: A purported $\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}$ consumer that reads a positive or negative monotone component while omitting the bounded-variation source row, finite variation ledger, signed edge rows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: boundedvariation, finite-variation-ledger, regseqrat, dyadicratcore, real: $\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}$ is not bijective with any listed sibling because it joins the

bounded-variation source, signed finite partition ledgers, monotone refinement rows, rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming as one decomposition packet.

Closure status for $\mathsf{NameCert}_{\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}}$.

Constructive story: A $\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}$ packet is generated from a BoundedVariationUp source row, a FiniteVariationLedgerUp partition-sum row, positive and negative signed edge ledgers, common-refinement monotonicity rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6299.1, Definition 6299.2, Definition 6299.3, Definition 6299.4, Definition 6299.5, and Definition 6299.6 close the bounded-variation source admission, signed finite-ledger exposure, common-refinement monotonicity, RegSeqRat readback, DyadicRatCore tolerance accounting, and Real seal nonescape obligations for bounded-variation and Riemann–Stieltjes consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanDecompositionBoundedVariation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host function quotients, selected total-variation suprema, measure-valued derivatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Scoped closure requires checked transport, replay, provenance, and local naming routes for BEDC.Derived.JordanDecompo

Chapter 6300

A Concrete Naming Certificate for $\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}$

Following the finite-cover proof of Heine–Cantor in chapter 9237, the $\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}$ packet records the compact-cover radius and dyadic oscillation ledger consumed before a uniform-continuity handoff is exposed. It sits beside the compact finite-window route of chapter 6293, the compact oscillation packet of chapter 3737, the finite lower-bound fold of chapter 4096, and the uniform modulus consumer of chapter 369. The packet is finite radius data over displayed covers and oscillation rows; it does not assert open-cover compactness, a selected Lebesgue number outside the ledger, quotient map equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6300.1 (Finite oscillation-radius ledger carrier)**.** *A* $\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, U, A, F, B, W, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-cover or finite-net source row.*
2. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row receiving the final tolerance-only radius handoff.*
3. *A records the displayed center-radius cover cells and their rational lower-bound candidates.*
4. *F is the finite lower-bound fold row over those candidate radii.*
5. *B is the dyadic oscillation-bound row attached to each displayed cover cell.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for source and target observations.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those observations.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for oscillation and radius comparisons.*
9. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, U, A, F, B, W, R, D have been displayed.*
10. *H records componentwise* hsame *transport for all cover, fold, oscillation, readback, tolerance, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a compact-cover request through radius candidates, finite lower-bound folding, dyadic oscillation checks, uniform-modulus handoff, and terminal Real sealing.*

12. *P is the* Pkg *provenance over* FiniteOscillationRadiusLedger$^{\uparrow}$, UniformModulus$^{\uparrow}$, FiniteLowerBoundFold$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{FiniteOscillationRadiusLedger}^{\uparrow}}$ *row.*

Accepted packets are compared only through the displayed finite cover, radius, fold, oscillation, readback, tolerance, seal, transport, replay, provenance, and naming rows.

Lean4 ✓ BEDC.Derived.FiniteOscillationRadiusLedgerUp.FiniteOscillationRadiusLedgerTasteGate
single carrier alignment

Theorem 6300.2 (Finite oscillation-radius ledger NameCert obligations)**.** *For every accepted* FiniteOscillationRadiusLedger$^{\uparrow}$ *carrier $O = (K, U, A, F, B, W, R, D, S, H, C, P, N)$, the local* NameCert$_{\text{FiniteOscillationRad}}$ *surface consists exactly of compact finite-cover exposure, uniform-modulus consumer exposure, displayed center-radius candidates, finite lower-bound folding, dyadic oscillation bounds, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6300.1. The compact-cover source and uniform-modulus consumer are K and U, while A, F, B supply the finite radius and oscillation ledger.

The radius handoff is finite. Candidate radii are listed in A, folded in F, and checked against the displayed dyadic oscillation row B before any downstream modulus row is read.

The readback remains on the same route. Rows W, R, D, S expose finite observations, regular rational windows, dyadic tolerance comparisons, and the terminal Real seal after the radius ledger has been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no row stores open-cover compactness, an external Lebesgue-number selector, quotient map equality, countable choice, or ambient Real completeness, the local NameCert surface cannot export those objects. □

Theorem 6300.3 (Finite oscillation-radius ledger uniform handoff)**.** *Every compact-uniform-continuity consumer of an accepted* FiniteOscillationRadiusLedger$^{\uparrow}$ *packet must read compact finite-cover rows, center-radius candidates, the finite lower-bound fold, dyadic oscillation bounds, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, and the terminal Real seal before it consumes the* UniformModulus$^{\uparrow}$ *handoff. The handoff is a finite ledger route, not an open-cover compactness theorem or a selected radius outside the packet.*

Proof. Apply Definition 6300.2. The compact-cover row, radius candidates, lower-bound fold, and dyadic oscillation row are all displayed before the uniform-modulus consumer may read the handoff.

The finite readback rows keep the same route visible. A consumer reaches W, R, D, S only after the cover and oscillation ledger has fixed the radius row, so the final Real-facing seal cannot replace the finite ledger by a host compactness or completeness argument.

The structural rows H, C, P, N preserve the same compact-cover and oscillation-radius path. They add no selected Lebesgue number outside the ledger, quotient map equality, countable choice, or ambient Real-completeness coordinate. □

Theorem 6300.4 (Finite oscillation-radius compact-uniform sibling link)**.** *Every accepted* FiniteOscillationRadiusLe *compact-uniform reader factors through* CompactUniformOscillationWindow$^{\uparrow}$, CompactUniformOscillation$^{\uparrow}$, FiniteLowerBoundFold$^{\uparrow}$, UniformModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *before the uniform handoff is read. For a carrier $O = (K, U, A, F, B, W, R, D, S, H, C, P, N)$, the rows $K, U, A, F, B, W, R, D, S, H, C, P, N$ display that route in the order required by the reader.*

Proof. Project the carrier of Definition 6300.1. The compact source row K and the center-radius candidate row A provide the compact-cover side of the route, while B is the oscillation-bound row read through chapter 6293 and chapter 3737.

The radius extraction is finite. Row F is the $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ fold of chapter 4096, and row U is the $\mathsf{UniformModulus}^{\uparrow}$ consumer row of chapter 369; therefore the uniform handoff is read only after the finite lower-bound and oscillation rows have been displayed.

The readback and seal rows keep the same path visible. Rows W, R, D, S pass through chapter 126, chapter 301, chapter 291, and chapter 38 before any compact-uniform consumer receives the final handoff.

Finally H, C, P, N transport, replay, source, and name the displayed route. These rows preserve the compact-uniform sibling dependency; they do not add host compactness, an external Lebesgue-number selector, quotient map equality, countable choice, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}$ reader that claims a uniform-modulus handoff while omitting compact finite-cover exposure, center-radius candidates, finite lower-bound folding, dyadic oscillation bounds, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real sealing, hsame transport, Cont replay, Pkg provenance, or local naming refutes the packet.

Independence witness: compact-uniform-oscillation-window, compact-uniform-oscillation, finite-lower-bound-fold, uniformmodulus, streamname, regseqrat, dyadicratcore, real: $\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}$ is not bijective with any listed sibling because it joins compact-cover radius candidates, dyadic oscillation checks, finite lower-bound folding, uniform-modulus handoff, readback, tolerance, Real sealing, transport, replay, provenance, and local naming as one ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}$ packet is generated from compact finite-cover rows, UniformModulusUp consumer rows, displayed center-radius candidates, a FiniteLowerBoundFoldUp row, dyadic oscillation bounds, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6300.1, Definition 6300.2, Definition 6300.3, and Definition 6300.4 seed the compact-cover radius, dyadic oscillation, sibling dependency, and uniform-continuity handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteOscillationRadiusLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, open-cover compactness, selected Lebesgue numbers outside the packet, quotient map equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-cover exposure, radius-candidate exposure, finite lower-bound folding, dyadic oscillation accounting, uniform-modulus handoff, finite readback, tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteOscillationRadiusLedgerUp.

Chapter 6301

A Concrete Naming Certificate for $\mathsf{BishopRegularRealSeal}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopRegularRealSeal}^{\uparrow}$ packet records the regular-rational seal by which a displayed Cauchy name reaches the public $\mathsf{Real}^{\uparrow}$ boundary. It sits between the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the completion modulus discipline of chapter 1469, and the terminal real-name seal of chapter 38. The packet names only finite windows, regularity budgets, dyadic tolerances, seal transport, replay, provenance, and a local certificate; it does not allocate quotient streams, selected limits, countable-choice schedules, host real equality, or ambient completeness.

Definition 6301.1 (Bishop regular-real seal carrier)**.** *A* $\mathsf{BishopRegularRealSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, G, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the rational-name observations available to the seal.*
2. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that supplies the dyadic precision and endpoint comparisons consumed by G.*
4. *M is the* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row recording the explicit completion modulus that makes the windows in W reusable for all later seal reads.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *boundary seal, available only after W, G, D, M have been displayed.*
6. *H stores componentwise* hsame *transport for the stream windows, regular readback, dyadic ledger, completion modulus, real seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay for every consumer route from W, G, D, M to E.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularRealSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealSeal}^{\uparrow}}$ *row.*

The carrier stores no quotient stream, selected representative, host limit, countable-choice schedule, real trichotomy, or ambient completeness witness.

Theorem 6301.2 (Bishop regular-real seal NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularRealSeal}^{\uparrow}$ *carrier* $R = (W, G, D, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows* $W, G, D, M, E, H, C, P, N$*, stream-window exposure through* W*, regular-rational readback through* G*, dyadic tolerance exposure through* D*, completion-modulus reuse through* M*, terminal real-seal exposure through* E*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6301.1. The analytic rows are exactly the stream windows, regular readback, dyadic ledger, completion modulus, and real seal, and the structural rows are exactly transport, replay, provenance, and local naming.

The window route begins at W. A consumer may inspect only the displayed finite observations named by the $\mathsf{StreamName}^{\uparrow}$ row before any regular-rational or real-facing read is available.

The regularity route then reads G, D, M together. The $\mathsf{RegSeqRat}^{\uparrow}$ readback consumes the dyadic tolerance row D, while the $\mathsf{BishopCompletionModulus}^{\uparrow}$ row records the completion budget that lets later consumers reuse the same windows.

Finally E, H, C, P, N expose, transport, replay, source, and name the terminal $\mathsf{Real}^{\uparrow}$ seal over that finite route. Since no carrier coordinate stores quotient streams, selected limits, host equality, countable choice, trichotomy, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6301.3 (Bishop regular-real seal RegSeqRat route)**.** *Every accepted* $\mathsf{BishopRegularRealSeal}^{\uparrow}$ *readback to* $\mathsf{RegSeqRat}^{\uparrow}$ *factors through the displayed route*

$$W \longmapsto D \longmapsto M \longmapsto G.$$

The stream-window row W *supplies the finite observations, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *supplies the tolerance ledger, the* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row* M *supplies the reusable completion budget, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* G *is the only regular rational readback exported by the packet.*

Proof. Start with Definition 6301.1. The row G is not a detached regular sequence; it appears only with the window row W, the dyadic ledger D, and the completion modulus M.

Apply Definition 6301.2. Stream-window exposure precedes regular readback, dyadic tolerance exposure supplies the comparison budget, and completion-modulus reuse records the stable tail discipline for later consumers.

Therefore any accepted $\mathsf{RegSeqRat}^{\uparrow}$ readback uses the route W, D, M, G. A quotient stream, selected representative, host limit, or choice schedule has no row from which to replace that route. □

Theorem 6301.4 (Bishop regular-real seal Real boundary)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *boundary read exported by an accepted* $\mathsf{BishopRegularRealSeal}^{\uparrow}$ *carrier factors through the finite route*

$$W \longmapsto G \longmapsto D \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

In particular, the public real-name boundary is reached only after the $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row have all been displayed.*

Proof. Read the terminal seal row in Definition 6301.1. The row E is stored downstream of W, G, D, M, so it cannot be consumed before the finite regularity route has been displayed.

Use Definition 6301.3. The regular rational readback already factors through the stream windows, dyadic tolerances, and completion modulus. Hence the terminal seal has the same preceding route whenever a real-facing consumer inspects it.

Finally apply Definition 6301.2. Transport, replay, provenance, and local naming preserve the same finite surface after E is reached. The exported $\mathsf{Real}^{\uparrow}$ boundary therefore contains no quotient stream row, selected limit, host real equality, countable-choice schedule, trichotomy, or ambient completeness coordinate. □

Falsifiable prediction: An accepted $\mathsf{BishopRegularRealSeal}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ boundary without displaying $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and a $\mathsf{BishopCompletionModulus}^{\uparrow}$ row refutes the carrier.

Independence witness: streamname, regseqrat, dyadicratcore, bishop-completion-modulus, real: no listed sibling is bijective to $\mathsf{BishopRegularRealSeal}^{\uparrow}$ because the packet jointly carries finite windows, regular readback, dyadic tolerances, completion-modulus reuse, terminal Real seal exposure, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularRealSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularRealSeal}^{\uparrow}$ packet is generated from StreamName finite windows, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a BishopCompletionModulus row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularRealSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6301.1, Definition 6301.2, Definition 6301.3, and Definition 6301.4 seed the finite regular-real seal route from displayed windows and tolerances to the public Real boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularRealSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{BishopRegularRealSeal}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, regular readback routing, completion-modulus reuse, Real boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularRealSealUp.

Chapter 6302

A Concrete Naming Certificate for $\mathsf{SyntacticMonoid}^{\uparrow}$

Following Myhill, Nerode, and Eilenberg, the $\mathsf{SyntacticMonoid}^{\uparrow}$ packet records the finite classifier monoid of a regular language as BEDC NameCert data. It sits beside the accepted-word surface of chapter 351, the right-congruence classifier of chapter 5729, and the canonical deterministic presentation of chapter 6188. The packet names finite congruence classes and their multiplication table before any language consumer may read a transition monoid, host quotient of all words, arbitrary automaton presentation, or regular-expression proof.

Definition 6302.1 (Syntactic monoid carrier)**.** *A* $\mathsf{SyntacticMonoid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, W, L, E, C, \mu, e, \rho, H, K, P, N)$$

with the following displayed rows:

1. *A is the alphabet row, exposing the finite symbols available to the word-spine reader.*
2. *W is the word-spine row, recording finite word concatenation windows over A.*
3. *L is the regular-language observation row read from* $\mathsf{RegularLanguage}^{\uparrow}$*.*
4. *E is the syntactic congruence row, tabulating when displayed contexts make two words indistinguishable by L.*
5. *C is the finite class row, naming the displayed congruence classes admitted by E.*
6. *μ is the multiplication row, recording class multiplication induced by finite word concatenation.*
7. *e is the identity-class row, naming the class of the empty word.*
8. *ρ is the recognition morphism row from displayed words to classes and from accepted classes back to the regular-language observation.*
9. *H records componentwise* hsame *transport for alphabet, word-spine, language observation, congruence, class, multiplication, identity, recognition, replay, provenance, and local naming rows.*
10. *K records displayed* Cont *replay from word observations through congruence-class multiplication and recognition.*
11. *P is the* Pkg *provenance over* $\mathsf{SyntacticMonoid}^{\uparrow}$*,* $\mathsf{RegularLanguage}^{\uparrow}$*,* $\mathsf{MyhillNerode}^{\uparrow}$*,* $\mathsf{MinimalDfa}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

12. N is the local $\mathsf{NameCert}_{\mathsf{SyntacticMonoid}^\uparrow}$ *row.*
The classifier compares accepted packets only through $A, W, L, E, C, \mu, e, \rho, H, K, P, N$. It has no coordinate for a host quotient over all words, selected representatives outside the displayed classes, arbitrary transition monoid presentation, nondeterministic branch, or regular-expression equivalence proof.

Theorem 6302.2 (Syntactic monoid NameCert obligations)**.** *For every accepted* $\mathsf{SyntacticMonoid}^\uparrow$ *carrier $M = (A, W, L, E, C, \mu, e, \rho, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SyntacticMonoid}^\uparrow}$ *surface consists exactly of alphabet exposure, word-spine exposure, regular-language observation, syntactic-congruence tabulation, finite class admission, multiplication-table replay, identity-class naming, recognition morphism readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6302.1. The alphabet row A, word-spine row W, and regular-language row L are displayed before any congruence or monoid data can be consumed.

Read E, C, μ, e, ρ next. The congruence row E classifies displayed words by finite context tests against L, the class row C names the admitted finite classes, and μ and e record multiplication and identity only on those classes. The recognition row ρ is therefore a finite route from words to classes and back to the accepted-language observation.

The structural rows H, K, P, N transport, replay, source, and name the same finite table. Since no further coordinate exists, the carrier cannot import a host word quotient, external representatives, arbitrary transition monoid presentation, nondeterministic branch, or regular-expression equivalence proof. □

Theorem 6302.3 (Syntactic monoid regular-language handoff)**.** *Every* $\mathsf{RegularLanguage}^\uparrow$, $\mathsf{MyhillNerode}^\uparrow$, *or* $\mathsf{MinimalDfa}^\uparrow$ *consumer of an accepted* $\mathsf{SyntacticMonoid}^\uparrow$ *packet first reads the displayed alphabet row, word-spine row, regular-language observation, syntactic congruence row, finite class row, multiplication table, identity class, and recognition morphism. The handoff through chapter 351, chapter 5729, and chapter 6188 therefore exports only the finite classifier-monoid route.*

Proof. Start with a consumer read of $M = (A, W, L, E, C, \mu, e, \rho, H, K, P, N)$. The regular-language sibling reads L only after the finite alphabet and word-spine rows have been displayed.

The Myhill–Nerode sibling then consumes the congruence row E as a finite right-congruence classifier. The finite class row C and multiplication table μ keep this handoff inside displayed class data rather than a host quotient of all words.

The minimal deterministic automaton sibling can read the recognition morphism ρ only after the identity row e and class multiplication have been shown. Thus the syntactic-monoid packet supplies a finite classifier monoid to those consumers, not an arbitrary automaton presentation or regular-expression proof. □

Closure status for $\mathsf{NameCert}_{\mathsf{SyntacticMonoid}^\uparrow}$**.**

Constructive story: A $\mathsf{SyntacticMonoid}^\uparrow$ packet is generated from finite alphabet, word-spine, regular-language observation, syntactic congruence, finite class, multiplication, identity, recognition, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SyntacticMonoid}^\uparrow}$, seed)

Scope closed: Definition 6302.1, Definition 6302.2, and Definition 6302.3 seed the finite classifier-monoid route over RegularLanguageUp, MyhillNerodeUp, and MinimalDfaUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SyntacticMonoid}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, transition-monoid equivalence, arbitrary automaton minimization, regular-expression equivalence, host quotients of all words, or selected external representatives.

Upgrade path: Obligation closure requires checked carrier admission, syntactic congruence stability, multiplication replay, identity exactness, recognition morphism readback, sibling handoff, transport, replay, provenance, and local naming for BEDC.Derived.SyntacticMonoidUp.

Chapter 6303

A Concrete Naming Certificate for $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$

The $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$ packet realizes the five-field explanation schematic of Definition 9462.560 as finite BEDC NameCert data. It sits beside the machine-readable audit interface of chapter 1232, the registry export surface of chapter 1216, the philosophy formal-target ledger of chapter 1282, the tensor NameCert surface, and the GroundCompiler audit-map packet of chapter 836. The packet names a certified explanation route from source and classifier rows through evidence, ledger gaps, and certification rather than treating explanatory prose as proof evidence.

Falsifiable prediction: A $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$ packet is refuted when a claimed explanation omits one of the source, classifier, evidence, ledger-gap, certification-route, transport, replay, provenance, or local naming rows, or when a ledger gap is presented as closed without a displayed certification route.

Independence witness: machinereadableauditinterface, registryexportsurface, philosophy-formal-target-ledger, tensornamecert, groundcompilerauditmap: no sibling is bijective to $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$ because each lacks at least one of the source, classifier, evidence, ledger-gap, certification-route, transport, replay, provenance, or local NameCert rows as one explanation packet.

Definition 6303.1 (Certified explanation schematic carrier)**.** *A* $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, C, E, G, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the source row, recording the behavior, claim, or object whose explanation is being certified.*
2. *C is the classifier row, recording the candidate explanatory classifier for the source.*
3. *E is the evidence row, exposing finite observations, proof-trace summaries, registry rows, or audit rows relevant to the classifier.*
4. *G is the ledger-gap row, recording the five-field deficit coordinates for source, pattern, classifier, stability, and ledger gaps.*
5. *R is the certification-route row, recording which displayed rows close the relevant coordinates and which remain refused.*

6. *H records componentwise* hsame *transport for source, classifier, evidence, gap, certification-route, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from source and classifier reads through evidence, ledger-gap accounting, and certification-route checking.*
8. *P is the* Pkg *provenance over* $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$, $\mathsf{GroundCompilerAuditMap}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CertifiedExplanationSchematic}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, C, E, G, R, H, K, P, N$. It has no coordinate for prose-only explanation, hidden proof evidence, unchecked export, unstated ledger closure, or a detached TasteGate verdict.

Theorem 6303.2 (Certified explanation schematic NameCert obligations)**.** *For every accepted* $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$ *carrier $X = (S, C, E, G, R, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CertifiedExplanationSchematic}^{\uparrow}}$ *surface consists exactly of source exposure, classifier exposure, evidence readback, five-field ledger-gap accounting, certification-route checking, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6303.1. The source row S and classifier row C fix the explanation target before evidence or closure data can be read.

Read the evidence and gap rows. The row E supplies the finite observation or audit material, while G records the five deficit coordinates from Definition 9462.560. A coordinate is not closed merely because it is named; it must be routed through R.

The certification-route row R records which displayed rows discharge the gap coordinates and which claims remain refused. The structural rows H, K, P, N transport, replay, source, and name the same route, so no prose-only explanation, hidden proof evidence, unchecked export, unstated ledger closure, or detached TasteGate verdict can enter the local NameCert surface. □

Theorem 6303.3 (Certified explanation schematic vision handoff)**.** *Every concrete read of the five-field schematic through* $\mathsf{CertifiedExplanationSchematic}^{\uparrow}$ *factors through the finite route*

$$S, C \longmapsto E, G \longmapsto R \longmapsto H, K, P, N.$$

The handoff to machine-readable audit, registry export, philosophy formal-target ledger, tensor NameCert, and GroundCompiler audit-map consumers remains a displayed NameCert route rather than an assertion that explanatory prose itself supplies theorem evidence.

Proof. Start with the source and classifier rows. They bind the explanation to a displayed behavior or object and to a concrete classifier before the five-field deficit vector is read.

The evidence row E and gap row G then expose the material and deficit coordinates. A downstream consumer can inspect these rows, but it cannot treat an open ledger coordinate as resolved until the certification-route row R displays the corresponding closure or refusal.

Finally read H, K, P, N. The provenance row may cite machine-readable audit, registry export, philosophy formal-target, tensor NameCert, or GroundCompiler audit-map consumers, but those siblings are reached only through the displayed route. Thus the schematic is concretized as a finite certified explanation packet and not as a prose-only explanation channel. □

The Lean follow-up must provide explicit Nontrivial CertifiedExplanationSchematic$^{\uparrow}$ and FieldFaithful CertifiedExp instances. The field-faithfulness witness must preserve $S, C, E, G, R, H, K, P, N$ as distinct rows before any TasteGate result can be cited by a checked paper marker.

Closure status for NameCert$_{\text{CertifiedExplanationSchematic}^{\uparrow}}$ ·

Constructive story: A CertifiedExplanationSchematic$^{\uparrow}$ packet is generated from source, classifier, evidence, ledger-gap, certification-route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{CertifiedExplanationSchematic}^{\uparrow}}$, seed)

Scope closed: Definition 6303.1, Definition 6303.2, and Definition 6303.3 seed the finite certified explanation route for the five-field schematic.

Formal verification: FormalStatus(NameCert$_{\text{CertifiedExplanationSchematic}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, TasteGate acceptance, Nontriviality, FieldFaithfulness, hidden theorem evidence, prose-only explanation, unchecked registry export, or detached ledger closure.

Upgrade path: Obligation closure requires checked carrier admission, evidence readback, five-field ledger accounting, certification-route exactness, sibling handoff, transport, replay, provenance, and local naming for BEDC.Derived.CertifiedExplanationSchematic

Chapter 6304

A Concrete Naming Certificate for $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$ packet records the finite envelope surface by which an upper-semicontinuous majorant is read through located real windows before any Real-facing consumer inspects a seal. It sits beside the lower-semicontinuous packet of chapter 1536, the one-sided $\mathsf{UpperReal}^{\uparrow}$ ledger, the located endpoint discipline of **??**, the finite $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a displayed located upper envelope; it is not a host limsup, quotient equality of real names, a choice-selected representative, or an ambient completeness principle.

Definition 6304.1 (Located upper-semicontinuous envelope carrier)**.** *A* $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, U, A, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *L is the source* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *row whose lower-side sublevel and epigraph windows are being enveloped.*
2. *U is the* $\mathsf{UpperReal}^{\uparrow}$ *majorant ledger, recording the upper real cut rows and their finite comparison requests.*
3. *A is the located-approximation row, requiring every accepted upper bound request to be accompanied by a displayed* $\mathsf{LocatedReal}^{\uparrow}$ *comparison window.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *row listing the finite windows inspected for the source, the upper ledger, and the located approximation.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the windows have been displayed.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the envelope value, visible only after L, U, A, W, R have been read.*
7. *H records componentwise* hsame *transport for the source, upper-ledger, located-approximation, window, readback, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from any envelope request through the same rows.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host limsup, a completed supremum operator, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6304.2 (Located upper-semicontinuous envelope obligation surface)**.** *For every accepted* $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$ *carrier* $E = (L, U, A, W, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission, lower-semicontinuous source exposure, upper-real majorant exactness, located-comparison routing, finite window readback, regular rational repacking, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming for the same finite packet.*

Proof. Project the carrier of Definition 6304.1. Its analytic rows are exactly L, U, A, W, R, Q, and its structural rows are exactly H, C, P, N.

The source and majorant obligations are read through L and U. The row L exposes only the displayed $\mathsf{LowerSemicontinuous}^{\uparrow}$ surface, while U records the one-sided $\mathsf{UpperReal}^{\uparrow}$ comparison ledger used by the envelope.

The located and Real-facing obligations are A, W, R, Q. They force every upper bound request through a $\mathsf{LocatedReal}^{\uparrow}$ comparison window, a finite $\mathsf{StreamName}^{\uparrow}$ inspection, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, and only then the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the refused host objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6304.3 (Located upper-semicontinuous envelope Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$ *packet reads the terminal envelope seal only through*

$$\mathsf{LowerSemicontinuous}^{\uparrow}, \mathsf{UpperReal}^{\uparrow}, \mathsf{LocatedReal}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the envelope may expose a located upper-semicontinuous Real-facing row, but it does not export a host limsup, a quotient equality principle, a choice-selected representative, or ambient Real completeness.

Proof. Begin with a consumer of the terminal row Q. By the carrier definition, there is no route to Q before the lower-semicontinuous source row L, the upper-real majorant ledger U, and the located comparison row A have been displayed.

The finite observation route then passes through the window row W and the regular rational readback row R. These rows make the envelope request a displayed finite packet rather than a semantic appeal to a completed upper envelope.

The transport, replay, provenance, and local naming rows preserve that same route. Hence every Real-seal read is bounded by the displayed $L, U, A, W, R, Q, H, C, P, N$ coordinates and cannot bypass them through a host limsup, quotient equality, choice, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$ Real-facing read factors through displayed $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: lowersemicontinuous, locatedreal, streamname, regseqrat, real: LocatedUpperSemicontin
is not bijective to any listed sibling because it jointly carries a lower-semicontinuous source, an

upper-real majorant ledger, located comparison windows, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6304.1, Definition 6304.2, and Definition 6304.3 seed the finite located upper-envelope route from lower-semicontinuous source data through upper-real and located-real comparison windows to a terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host limsup construction, quotient equality of real names, selected envelope representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-real majorant exactness, located-comparison routing, finite-window readback, regular rational repacking, Real seal descent, transport, replay, provenance, and local naming for BEDC.Derived.LocatedUpperSemicontinuousEnvelopeUp.

Constructive story: A $\mathsf{LocatedUpperSemicontinuousEnvelope}^{\uparrow}$ packet is generated from a LowerSemicontinuous source row, an UpperReal majorant ledger, LocatedReal comparison windows, StreamName finite observations, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6305

A Concrete Naming Certificate for NormalizationByEvaluation$^{\uparrow}$

Following Berger and Schwichtenberg, normalization by evaluation is read as a finite semantic-evaluation and reification packet for typed terms. The NormalizationByEvaluation$^{\uparrow}$ carrier sits beside the lambda-calculus certificate of chapter 200, the first-order syntax interface of chapter 197, and the candidate-mediated MetaCIC normalization audit of chapter 5925. It names only the displayed typed-term syntax, environment, semantic-value, neutral-reflection, readback, evaluation-ledger, transport, replay, provenance, and local NameCert rows needed for a readback consumer. It does not assert a host normalization function, unrestricted subject reduction, evidence-free MetaCIC strong normalization, quotient syntax equality, or a completed semantic model.

Definition 6305.1 (NormalizationByEvaluation carrier)**.** *A* NormalizationByEvaluation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, G, V, NF, R, Ev, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-term row, carrying the source term, its type, and the binder context visible to the readback consumer.*
2. *G is the environment row, recording finite semantic assignments for the free variables and context entries named by T.*
3. *V is the semantic-value row obtained by evaluating the displayed term under G through the packet ledger.*
4. *NF is the neutral-reflection row, separating variables and neutral applications that are reflected into semantic values from already reified normal forms.*
5. *R is the normal-form readback row, turning accepted semantic values into displayed beta-normal eta-long syntax when the packet admits such readback.*
6. *Ev is the evaluation ledger, recording each semantic-evaluation step, reification step, substitution replay, and refusal boundary used by the carrier.*
7. *H records componentwise* hsame *transport for typed terms, environments, semantic values, neutral-reflection rows, readback rows, evaluation ledgers, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a requested typed-term read through T, G, V, NF, R, Ev.*
9. *P is the* Pkg *provenance over* $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NormalizationByEvaluation}^{\uparrow}}$ *row.*

The classifier accepts the packet only when semantic evaluation and readback are both recorded as finite rows. No coordinate may be a host-language evaluator, a global normalization oracle, a quotient of syntax trees, or an unlogged semantic model.

Theorem 6305.2 (NormalizationByEvaluation NameCert obligations)**.** *For every accepted* NormalizationByEvaluat *carrier $E = (T, G, V, NF, R, Ev, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NormalizationByEvaluation}^{\uparrow}}$ *surface consists of the following six obligation rows:*

1. *carrier admission for the typed-term row, environment row, semantic-value row, neutral-reflection row, readback row, evaluation ledger, transport, replay, provenance, and local naming rows;*
2. *semantic evaluation, requiring V to be obtained from the displayed term and environment through the finite ledger Ev rather than a hidden evaluator;*
3. *neutral reflection, requiring reflected variables and neutral applications in NF to remain tied to the binder context and semantic assignments named by T, G;*
4. *reification and readback, requiring R to read only accepted semantic values and neutral reflections before producing a displayed normal form;*
5. *substitution stability, requiring context extension and substitution replay to pass through the same T, G, V, NF, R, Ev route under componentwise* hsame *transport;*
6. *no host normalization oracle, excluding external evaluators, quotient syntax equality, completed semantic models, unrestricted subject reduction, and evidence-free MetaCIC strong normalization.*

No accepted NameCert row is stored outside these finite coordinates.

Proof. Carrier admission is projection from Definition 6305.1. The tuple lists exactly the typed-term, environment, semantic-value, neutral-reflection, readback, ledger, transport, replay, provenance, and local-name rows.

Semantic evaluation is confined to the ledger Ev. A consumer may inspect V only after the displayed term T and environment G have been replayed, so the packet cannot consult a separate evaluator.

Neutral reflection and readback are then separated by NF and R. Reflection keeps variables and neutral applications attached to the visible context, while readback consumes accepted semantic values and neutral rows before producing normal-form syntax.

Substitution stability is recorded by the same route. Componentwise transport H and continuation replay C move the typed-term context, environment assignments, semantic values, neutral rows, readback rows, and ledger rows together, so substitution cannot bypass the displayed evaluation packet.

The provenance and local naming rows restrict the sibling imports to the lambda-calculus, first-order syntax, and candidate-mediated MetaCIC normalization surfaces cited above. Since no carrier coordinate stores a host evaluator, quotient syntax equality, completed semantic model, or evidence-free strong-normalization theorem, the listed rows are the whole NameCert obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{NormalizationByEvaluation}^{\uparrow}$ readback factors through the typed-term row, environment row, semantic-value row, neutral-reflection row, normal-form readback row, finite evaluation ledger, componentwise transport, continuation replay, provenance, and local NameCert before any consumer may cite a normal form.

Independence witness: lambdacalc, firstorder, metacic-candidate-strong-normalization: NormalizationByEvaluat is not bijective to any listed sibling because it jointly carries semantic evaluation, neutral reflection, readback, substitution replay, and no-oracle refusal rows. LambdaCalcUp carries beta syntax without the semantic-value/readback ledger; FirstOrderUp carries formula syntax without neutral reflection; MetaCICCandidateStrongNormalizationUp carries candidate evidence without an NBE readback packet.

Closure status for $\mathsf{NameCert}_{\mathsf{NormalizationByEvaluation}^{\uparrow}}$.

Constructive story: A $\mathsf{NormalizationByEvaluation}^{\uparrow}$ packet is generated from a typed-term row, environment row, semantic-value row, neutral-reflection row, normal-form readback row, finite evaluation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalizationByEvaluation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6305.1 and Definition 6305.2 seed the finite semantic-evaluation and readback packet for typed terms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalizationByEvaluation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted MetaCIC normalization, subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed semantic models, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, semantic evaluation, neutral reflection, readback, substitution stability, and no-oracle refusal for BEDC.Derived.NormalizationByEvaluationUp.

Chapter 6306

A Concrete Naming Certificate for $\mathsf{NeutralReifier}^{\uparrow}$

The $\mathsf{NeutralReifier}^{\uparrow}$ packet isolates the neutral-reflection and semantic readback component used by normalization-by-evaluation. It realizes the MetaCIC normalization audit route of chapter 9383 as finite neutral, semantic-value, readback, transport, replay, provenance, and local NameCert rows, while sitting beside the lambda-calculus certificate of chapter 200, the candidate-mediated strong-normalization packet of chapter 5925, and the normalization-by-evaluation packet of chapter 6305. The packet names the reifier component only; it does not assert global normalization, unrestricted MetaCIC subject reduction, host evaluator soundness, or quotient equality of terms.

Definition 6306.1 (NeutralReifier carrier)**.** *A* $\mathsf{NeutralReifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, Z, V, U, R, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed neutral-term row, recording the context, type, and neutral spine presented to the reifier.*
2. *Z is the neutral-reflection row, naming variables, eliminator spines, and application heads that may be reflected into semantic values.*
3. *V is the semantic-value row produced by reflection or by a prior accepted evaluation packet.*
4. *U is the universe or type-level guard row controlling which readback shape is allowed for the displayed semantic value.*
5. *R is the readback row that produces a normal neutral or normal form from Z, V, U.*
6. *A is the audit-route row binding the packet to the candidate-mediated MetaCIC normalization route of chapter 9383.*
7. *H records componentwise* hsame *transport for neutral terms, reflection rows, semantic values, type guards, readback rows, audit rows, replay, provenance, and local names.*
8. *C records displayed* Cont *replay from a requested reification read through T, Z, V, U, R, A.*
9. *P is the* Pkg *provenance over* $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$, $\mathsf{NormalizationByEvaluation}^{\uparrow}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NeutralReifier}^{\uparrow}}$ *row.*

The classifier accepts the packet only when neutral reflection and readback remain finite displayed rows tied to the audit route. It has no slot for a host normalizer, a semantic equality oracle, a quotient of terms, or an unconditional strong-normalization theorem.

Theorem 6306.2 (NeutralReifier NameCert obligations)**.** *For every accepted* $\mathsf{NeutralReifier}^{\uparrow}$ *carrier* $Q = (T, Z, V, U, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NeutralReifier}^{\uparrow}}$ *surface consists of the following six rows:*

1. *carrier admission for neutral terms, neutral reflection, semantic values, type guards, readback, audit-route, transport, replay, provenance, and local naming;*
2. *neutral reflection, requiring every reflected variable or eliminator spine in* Z *to be tied to the displayed context and typed neutral term row* T*;*
3. *semantic value admission, requiring* V *to arise from reflection or from an accepted evaluation packet named in the provenance row;*
4. *guarded readback, requiring* R *to read* Z, V, U *before producing a normal neutral or normal form;*
5. *transport and replay stability, requiring componentwise* hsame *and displayed* Cont *to preserve the same* T, Z, V, U, R, A *route;*
6. *audit nonescape, excluding host normalization oracles, semantic equality oracles, quotient syntax equality, unrestricted subject reduction, and evidence-free strong normalization.*

No consumer of the packet receives any stronger MetaCIC normalization claim than these rows display.

Proof. Carrier admission is immediate from Definition 6306.1. The tuple exposes neutral terms, reflection, semantic values, type guards, readback, the audit route, transport, replay, provenance, and local naming as the only rows.

Neutral reflection is tied to T and Z. Variables and eliminator spines are reflected only through the displayed context and typed neutral surface, so the packet cannot create a semantic value without a visible neutral source.

Semantic admission and guarded readback then pass through V, U, R. The value row is either reflected from Z or imported through an accepted evaluation packet named by P, and the readback row must consume the displayed type guard before producing syntax.

Transport and replay stability use H and C. These rows move the same neutral, semantic-value, type-guard, readback, and audit-route coordinates together, preserving the route into chapter 9383.

The audit row A, provenance P, and local name N keep the packet at the reifier component boundary. Since the carrier has no coordinate for a host normalizer, semantic equality oracle, quotient syntax equality, unrestricted subject reduction, or evidence-free strong normalization, the obligation surface is exactly the six rows listed. □

Falsifiable prediction: Every accepted $\mathsf{NeutralReifier}^{\uparrow}$ readback factors through the neutral-term row, neutral-reflection row, semantic-value row, type guard, readback row, MetaCIC audit-route row, componentwise transport, continuation replay, provenance, and local $\mathsf{NameCert}$ before any consumer may cite a normal neutral or normal form.

Independence witness: lambdacalc, metacic-candidate-strong-normalization, normalization-by-evaluation: $\mathsf{NeutralReifier}^{\uparrow}$ is not bijective to any listed sibling because it isolates neutral reflection, guarded readback, and MetaCIC audit-route replay as one packet. LambdaCalcUp has beta syntax without semantic reification; MetaCICCandidateStrongNormalizationUp has candidate evidence

without reifier rows; NormalizationByEvaluationUp includes full evaluation and substitution stability beyond the neutral reifier component.

Closure status for $\mathsf{NameCert}_{\mathsf{NeutralReifier}^{\uparrow}}$.

Constructive story: A $\mathsf{NeutralReifier}^{\uparrow}$ packet is generated from a typed neutral-term row, neutral-reflection row, semantic-value row, type guard, readback row, MetaCIC audit-route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NeutralReifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6306.1 and Definition 6306.2 seed the finite neutral-reflection and readback component for the MetaCIC normalization audit route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NeutralReifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted MetaCIC normalization, subject reduction, global confluence, semantic equality, quotient syntax equality, host evaluator soundness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, neutral reflection, semantic-value admission, guarded readback, transport stability, and audit nonescape for BEDC.Derived.NeutralReifierUp.

Chapter 6307

A Concrete Naming Certificate for $\mathsf{CayleyHamilton}^{\uparrow}$

Following Cayley and Hamilton, the $\mathsf{CayleyHamilton}^{\uparrow}$ packet records the characteristic-polynomial annihilation law as a finite matrix-polynomial certificate. It sits over the matrix carrier of chapter 49, the polynomial carrier of chapter 50, the scalar $\mathsf{Ring}^{\uparrow}$ structure of chapter 43, and the coefficient $\mathsf{CommRing}^{\uparrow}$ structure of chapter 44. The packet exposes a square matrix, its finite coefficient ledger, the characteristic-polynomial row, the matrix-polynomial evaluation row, and a zero-matrix annihilation witness before any spectral or determinant-facing consumer can read the claim.

The certificate is a NameCert boundary for the finite algebraic identity. It does not choose eigenvalues, diagonalize a matrix, assert field algebraic closure, or import host determinant semantics.

Definition 6307.1 (Cayley-Hamilton carrier)**.** *A* $\mathsf{CayleyHamilton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (R, n, A, \chi, E, Z, H, K, P, N)$$

with the following displayed rows:

1. *R is the scalar* $\mathsf{CommRing}^{\uparrow}$ *coefficient source, read together with its underlying* $\mathsf{Ring}^{\uparrow}$ *addition, multiplication, zero, one, and distributivity rows;*
2. *n is the finite square-size row for the matrix index carrier;*
3. *A is the* $\mathsf{Mat}^{\uparrow}$ *row for a carried $n \times n$ matrix over R;*
4. *χ is the* $\mathsf{Poly}^{\uparrow}$ *row naming the characteristic polynomial of A as a finite coefficient ledger over R;*
5. *E is the matrix-polynomial evaluation row obtained by substituting A into χ using the finite matrix multiplication and addition ledgers;*
6. *Z is the zero-matrix comparison row certifying that the evaluated matrix-polynomial row is the displayed zero matrix;*
7. *H records componentwise* hsame *transport for R, n, A, χ, E, Z;*
8. *K records the displayed* Cont *replay route from the scalar and matrix rows through the polynomial evaluation row to the zero-matrix witness;*

9. *P is the* Pkg *provenance over* $\mathsf{Mat}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CayleyHamilton}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose rows are the displayed coefficient source, square-size row, matrix row, characteristic-polynomial row, matrix-polynomial evaluation row, zero-matrix comparison, transport, replay, provenance, and local naming data. It has no coordinate for an eigenvalue, diagonal form, ambient algebraic closure, determinant oracle, or host polynomial identity.

Lean4 ✓ `BEDC.Derived.CayleyHamiltonUp.CayleyHamiltonTasteGate single carrier alignment`

Theorem 6307.2 (Cayley-Hamilton NameCert obligations)**.** *For every accepted* $\mathsf{CayleyHamilton}^{\uparrow}$ *carrier* $C = (R, n, A, \chi, E, Z, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CayleyHamilton}^{\uparrow}}$ *surface consists exactly of carrier admission for the scalar* $\mathsf{CommRing}^{\uparrow}$ *and* $\mathsf{Ring}^{\uparrow}$ *rows, the finite square* $\mathsf{Mat}^{\uparrow}$ *row, the finite* $\mathsf{Poly}^{\uparrow}$ *characteristic-polynomial row, the displayed matrix-polynomial evaluation row, the zero-matrix comparison row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The annihilation obligation requires E to evaluate the same χ at the same A over the same scalar structure, and requires Z to compare that evaluation with the displayed zero matrix. No accepted packet exports eigenvalues, diagonalization, algebraic closure, a determinant oracle, host matrix equality, or a spectral decomposition.*

Proof. Project the carrier of Definition 6307.1. The accepted packet lists exactly $R, n, A, \chi, E, Z, H, K, P, N$, so every algebraic read starts from the displayed coefficient, matrix, polynomial, evaluation, and zero-comparison rows.

The evaluation obligation is finite. The row χ is a $\mathsf{Poly}^{\uparrow}$ coefficient ledger over the same scalar source R, and the row E is obtained by the displayed finite matrix addition and multiplication route over the $\mathsf{Mat}^{\uparrow}$ carrier A.

The annihilation witness is the comparison row Z. It relates the matrix-polynomial evaluation row to the zero matrix inside the same square-size and scalar structure, and transport through H preserves those displayed rows componentwise.

Finally, replay and provenance through K, P, N expose only the NameCert route just described. Since the carrier has no eigenvalue, diagonalization, algebraic-closure, determinant-oracle, host-equality, or spectral-decomposition coordinate, the listed obligations exhaust the certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CayleyHamilton}^{\uparrow}}$.

Constructive story: A $\mathsf{CayleyHamilton}^{\uparrow}$ packet is generated from a scalar CommRingUp and RingUp source, a finite square MatrixUp row, a PolynomialUp characteristic-polynomial ledger, a matrix-polynomial evaluation row, a zero-matrix comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CayleyHamilton}^{\uparrow}}$, seed)

Scope closed: Definition 6307.1 and Definition 6307.2 seed the finite matrix-polynomial certificate over displayed scalar, matrix, polynomial, evaluation, zero-comparison, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CayleyHamilton}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CayleyHamiltonUp.CayleyHamiltonTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close eigenvalue construction, diagonalization, algebraic closure, determinant semantics, spectral decomposition, Lean verification, or bridge checking for $\mathsf{CayleyHamilton}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, characteristic-polynomial evaluation exactness, zero-matrix comparison stability, transport, replay, provenance, and local naming for BEDC.Derived.CayleyHamiltonUp.

Chapter 6308

A Concrete Naming Certificate for $\mathsf{StandardBorelSpace}^{\uparrow}$

Following Kechris' descriptive set theory, the $\mathsf{StandardBorelSpace}^{\uparrow}$ packet records a Polish presentation together with a generated Borel event classifier. It sits over the Polish presentation surface of chapter 1490, the Borel-code classifier of chapter 3384, the terminal real-name seal of chapter 38, the finite stream interface of chapter 126, and the regular rational readback surface of chapter 301. The packet is a measurable-name interface for probability and distribution consumers; it is not a host measurable-space import, quotient completion, selected point representation, or ambient sigma-algebra oracle.

Definition 6308.1 (Standard Borel space carrier)**.** *A* $\mathsf{StandardBorelSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, B, R, W, G, E, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *presentation row, including the displayed complete separable metric data and dense naming discipline consumed by the packet.*
2. *B is the* $\mathsf{BorelSet}^{\uparrow}$ *code row generated from the topology carried by P.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row used for real-valued observable boundaries.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read presented points and event probes.*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row used by real-valued event thresholds.*
6. *E is the event-classifier row assigning each displayed Borel code its finite membership-probe schedule over W, G, R.*
7. *H records componentwise* hsame *transport for $P, B, R, W, G, E, C, Q, N$.*
8. *C records displayed* Cont *replay from Polish presentation data through Borel-code generation to event-classifier reads.*
9. *Q is the* Pkg *provenance over* $\mathsf{StandardBorelSpace}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StandardBorelSpace}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose Borel event reads are generated from the displayed Polish presentation and whose real-valued observable thresholds pass through the stream, regular-rational, and real-seal rows. It has no coordinate for a host measurable space, unrestricted powerset sigma-algebra, quotient presentation, selected representative, or ambient probability measure.

Lean4 (statement) `BEDC.Derived.StandardBorelSpaceUp`

Theorem 6308.2 (Standard Borel space NameCert obligations)**.** *For every accepted* $\mathsf{StandardBorelSpace}^{\uparrow}$ *carrier*

$$S = (P, B, R, W, G, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{StandardBorelSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{PolishSpace}^{\uparrow}$ *presentation row, the generated* $\mathsf{BorelSet}^{\uparrow}$ *code row, the* $\mathsf{Real}^{\uparrow}$ *observable boundary, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the event-classifier row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The event classifier may accept only Borel codes generated from* P *and threshold reads routed through* W, G, R*. It exports no host measurable space, unrestricted sigma-algebra, selected point representation, quotient completion, probability measure, or ambient measurability oracle.*

Proof. Project the carrier of Definition 6308.1. The presentation and classifier data are exactly P, B, E, while W, G, R are the only rows available for point windows and real-valued threshold reads.

The Borel-code route is generated from P. The row B records Borel codes over the topology displayed by the $\mathsf{PolishSpace}^{\uparrow}$ presentation, and E may classify only those codes against the finite window and regular-rational rows.

The observable route is finite. A real-valued threshold read must pass through W for stream windows, G for regular rational readback, and R for the terminal real-name seal before the classifier row can be consumed.

Finally H, C, Q, N transport, replay, source, and name the same displayed packet. Since the carrier has no coordinate for a host measurable space, powerset sigma-algebra, selected representative, quotient completion, probability measure, or ambient measurability oracle, the listed rows exhaust the NameCert obligations. □

Theorem 6308.3 (Standard Borel Polish-Borel handoff)**.** *Every accepted* $\mathsf{StandardBorelSpace}^{\uparrow}$ *event read factors through the displayed route*

$$\mathsf{PolishSpace}^{\uparrow} \longmapsto \mathsf{BorelSet}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a probability, distribution, or measurable-kernel consumer may inspect only generated Borel event codes and finite real-threshold readbacks; it may not replace the packet by a host measurable space, a selected Polish representative, quotient real equality, an unrestricted sigma-algebra, or an ambient probability object.

Proof. Start with the carrier rows of Definition 6308.1. The only Borel row is B, and it is tied to the Polish presentation row P rather than to an external measurable-space structure.

Apply Definition 6308.2. It binds each event-classifier read to the generated Borel code and then routes real-valued probes through W, G, R.

The structural rows H, C, Q, N preserve that route under transport, replay, provenance, and local naming. A downstream consumer therefore receives a generated Borel classifier over the displayed Polish presentation, not an imported measurable-space object or an unrestricted sigma-algebra. □

Closure status for $\mathsf{NameCert}_{\mathsf{StandardBorelSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{StandardBorelSpace}^{\uparrow}$ packet is generated from a PolishSpace presentation, a BorelSet code row, a Real observable boundary, StreamName windows, RegSeqRat threshold readback, an event-classifier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StandardBorelSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6308.1, Definition 6308.2, and Definition 6308.3 seed the generated Borel event-classifier interface over displayed Polish, Borel-code, stream, regular-rational, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StandardBorelSpace}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close host measurable spaces, unrestricted sigma-algebras, quotient presentations, selected point representatives, probability measures, Lean checking, or bridge checking for $\mathsf{StandardBorelSpace}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, generated Borel-code stability, event-classifier stability, real-threshold routing, transport, replay, provenance, and local naming for BEDC.Derived.StandardBorelSpaceUp.

Chapter 6309

A Concrete Naming Certificate for $\mathsf{FiniteFourierEnergy}^{\uparrow}$

Following Parseval and Plancherel's finite-energy route in Fourier analysis, the $\mathsf{FiniteFourierEnergy}^{\uparrow}$ packet records the finite energy certificate that can be read between the Fourier observation surface of chapter 124 and the Parseval identity surface of chapter 1940. It consumes circle source rows, inner-product pairing rows, integral energy rows, rational readback rows, dyadic tolerance rows, and terminal Real seals without claiming an ambient Plancherel theorem, inversion theorem, completed Hilbert space, or quotient coefficient object.

Definition 6309.1 (Finite Fourier energy carrier)**.** *A* $\mathsf{FiniteFourierEnergy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, V, S, I, J, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Fourier}^{\uparrow}$ *finite observation row, listing the sampled modes, coefficient probes, transform-window probes, and truncation bounds under inspection.*
2. *V is the* $\mathsf{Parseval}^{\uparrow}$ *finite identity row, recording the coefficient-energy ledger and matching integral-energy ledger already displayed by the Parseval packet.*
3. *S is the circle source row, exposing only the finite phase samples and source classifier data consumed by the Fourier probes.*
4. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row for the coefficient and source rows.*
5. *J is the* $\mathsf{Integral}^{\uparrow}$ *energy row that reads the same finite source window as an integral-energy observation.*
6. *Q is the rational-readback row, using* $\mathsf{RegSeqRat}^{\uparrow}$ *data for finite sums, pairings, integral observations, and displayed energy comparisons.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for summation, pairing, integral readback, Parseval comparison, and downstream energy-window reuse.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the Fourier, Parseval, circle, inner-product, integral, rational-readback, and dyadic-tolerance rows have been displayed.*
9. *H stores componentwise* hsame *transport for all displayed rows.*

10. *C records the displayed* Cont *replay route from Fourier coefficient windows through Parseval energy comparison and into the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteFourierEnergy}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{Parseval}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteFourierEnergy}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, V, S, I, J, Q, D, R, H, C, P, N$. It has no coordinate for ambient Plancherel, Fourier inversion, completed Hilbert-space norm equality, host function equality, selected representatives, or quotient coefficient classes.

Theorem 6309.2 (Finite Fourier energy NameCert obligations)**.** *For every accepted* $\mathsf{FiniteFourierEnergy}^{\uparrow}$ *carrier $E = (F, V, S, I, J, Q, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteFourierEnergy}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Fourier, Parseval, circle, inner-product, integral, rational-readback, dyadic-tolerance, Real-seal, transport, replay, provenance, and local naming rows; coefficient-window exactness through F; Parseval-row attachment through V; source and pairing exposure through S, I; integral-energy exposure through J; rational and dyadic accounting through Q, D; Real-seal non-escape through R; and componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N.*

Proof. Project the carrier in Definition 6309.1. The finite inventory is exactly $F, V, S, I, J, Q, D, R, H, C, P, N$, so the NameCert obligations cannot cite a hidden analytic coordinate.

The energy-facing rows are read in order. The Fourier row F supplies the finite coefficient and transform windows, the Parseval row V supplies the finite energy identity surface, the circle row S supplies the finite source samples, and the pairing and integral rows I, J expose the two sides of the energy comparison.

The numerical endpoint is also finite. Rational readback Q and dyadic tolerance D record the visible arithmetic data before the Real seal R is reached.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no Plancherel, inversion, completed norm, host equality, representative-selection, or quotient coordinate, none of those conclusions can be projected from the packet. □

Theorem 6309.3 (Finite Fourier energy Parseval route)**.** *Every consumer read of a* $\mathsf{FiniteFourierEnergy}^{\uparrow}$ *packet factors through the finite Fourier observation surface of chapter 124 and the finite Parseval energy-identity surface of chapter 1940. The route may expose Fourier coefficient windows, Parseval finite-energy ledgers, circle samples, inner-product pairings, integral observations, rational readback, dyadic tolerances, and Real seals, but it exports no ambient Plancherel theorem, inversion theorem, completed Hilbert-space norm equality, host function equality, selected representative, or quotient coefficient class.*

Lean4 ✓ `BEDC.Derived.FiniteFourierEnergyUp.FiniteFourierEnergy parseval route`

Proof. Start with the rows F and V of Definition 6309.1. The row F is explicitly the finite Fourier observation row, while V is explicitly the finite Parseval identity row.

Attach the source, pairing, and energy rows S, I, J. They keep the route on finite circle samples, inner-product witnesses, and integral observations rather than on a completed ambient transform.

Read Q, D, R next. Rational readback and dyadic tolerance data are visible before the Real seal, so the terminal row is only the displayed finite energy comparison.

The non-energy rows H, C, P, N preserve this same factorization under transport, replay, provenance, and naming. Therefore every consumer route factors through the Fourier and Parseval siblings and stops before the excluded Plancherel, inversion, completion, host-equality, representative-selection, or quotient conclusions. □

Falsifiable prediction: Every $\mathsf{FiniteFourierEnergy}^{\uparrow}$ energy read factors through Fourier finite observations, Parseval finite-energy ledgers, circle source samples, InnerProduct pairings, Integral energy observations, RegSeqRat rational readback, DyadicRatCore tolerances, Real seals, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: fourier, parseval, s1, innerproduct, integral, regseqrat, dyadicratcore, real: $\mathsf{FiniteFourierEnergy}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite Fourier observation row, finite Parseval identity row, source, pairing, integral, rational-readback, dyadic-tolerance, Real-seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteFourierEnergy}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteFourierEnergy}^{\uparrow}$ packet is generated from finite Fourier observations, a finite Parseval identity row, circle source samples, inner-product pairings, integral energy observations, rational readback, dyadic tolerance accounting, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteFourierEnergy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6309.1, Definition 6309.2, and Definition 6309.3 seed the finite Fourier energy certificate consumed by downstream Plancherel-facing work.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteFourierEnergy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient Plancherel, Fourier inversion, convergence closure, completed Hilbert-space norm equality, host function equality, selected representatives, quotient coefficient classes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Fourier-window exactness, Parseval-row attachment, circle-source exposure, inner-product and integral-energy accounting, rational readback, dyadic tolerance accounting, Real seal non-escape, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.FiniteFourierEnergyUp.

Chapter 6310

A Concrete Naming Certificate for $\mathsf{ProximitySpace}^{\uparrow}$

Following Efremovic and Naimpally–Warrack on proximity spaces, the $\mathsf{ProximitySpace}^{\uparrow}$ packet records nearness as finite NameCert data rather than as a quotient of filters or a selected completion object. It sits between the separated uniform boundary of chapter 1876, the completion route of chapter 3560, and the complete uniform-space seal of chapter 1588. The packet supplies a conservative L10 nearness interface for Real and Completion consumers; it does not assert compactness, choose completion points, or import choice principles.

Definition 6310.1 (Proximity-space carrier)**.** *A* $\mathsf{ProximitySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (N, D, S, K, H, C, G, L)$$

with the following displayed rows:

1. *N is the nearness row, recording finite positive proximity observations between carried finite marks and the displayed neighborhood tests that witness them.*
2. *D is the diagonal and apartness row, requiring every accepted self-nearness read to pass through the displayed diagonal evidence and every rejected nearness read to expose its finite apartness witness.*
3. *S is the symmetry row, recording that a displayed nearness read may be replayed in the opposite order without introducing a host equality of points.*
4. *K is the composition row, recording the finite interpolation evidence used when two displayed nearness reads are composed through an admitted middle observation.*
5. *H records componentwise* hsame *transport for nearness, diagonal and apartness, symmetry, composition, continuation, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the route*

$$N, D, S, K \longmapsto H.$$

7. *G is the* Pkg *provenance over* $\mathsf{ProximitySpace}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, $\mathsf{UniformSpaceCompletion}^{\uparrow}$, $\mathsf{CompleteUniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{ProximitySpace}^{\uparrow}}$ *row.*

The classifier compares accepted proximity packets only through N, D, S, K, H, C, G, L. It has no coordinate for quotient filters, selected completions, open-cover compactness, countable choice, host equality of points, or ambient completeness.

Theorem 6310.2 (Proximity-space NameCert obligations)**.** *For every accepted* $\mathsf{ProximitySpace}^{\uparrow}$ *carrier* $P = (N, D, S, K, H, C, G, L)$*, the local* $\mathsf{NameCert}_{\mathsf{ProximitySpace}^{\uparrow}}$ *surface consists exactly of carrier admission, finite nearness exposure, diagonal and apartness exactness, symmetry replay, finite composition, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every L10 completion or uniformity consumer must read the displayed route*

$$N, D, S, K \longmapsto H, C, G, L$$

before using proximity as evidence for a separated or complete uniform-space boundary.

Proof. Project the carrier of Definition 6310.1. The nearness row N is the only row from which a consumer can read positive proximity observations, and the diagonal and apartness row D is the only row from which it can read self-nearness or rejected-nearness evidence.

The symmetry row S and the composition row K are finite replay rules. They transport a displayed nearness observation across order reversal or through an admitted middle observation, but they do not add a quotient relation or a hidden completion point.

Finally inspect H, C, G, L. These rows transport, replay, source, and name the same finite route. Since no row contains quotient filters, selected completions, open-cover compactness, countable choice, host equality, or ambient completeness, the local NameCert surface exports none of those objects. □

Theorem 6310.3 (Proximity-space uniform-completion boundary)**.** *Every separated uniform-space or completion-facing consumer of an accepted* $\mathsf{ProximitySpace}^{\uparrow}$ *packet must read nearness through the finite diagonal, symmetry, and composition rows before entering the L10 uniform route. The boundary is*

$$\mathsf{ProximitySpace}^{\uparrow} \longmapsto \mathsf{SeparatedUniformSpace}^{\uparrow} \longmapsto \mathsf{UniformSpaceCompletion}^{\uparrow} \longmapsto \mathsf{CompleteUniformSpace}^{\uparrow}.$$

The downstream reads are the separated uniform boundary of chapter 1876, the uniform-space completion route of chapter 3560, and the complete uniform-space seal of chapter 1588. The proximity packet itself supplies only finite nearness data and does not construct quotient filters, select completions, prove open-cover compactness, or provide choice principles.

Proof. Begin with the carrier projection in Definition 6310.1. A consumer receives the finite nearness row N, the diagonal and apartness row D, the symmetry row S, and the composition row K before any downstream uniform object is read.

Use Definition 6310.2. It keeps the structural rows H, C, G, L attached to the same displayed nearness route, so a consumer cannot replace the route by a host proximity relation or a quotient of filters.

The separated uniform-space boundary is then the first downstream reader. It consumes the diagonal, symmetry, and composition information only as finite evidence compatible with chapter 1876.

Completion-facing consumers may then pass to chapter 3560 and chapter 1588. Since the proximity carrier has no coordinate for quotient filters, selected completions, open-cover compactness, countable choice, host equality, or ambient completeness, none of those objects is introduced by this boundary. □

Theorem 6310.4 (Proximity-space finite nearness stability)**.** *Let $P = (N, D, S, K, H, C, G, L)$ be an accepted* $\mathsf{ProximitySpace}^{\uparrow}$ *carrier. Any replay of a displayed nearness observation under* hsame*, symmetry, or finite composition remains inside the same finite route*

$$N, D, S, K \longmapsto H, C, G, L.$$

Thus proximity stability is a property of displayed BHist *rows and not a quotient-filter equality, selected completion, open-cover compactness theorem, countable-choice selector, host equality, or ambient completeness claim.*

Proof. Project the accepted packet. The only nearness observations available to the consumer are the finite rows displayed by N, with diagonal and apartness evidence controlled by D.

Symmetry and composition are read through S and K. A replay in the opposite order or through a finite middle observation therefore stays inside the carrier rather than creating a new comparison principle.

Componentwise hsame transport and displayed Cont replay are the structural rows H and C. They preserve the same route, while G and L provide provenance and local naming only. No excluded quotient, selected completion, compactness, choice, host equality, or ambient completeness object is present in the packet. □

Falsifiable prediction: Every accepted $\mathsf{ProximitySpace}^{\uparrow}$ consumer reads finite nearness, diagonal and apartness, symmetry, composition, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it may pass to separated uniformity or completion-facing rows.

Independence witness: separateduniformspace, uniformspacecompletion, completeuniformspace: $\mathsf{ProximitySpace}^{\uparrow}$ is not bijective to any listed sibling because it uniquely names finite nearness, diagonal and apartness, symmetry, and composition rows before the uniform and completion route is consumed.

Closure status for $\mathsf{NameCert}_{\mathsf{ProximitySpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ProximitySpace}^{\uparrow}$ packet is generated from a finite nearness row, a diagonal and apartness row, symmetry and composition rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProximitySpace}^{\uparrow}}$, seed)

Scope closed: Definition 6310.1, Definition 6310.2, Definition 6310.3, and Definition 6310.4 seed the finite nearness interface over diagonal, apartness, symmetry, composition, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProximitySpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected completions, open-cover compactness, choice principles, host equality of points, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite nearness exposure, diagonal and apartness exactness, symmetry replay, finite composition, transport, replay, provenance, and non-escape for BEDC.Derived.ProximitySpaceUp.

Chapter 6311

A Concrete Naming Certificate for $\mathsf{CauchyTailSupremum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyTailSupremum}^{\uparrow}$ packet records the finite BEDC surface by which a supremum-bound read of a Cauchy tail is consumed after the displayed tail-bound, threshold, window, dyadic, regular-readback, and real-seal rows are already visible. It sits after the tail-bound certificate of chapter 2071, the threshold discipline of chapter 1423, the finite stream window of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a bounded-tail consumer surface; it does not assert an ambient completeness principle, an arbitrary host supremum, or a selected limit of a Cauchy stream.

Definition 6311.1 (Cauchy tail supremum carrier)**.** *A* $\mathsf{CauchyTailSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, W, D, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CauchyTailBound}^{\uparrow}$ *source row, recording the accepted tail-bound packet from which the bounded-tail read starts.*
2. *M is the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold row, naming the stage after which the tail is read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row, listing the inspected tail positions and the finite requests attached to them.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *upper-bound ledger, recording the dyadic radius, slack comparison, and upper-bound cells used by the supremum-bound read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window and dyadic ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row visible only after the tail-bound source, threshold, window, dyadic ledger, and regular readback have been displayed.*
7. *U is the supremum-bound row, recording the finite assertion that the displayed upper-bound ledger bounds every inspected tail read admitted by B, M, W, D, R, E.*
8. *H records componentwise* hsame *transport for the tail-bound source, threshold, window, dyadic ledger, readback, Real seal, supremum-bound row, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$B, M, W, D \longmapsto R \longmapsto E \longmapsto U.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyTailSupremum}^{\uparrow}$, $\mathsf{CauchyTailBound}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{RegularCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailSupremum}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $B, M, W, D, R, E, U, H, C, P, N$. There is no coordinate for a host supremum operator, quotient stream equality, selected limit, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyTailSupremumUp.CauchyTailSupremumTasteGate single carrier alignment`

Theorem 6311.2 (Cauchy tail supremum NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailSupremum}^{\uparrow}$ *carrier*

$$S = (B, M, W, D, R, E, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailSupremum}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows,* $\mathsf{CauchyTailBound}^{\uparrow}$ *source exposure through B,* $\mathsf{RealCauchyModulus}^{\uparrow}$ *threshold exposure through M,* $\mathsf{StreamName}^{\uparrow}$ *tail-window exactness through W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *upper-bound accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal descent through E, supremum-bound accountability through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 6311.1. The accepted packet exposes exactly $B, M, W, D, R, E, U, H, C, P, N$.

The source and threshold obligations are B and M. A consumer first reads the accepted $\mathsf{CauchyTailBound}^{\uparrow}$ source and then the $\mathsf{RealCauchyModulus}^{\uparrow}$ threshold that restricts which tail positions may be inspected.

The finite readback obligations are W, D, R, E. The window row lists the visible tail positions, the dyadic ledger records the upper-bound cells and slack comparison, the regular readback packages those observations, and the Real seal is downstream of those displayed rows.

The supremum-bound obligation is U. It records only the finite upper-bound assertion over the admitted tail-window reads, while H, C, P, N transport, replay, source, and name the same packet. Since no excluded principle is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6311.3 (Cauchy tail supremum Real boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyTailSupremum}^{\uparrow}$ *carrier must read the supremum-bound row only through the finite route*

$$\mathsf{CauchyTailBound}^{\uparrow}, \mathsf{RealCauchyModulus}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyTailS}$$

Thus the packet supplies a displayed upper bound for admitted Cauchy-tail reads, but it supplies no host supremum, quotient stream equality, selected limit, countable-choice schedule, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

Proof. Begin with an accepted carrier $S = (B, M, W, D, R, E, U, H, C, P, N)$. Projection gives the tail-bound source, threshold row, finite tail window, dyadic upper-bound ledger, regular readback, Real seal, and supremum-bound row.

The route to U is downstream of B, M, W, D, R, E. A consumer cannot read the supremum-bound row until the tail-bound source and threshold have admitted the inspected window and the dyadic ledger has recorded the upper-bound cells consumed by the regular readback.

The Real-facing boundary is the seal row E, and it is already downstream of the finite tail route. Componentwise hsame transport and displayed Cont replay preserve that order, while Pkg provenance and the local NameCert row only source and name the same data.

Therefore the exported object is the finite supremum-bound packet itself. No coordinate remains from which a host supremum, quotient stream equality, selected limit, countable-choice schedule, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge credential could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailSupremum}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailSupremum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6311.1, Definition 6311.2, and Definition 6311.3 seed the finite supremum-bound route for Cauchy-tail reads over displayed tail-bound, threshold, window, dyadic, readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailSupremum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host supremum, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, CauchyTailBound source exposure, modulus-threshold exposure, StreamName tail-window exactness, DyadicRatCore upper-bound accounting, RegSeqRat readback, Real seal descent, supremum-bound accountability, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailSupremumUp

Constructive story: A $\mathsf{CauchyTailSupremum}^{\uparrow}$ packet is generated from a CauchyTailBound source row, a RealCauchyModulus threshold row, StreamName tail-window rows, a DyadicRatCore upper-bound ledger, RegSeqRat readback, a RealUp seal, a supremum-bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6312

A Concrete Naming Certificate for $\mathsf{SingularHomology}^{\uparrow}$

Following Eilenberg and Steenrod, the $\mathsf{SingularHomology}^{\uparrow}$ packet records singular homology as a finite NameCert-facing ledger of singular-simplex rows, chain rows, boundary rows, and cycle-boundary classifier rows. It refines the homology carrier of chapter 98, reads simplex incidence beside the finite combinatorics of chapter 238, keeps cochain duality separate from the cohomology certificate of chapter 99, and attaches all simplex domains and endpoint evaluations to the Topology packet of chapter 88. The chapter names the local certificate surface for singular chains; it does not assert exactness of long sequences, homotopy invariance, excision, universal coefficients, or de Rham comparison.

Definition 6312.1 (SingularHomology carrier)**.** *A* $\mathsf{SingularHomology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, \Delta, \Sigma, C, B, Z, Q, H, T, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Topology}^{\uparrow}$ *carrier row naming the inspected space, its displayed opens, and the finite continuity witnesses used by singular simplices.*
2. *Δ is the finite simplex-domain row. It lists dimensions, face inclusions, vertex orders, and endpoint evaluations for the displayed standard simplices.*
3. *Σ is the singular-simplex row. Each entry records a displayed continuous map from a simplex domain in Δ into the topological space row X.*
4. *C is the chain row. It stores finite formal integer combinations of the displayed singular simplices and records the degree of each chain.*
5. *B is the boundary row. It records the alternating face ledger for each chain row using only the listed face maps and singular-simplex restrictions.*
6. *Z is the cycle-boundary classifier row. It separates rows whose boundary is the displayed zero chain from rows displayed as a boundary of a chain in the next degree.*
7. *Q is the quotient-facing homology-name row. It names the cycle modulo boundary classifier as local BEDC data rather than as host quotient equality.*

8. *H stores componentwise* hsame *transport for topology, simplex-domain, singular-simplex, chain, boundary, cycle-boundary classifier, quotient-facing name, continuation, provenance, and local naming rows.*
9. *T stores displayed* Cont *replay from simplex domains to singular maps, from singular maps to chains, from chains to boundaries, and from cycle-boundary classifiers to the local homology name.*
10. *P is the* Pkg *provenance over* $\mathsf{SingularHomology}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SingularHomology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for ambient abelian-group quotients, choice of representatives, arbitrary topological colimits, exact-sequence machinery, homotopy invariance, excision, or de Rham integration.

Theorem 6312.2 (SingularHomology NameCert obligations)**.** *For every accepted* $\mathsf{SingularHomology}^{\uparrow}$ *carrier $S = (X, \Delta, \Sigma, C, B, Z, Q, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SingularHomology}^{\uparrow}}$ *surface is exhausted by topology admission for X, simplex-domain admission for Δ, singular-simplex continuity for Σ, finite chain admission for C, boundary-row computation for B, cycle-boundary classification for Z, quotient-facing homology naming for Q, componentwise* hsame *transport through H, displayed* Cont *replay through T, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier row by row. The topology, simplex-domain, singular-simplex, chain, boundary, classifier, and homology-name coordinates are the only mathematical data visible to the local certificate.

The structural rows preserve that surface. Componentwise hsame transport in H can identify only displayed coordinates, the replay row T can traverse only the displayed route from simplex domains to homology names, and P, N record provenance and local naming for that same route.

The cited sibling chapters provide the intended boundaries: chapter 98 supplies the homology naming pattern, chapter 238 supplies finite face bookkeeping, chapter 99 remains the separate dual certificate surface, and chapter 88 supplies topological continuity data. Since no other row is present, the listed obligations exhaust the local NameCert surface. □

Theorem 6312.3 (SingularHomology boundary-square-zero ledger)**.** *For every accepted* $\mathsf{SingularHomology}^{\uparrow}$ *carrier $S = (X, \Delta, \Sigma, C, B, Z, Q, H, T, P, N)$, the displayed boundary ledger B contains the local witness that applying the singular boundary route twice reaches the displayed zero chain row. The witness is computed only from the alternating face rows in Δ, the singular-simplex restrictions in Σ, the chain row C, and the replay data in T; it does not use host quotient equality, selected chain representatives, homotopy invariance, excision, or a de Rham comparison theorem.*

Proof. Read the simplex-domain row Δ. Its face-inclusion ledger lists the two ways each codimension-two face appears in an iterated boundary, with opposite alternating signs.

Next read the singular-simplex row Σ and the chain row C. Restricting singular simplices along the two displayed face routes produces the same listed simplex face with opposite signs, so the iterated boundary entries cancel inside the finite chain ledger.

Finally replay the result through B, Z, Q, H, T, P, N. The boundary row records the cancellation as a displayed zero-chain witness, the classifier row Z consumes it as the cycle side of the cycle-boundary ledger, and the local homology-name row Q receives only that finite witness. No excluded global theorem or external quotient principle is available in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{SingularHomology}^{\uparrow}}$.

Constructive story: A $\mathsf{SingularHomology}^{\uparrow}$ packet is generated from a Topology row, finite simplex-domain rows, singular-simplex rows, chain rows, boundary rows, cycle-boundary classifier rows, quotient-facing homology names, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SingularHomology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6312.1, Definition 6312.2, and Definition 6312.3 seed the finite singular-chain certificate surface and its boundary-square-zero ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SingularHomology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim exactness of long sequences, homotopy invariance, excision, universal coefficients, de Rham comparison, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, singular-simplex continuity, chain admission, boundary computation, cycle-boundary classification, transport stability, and local NameCert replay for BEDC.Derived.SingularHomologyUp.

Chapter 6313

A Concrete Naming Certificate for $\mathsf{KaramataInequality}^{\uparrow}$

Following Hardy–Littlewood–Polya, the $\mathsf{KaramataInequality}^{\uparrow}$ packet records the finite majorization route by which a convex-function row and two ordered finite vector rows produce the Karamata comparison. It consumes the Jensen route of chapter 2235, the convex-carrier surface of chapter 208, the rational coefficient source of chapter 37, the vector carrier of chapter 47, the real-name boundary of chapter 38, and the endpoint comparison discipline of chapter 1674. The packet names the traditional majorization inequality as finite BEDC data; it does not import a host convex function, quotient equality of real names, selected extrema, trichotomy, countable choice, or ambient real completeness.

Definition 6313.1 (Karamata inequality carrier)**.** *A* $\mathsf{KaramataInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, X, Y, M, A, J, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *F is the convex-function source row, including the displayed domain, codomain, convexity ledger, and function-read route.*
2. *X and Y are the two finite vector rows over* $\mathsf{VecSpace}^{\uparrow}$*, with their coordinate reads and finite ordering windows.*
3. *M is the majorization ledger, recording the prefix-sum comparisons, total-sum agreement, and rational coefficient witnesses read through* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*.*
4. *A is the* $\mathsf{ConvexSet}^{\uparrow}$ *affine-spine row certifying that the Jensen decompositions used by the comparison stay inside the displayed convex carrier.*
5. *J is the* $\mathsf{JensenInequality}^{\uparrow}$ *handoff row, recording the finite Jensen calls used to convert the majorization ledger into image-sum comparisons.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row for the displayed sum of convex images.*
7. *Q is the* $\mathsf{RealMinMax}^{\uparrow}$ *endpoint row used when a consumer reads the ordered finite comparison.*
8. *H records componentwise* hsame *transport for F, X, Y, M, A, J, R, Q and the local naming row.*
9. *C records displayed* Cont *replay from majorization rows through the Jensen handoff, real comparison, endpoint row, provenance, and local name.*

10. *P is the* Pkg *provenance over* $\mathsf{KaramataInequality}^{\uparrow}$, $\mathsf{JensenInequality}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealMinMax}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{KaramataInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, X, Y, M, A, J, R, Q, H, C, P, N$. It has no coordinate for a host convex function, quotient equality of real names or functions, selected rearrangements, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6313.2 (Karamata inequality NameCert obligations)**.** *For every accepted* $\mathsf{KaramataInequality}^{\uparrow}$ *carrier $K = (F, X, Y, M, A, J, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KaramataInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the convex-function source row, the two finite vector rows, the majorization ledger, the convex-set affine-spine row, the Jensen handoff row, the real comparison row, the endpoint row, structural rows H, C, P, and local naming row N; prefix-sum and total-sum accountability through M; affine-spine accountability through A; Jensen-mediated comparison through J, R, Q; and componentwise transport, replay, provenance, and naming for the same finite route.*

Proof. Project the accepted packet $K = (F, X, Y, M, A, J, R, Q, H, C, P, N)$. The carrier definition exposes exactly the convex-function source, finite vector inputs, majorization ledger, affine-spine route, Jensen handoff, real comparison, endpoint comparison, transport, replay, provenance, and naming rows.

The majorization ledger M is read before the inequality row. It supplies the prefix-sum comparisons, total-sum agreement, and rational coefficient witnesses, while A supplies the displayed $\mathsf{ConvexSet}^{\uparrow}$ route that keeps each Jensen decomposition inside the accepted convex carrier.

The handoff row J then invokes only the already displayed Jensen certificate. The comparison rows R, Q carry the resulting real and endpoint comparisons, and H, C, P, N preserve and name that route. Since no host convex-function object, quotient equality, selected rearrangement, or ambient completeness coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 6313.3 (Karamata inequality Jensen-majorization handoff)**.** *Every accepted* $\mathsf{KaramataInequality}^{\uparrow}$ *packet routes its public comparison through*

$$X, Y, M \longmapsto A \longmapsto J \longmapsto R, Q \longmapsto H, C, P, N.$$

Consequently a consumer must read the two finite vector rows, the majorization ledger, the $\mathsf{ConvexSet}^{\uparrow}$ *affine-spine row, the* $\mathsf{JensenInequality}^{\uparrow}$ *handoff row, the* $\mathsf{Real}^{\uparrow}$ *comparison row, the* $\mathsf{RealMinMax}^{\uparrow}$ *endpoint row, componentwise transport, replay, provenance, and local naming before it can cite the Karamata inequality surface.*

Proof. Start with a consumer read of the Karamata comparison. By Definition 6313.1, the only majorization data are the vector rows X, Y and the ledger M.

The affine-spine row A is downstream of those finite rows. It keeps the displayed decompositions inside the same convex carrier before any Jensen call is read.

Apply the Jensen handoff row J. It is a reference to the finite NameCert surface of chapter 2235, so the consumer receives the Jensen comparison only after the majorization and affine-spine data have been displayed.

Finally R, Q, H, C, P, N expose the real comparison, endpoint comparison, transport, replay, provenance, and local naming. Thus no consumer can bypass the finite majorization route by invoking a host convexity theorem or ambient real-completeness principle. □

Falsifiable prediction: Every $\mathsf{KaramataInequality}^{\uparrow}$ consumer reads a convex-function source row, two finite VecSpace rows, a majorization ledger, a ConvexSet affine-spine row, a JensenInequality handoff row, Real comparison rows, RealMinMax endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the Karamata inequality surface is public.

Independence witness: jenseninequality, convexset, rat, vecspace, real, realminmax: $\mathsf{KaramataInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two ordered finite vector rows, a majorization ledger, affine-spine data, Jensen handoff, real comparison, endpoint comparison, transport, replay, provenance, and local NameCert data as one finite inequality packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KaramataInequality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KaramataInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6313.1, Definition 6313.2, and Definition 6313.3 seed the finite Karamata inequality route over convex-function, majorization, Jensen, ConvexSet, Rat, VecSpace, Real, and RealMinMax rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KaramataInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host convex functions, quotient equality of real names or functions, selected rearrangements, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, majorization ledger accountability, ConvexSet affine-spine exactness, Jensen handoff exactness, Real comparison nonescape, endpoint comparison handoff, and public export scope for BEDC.Derived.KaramataInequalityUp.

Constructive story: A $\mathsf{KaramataInequality}^{\uparrow}$ packet is generated from a convex-function source row, two finite VecSpace rows, a majorization ledger, a ConvexSet affine-spine row, a JensenInequality handoff row, Real comparison rows, RealMinMax endpoint rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6314

A Concrete Naming Certificate for $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$

The $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$ packet realizes the redex-frontier inspection route of chapter 9383 as finite NameCert data. It sits beside the critical-path route of chapter 765, the normal-form consistency seal of chapter 740, and the normalization frontier packet of chapter 892. The packet records a bounded typed-term window, the displayed redex-frontier row, candidate-mediated strong-normalization handoff data, and the audit ledger that a consumer must read before making any normalization-audit conclusion.

Definition 6314.1 (Finite-window normalization audit carrier)**.** *A* $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (W, R, K, F, S, L, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite typed-term window, including the inspected closed typed terms and the local depth or fuel boundary for the audit.*
2. *R is the redex-frontier row, recording exactly which beta-frontier and neutral-frontier cells are visible in the window.*
3. *K is the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *handoff row, naming the consistency-facing route that any audit consumer must preserve.*
4. *F is the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *row, separating candidate evidence, finished-normal use, and subject-reduction obstruction data.*
5. *S is the* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *row, consumed only after the frontier rows have been displayed.*
6. *L is the normalization audit ledger, recording candidate-mediated strong-normalization evidence, no-infinite-reduction projections, and refused global-normalization claims.*
7. *H records componentwise* hsame *transport for W, R, K, F, S, L and the local naming row.*
8. *C records displayed* Cont *replay from the finite window through redex-frontier inspection, candidate handoff, consistency-seal use, audit ledger, provenance, and local name.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFro}$ $\mathsf{NormalFormConsistencySeal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $W, R, K, F, S, L, H, C, P, N$. It has no coordinate for global strong normalization, full closed consistency, closed subject reduction, unrestricted beta-conversion decidability, hidden normalization transport, or host equality of MetaCIC terms.

Theorem 6314.2 (Finite-window normalization audit NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$ *carrier $A = (W, R, K, F, S, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowNormalizatio}}$ *surface consists exactly of carrier admission for the finite typed-term window, redex-frontier row, critical-path handoff row, normalization-frontier row, normal-form consistency seal row, normalization audit ledger, componentwise transport, displayed replay, provenance, and local naming. The audit conclusion is public only after the window W, frontier R, F, candidate handoff data in L, consistency-seal row S, transport H, replay C, provenance P, and local name N have been displayed.*

Proof. Project the accepted carrier $A = (W, R, K, F, S, L, H, C, P, N)$. The carrier definition exposes exactly the finite typed-term window, redex-frontier row, critical-path handoff, normalization frontier, consistency seal, audit ledger, transport, replay, provenance, and naming rows.

The window and redex-frontier rows are read first. They determine which finite terms and which frontier cells are inspected, so no conclusion can range over arbitrary closed typed terms.

The handoff rows K, F, S then attach the inspection to the existing MetaCIC critical path, normalization frontier, and normal-form consistency seal. The ledger row L records candidate-mediated strong-normalization evidence and refused global claims, while H, C, P, N preserve and name the same route.

Because the carrier has no coordinate for global strong normalization, closed subject reduction, full closed consistency, unrestricted beta-conversion, hidden normalization transport, or host equality, the listed rows exhaust the local NameCert obligations. □

Theorem 6314.3 (Finite-window normalization audit redex frontier)**.** *Every accepted* FiniteWindowNormalizationA *packet routes a normalization-audit read through*

$$W \longmapsto R \longmapsto F, L \longmapsto K, S \longmapsto H, C, P, N.$$

Thus a consumer must expose the finite typed-term window, redex-frontier row, candidate-mediated normalization frontier, audit ledger, MetaCIC critical-path row, normal-form consistency seal, componentwise transport, replay, provenance, and local naming before any normalization-audit conclusion is public.

Proof. Start with an audit consumer read. The finite window W is the only source of inspected terms, and the redex-frontier row R is the only source of visible frontier cells.

The normalization frontier F and audit ledger L are read after that window. They keep candidate evidence, finished-normal use, no-infinite-reduction consequences, and subject-reduction obstruction data attached to the displayed inspection.

The critical-path row K and consistency-seal row S are then consumed as handoff rows. They do not turn the packet into a proof of global normalization or full closed consistency; they only record how the finite audit may cite the existing MetaCIC route and seal.

Finally H, C, P, N transport, replay, source, and name the same finite route. Therefore every normalization-audit conclusion remains confined to the displayed window and redex frontier. □

Falsifiable prediction: Every accepted $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$ read exposes the finite typed-term window, redex-frontier row, candidate handoff, normalization audit ledger, hsame

transport, Cont replay, Pkg provenance, and local NameCert row before any normalization-audit conclusion is public.

Independence witness: metaciccriticalpath, normalformconsistencyseal, metacicnormalization-frontier, metacicclosuretrace: none is bijective with $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$ because the audit packet jointly binds the finite term window, redex frontier, candidate-mediated SN handoff, audit ledger, transport, replay, provenance, and local naming.

The Lean TasteGate surface for this packet must provide explicit $\mathsf{Nontrivial\ FiniteWindowNormalizationAudit}^{\uparrow}$ and $\mathsf{FieldFaithful\ FiniteWindowNormalizationAudit}^{\uparrow}$ instances preserving $W, R, K, F, S, L, H, C, P, N$ as distinct displayed rows before a checked target may cite the packet as a verified carrier-alignment theorem.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6314.1, Definition 6314.2, and Definition 6314.3 seed the finite normalization-audit route over typed-term windows, redex frontiers, critical-path rows, normalization-frontier rows, normal-form consistency seals, audit ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global strong normalization, full closed consistency, closed subject reduction, unrestricted beta-conversion decidability, hidden normalization transport, host equality of MetaCIC terms, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, redex-frontier exactness, candidate-mediated audit ledger exposure, critical-path handoff, normal-form seal handoff, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for BEDC.Derived.FiniteWindowNormalizationAuditUp.

Constructive story: A $\mathsf{FiniteWindowNormalizationAudit}^{\uparrow}$ packet is generated from a finite typed-term window, redex-frontier row, MetaCIC critical-path row, normalization-frontier row, normal-form consistency seal row, candidate-mediated audit ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6315

A Concrete Naming Certificate for $\mathsf{BishopRegularSequence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopRegularSequence}^{\uparrow}$ packet records the lawlike regular rational sequence before it is sealed as a $\mathsf{Real}^{\uparrow}$ name. It sits between the dyadic observation core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the Cauchy-modulus schedule of chapter 292, and the terminal real-name boundary of chapter 38. The packet names finite observations, windows, regularity rows, tail schedules, seal handoff, transport, replay, provenance, and a local certificate; it does not allocate quotient streams, selected representatives, countable-choice schedules, host real equality, or ambient completeness.

Definition 6315.1 (Bishop regular-sequence carrier)**.** *A* $\mathsf{BishopRegularSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, naming the dyadic rational values and tolerance comparisons available to the sequence.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing the inspected prefixes and tail windows of the lawlike sequence.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row attached to the same windows and dyadic observations.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row, recording the finite tail threshold supplied for each dyadic tolerance request.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff, available only after D, W, R, M have been displayed.*
6. *H stores componentwise* hsame *transport for the observation, window, regularity, modulus, seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from observations and windows through regularity and modulus data to the seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularSequence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, hidden representatives, countable choice, host real equality, or an ambient completeness principle.

Theorem 6315.2 (Bishop regular-sequence NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularSequence}^{\uparrow}$ *carrier* $B = (D, W, R, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularSequence}^{\uparrow}}$ *surface consists of the following five obligation rows:*

1. *carrier admission for the displayed packet* $D, W, R, M, E, H, C, P, N$*;*
2. *observation and window exposure through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$*;*
3. *regularity and tail-modulus exposure through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{CauchyModulus}^{\uparrow}$*;*
4. *terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff through* E *after the observation, window, regularity, and modulus rows are visible;*
5. *structural stability through* hsame*,* Cont*,* Pkg*, and the local* $\mathsf{NameCert}$ *row.*

No accepted obligation row may be discharged by quotient streams, a selected limit, countable choice, host real equality, or ambient Real completeness.

Proof. Project the carrier of Definition 6315.1. The analytic rows are exactly D, W, R, M, E, and the structural rows are exactly H, C, P, N.

The observation and window rows are read first. The $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies dyadic values and tolerance comparisons, while the $\mathsf{StreamName}^{\uparrow}$ row supplies the finite inspected windows.

Next read the regularity and modulus rows. The $\mathsf{RegSeqRat}^{\uparrow}$ row states the displayed regularity of the same windows, and the $\mathsf{CauchyModulus}^{\uparrow}$ row supplies the finite tail threshold for each dyadic tolerance request.

Finally the seal handoff and structural rows are consumed. The $\mathsf{Real}^{\uparrow}$ row E is downstream of D, W, R, M, and H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no coordinate for the refused host-level data, the five obligations exhaust the local NameCert surface. □

Theorem 6315.3 (Bishop regular-sequence tail-modulus induction)**.** *For every accepted* $\mathsf{BishopRegularSequence}^{\uparrow}$ *carrier* $B = (D, W, R, M, E, H, C, P, N)$ *and every finite dyadic tolerance request read through* D*, primitive induction on the displayed tail schedule* M *produces a window threshold in* W *such that all later inspected windows preserve the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row* R *before the* $\mathsf{Real}^{\uparrow}$ *seal handoff* E *is exposed. The induction stays inside the route*

$$D \longmapsto M \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

It does not select an external infinite tail, quotient two streams, choose a representative, or invoke ambient completeness.

Proof. Begin with a dyadic tolerance request in D. The request is finite BEDC data, so it can be passed to the displayed $\mathsf{CauchyModulus}^{\uparrow}$ schedule row M without invoking an external selector.

Induct on the finite tail schedule carried by M. The base case exposes the first admissible window in W for the requested tolerance. The successor step refines the inspected window while preserving the same dyadic tolerance row and the same $\mathsf{StreamName}^{\uparrow}$ route.

Use the regularity row R after the window threshold is displayed. The $\mathsf{RegSeqRat}^{\uparrow}$ row is attached to D and W, so every later inspected window remains a regular rational readback inside the same packet.

Finally expose E, H, C, P, N. The $\mathsf{Real}^{\uparrow}$ seal is reached only after the induced tail threshold and regularity row are visible, and the structural rows replay the same finite route. Thus the

induction provides a tail-modulus handoff for the public seal without quotient streams, selected limits, hidden representatives, or ambient completeness. □

Falsifiable prediction: A claimed $\mathsf{BishopRegularSequence}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying $\mathsf{DyadicRatCore}^{\uparrow}$ observations, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ regularity, and a $\mathsf{CauchyModulus}^{\uparrow}$ tail schedule refutes the carrier.

Independence witness: dyadicratcore, streamname, regseqrat, cauchymodulus, real: no listed sibling is bijective to $\mathsf{BishopRegularSequence}^{\uparrow}$ because the packet jointly carries dyadic observations, finite sequence windows, regularity rows, tail-modulus schedules, Real seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularSequence}^{\uparrow}$ packet is generated from DyadicRatCore observations, StreamName finite windows, RegSeqRat regularity rows, a CauchyModulus tail schedule, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6315.1, Definition 6315.2, and Definition 6315.3 seed the finite regular-sequence route from dyadic observations and windows to the Real seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{BishopRegularSequence}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, observation and window exposure, regularity readback, tail-modulus induction, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularSequence

Chapter 6316

A Concrete Naming Certificate for $\mathsf{SystemF}^{\uparrow}$

Following Girard and Reynolds, $\mathsf{SystemF}^{\uparrow}$ is read here as the finite NameCert surface for the polymorphic typed lambda calculus. It sits between the term-syntax carrier of chapter 200, the first-order symbol and formula interface of chapter 197, the computability boundary of chapter 199, the type-like classifier surface of chapter 3600, and the typed normalization packets of chapter 6305 and chapter 6306. The packet names polymorphic syntax and typing as displayed BEDC rows; it does not export an ambient host calculus, quotient syntax equality, impredicative set semantics, or a global normalization theorem.

Definition 6316.1 (System F carrier)**.** *A* $\mathsf{SystemF}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, A, L, E, T, B, I, H, C, P, N)$$

with the following displayed rows:

1. *X is the term-variable row, naming de Bruijn or locally named term variables through finite* BHist *syntax endpoints.*
2. *A is the type-variable row, naming type variables separately from term variables and recording their binder depth.*
3. *L is the lambda row, carrying term abstraction and term application over the* $\mathsf{LambdaCalc}^{\uparrow}$ *syntax surface.*
4. *E is the type row, carrying type variables, arrow types, and universal type binders as displayed finite syntax.*
5. *T is the typing-context row, listing term-variable assumptions, type-variable assumptions, and the finite scope in which a judgment is read.*
6. *B is the beta and type-instantiation route row, recording term beta contraction and universal-type instantiation as ledgered source and endpoint rows.*
7. *I is the type-abstraction and type-application row, recording Λ-abstraction over type variables and application of polymorphic terms to displayed type rows.*
8. *H records componentwise* hsame *transport for term variables, type variables, lambda syntax, type syntax, contexts, beta and instantiation routes, abstraction/application rows, replay, provenance, and local names.*

9. *C records displayed* Cont *replay from a requested typing or reduction read through X, A, L, E, T, B, I.*
10. *P is the* Pkg *provenance over* $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{Computable}^{\uparrow}$, $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{NormalizationByEvaluation}^{\uparrow}$, $\mathsf{NeutralReifier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SystemF}^{\uparrow}}$ *row.*

The classifier accepts a packet only when term syntax, type syntax, typing context, beta routes, and type-instantiation routes are all displayed as finite rows. No coordinate may be a host parser, a host type checker, an external alpha-equivalence quotient, or an unlogged semantic model.

Theorem 6316.2 (System F NameCert obligations)**.** *For every accepted* $\mathsf{SystemF}^{\uparrow}$ *carrier $F = (X, A, L, E, T, B, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SystemF}^{\uparrow}}$ *surface consists exactly of carrier admission, typing-surface exactness, type-abstraction stability, beta/type-instantiation nonescape, and provenance exhaustion over the displayed rows. In particular, every consumer of a* $\mathsf{SystemF}^{\uparrow}$ *typing, beta, or type-instantiation conclusion must first read the route*

$$X, A, L, E, T, B, I, H, C, P, N.$$

The packet supplies polymorphic typed-lambda-calculus data, but it supplies no host-level type checker, quotient equality of terms or types, impredicative semantic universe, parametricity theorem, subject-reduction theorem beyond the displayed route, or global normalization result.

Proof. Carrier admission is projection from Definition 6316.1. The tuple exposes term variables, type variables, lambda syntax, type syntax, typing context, beta/type-instantiation routes, type abstraction/application rows, transport, replay, provenance, and local naming as the only accepted coordinates.

Typing-surface exactness follows by reading the context row T together with the term and type syntax rows X, A, L, E. A typing judgment is accepted only when its variable assumptions, type assumptions, binder scopes, term endpoint, and type endpoint are all present in those displayed rows.

Type-abstraction stability is the role of I. The type-variable row A records the binder being abstracted, the context row T records the extended scope, and componentwise transport H preserves the same abstraction or type-application endpoint under hsame.

Beta and type-instantiation nonescape is enforced by B and C. A term beta read must pass through the displayed lambda source and substitution endpoint, while a polymorphic instantiation read must pass through the displayed universal type binder and argument type row; replay cannot jump to a host evaluator or external substitution function.

Provenance exhaustion is supplied by P and N. The cited sibling chapters provide the finite syntax, typing-shape, computability, type-like, and normalization-facing surfaces consumed by the packet, and no additional row is available from which a consumer could recover quotient syntax equality, impredicative semantics, parametricity, subject reduction, or global normalization. □

Falsifiable prediction: Every accepted $\mathsf{SystemF}^{\uparrow}$ typing, beta, or type-instantiation read factors through the term-variable row, type-variable row, lambda syntax row, type syntax row, typing-context row, beta/type-instantiation route, type-abstraction/application row, componentwise transport, continuation replay, provenance, and local NameCert before any consumer may cite the conclusion.

Independence witness: lambdacalc, firstorder, computable, typelike, normalization-by-evaluation, neutral-reifier: $\mathsf{SystemF}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries term variables, type variables, typed lambda syntax, universal type abstraction and application, typing contexts, beta routes, type-instantiation routes, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SystemF}\uparrow}$**.**

Constructive story: A $\mathsf{SystemF}^{\uparrow}$ packet is generated from term-variable rows, type-variable rows, lambda syntax rows, type syntax rows, typing-context rows, beta/type-instantiation route rows, type-abstraction/application rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SystemF}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6316.1 and Definition 6316.2 seed the finite polymorphic typed-lambda-calculus packet and its NameCert obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SystemF}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient syntax equality, impredicative set semantics, parametricity, closed subject reduction, global normalization, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, typing-surface exactness, type-abstraction stability, beta/type-instantiation nonescape, and provenance exhaustion for BEDC.Derived.SystemFUp.

Chapter 6317

A Concrete Naming Certificate for $\mathsf{CompilerClosureSelfCompilation}^{\uparrow}$

The $\mathsf{CompilerClosureSelfCompilation}^{\uparrow}$ packet realizes the compiler-closure self-compilation audit surface of chapter 9411 as finite BEDC rows. It sits beside the subject-reduction-discharge-socket chapter chapter 719, the metacic-subject-reduction-trace chapter chapter 723, the normalization-by-evaluation chapter chapter 6305, the neutral-reifier chapter chapter 6306, and the public-local-reflective-compilation chapter chapter 3963. The packet names the finite flow from genome data to compiler phenotype, feedback, export seal, and audit ledger; it does not claim an unrestricted reflective compiler, hidden host prompt state, closed subject reduction, or unbounded self-application.

Definition 6317.1 (CompilerClosureSelfCompilation carrier)**.** *A* $\mathsf{CompilerClosureSelfCompilation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, \Phi, F, L, E, S, H, C, P, N)$$

with the following displayed rows:

1. *G is the genome-flow row, recording the finite source theorem-flow, carrier rows, and compiler-facing genome entries supplied to the self-compilation audit.*
2. *Φ is the compiler-phenotype row, recording the expressed compiler behavior as a finite BEDC object rather than a host executable.*
3. *F is the feedback-ledger row, recording how accepted compiler observations feed back into the next accepted genome-flow row.*
4. *L is the audit-ledger row, recording the finite evidence obligations that link genome flow, phenotype, feedback, and accepted output.*
5. *E is the export-seal row, recording which generated artifacts may be exported as public compiler data and which remain local audit evidence.*
6. *S is the sibling-route row, naming subject-reduction-discharge-socket, metacic-subject-reduction-trace, normalization-by-evaluation, neutral-reifier, and public-local-reflective-compilation as the only imported certificate surfaces.*
7. *H records componentwise* hsame *transport for genome flow, compiler phenotype, feedback ledger, audit ledger, export seal, sibling routes, replay, provenance, and local names.*
8. *C records displayed* Cont *replay from a requested self-compilation read through G, Φ, F, L, E, S.*

9. *P is the* Pkg *provenance over* SubjectReductionDischargeSocket$^{\uparrow}$, MetaCICSubjectReductionTrace$^{\uparrow}$, NormalizationByEvaluation$^{\uparrow}$, NeutralReifier$^{\uparrow}$, PublicLocalReflectiveCompilation$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompilerClosureSelfCompilation}^{\uparrow}}$ *row.*

The classifier accepts a packet only when genome flow, compiler phenotype, feedback, export, transport, replay, provenance, and local naming are all displayed as finite rows. No coordinate stores a host compiler executable, hidden global state, an unrestricted reflective evaluator, or a closed subject-reduction theorem.

Theorem 6317.2 (CompilerClosureSelfCompilation NameCert obligations)**.** *For every accepted* CompilerClosureSelfCompilation$^{\uparrow}$ *carrier $K = (G, \Phi, F, L, E, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompilerClosureSelfCompila}}$ *surface consists exactly of genome-flow admission, compiler-phenotype exposure, feedback-ledger replay, export-seal exactness, transport stability, replay stability, provenance exhaustion, and local naming over the displayed rows. In particular, every consumer of a compiler-closure self-compilation conclusion must first read the route*

$$G, \Phi, F, L, E, S, H, C, P, N.$$

The route exports no host compiler executable, hidden prompt state, global reflective authority, unlogged feedback loop, closed subject-reduction proof, or unbounded self-application.

Proof. Genome-flow admission projects the row G from the carrier. The input flow is finite theorem and carrier data, so a consumer cannot replace it by an ambient repository state or hidden prompt stream.

Compiler-phenotype exposure is the row Φ. It records expressed compiler behavior as a displayed object and therefore separates compiler phenotype from a host executable or external build system.

Feedback-ledger replay uses F and L. The accepted observation must be listed in the feedback ledger and tied to the audit ledger before it can affect the next genome-flow row.

Export-seal exactness is supplied by E. Public compiler data may leave the packet only through the seal, while local audit rows remain local and cannot be promoted to public authority by replay alone.

Transport and replay stability follow from H and C. These rows move genome flow, phenotype, feedback, ledger, export, and sibling-route data together, so no consumer can bypass the displayed sequence.

Provenance exhaustion is supplied by S, P, N. The only sibling surfaces available are subject-reduction-discharge-socket, metacic-subject-reduction-trace, normalization-by-evaluation, neutral-reifier, and public-local-reflective-compilation, and none of them adds a host compiler executable, hidden prompt state, closed subject-reduction proof, or unrestricted self-application coordinate. □

Falsifiable prediction: Every accepted CompilerClosureSelfCompilation$^{\uparrow}$ self-compilation read factors through the genome-flow row, compiler-phenotype row, feedback ledger, audit ledger, export seal, sibling-route row, componentwise transport, continuation replay, provenance, and local NameCert before any consumer may cite compiler-closure output.

Independence witness: subject-reduction-discharge-socket, metacic-subject-reduction-trace, normalization-by-evaluation, neutral-reifier, public-local-reflective-compilation: CompilerClosureSelfCompilation$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries genome flow, compiler phenotype,

feedback ledger, audit ledger, export seal, sibling routing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CompilerClosureSelfCompilation}^{\uparrow}}$.

Constructive story: A $\mathsf{CompilerClosureSelfCompilation}^{\uparrow}$ packet is generated from genome-flow rows, compiler-phenotype rows, feedback-ledger rows, audit-ledger rows, export-seal rows, sibling-route rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompilerClosureSelfCompilation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6317.1 and Definition 6317.2 seed the finite compiler-closure self-compilation packet and its audit surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompilerClosureSelfCompilation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted reflective compilation, hidden prompt state, closed subject reduction, host compiler semantics, or Lean verification.

Upgrade path: Obligation closure requires checked genome-flow admission, compiler-phenotype exposure, feedback-ledger replay, export-seal exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompilerClosureSelfCompilationUp.

Chapter 6318

A Concrete Naming Certificate for $\mathsf{ChoiceSequenceReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Troelstra–van Dalen on choice sequences, the $\mathsf{ChoiceSequenceReal}^{\uparrow}$ packet names a finite-prefix real surface before any consumer reads an infinite branch. It sits after the finite StreamName window of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. It also shares the choice-free boundary discipline of chapter 1406: finite prefixes may be inspected, but no selected limit, quotient stream equality, countable choice, trichotomy, or ambient Real completeness is exported.

Definition 6318.1 (ChoiceSequenceReal carrier)**.** *A* $\mathsf{ChoiceSequenceReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (F, S, R, D, E, H, T, P, N)$$

with the following displayed rows:

1. *F is the finite prefix schedule. It lists the admitted prefix length, the unary request indices, and the displayed dependency of each read on earlier finite choices.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite stream observations exposed by F before any infinite branch is named.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It stores the regular rational values read from the finite stream window and the visible modulus entries used by later real-name consumers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the signed dyadic mantissa, denominator, radius, and terminal half-radius rows used to certify the readback tolerance.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It may be consumed only after F, S, R, D have been displayed, and it stores no selected endpoint beyond that finite route.*
6. *H records componentwise* hsame *transport for finite prefixes, stream windows, regular rational readback, dyadic tolerance rows, Real seal rows, replay, provenance, and local naming.*
7. *T records displayed* Cont *replay from finite prefix schedules to StreamName windows, from StreamName windows to RegSeqRat readback, from dyadic tolerance rows to the terminal Real seal, and from structural rows to local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{ChoiceSequenceReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{ChoiceSequenceReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, R, D, E, H, T, P, N$. It has no coordinate for quotient stream equality, selected infinite branches, countable choice, trichotomy of arbitrary reals, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6318.2 (ChoiceSequenceReal NameCert obligations)**.** *For every accepted* $\mathsf{ChoiceSequenceReal}^{\uparrow}$ *carrier $C = (F, S, R, D, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChoiceSequenceReal}^{\uparrow}}$ *surface consists exactly of finite prefix admission, StreamName window exposure, RegSeqRat regular readback, DyadicRatCore tolerance ledger admission, Real seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must read the displayed route*

$$F, S, R, D \longmapsto E, H, T, P, N$$

before it can consume the packet as real-name evidence.

Proof. Project the accepted carrier row by row. The finite prefix schedule F, the stream window S, the regular rational readback R, and the dyadic tolerance ledger D are the only rows that carry mathematical read data.

The Real seal row E is downstream from those rows. It can be replayed only through the displayed Cont route T and transported only through the componentwise hsame row H.

The provenance and naming rows P, N name the same route. Since no other coordinate is present, the local certificate has no source for quotient stream equality, selected infinite branches, countable choice, trichotomy, metric completeness, or ambient Real completeness. □

Theorem 6318.3 (ChoiceSequenceReal finite-prefix regularity)**.** *Let $C = (F, S, R, D, E, H, T, P, N)$ be an accepted* $\mathsf{ChoiceSequenceReal}^{\uparrow}$ *carrier. Any finite extension of the displayed prefix schedule whose new reads preserve the same StreamName window discipline and DyadicRatCore tolerance ledger has a RegSeqRat readback on a common finite window before the downstream* $\mathsf{Real}^{\uparrow}$ *seal is opened.*

The regularity read is determined by F, S, R, D, H, T, P, N. It does not choose an infinite branch, identify quotient streams, select a limit, use countable choice, appeal to metric completeness, or import ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite prefix schedule F and its StreamName window S. A finite extension supplies more displayed reads but remains a finite BHist row.

Use the RegSeqRat readback row R and the DyadicRatCore tolerance ledger D on the combined finite window. The common window has the same regular rational values and tolerance rows needed by the downstream seal.

Finally transport and replay through H and T, with provenance and local naming recorded by P and N. The argument never leaves the finite packet, so it cannot introduce a selected branch, quotient stream equality, a chosen limit, countable choice, metric completeness, or ambient Real completeness. □

Theorem 6318.4 (ChoiceSequenceReal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or Completion-facing read of an accepted* $\mathsf{ChoiceSequenceReal}^{\uparrow}$ *packet factors through the finite prefix schedule, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, structural transport, replay, provenance, and local NameCert rows displayed by the carrier. No consumer can bypass those rows by appealing to a selected limit, countable choice, quotient stream equality, trichotomy, metric completeness, bridge row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 6318.2. It identifies the only local certificate rows available to a Real or Completion consumer.

Then apply Definition 6318.3. Finite prefix extensions and their regular readbacks remain inside the displayed StreamName, RegSeqRat, and DyadicRatCore route before the Real seal is consumed.

The sibling surfaces provide the boundary of the route: chapter 126 supplies finite stream windows, chapter 301 supplies regular rational readback, chapter 291 supplies dyadic tolerance rows, chapter 38 supplies the terminal seal, and chapter 1406 records the compatible nonselection discipline. Hence the packet exports no bypass through the excluded global objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceSequenceReal}\uparrow}$.

Constructive story: A $\mathsf{ChoiceSequenceReal}^{\uparrow}$ packet is generated from a finite prefix schedule, StreamName finite windows, RegSeqRat regular readback, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceSequenceReal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6318.1, Definition 6318.2, Definition 6318.3, and Definition 6318.4 seed the finite-prefix real-name packet for the open L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceSequenceReal}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, countable choice, quotient stream equality, trichotomy, metric completeness, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix regularity, terminal Real-seal nonescape, transport stability, replay exactness, and local NameCert replay for BEDC.Derived.ChoiceSequenceRealUp.

Chapter 6319

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$

The $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ packet realizes the shell-level reading of chapter 9463 as finite boundary-shadow, visual-boundary, phase-distance, transport, provenance, and NameCert rows. It unifies the boundary-shadow route of chapter 3813, the visual boundary route of chapter 4181, the phase-distance observer-expansion route of chapter 6017, the observer phase groupoid of chapter 6146, and the Poincare disk metric boundary of chapter 6209. The shell is a boundary-facing packet, not a physical cosmology and not a center-inside-disk assertion.

Definition 6319.1 (Hyperbolic observer phase shell carrier)**.** *A* $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, V, D, G, M, H, T, P, N)$$

with the following displayed rows:

1. *B is the boundary-shadow row, recording the finite far-end shadow data through which observer expansion is read at the boundary rather than at an interior center.*
2. *V is the visual-boundary row, recording the finite visual-boundary readback attached to the displayed boundary shadow.*
3. *D is the phase-distance row, recording the finite distance comparison used by observer expansion before any global hyperbolic geometry is invoked.*
4. *G is the observer phase groupoid row, recording source, target, inverse, and composition data for the reversible phase-surface transport visible in the shell.*
5. *M is the Poincare-disk metric row, recording only the finite disk metric comparisons needed by B, V, D, G.*
6. *H records componentwise* hsame *transport for boundary-shadow, visual-boundary, phase-distance, groupoid, disk-metric, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay from boundary shadows to visual-boundary reads, from visual-boundary reads to phase-distance comparisons, from phase-distance comparisons to observer phase transport, and from those rows to local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$*, hyperbolic observer expansion, hyperbolic visual boundary, phase-distance observer expansion, observer phase groupoid, Poincare disk metric,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}}$ *row.*
The classifier compares accepted shells only through $B, V, D, G, M, H, T, P, N$. It has no coordinate for an interior center of the far end, physical cosmology, host global hyperbolic space, untracked geodesic completion, or ambient real completeness.

Theorem 6319.2 (Hyperbolic observer phase shell NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ *carrier $S = (B, V, D, G, M, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}}$ *surface is exhausted by boundary-shadow admission, visual-boundary readback, phase-distance comparison, observer phase groupoid transport, Poincare-disk metric comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every shell read factors through*

$$B, V, D, G, M \longmapsto H, T, P, N.$$

Proof. Project the accepted shell carrier. The boundary-shadow, visual-boundary, phase-distance, observer phase groupoid, and disk-metric rows are the only geometric rows visible to the local certificate.

The structural rows preserve that visible route. Componentwise hsame transport can move only displayed coordinates, and displayed Cont replay can traverse only the listed route from boundary shadow through local naming.

The provenance and local naming rows record the same finite packet. Since no other row is present, a shell consumer receives no interior center, physical-cosmology datum, host global hyperbolic space, untracked geodesic completion, or ambient real-completeness principle. □

Theorem 6319.3 (Hyperbolic observer phase shell boundary nonescape)**.** *Any observer-expansion read of an accepted* $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ *packet is boundary-facing: it must read the boundary-shadow row, visual-boundary row, phase-distance row, observer phase groupoid row, Poincare-disk metric row, transport, replay, provenance, and local naming before it may use the shell as phase geometry evidence. The read cannot move the far end into an interior disk center, interpret the shell as physical cosmology, or appeal to host global geometry, untracked completion, or ambient real completeness.*

Proof. Use Definition 6319.2 to expose the shell route. The only admissible reads are the rows $B, V, D, G, M, H, T, P, N$.

The boundary-shadow row B and visual-boundary row V force the read to remain boundary-facing. The phase-distance and groupoid rows D, G may compare and transport observer phases, but they do so through displayed finite rows rather than through a hidden global hyperbolic object.

The disk-metric row M supplies only the local Poincare metric comparisons named by the packet. Transport, replay, provenance, and local naming preserve that packet, so no excluded center, cosmology, completion, or ambient real-completeness object can enter the read. □

Falsifiable prediction: Every shell read of an accepted $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ packet factors through boundary-shadow, visual-boundary, phase-distance, transport, provenance, and local $\mathsf{NameCert}$ rows before any observer-expansion conclusion is consumed.

Independence witness: hyperbolic-observer-expansion, hyperbolic-visual-boundary, phase-distance-observer-expansion, observer-phase-groupoid, poincare-disk-metric: $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ is not bijective to any listed sibling because it uniquely names their boundary-shadow, visual-boundary, phase-distance, transport, provenance, and local NameCert rows as one shell-level carrier.

The later TasteGate file for this shell must require Lean ‘Nontrivial‘ and ‘FieldFaithful‘ instances before any positive discovery or classifier-shift gate is recorded. Without those instances, the shell remains a finite NameCert packet and not a field-sensitive discovery claim.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseShell}\uparrow}$.

Constructive story: A $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ packet is generated from boundary-shadow rows, visual-boundary rows, phase-distance rows, observer phase groupoid rows, Poincare-disk metric rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseShell}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6319.1, Definition 6319.2, and Definition 6319.3 seed the shell-level boundary-facing observer-expansion packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseShell}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an interior far-end center, physical cosmology, host global hyperbolic geometry, untracked geodesic completion, Lean verification, bridge checking, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow admission, visual-boundary readback, phase-distance comparison, observer phase groupoid transport, disk-metric comparison, transport stability, replay exactness, and local NameCert replay for BEDC.Derived.HyperbolicObserverPhaseShellUp.

Chapter 6320

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$ packet records the finite diagonal route by which dyadic endpoint data becomes a regular-Cauchy name before any $\mathsf{Real}^{\uparrow}$ consumer may read it as a Real-facing presentation. It sits between the dyadic arithmetic core of chapter 291, the finite window surface of chapter 126, the regular-rational readback route of chapter 301, and the terminal Real naming packet of chapter 38. The certificate is a displayed embedding route for constant and diagonal Cauchy names; it is not a quotient-sequence equality, selected limit, ambient completeness theorem, or host Real construction.

Definition 6320.1 (Regular Cauchy diagonal embedding carrier)**.** *A* $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, including the dyadic source value and the dyadic tolerance ledger inspected by the diagonal route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row recording the finite windows at which the diagonal name is read.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row recording the regular-rational sequence obtained from the dyadic endpoint and window data.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *consumer row, available only as a named endpoint read of the displayed regular-Cauchy presentation.*
5. *H records componentwise* hsame *transport for the dyadic endpoint, stream windows, regular-rational readback, Real consumer row, and local naming row.*
6. *C records displayed* Cont *replay from dyadic endpoint data through stream windows, regular-rational readback, the Real consumer row, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, S, Q, R, H, C, P, N. It has no coordinate for quotient sequence equality, selected representatives, an ambient Real limit, countable choice, or host equality of completed Real values.

Theorem 6320.2 (Regular Cauchy diagonal embedding NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$ *carrier* $E = (D, S, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagona}}$ *surface consists exactly of carrier admission for the dyadic endpoint row, stream-window row, regular-rational readback row, Real consumer row, componentwise transport, displayed replay, provenance, and local naming. Every Real-facing read must expose D, S, Q, H, C, P, N before it may consume R as the public endpoint row.*

Proof. Project the carrier of Definition 6320.1. The source row is D, the finite observation row is S, the regular-Cauchy readback row is Q, and the endpoint consumer row is R.

The naming surface orders those rows. A Real-facing read starts from the dyadic endpoint and tolerance ledger, then opens the StreamName windows, then reads the RegSeqRat presentation produced by the diagonal route.

The structural rows H, C, P, N preserve this same route under transport, replay, provenance, and local naming. Since the carrier contains no quotient sequence equality, selected representative, ambient limit, countable-choice schedule, or host equality coordinate, the listed rows exhaust the local certificate obligations. □

Theorem 6320.3 (Regular Cauchy diagonal embedding constant-sequence stability)**.** *If two accepted* $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$ *packets have classifier-equivalent dyadic endpoint rows and are read through the same* $\mathsf{StreamName}^{\uparrow}$ *windows, then their diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows remain componentwise* hsame *before the shared* $\mathsf{Real}^{\uparrow}$ *consumer row is public. Thus a constant dyadic endpoint cannot be separated by the diagonal embedding unless the displayed dyadic endpoint, stream-window, or regular-rational readback row is separated.*

Proof. Read both packets through Definition 6320.1. Classifier equivalence fixes the dyadic endpoint row D and the shared windows fix the observation row S.

The regular-rational readback row Q is downstream of exactly those two rows. By Definition 6320.2, a Real-facing read cannot inspect R before the dyadic endpoint, stream windows, regular readback, transport, replay, provenance, and local naming rows have been displayed.

The componentwise hsame row H therefore transports the equality of the dyadic and window data to the regular-rational readback. Any separation of the constant diagonal presentation must be visible in D, S, or Q, not in a hidden quotient, selected representative, ambient Real limit, or host equality. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$ read exposes the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any $\mathsf{Real}^{\uparrow}$ endpoint row is public.

Independence witness: dyadicratcore, streamname, regseqrat, real: no listed sibling is bijective with $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$ because the packet jointly binds the dyadic endpoint, finite windows, diagonal regular-rational readback, Real consumer row, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalEmbedding}^{\uparrow}$ packet is generated from a DyadicRatCore endpoint row, StreamName windows, RegSeqRat diagonal readback, a Real consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyDiagonalEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 6320.1, Definition 6320.2, and Definition 6320.3 seed the finite diagonal route from dyadic endpoints through stream windows and regular-rational readback to Real-facing consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyDiagonalEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient sequence equality, selected representatives, ambient Real completeness, selected limits, countable choice, Lean verification, or bridge checking for RegularCauchyDiagonalEmbedding$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, diagonal readback exactness, constant-sequence stability, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyDiagonalEmbeddingUp.

Chapter 6321

A Concrete Naming Certificate for $\mathsf{MetaCICResidualContextCut}^{\uparrow}$

The $\mathsf{MetaCICResidualContextCut}^{\uparrow}$ packet realizes the subject-reduction obstruction of chapter 9377 as finite typed-context, residual-cut, candidate-boundary, and provenance rows. It sits beside the finite-window normalization audit of chapter 6314, the MetaCIC critical path of chapter 765, and the subject-reduction discharge packets already attached to the obstruction map. The packet names a boundary where a reduction residual must preserve enough context data before a candidate-normalization or subject-reduction consumer may proceed.

Definition 6321.1 (MetaCIC residual-context cut carrier)**.** *A* $\mathsf{MetaCICResidualContextCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, R, B, A, O, H, C, P, N)$$

with the following displayed rows:

1. *G is the typed-context row, recording the inspected context, binder boundary, closedness window, and typing judgement visible to the packet.*
2. *R is the residual-cut row, recording the beta or congruence residual whose source and target must remain attached to G.*
3. *B is the candidate-boundary row, recording the candidate-normalization evidence or refusal boundary available at the inspected residual.*
4. *A is the subject-reduction obstruction row, naming the four discharge obligations and the checked obstruction boundary read from chapter 9377.*
5. *O is the observation ledger, recording which typed-context, residual, candidate, and obstruction fields are public to downstream reads.*
6. *H records componentwise* hsame *transport for G, R, B, A, O and the local naming row.*
7. *C records displayed* Cont *replay from typed-context inspection through residual cut, candidate boundary, obstruction row, observation ledger, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualContextCut}^{\uparrow}$*, typed-context rows, residual-cut rows, candidate-normalization boundaries, subject-reduction obstruction rows,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualContextCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, R, B, A, O, H, C, P, N$. It has no coordinate for an unconditional closed subject-reduction theorem, hidden substitution lemma, unrestricted normalization theorem, host equality of terms, or global conversion oracle.

Theorem 6321.2 (MetaCIC residual-context cut NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICResidualContextCut}^{\uparrow}$ *carrier* $K = (G, R, B, A, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualContextCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the typed-context row, residual-cut row, candidate-boundary row, subject-reduction obstruction row, observation ledger, componentwise transport, displayed replay, provenance, and local naming. Every accepted read factors through* $G, R, B, A, O, H, C, P, N$ *before it may cite the residual as a subject-reduction or normalization boundary.*

Proof. Project the carrier of Definition 6321.1. The typed-context row G fixes the visible context and judgement, and the residual-cut row R fixes the source-target residual attached to that context.

The candidate-boundary row B and obstruction row A are read next. They attach the residual to candidate-normalization evidence and to the four-obligation subject-reduction interface, without turning either surface into a hidden global theorem.

The observation ledger O records which fields are public. The structural rows H, C, P, N then transport, replay, source, and name exactly the displayed route, so no unconditional closed subject-reduction theorem, hidden substitution lemma, unrestricted normalization theorem, host term equality, or conversion oracle can be exported. □

Theorem 6321.3 (MetaCIC residual-context cut subject-reduction obstruction)**.** *Every* MetaCICResidualContextC *packet that is accepted as a subject-reduction boundary exposes the route*

$$G \longmapsto R \longmapsto B, A \longmapsto O \longmapsto H, C, P, N.$$

Consequently the packet may name a residual-context obstruction, but it cannot supply an unconditional closed subject-reduction theorem unless the typed-context, residual-cut, candidate-boundary, and obstruction rows are replaced by checked discharge data outside this packet.

Proof. Begin with an accepted subject-reduction boundary read. The carrier definition supplies the typed-context row G and the residual-cut row R as the only source of local context and reduction data.

Apply Definition 6321.2. The candidate-boundary row B and subject-reduction obstruction row A must be displayed before the observation ledger or any downstream consumer can read the packet.

The route closes through O, H, C, P, N. These rows expose, transport, replay, source, and name the boundary, but none of them contains the missing four discharge obligations as checked data. The packet therefore records the obstruction boundary rather than converting it into a closed subject-reduction theorem. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualContextCut}^{\uparrow}$ read factors through typed-context, residual-cut, candidate-boundary, hsame, Cont, Pkg, and NameCert rows before any subject-reduction or normalization-boundary conclusion is public.

Independence witness: metacic-confluence-critical-pair-boundary, metacic-normalization-window-confluence, metacic-candidate-set-normalization, closed-pi-domain-subject-reduction: none is bijective with $\mathsf{MetaCICResidualContextCut}^{\uparrow}$ because this packet jointly binds the typed-context row, residual-cut row, candidate-boundary row, subject-reduction obstruction row, observation ledger, transport, replay, provenance, and local NameCert.

The Lean TasteGate surface for this packet must later provide explicit Nontrivial MetaCICResidualContextCut$^{\uparrow}$ and FieldFaithful MetaCICResidualContextCut$^{\uparrow}$ instances in $BEDC.Derived.MetaCICResidualContextCutUp.Ta$ preserving $G, R, B, A, O, H, C, P, N$ as distinct displayed rows before a checked target may cite the packet as a verified carrier-alignment theorem.

Closure status for NameCert$_{\text{MetaCICResidualContextCut}^{\uparrow}}$.

Constructive story: A MetaCICResidualContextCut$^{\uparrow}$ packet is generated from a typed-context row, residual-cut row, candidate-boundary row, subject-reduction obstruction row, observation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICResidualContextCut}^{\uparrow}}$, seed)

Scope closed: Definition 6321.1, Definition 6321.2, and Definition 6321.3 seed the finite residual-context obstruction route over typed contexts, residual cuts, candidate boundaries, observation ledgers, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICResidualContextCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unconditional closed subject reduction, beta-substitution preservation, application-argument stability, lambda-domain preservation, Pi-domain preservation, global normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-context exactness, residual-cut exactness, candidate-boundary exposure, obstruction-row exposure, observation-ledger replay, and Nontrivial and FieldFaithful instances for BEDC.Derived.MetaCICResidualContextCutUp.

Chapter 6322

A Concrete Naming Certificate for $\mathsf{OpialCondition}^{\uparrow}$

Following Opial's fixed-point tradition, the $\mathsf{OpialCondition}^{\uparrow}$ packet records the finite certificate surface by which a bounded sequence window, a candidate weak-limit row, and a limsup-distance comparison are made available to nonexpansive fixed-point consumers without importing weak compactness, selected weak limits, or countable choice. It depends on the metric carrier of chapter 57, the Banach carrier of **??**, the regular Cauchy nonexpansive transport route of chapter 2105, and the L10 sequence/readback route represented by chapter 6315 and chapter 1413.

Definition 6322.1 (Opial condition carrier)**.** *An* $\mathsf{OpialCondition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (M, B, S, W, L, D, F, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row on which distance readings are measured.*
2. *B is the ambient* $\mathsf{BanachSpace}^{\uparrow}$ *row, exposing only the linear and norm data needed to read the same metric distances through the Banach carrier.*
3. *S is the bounded sequence row, displayed through the L10 sequence/readback route rather than through an infinite choice object.*
4. *W is the finite bounded-sequence window opened around the requested tail and tolerance.*
5. *L is the candidate limit row. It is a named point read against M and B, not a selected weak limit supplied by a compactness principle.*
6. *D is the displayed limsup-distance comparison ledger*

$$\limsup_n d(S_n, L) < \limsup_n d(S_n, Y)$$

   for each displayed competing point row Y whose carrier classifier is distinct from L.

7. *F is the nonexpansive-map handoff row. It records that a* $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$ *consumer may read S, W, L, and D when checking the fixed-point boundary for a displayed map, but may not manufacture a limit or a compactness witness.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row for the distance values used in D.*

9. *H records componentwise* hsame *transport for the metric row, Banach row, sequence row, finite window, candidate limit, limsup ledger, nonexpansive handoff, readback rows, continuation replay, provenance, and local naming row.*

10. *C records displayed* Cont *replay from each finite fixed-point request through*

$$M, B, S, W, L, D, F, R \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{OpialCondition}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{OpialCondition}^{\uparrow}}$ *row.*

The carrier has no coordinate for weak compactness, a selected weak cluster point, quotient stream equality, excluded middle, countable choice, a demiclosedness theorem, or an ambient fixed-point theorem.

Theorem 6322.2 (Opial condition NameCert obligations)**.** *For every accepted* $\mathsf{OpialCondition}^{\uparrow}$ *carrier*

$$O = (M, B, S, W, L, D, F, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OpialCondition}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric row, Banach row, bounded sequence row, finite window, candidate limit, limsup-distance ledger, nonexpansive handoff, rational and Real readback, transport, replay, provenance, and local naming rows;*

2. *sequence exposure, requiring every limsup-distance read to begin with the displayed L10 sequence/readback route and the finite bounded window W;*

3. *candidate discipline, requiring L to be a displayed point row and forbidding replacement of L by a selected weak cluster point;*

4. *limsup comparison exactness, requiring D to display the strict comparison between the distance tail at L and each displayed competing row Y distinct from L;*

5. *nonexpansive handoff, requiring F to export only the rows needed by a* $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$ *fixed-point-boundary consumer;*

6. *provenance and local naming, requiring H, C, P, N to transport, replay, source, and name only the displayed Opial route.*

No $\mathsf{OpialCondition}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 6322.1. The accepted packet displays exactly the metric, Banach, sequence, finite-window, candidate-limit, comparison, handoff, readback, transport, replay, provenance, and naming coordinates.

The sequence and candidate obligations are forced by S, W, L. The sequence is opened only through the finite L10 readback route, and the limit candidate is a displayed point row, so the certificate has no position from which to extract a selected weak cluster point.

The comparison obligation is the role of D. Each accepted competing row Y is first displayed as distinct from L, and then the limsup-distance inequality is read through the rational and Real readback row R.

Finally F, H, C, P, N close the route. The nonexpansive handoff exports the visible rows to fixed-point-boundary consumers, while the structural rows preserve only the displayed coordinates

and leave no carrier position for weak compactness, demiclosedness, countable choice, or an ambient fixed-point theorem. □

Theorem 6322.3 (Opial condition nonexpansive handoff)**.** *Every* $\mathsf{RegularCauchyNonexpansiveMap}^{\uparrow}$*-facing consumer read accepted by an* $\mathsf{OpialCondition}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{BanachSpace}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{RegularCauchyNonexpansiveMap}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Equivalently, an accepted fixed-point-boundary read may consume the displayed bounded sequence window, candidate limit row, limsup-distance comparison, and nonexpansive handoff, but it cannot bypass them by weak compactness, a selected weak limit, demiclosedness, countable choice, or an ambient fixed-point theorem.

Proof. Use the obligation theorem Definition 6322.2. It exposes a nonexpansive handoff only after the metric and Banach rows, the bounded sequence row, the finite window, the candidate limit row, the limsup-distance comparison ledger, and the rational and Real readback row have all been displayed.

The displayed Cont route then replays each fixed-point-boundary request through the same rows. Thus a nonexpansive-map consumer reads the Opial comparison as finite certificate data rather than as a compactness principle.

Inspecting the carrier definition gives the exclusion. There is no coordinate for weak compactness, selected weak limits, demiclosedness, countable choice, or a detached fixed-point theorem, so any consumer requiring one of those objects is outside the local classifier. □

Closure status for $\mathsf{NameCert}_{\mathsf{OpialCondition}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OpialCondition}^{\uparrow}$ packet is generated from metric and Banach rows, a bounded sequence row, a finite bounded-sequence window, a displayed candidate limit, a limsup-distance comparison ledger, a nonexpansive-map handoff, RegSeqRat and Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OpialCondition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6322.1, Definition 6322.2, and Definition 6322.3 seed the finite Opial-condition route from displayed bounded sequence data through limsup-distance comparison to nonexpansive fixed-point-boundary consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OpialCondition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim weak compactness, selected weak limits, demiclosedness, countable choice, an ambient fixed-point theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, limsup-distance comparison exactness, nonexpansive handoff stability, and BEDC.Derived.OpialConditionUp formalization.

Chapter 6323

A Concrete Naming Certificate for $\mathsf{FiniteIntersectionCompactness}^{\uparrow}$

Following Bishop and Bridges' constructive compactness practice and Kelley's finite-intersection formulation of compactness, the $\mathsf{FiniteIntersectionCompactness}^{\uparrow}$ packet records the finite-window compactness data that a completion corridor may inspect without importing a general open-cover theorem. It sits beside the finite-intersection property row of chapter 1792, the compact metric certificate of chapter 129, the closed-interval Cauchy completion row of chapter 1778, the finite epsilon-net row of chapter 1767, and the Real seal of chapter 38. Those neighbors provide the traditional compactness vocabulary; this certificate keeps the usable claim finite, row-displayed, and local to the BEDC NameCert surface.

Definition 6323.1 (Finite-intersection compactness carrier)**.** *A* $\mathsf{FiniteIntersectionCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, K, J, E, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite-intersection-property row read from chapter 1792;*
2. *K is the compact-metric source row read from chapter 129;*
3. *J is the closed-interval Cauchy-completion window read from chapter 1778;*
4. *E is the finite epsilon-net witness row read from chapter 1767;*
5. *R is the terminal Real-facing seal read from chapter 38;*
6. *H stores componentwise* hsame *transport for finite-intersection rows, compact-metric rows, closed-interval completion windows, finite epsilon-net witnesses, Real seals, provenance, and local naming;*
7. *C stores displayed* Cont *replay for the same finite-window route;*
8. *P records* Pkg *provenance over* $\mathsf{FiniteIntersectionProperty}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ClosedIntervalCauchyCompletion}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *data;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteIntersectionCompactness}^{\uparrow}}$ *row.*

The carrier records only finite-window compactness data. It contains no coordinate for general open-cover compactness, countable choice, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6323.2 (Finite-intersection compactness NameCert obligations)**.** *For the carrier of Definition 6323.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteIntersectionCompactness}^{\uparrow}}$ *obligation surface consists exactly of the finite-intersection-property row* I*, compact-metric source row* K*, closed-interval Cauchy-completion window* J*, finite epsilon-net witness row* E*, Real seal row* R*, componentwise transport* H*, continuation replay* C*, provenance* P*, and local naming* N*. A consumer may cite the packet only as finite-window compactness data over those rows.*

Proof. Project the carrier tuple $F = (I, K, J, E, R, H, C, P, N)$. The finite-intersection, compact-metric, closed-interval completion, finite epsilon-net, and Real-facing rows are displayed as separate coordinates before any compactness read is available.

Use chapter 1792 for the finite-intersection row and chapter 129 for the compact-metric source. These rows expose finite compatibility and the metric carrier without producing a general open-cover theorem.

Use chapter 1778, chapter 1767, and chapter 38 for the completion window, finite search net, and terminal seal. They keep the read inside finite windows and Real-facing certificates rather than quotient equality or ambient completeness.

The rows H, C, P, N only transport, replay, cite, and name that same finite route. Since no coordinate stores countable choice, trichotomy, quotient real equality, ambient Real completeness, or open-cover compactness, none is exported by the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntersectionCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteIntersectionCompactness}^{\uparrow}$ packet is generated from finite-intersection-property data, compact-metric source rows, closed-interval Cauchy-completion windows, finite epsilon-net witnesses, Real-facing seals, componentwise transport, continuation replay, provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteIntersectionCompactness}^{\uparrow}}$, seed)

Scope closed: Definition 6323.1 and Definition 6323.2 seed finite-window compactness data over finite-intersection, compact-metric, closed-interval completion, finite epsilon-net, and Real-facing rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteIntersectionCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general open-cover compactness, countable choice, quotient real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission and finite-window compactness obligations for BEDC.Derived.FiniteIntersectionCompactnessUp.

Chapter 6324

A Concrete Naming Certificate for $\mathsf{MichaelLine}^{\uparrow}$

Following Michael and Kelley topology, the $\mathsf{MichaelLine}^{\uparrow}$ packet records the classical Michael-line presentation as a finite topology-adjacent NameCert object. It reads the real-order topology rows of chapter 1890, the indexed open-row discipline of chapter 88, and the observable-open truth classifier of chapter 1860. The packet names only the displayed real-order, distinguished-row, isolated-point, and observable-open handoff data needed by topology consumers; it does not import a host powerset, a choice-selected irrational subset, a quotient point equality, or an ambient completeness theorem for the real line.

Definition 6324.1 (Michael line carrier)**.** *A* $\mathsf{MichaelLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, T, D, O, S, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RealOrderTopology}^{\uparrow}$ *source row, carrying the named real-order intervals and endpoint comparisons available from chapter 1890.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing indexed open rows, finite neighbourhood membership reads, and topology closure witnesses from chapter 88.*
3. *D is the distinguished-row ledger marking the points whose singleton neighbourhood row is admitted by the Michael-line presentation.*
4. *O is the ordinary real-order open row used for points outside the distinguished ledger.*
5. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth row, recording whether the currently inspected named point is read through the ordinary open row or through the isolated singleton row.*
6. *L is the topology handoff row that exports the ordinary and isolated neighbourhood reads back to the indexed open surface of T.*
7. *H records componentwise* hsame *transport for the real-order source, topology source, distinguished ledger, ordinary open row, observable truth row, handoff row, continuation row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from point inspection to distinguished-row lookup, from lookup to observable-open truth, and from observable truth to the topology handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{MichaelLine}^{\uparrow}$, $\mathsf{RealOrderTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MichaelLine}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $R, T, D, O, S, L, H, C, P, N$. It has no coordinate for an ambient powerset of reals, a selected subset outside the distinguished ledger, quotient equality of points, open-cover compactness, real completeness, or a standard bridge.

Theorem 6324.2 (Michael line NameCert obligations)**.** *For an accepted* $\mathsf{MichaelLine}^{\uparrow}$ *carrier $M = (R, T, D, O, S, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MichaelLine}^{\uparrow}}$ *surface has five obligations:*

1. *carrier exposure for the displayed tuple $R, T, D, O, S, L, H, C, P, N$;*
2. *real-order source discipline, requiring ordinary neighbourhood reads to be supplied by R and its interval rows;*
3. *distinguished-row discipline, requiring isolated singleton reads to pass through the finite ledger D;*
4. *observable-open truth, requiring the choice between ordinary and isolated reads to be witnessed by the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *row S;*
5. *topology handoff and non-escape, requiring all exported open rows to pass through L, H, C, P, N without host powersets, selected subsets, quotient point equality, open-cover compactness, real completeness, or a standard bridge.*

Proof. Carrier exposure is projection from Definition 6324.1. The real-order source R and topology source T are the only ambient sibling rows available to the packet.

For an ordinary point read, the open neighbourhood is supplied by the real-order row R and then routed through the topology handoff L. For an isolated read, the distinguished ledger D must first display the singleton neighbourhood row.

The $\mathsf{SierpinskiSpace}^{\uparrow}$ row S records the observable-open truth value separating those two routes. By chapter 1860, this is a finite classifier read rather than a host-level predicate over all subsets of reals.

Finally H, C, P, N transport, replay, source, and name the same handoff. Since the carrier has no coordinate for host powersets, selected subsets, quotient point equality, open-cover compactness, real completeness, or bridge data, the five obligations exhaust the local NameCert surface. □

Theorem 6324.3 (Michael line Sierpinski topology handoff)**.** *Every accepted* $\mathsf{MichaelLine}^{\uparrow}$ *topology read reaches the public* $\mathsf{Topology}^{\uparrow}$ *surface only after the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row has selected one of the displayed real-order or isolated-neighbourhood routes. For*

$$M = (R, T, D, O, S, L, H, C, P, N),$$

the exported open row is computed through

$$R, D, O, S, H, C, P, N \longrightarrow L \longrightarrow T.$$

No host powerset, choice-selected distinguished subset, quotient point equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge supplies the handoff.*

Proof. Project the carrier rows from Definition 6324.1. The only routes to a neighbourhood read are the ordinary real-order row O sourced by R and the isolated singleton route sourced by the distinguished ledger D.

The observable-open row S is read before the topology handoff. It records which finite route is visible for the inspected point and gives the handoff a displayed $\mathsf{SierpinskiSpace}^{\uparrow}$ truth row instead of an ambient subset predicate.

The row L then exports the selected route to the indexed open surface T of chapter 88. Componentwise transport through H and continuation replay through C preserve the same ordinary-or-isolated decision, while P and N record provenance and local naming.

Thus the handoff is a finite BEDC route through the sibling certificates chapter 1890, chapter 1860, and chapter 88. The excluded host objects have no carrier coordinate, so they cannot supply topology data to $\mathsf{MichaelLine}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{MichaelLine}^{\uparrow}}$.

Constructive story: A $\mathsf{MichaelLine}^{\uparrow}$ packet is generated from displayed real-order topology rows, indexed topology source rows, distinguished singleton rows, observable-open truth, topology handoff, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MichaelLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6324.1, Definition 6324.2, and Definition 6324.3 seed the finite Michael-line boundary over $\mathsf{RealOrderTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, and $\mathsf{SierpinskiSpace}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MichaelLine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets, choice-selected subsets, open-cover compactness, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or standard bridges.

Upgrade path: Obligation closure requires checked carrier admission, distinguished-row membership, observable-open truth, topology handoff, transport, replay, provenance, and no-escape for BEDC.Derived.MichaelLineUp.

Chapter 6325

A Concrete Naming Certificate for $\mathsf{AssouadDimension}^{\uparrow}$

Following Assouad and Heinonen, the $\mathsf{AssouadDimension}^{\uparrow}$ packet records the finite metric-dimension surface by which a metric source, a scale ratio, and a uniformly bounded local cover become inspectable NameCert data. It sits over the metric carrier of chapter 57, reads local doubling cover rows from chapter 2035, routes radius and exponent comparisons through chapter 38, and exposes cover-refinement data to the covering-dimension sibling chapter 1853. The packet names a finite scale-cover ledger; it does not assert a host infimum of exponents, choose optimal covers, import Hausdorff measure, or identify metric spaces by ambient equality.

Definition 6325.1 (Assouad dimension carrier)**.** *An* $\mathsf{AssouadDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, M, D, R, S, E, B, K, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying point-history carrier and classifier row.*
2. *M is the inherited* $\mathsf{Met}^{\uparrow}$ *distance row over X.*
3. *D is the* $\mathsf{DoublingMetric}^{\uparrow}$ *or* $\mathsf{DoublingMetricSpace}^{\uparrow}$ *local cover row, exposing finite covers of displayed balls by smaller displayed balls.*
4. *R is the radius-ratio ledger. It names positive radii $0 < r < R$ through* $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback rows and records the comparison needed for the scale ratio.*
5. *S is the exponent-bound row. It stores the displayed rational or real candidate s and the coefficient row used in the Assouad cover estimate.*
6. *E is the local cover-count estimate row, recording that each displayed R-ball admits a finite r-ball cover whose count is bounded by the displayed coefficient and scale exponent.*
7. *B is the finite center-bundle row for the r-ball cover, carried as a closed* $\mathsf{ProbeBundle}$ *over X.*
8. *K is the covering-dimension handoff row. It exposes only the finite cover and refinement data readable by chapter 1853.*
9. *Q is the scale-comparison provenance row connecting D, R, S, E, B, K without adding a host logarithm or an exponent infimum.*

10. *H records componentwise* hsame *transport for the metric row, doubling row, radius ledger, exponent row, cover-count row, center bundle, covering-dimension handoff, provenance row, replay row, package row, and local naming row.*

11. *C records displayed* Cont *replay from each metric-ball cover request through*

$$X, M, D, R, S, E, B, K, Q \longmapsto H, P, N.$$

12. *P is the* Pkg *provenance over* $\mathsf{AssouadDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DoublingMetric}^{\uparrow}$, $\mathsf{DoublingMetricSpace}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{AssouadDimension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a selected optimal cover, a least exponent, Hausdorff dimension, host logarithms, quotient metric-space equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6325.2 (Assouad dimension NameCert obligations)**.** *For every accepted* $\mathsf{AssouadDimension}^{\uparrow}$ *carrier*

$$A = (X, M, D, R, S, E, B, K, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AssouadDimension}^{\uparrow}}$ *surface consists exactly of carrier admission for the point and metric rows; local doubling-cover admission through D; positive radius-ratio exposure through R; exponent-bound and coefficient exposure through S; finite cover-count exactness through E; center-bundle admission through B; covering-dimension handoff through K; scale-comparison provenance through Q; and componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N.*

Proof. Project the accepted carrier of Definition 6325.1. The point row X, metric row M, doubling row D, radius-ratio ledger R, exponent-bound row S, cover-count estimate E, center bundle B, and covering-dimension handoff K are all displayed before the local naming row is consumed.

The cover obligation is read from D, E, B. The doubling row opens the relevant metric ball, the center bundle lists the finite r-ball centers, and the cover-count estimate records the displayed Assouad bound for the same radius pair.

The scale obligation is read from R, S, Q. These rows carry positive radii, the candidate exponent, the coefficient, and the comparison route needed by the estimate without adding a host logarithm or a least exponent.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row stores an optimal cover selector, Hausdorff-measure comparison, quotient metric equality, countable choice, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6325.3 (Assouad dimension doubling handoff)**.** *Every* $\mathsf{DoublingMetric}^{\uparrow}$, $\mathsf{DoublingMetricSpace}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{AssouadDimension}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{DoublingMetric}^{\uparrow},\ \mathsf{DoublingMetricSpace}^{\uparrow},\ \mathsf{CoveringDimension}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{ProbeBundle},\ \mathsf{BHist},\ \mathsf{hsame}$$

through the rows $X, M, D, R, S, E, B, K, Q, H, C, P, N$. In particular, doubling consumers receive only the local ball-cover ledger, covering-dimension consumers receive only the finite cover and refinement handoff, and Real-facing consumers receive radius and exponent reads only after the displayed metric-cover route has been inspected.

Proof. Start with a doubling consumer. The metric row M and local doubling row D expose the parent ball and the smaller-ball cover request, while B records the finite center bundle and E records the displayed cover-count estimate.

Next consider a covering-dimension consumer. It reaches the packet through K, which is downstream of the same finite cover data D, E, B and the scale-comparison provenance Q. Hence it reads refinement-ready cover data rather than a host dimension theorem.

Finally inspect a Real-facing radius or exponent read. The rows R and S provide positive radii, the scale ratio, the candidate exponent, and the coefficient, but only along the route replayed by C and transported by H.

Thus every doubling, covering-dimension, or Real-facing use remains inside the displayed finite route and cannot import selected optimal covers, exponent infima, Hausdorff measure, quotient metric-space equality, countable choice, or ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{AssouadDimension}^{\uparrow}$ cover read displays one point-history carrier, one metric-distance row, one local doubling-cover row, one positive radius-ratio ledger, one exponent-bound row, one finite cover-count estimate, one center ProbeBundle, one covering-dimension handoff, scale-comparison provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metric, doublingmetric, coveringdimension, real: $\mathsf{AssouadDimension}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric source, radius-ratio ledger, exponent-bound row, finite local cover-count estimate, center bundle, covering-dimension handoff, and Real-facing scale route in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{AssouadDimension}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AssouadDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6325.1, Definition 6325.2, and Definition 6325.3 seed the finite Assouad dimension route over metric, doubling-metric, covering-dimension, and Real-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AssouadDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim optimal cover selection, a least exponent, Hausdorff dimension, host logarithm analysis, quotient metric-space equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-ratio exposure, exponent-bound rows, finite local cover-count exactness, covering-dimension handoff, transport, replay, provenance, and local NameCert rows for BEDC.Derived.AssouadDimensionUp.

Constructive story: An $\mathsf{AssouadDimension}^{\uparrow}$ packet is generated from a point-history carrier, a MetricUp distance row, a local doubling-cover row, positive radius-ratio data, an exponent-bound row, a finite cover-count estimate, a center ProbeBundle, a covering-dimension handoff row, scale-comparison provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6326

A Concrete Naming Certificate for $\mathsf{HeineBorelFiniteSubcover}^{\uparrow}$

Following Bishop and Bridges' constructive finite-cover treatment, the $\mathsf{HeineBorelFiniteSubcover}^{\uparrow}$ packet records the finite dyadic closed-interval subcover data that interval-cover and uniform-modulus consumers may inspect without importing a general Heine–Borel theorem for arbitrary $\mathsf{Real}^{\uparrow}$ subsets. It sits on the dyadic interval-cover route of chapter 1428, the dyadic rational arithmetic core of chapter 291, the finite scheduling surface of chapter 126, the regular rational readback route of chapter 301, and the terminal Real seal of chapter 38. The certificate is only a finite dyadic closed-interval subcover packet; it does not claim general Heine–Borel compactness for arbitrary $\mathsf{Real}^{\uparrow}$ subsets or arbitrary open covers.

Definition 6326.1 (Heine–Borel finite subcover carrier)**.** *A* $\mathsf{HeineBorelFiniteSubcover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (I, D, W, R, S, T, C, P, N)$$

with the following displayed rows:

1. *I is the dyadic closed-interval cover row read from chapter 1428;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and mesh-comparison row read from chapter 291;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite scheduling row that indexes the inspected cover windows;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint, mesh, and inclusion comparisons;*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the closed interval endpoints and covered points;*
6. *T records componentwise* hsame *transport for cover rows, dyadic endpoint rows, stream windows, regular rational readback, Real seals, provenance, and local naming;*
7. *C records displayed* Cont *replay from an interval-cover request through I, D, W, R, S to the finite subcover output;*
8. *P records* Pkg *provenance over* $\mathsf{HeineBorelFiniteSubcover}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *data;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteSubcover}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, powerset compactness, countable choice, excluded middle, quotient Real equality, or ambient completeness.

Theorem 6326.2 (Heine–Borel finite subcover obligation surface)**.** *For the carrier of Definition 6326.1, the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteSubcover}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for* $I, D, W, R, S, T, C, P, N$*, cover-window exposure through* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$*, endpoint and mesh comparison through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, terminal interval sealing through* $\mathsf{Real}^{\uparrow}$*, componentwise transport, replay stability, provenance, local naming, and ledger non-escape from non-finite compactness principles.*

Proof. Project the finite packet $H = (I, D, W, R, S, T, C, P, N)$. The dyadic interval-cover row, dyadic rational row, finite stream-window row, regular rational readback row, and Real seal are displayed before a subcover output can be read.

Use chapter 1428 for the cover request and chapter 291 for endpoint arithmetic. These rows keep the cover finite and dyadic rather than an arbitrary open cover of an arbitrary subset.

Use chapter 126, chapter 301, and chapter 38 for scheduling, rational comparison, and the terminal closed-interval seal. The rows T, C, P, N only transport, replay, cite, and name the same finite route. Since no coordinate stores powerset compactness, arbitrary cover choice, quotient Real equality, or ambient completeness, none is exported by the obligation surface. □

Theorem 6326.3 (Heine–Borel finite subcover NameCert route)**.** *Every accepted* $\mathsf{HeineBorelFiniteSubcover}^{\uparrow}$ *packet routes a dyadic closed-interval cover request through*

$$\mathsf{DyadicIntervalCover}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The exported certificate is a finite subcover row for the named closed interval and the displayed dyadic cover windows, not a proof of arbitrary $\mathsf{Real}^{\uparrow}$ *compactness.*

Proof. Start with the carrier admission of Definition 6326.1. It fixes the only readable source rows as I, D, W, R, S and the structural rows as T, C, P, N.

Apply the obligation surface of Definition 6326.2. Cover-window exposure, endpoint comparison, stream scheduling, rational readback, and Real sealing are each projections from the same finite packet.

It remains to identify the exported object. The replay row C can only replay the displayed route, and the provenance row P names exactly the listed dependencies. Thus the consumer obtains a finite dyadic closed-interval subcover certificate and no general compactness principle. □

Falsifiable prediction: Every $\mathsf{HeineBorelFiniteSubcover}^{\uparrow}$ consumer read factors through a displayed $\mathsf{DyadicIntervalCover}^{\uparrow}$ cover row, a $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint row, a $\mathsf{StreamName}^{\uparrow}$ finite window, a $\mathsf{RegSeqRat}^{\uparrow}$ comparison row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicintervalcover, dyadicratcore, streamname, regseqrat, real: $\mathsf{HeineBorelFiniteSubcov}$ is not bijective to any listed sibling because it jointly carries the finite dyadic cover request, endpoint arithmetic, scheduling window, rational readback, Real seal, transport, replay, provenance, and local NameCert rows as one finite subcover packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteSubcover}^{\uparrow}}$.

Constructive story: A $\mathsf{HeineBorelFiniteSubcover}^{\uparrow}$ packet is generated from a dyadic closed-interval cover row, dyadic endpoint arithmetic, finite StreamName windows, RegSeqRat readbacks, a terminal Real seal, componentwise transport, continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteSubcover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6326.1, Definition 6326.2, and Definition 6326.3 seed the finite dyadic closed-interval subcover certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteSubcover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, powerset compactness, countable choice, excluded middle, quotient Real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission and NameCert obligation theorems for BEDC.Derived.HeineBorelFini

Chapter 6327

A Concrete Naming Certificate for $\mathsf{RealModulusComparison}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers with explicit moduli of convergence, the $\mathsf{RealModulusComparison}^{\uparrow}$ packet records how two Real-facing convergence-modulus certificates are compared without quotienting streams or selecting representatives. It sits after the comparison surface of chapter 636, the convergence ledger of chapter 2074, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal Real seal of chapter 38. The packet is a finite NameCert bridge between rate certificates; it is not a selected limit, a quotient equality of real names, a countable-choice schedule, or an ambient completeness principle.

Definition 6327.1 (Real modulus comparison carrier)**.** *A* $\mathsf{RealModulusComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, M_0, M_1, S, R, D, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CauchyModulusComparison}^{\uparrow}$ *comparison row naming the cofinal comparison between the two displayed schedules.*
2. *M_0 and M_1 are* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger rows for the two Real-facing convergence certificates under comparison.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule shared by the requested comparison read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row reached from the same finite windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that names the requested precision and the dyadic comparison budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the two modulus ledgers, finite windows, readback row, tolerance row, and comparison row have been displayed.*
7. *H records componentwise* hsame *transport for the comparison row, both modulus ledgers, stream schedule, readback row, dyadic tolerance row, Real seal, replay, provenance, and local naming.*
8. *T records displayed* Cont *replay from a comparison request through $S, R, D, M_0, M_1, C, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealModulusComparison}^{\uparrow}$, $\mathsf{CauchyModulusComparison}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RealModulusComparison}^{\uparrow}}$ *row.*

Accepted packets are compared only through $C, M_0, M_1, S, R, D, E, H, T, P, N$. There is no coordinate for selected limits, quotient stream equality, countable choice, host Real equality, or ambient Real completeness.

Theorem 6327.2 (Real modulus comparison NameCert obligations)**.** *For every accepted* $\mathsf{RealModulusComparison}^{\uparrow}$ *carrier*

$$K = (C, M_0, M_1, S, R, D, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealModulusComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for K, dyadic tolerance exposure through D, finite-window handoff through S, regular-rational readback through R, cofinal modulus comparison through C, M_0, M_1, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through T, package provenance through P, and local naming through N. Every Real or Completion consumer must read these rows before it may use comparison data between convergence-modulus packets.*

Proof. Project the carrier of Definition 6327.1. The rows M_0, M_1 are the only Real-facing convergence-modulus ledgers, and C is the only comparison row between them.

The finite observation route is ordered by S, R, D. A comparison request first opens the displayed $\mathsf{StreamName}^{\uparrow}$ windows, then reads regular rational data through R, and then names the requested dyadic tolerance through D before the cofinal comparison row can be consumed.

The Real seal E is terminal for this packet. It is reached only after the two modulus ledgers and their comparison row have been displayed, while H, T, P, N transport, replay, source, and name that same route.

Since the carrier has no coordinate for selected limits, quotient stream equality, countable choice, host Real equality, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{RealModulusComparison}^{\uparrow}$ comparison read factors through one $\mathsf{CauchyModulusComparison}^{\uparrow}$ row, two $\mathsf{RealModulusOfConvergence}^{\uparrow}$ ledger rows, one $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ before any Real or Completion consumer may use the comparison.

Independence witness: cauchymoduluscomparison, realmodulusofconvergence, streamname, regseqrat, dyadicratcore, real: $\mathsf{RealModulusComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the comparison row, two Real-modulus ledgers, finite stream schedule, regular readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealModulusComparison}^{\uparrow}$ packet is generated from a CauchyModulusComparisonUp row, two RealModulusOfConvergenceUp ledger rows, StreamNameUp finite windows, RegSeqRatUp readback, DyadicRatCoreUp tolerances, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealModulusComparison}^{\uparrow}}$, seed)

Scope closed: Definition 6327.1 and Definition 6327.2 seed the finite comparison surface for Real-facing convergence-modulus certificates.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealModulusComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, host Real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window handoff, regular-rational readback, cofinal modulus comparison, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealModulusComparisonUp.

Chapter 6328

A Concrete Naming Certificate for $\mathsf{WhiteheadProduct}^{\uparrow}$

Following J. H. C. Whitehead on products in homotopy groups, the $\mathsf{WhiteheadProduct}^{\uparrow}$ packet names the bracket of two pointed sphere maps by finite BEDC rows. It sits beside the circle source of chapter 58, the deformation classifier of chapter 156, and the horn-and-face bookkeeping of chapter 157. The certificate records pointed sphere maps, a commutator attachment, a bracket classifier, componentwise transport, replay, provenance, and local naming; it does not import a completed homotopy group, a CW attaching theorem, or a host quotient of maps.

Definition 6328.1 ($\mathsf{WhiteheadProduct}^{\uparrow}$ finite carrier)**.** *A* $\mathsf{WhiteheadProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Omega = (S_m, S_n, a, b, \partial, \kappa, \beta, H, C, P, N).$$

Its displayed rows are as follows:

1. *S_m and S_n are pointed sphere-source rows. Each records a finite basepoint, boundary, and face ledger read through the sphere source surface of chapter 58 and the simplicial face discipline of chapter 157.*

2. *a and b are pointed sphere-map rows into the same displayed target packet. Their basepoint rows agree with the target basepoint by visible* hsame *transport, and their homotopy admissibility is read through chapter 156.*

3. *∂ is the attachment row for the boundary of the product cell. It records the two coordinate-face routes, the basepoint collar, and the finite source-face identifications used to read the commutator boundary.*

4. *κ is the commutator row. It lists the ordered route $aba^{-1}b^{-1}$ along the displayed boundary faces, together with the face-by-face signs and basepoint returns needed to keep the pointed condition visible.*

5. *β is the homotopy-bracket classifier row. It classifies two accepted packets by componentwise* $\mathsf{Homotopy}^{\uparrow}$ *comparison of a and b, by* hsame *comparison of the sphere-source rows, and by equality of the displayed attachment and commutator ledgers.*

6. *H records componentwise* hsame *transport for $S_m, S_n, a, b, \partial, \kappa, \beta, C, P, N$.*

7. *C records displayed* Cont *replay for the two pointed map rows, the boundary attachment route, the commutator readback, and the bracket classifier readback.*

8. *P is the* Pkg *provenance over* $\mathsf{WhiteheadProduct}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{WhiteheadProduct}^{\uparrow}}$ *row.*

The carrier is accepted only when all rows occur in the same displayed finite packet. Thus the Whitehead product is presented as an inspectable sphere-attachment and commutator ledger rather than as an element of an ambient homotopy group.

Theorem 6328.2 ($\mathsf{WhiteheadProduct}^{\uparrow}$ NameCert obligations)**.** *For every accepted* $\mathsf{WhiteheadProduct}^{\uparrow}$ *carrier*

$$\Omega = (S_m, S_n, a, b, \partial, \kappa, \beta, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WhiteheadProduct}^{\uparrow}}$ *surface consists exactly of sphere-source admission, pointed map admission, attachment admission, commutator ledger exactness, homotopy-bracket classification, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A downstream homotopy consumer may inspect $S_m, S_n, a, b, \partial, \kappa, \beta, H, C, P, N$ as the finite bracket packet, but it cannot replace the packet by a host homotopy-group element or by an uncarried attaching map.*

Proof. Carrier admission is projection from Definition 6328.1. The rows $S_m, S_n, a, b, \partial, \kappa, \beta, H, C, P, N$ already list the two pointed source spheres, the two pointed maps, the attachment boundary, the commutator route, the classifier, transport, replay, provenance, and local name.

The NameCert comparison is the classifier row β. It compares the two pointed map rows through $\mathsf{Homotopy}^{\uparrow}$, compares the sphere-source rows through their displayed source classifiers, and then checks that the attachment and commutator rows have the same finite face itinerary. No comparison step quantifies over all maps from a product cell or over a completed homotopy group.

The stability fields are exactly H and C. Transport along H keeps the component rows in the same packet positions, and replay along C keeps the boundary attachment, commutator readback, and bracket classifier visible under the same provenance P.

The local name N is therefore attached to the finite bracket packet itself. Since each public coordinate has been accounted for by admission, classification, transport, replay, and provenance, there is no remaining route through which a consumer can demand an ambient Whitehead-product theorem. □

Theorem 6328.3 ($\mathsf{WhiteheadProduct}^{\uparrow}$ sphere-attachment route)**.** *Let $\Omega = (S_m, S_n, a, b, \partial, \kappa, \beta, H, C, P, N)$ be an accepted* $\mathsf{WhiteheadProduct}^{\uparrow}$ *carrier. Any consumer that reads the bracket as a sphere-attachment factors through the pointed sphere rows S_m, S_n, the pointed maps a, b, the attachment row ∂, the commutator row κ, the homotopy-bracket classifier β, the componentwise transport H, the displayed replay C, the provenance P, and the local name N. The consumer may read the ordered boundary route and the homotopy classifier, but it cannot substitute a quotient of maps, an unbounded cell complex, or a completed homotopy-group operation.*

Proof. Project the two pointed sphere rows and the two pointed map rows. Their basepoints and boundary faces are already displayed by S_m, S_n, a, b, and their admissibility is routed through the sibling sphere, simplicial-set, and homotopy certificates named in the carrier.

Next project the attachment row ∂. It exposes only the finite boundary itinerary: coordinate faces, basepoint collar, and source-face identifications. The commutator row κ reads that itinerary in the order $aba^{-1}b^{-1}$ and records the signs and basepoint returns needed for a pointed bracket.

Finally apply the classifier and stability rows. The row β classifies the bracket by the transported pointed maps and the identical finite attachment itinerary, while H and C preserve that itinerary under componentwise transport and replay.

Thus the sphere-attachment consumer sees precisely the finite BHist bracket route with Pkg provenance and local NameCert naming. No step introduces a host quotient, a global CW-complex construction, or a stronger homotopy-group operation. □

Closure status for $\mathsf{NameCert}_{\mathsf{WhiteheadProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{WhiteheadProduct}^{\uparrow}$ packet is generated from two pointed sphere-source rows, two pointed sphere-map rows, a finite boundary attachment row, an ordered commutator row, a homotopy-bracket classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WhiteheadProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6328.1, Definition 6328.2, and Definition 6328.3 seed the finite pointed sphere-map, attachment, commutator, homotopy-bracket classifier, transport, replay, provenance, and local naming surface for the Whitehead product.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WhiteheadProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close higher homotopy-group algebra, Jacobi identities, suspension naturality, a CW-complex model, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires BEDC.Derived.WhiteheadProductUp to encode and check carrier admission, pointed sphere-map admission, attachment exactness, commutator exactness, bracket classification, transport, replay, provenance, and local naming.

Chapter 6329

A Concrete Naming Certificate for $\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}$

Following Bishop and Bridges constructive compact metric analysis, the $\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}$ packet records the finite located-net selection surface consumed by L10 regular-sequence and Real readback routes. It sits on the compact-metric source of chapter 129, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet selects only finite located-net rows already displayed by the carrier; it does not assert open-cover compactness, selected subcovers, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6329.1 (Compact metric located-net selection carrier)**.** *A* $\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact metric packet whose finite net may be inspected.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row against which located distances and selected net radii are read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the tolerance request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that transports the located net window into the regular rational route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for compact-metric, dyadic, window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located-net request through K, D, W, R and into the terminal seal E.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected subcovers, quotient real equality, countable choice, an infinite choice sequence of net points, or ambient Real completeness.

Theorem 6329.2 (Compact metric located-net selection obligations)**.** *For every accepted* CompactMetricLocatedNe *carrier* $L = (K, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}}$ *surface consists exactly of compact-metric source exposure through* K*, dyadic tolerance exposure through* D*, finite StreamName window exposure through* W*, RegSeqRat readback through* R*, terminal Real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The compact-metric row K supplies the only source of finite net data, while D, W, R, E are the only analytic rows available before a Real-facing read is exposed.

Read the located-net request through the displayed L10 route. The dyadic tolerance row fixes the finite radius request, the StreamName row opens only the needed observation window, and the RegSeqRat row records the regular rational readback for that window.

The structural tail is exhausted by H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the same finite packet, so the NameCert obligations cannot export open-cover compactness, selected subcovers, quotient equality, countable choice, or ambient Real completeness. □

Theorem 6329.3 (Compact metric located-net selection L10 handoff)**.** *Every L10 regular-sequence or Real readback consumer of an accepted* $\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}$ *carrier must first read the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports a located finite-net window over displayed compact-metric and dyadic rows, not open-cover compactness, a selected subcover, quotient real equality, countable choice, or ambient Real completeness.

Proof. Begin with the NameCert obligations. They expose $K, D, W, R, E, H, C, P, N$ before any consumer can treat the located-net selection as available.

The L10 route is ordered by projection from the carrier. The compact metric row is read first, the dyadic tolerance row determines the requested finite radius, the StreamName window supplies the inspected observations, and the RegSeqRat row performs the regular rational readback.

Only after those rows are visible may the terminal Real seal be consumed. Since no coordinate stores open-cover compactness, selected subcovers, quotient equality, countable choice, or ambient Real completeness, the handoff remains a finite located-net readback surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}$ packet is generated from compact-metric source rows, dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, terminal Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}}$, seed)

Scope closed: Definition 6329.1, Definition 6329.2, and Definition 6329.3 seed the finite located-net selection surface for L10 RegSeqRat and Real readback consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactMetricLocatedNetSelection}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.CompactMetricLocatedNetSelectionUp`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient real equality, countable choice, an infinite choice sequence of net points, ambient Real completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-net row exposure, dyadic tolerance routing, finite-window readback, terminal Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactMetricLocatedN

Chapter 6330

A Concrete Naming Certificate for $\mathsf{TriebelLizorkinSpace}^{\uparrow}$

Following Triebel–Lizorkin theory and constructive regularity spaces, the $\mathsf{TriebelLizorkinSpace}^{\uparrow}$ packet records the finite mixed scale-position surface by which a smoothness request can inspect local dyadic data before aggregating it into a global regularity name. It sits beside the Besov aggregate of chapter 4204, the Sobolev weak-gradient ledger of chapter 440, the Holder pointwise boundary of chapter 1766, the weak-derivative action row of chapter 2210, the dyadic scale budget of chapter 291, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite scale windows, local position probes, mixed aggregation rows, dyadic tolerances, regular rational readback, real seals, transport, replay, provenance, and local naming; it does not assert a completed distribution space, Littlewood–Paley decomposition equality, quotient function identity, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6330.1 (Triebel–Lizorkin space carrier)**.** *A* $\mathsf{TriebelLizorkinSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, Hd, W, D, R, E, Q, L, A, M, G, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, recording the weak-gradient and integrability ledger consumed by the local regularity request.*
2. *Hd is the* $\mathsf{HolderContinuity}^{\uparrow}$ *boundary row, recording the visible power-law control used when the packet exposes pointwise smoothness data.*
3. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *action row, naming the finite test probes and derivative observations inspected by the scale-position request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale ledger, recording dyadic scale, radius, and comparison budgets for each displayed window.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational magnitudes attached to the selected scale-position cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Hd, W, D, R have been displayed.*
7. *Q is the finite window schedule selecting the visible scale levels, local position probes, and comparison requests carried by this packet.*

8. *L is the local position-bundle row, recording the finite family of probe locations attached to each visible dyadic scale.*
9. *A is the mixed aggregation row. It records that local position data is aggregated inside each scale before the global regularity request is named.*
10. *M is the Besov comparison row, exposing the difference between the Triebel–Lizorkin mixed scale-position route and the aggregate Besov route of chapter 4204.*
11. *G stores componentwise* hsame *transport for the source, boundary, weak-action, dyadic, regular-rational, real-seal, window, local-position, mixed-aggregation, Besov-comparison, replay, provenance, and local naming rows.*
12. *C stores displayed* Cont *replay from a Triebel–Lizorkin regularity request through*
$$S, Hd, W, D, R, E, Q, L, A, M \longmapsto G, P, N.$$
13. *P is the* Pkg *provenance over* $\mathsf{TriebelLizorkinSpace}^{\uparrow}$, $\mathsf{BesovSpace}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{TriebelLizorkinSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, Hd, W, D, R, E, Q, L, A, M, G, C, P, N$. It has no coordinate for a completed distribution space, quotient equality of function spaces, selected Littlewood–Paley representatives, host equality of local probes, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6330.2 (Triebel–Lizorkin space NameCert obligations)**.** *For every accepted* $\mathsf{TriebelLizorkinSpace}^{\uparrow}$ *carrier*
$$T = (S, Hd, W, D, R, E, Q, L, A, M, G, C, P, N),$$
the local $\mathsf{NameCert}_{\mathsf{TriebelLizorkinSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Sobolev row, Holder row, weak-derivative action row, dyadic scale ledger, regular rational readback row, terminal real seal, finite window schedule, local position bundle, mixed aggregation row, Besov comparison row, componentwise transport, displayed replay, provenance, and local naming rows. Every PDE, trace, interpolation, or nonlinear regularity consumer of the packet must read through those rows before it cites the Triebel–Lizorkin smoothness boundary.*

Proof. Carrier admission is projection from Definition 6330.1. The source rows are S, Hd, W, the scale and readback rows are D, R, E, Q, the mixed scale-position rows are L, A, M, and the structural rows are G, C, P, N.

The Sobolev, Holder, and weak-derivative rows supply the analytic source surface. The Sobolev row carries weak-gradient and integrability data, the Holder row carries the visible pointwise boundary, and the weak-derivative row carries the finite test-action observations.

The dyadic, regular-rational, and real-seal rows fix the numerical part of the packet. The window schedule Q selects the displayed scale levels, D attaches the tolerance budget, R reads back the regular rational magnitudes, and E seals the resulting real-facing data.

The local position bundle L and mixed aggregation row A are the Triebel–Lizorkin-specific surface. The Besov comparison row M records that the packet keeps scale and position coupled before a global regularity name is exported.

Finally G, C, P, N transport, replay, source, and name the same finite route. Since no completed distribution space, quotient function-space equality, selected Littlewood–Paley representative, host equality of probes, countable choice, or ambient completeness coordinate appears in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6330.3 (Triebel–Lizorkin dyadic scale route)**.** *Every L10 or L11 regularity consumer of an accepted* $\mathsf{TriebelLizorkinSpace}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Sobolev}^{\uparrow},\quad \mathsf{WeakDerivative}^{\uparrow},\quad \mathsf{HolderContinuity}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BesovSpace}^{\uparrow},\quad \mathsf{BHi}$$

The route exports local scale-position windows, dyadic tolerance control, regular rational readback, terminal real seals, the explicit comparison with the Besov aggregate, componentwise transport, continuation replay, provenance, and local naming. It exports no completed distribution space, quotient function space, selected Littlewood–Paley representative, host equality of functions or local probes, countable-choice row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 6330.2. They require every accepted regularity read to pass through the Sobolev, Holder, and weak-derivative rows before any downstream smoothness boundary is cited.

Next read the finite scale-position data. The window schedule Q chooses the visible dyadic levels, the local position bundle L records the probe locations at those levels, and the mixed aggregation row A keeps those observations coupled before the global name is exported.

The dyadic ledger D, regular rational row R, and terminal real seal E report the numerical data attached to the same windows. The Besov comparison row M exposes the sibling aggregate route without identifying the two carriers.

Thus an L10 or L11 consumer receives exactly the displayed chain from Sobolev and weak-derivative evidence through Holder, dyadic, regular-rational, real-seal, Besov-comparison, and structural rows. The excluded distribution-space, quotient, representative-selection, host-equality, choice, and ambient-completeness objects have no carrier coordinate and cannot be exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{TriebelLizorkinSpace}^{\uparrow}$ regularity consumer must read Sobolev, HolderContinuity, WeakDerivative, DyadicRatCore, RegSeqRat, Real, BesovSpace, local position-bundle, mixed aggregation, hsame, Cont, Pkg, and local NameCert rows before citing the Triebel–Lizorkin smoothness boundary.

Independence witness: besov-space, sobolev, holder-continuity, weak-derivative, dyadicratcore, regseqrat, real: $\mathsf{TriebelLizorkinSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries smoothness-source rows, local scale-position probes, mixed aggregation, dyadic scale budgets, regular rational readback, real seals, Besov comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TriebelLizorkinSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TriebelLizorkinSpace}^{\uparrow}$ packet is generated from Sobolev, HolderContinuity, WeakDerivative, DyadicRatCore, RegSeqRat, Real, finite window, local position-bundle, mixed aggregation, Besov comparison, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TriebelLizorkinSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6330.1, Definition 6330.2, and Definition 6330.3 seed the finite constructive Triebel–Lizorkin route over Sobolev, HolderContinuity, WeakDerivative, DyadicRatCore, RegSeqRat, Real, BesovSpace, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TriebelLizorkinSpace}^{\uparrow}}, \mathsf{unformalized})$

Lean4 (statement) `BEDC.Derived.TriebelLizorkinSpaceUp`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, completed distribution spaces, Littlewood–Paley representative selection, quotient function spaces, host equality of functions or probes, countable choice, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local scale-position window exactness, mixed aggregation stability, dyadic-scale ledger stability, regular rational readback, Real seal nonescape, Besov comparison, transport, replay, provenance, and local naming for BEDC.Derived.TriebelLizorkinSpaceUp.

Chapter 6331

A Concrete Naming Certificate for $\mathsf{DyadicRegularBridge}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy data, the $\mathsf{DyadicRegularBridge}^{\uparrow}$ packet records the finite bridge from dyadic tolerance rows to regular rational readback and the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits after the dyadic rational core of chapter 291, the finite stream-window schedule of chapter 126, the regular rational readback of chapter 301, the Cauchy modulus route of chapter 292, and the real-name boundary of chapter 38. The bridge gives Real and Completion consumers a displayed BEDC route from finite dyadic tolerances to regular Cauchy real seals, without using quotient stream equality, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6331.1 (Dyadic regular bridge carrier)**.** *A* $\mathsf{DyadicRegularBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, Q, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, containing the dyadic radius and comparison rows used by the bridge.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming the inspected stream prefixes.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that interprets the scheduled windows as regular rational data.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *scheduling row, matching dyadic tolerances to the finite windows that Q reads.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, W, Q, M have been displayed.*
6. *H records componentwise* hsame *transport for dyadic, window, readback, modulus, real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from dyadic tolerances to scheduled windows, from scheduled windows to regular readback, and from regular readback to the real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRegularBridge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRegularBridge}^{\uparrow}}$ *row.*

The classifier accepts only those reads that pass through $D, W, Q, M, E, H, C, P, N$. It has no coordinate for a quotient of streams, a chosen limiting point, countable-choice selection, host real equality, or ambient completeness.

Theorem 6331.2 (Dyadic regular bridge NameCert obligations)**.** *For every accepted* $\mathsf{DyadicRegularBridge}^{\uparrow}$ *carrier* $B = (D, W, Q, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicRegularBridge}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite-window scheduling, regular rational readback, Cauchy modulus scheduling, terminal real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6331.1. The rows $D, W, Q, M, E, H, C, P, N$ are the full finite inventory available to a bridge consumer.

The analytic part is ordered. The dyadic ledger D supplies the finite tolerance rows; the schedule W selects the inspected windows; the readback Q interprets those windows as regular rational data; and the modulus row M records which windows answer which dyadic tolerances.

The terminal seal E is reached only after those rows have been displayed. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem is available inside the packet. □

Theorem 6331.3 (Dyadic regular bridge Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{DyadicRegularBridge}^{\uparrow}$ *carrier* $B = (D, W, Q, M, E, H, C, P, N)$ *factors through the dyadic tolerance ledger* D*, finite stream-window schedule* W*, regular rational readback* Q*, Cauchy modulus schedule* M*, terminal real seal* E*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming* N*.*

Proof. Start from a Real-facing bridge read. The carrier contains exactly one terminal real-seal row, namely E, so any such read must arrive at E through the displayed bridge rows.

The source of the route is D. The finite window row W and the modulus row M make the tolerance schedule visible, while Q supplies the regular rational readback consumed by the seal.

Finally H, C, P, N preserve the same route under transport, continuation replay, package provenance, and local naming. Since the carrier contains no quotient stream equality, chosen limit, countable-choice selector, host real equality, or ambient completeness row, the Real seal route is exactly the finite BEDC route through $D, W, Q, M, E, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRegularBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicRegularBridge}^{\uparrow}$ packet is generated from dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, CauchyModulus scheduling, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicRegularBridge}^{\uparrow}}$, seed)

Scope closed: Definition 6331.1, Definition 6331.2, and Definition 6331.3 seed the finite dyadic-to-regular-to-real bridge route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicRegularBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window scheduling, regular readback, Cauchy modulus scheduling, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicRegularBridgeUp.

The $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$ route reads event-row material through chapter 6508 before the hendeca event-flow spine consumes it, so the capstone surface stays singular.

Chapter 6332

A Concrete Naming Certificate for $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$

The $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$ packet is the arity-eleven event-flow capstone for the carrier-isomorphism bucket. It sits beside the ordered sequence window of chapter 1377, the closed-ball compactness packet of chapter 3548, the regulated integral handoff of chapter 1557, the deca sequence capstone of chapter 1368, and the dodeca tuple capstone of chapter 1369. The chapter names one finite event-flow carrier that exposes exactly eleven event rows before any bucket member read.

Lean4 (statement) `BEDC.Derived.BHistHendecaEventFlowNameCertUp`

Falsifiable prediction: Every accepted $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$ packet exposes exactly eleven event-flow rows before any bucket member read.

Independence witness: closed-ball-compactness, regulated-integral, b-hist-deca-sequence-name-cert, and b-hist-dodeca-sequence-name-cert: none is bijective because $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$ carries eleven ordered event-flow rows together with transport, replay, provenance, and local naming, while the siblings provide compactness, integration, arity-ten sequence, or arity-twelve tuple surfaces.

Definition 6332.1 (BHist hendeca event-flow NameCert carrier)**.** *A* $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, H, C, P, N)$$

whose first eleven rows are the ordered event-flow rows admitted by the capstone. The rows H, C, P, N *record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}}$ *row. A consumer may inspect a bucket member only after the eleven event-flow rows and the four structural rows have been displayed.*

Theorem 6332.2 (BHist hendeca event-flow NameCert obligations)**.** *Every accepted* $\mathsf{BHistHendecaEventFlowName}$ *packet exposes exactly the rows* $R_0, \ldots, R_{10}, H, C, P, N$ *before any carrier-isomorphism bucket member is read. The local NameCert surface consists of eleven-row event admission, order preservation, componentwise* hsame *transport, displayed* Cont *replay, package provenance, local naming, and refusal of hidden twelfth rows, unordered tuple membership, host equality, or bucket-wide replacement of the sibling chapters.*

Proof. Project the carrier of Definition 6332.1. The first eleven coordinates are the only event-flow rows, and the remaining coordinates are exactly the transport, replay, provenance, and local naming rows.

Order preservation is part of the displayed packet: the consumer reads R_0 through R_{10} as a finite sequence of event-flow rows, not as an unordered tuple or a bucket-level classifier.

The structural rows H, C, P, N preserve and name that same eleven-row event surface. Since no coordinate contains a hidden twelfth row, host equality classifier, or replacement for the closed-ball compactness, regulated-integral, deca-sequence, or dodeca-tuple siblings, every accepted read remains inside the displayed capstone. □

Theorem 6332.3 (BHist hendeca event-flow TasteGate follow-up)**.** *The Lean-facing follow-up for* $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$ *is the packet family under* Derived/BHistHendecaEventFlowNameCertUp/TasteGa *with explicit* Nontrivial *and* FieldFaithful *instances. The carrier must keep all eleven event-flow rows recoverable from the admitted packet before any bucket member read is accepted.*

Proof. The carrier definition lists eleven event rows and four structural rows. A nontrivial instance must display two distinct admitted packets, while field faithfulness must recover every listed row from the carrier projection.

The NameCert obligations identify the acceptance boundary. Any Lean gate that omits one event row, merges two positions, reads a bucket member first, or hides a twelfth row fails the displayed paper carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$ packet is generated from eleven ordered event-flow rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}}$, seed)

Scope closed: Definition 6332.1, Definition 6332.2, and Definition 6332.3 seed the arity-eleven event-flow capstone surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.BHistHendecaEventFlowNameCertUp`

Bridge status: none

Not claimed: This chapter does not close theorem checking, bridge checking, unordered bucket tuple equivalence, a hidden twelfth event row, host equality, or replacement of any sibling carrier.

Upgrade path: Obligation closure requires checked eleven-row event admission, order preservation, transport, replay, provenance, local naming, Nontrivial, and FieldFaithful data for BEDC.Derived.BHistHendecaEventFlowNameCertUp.

Chapter 6333

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$ packet records the finite boundary at which a regular Cauchy rational name exposes a located split before the terminal real-name seal is read. It sits between the regular rational source of chapter 301, the located-real surface of **??**, the dyadic tolerance ledger of chapter 291, the finite window interface of chapter 126, the terminal Real naming packet of chapter 38, and the generator-internal closure discipline of chapter 9389. The packet is a displayed L10 split witness for Real and Completion consumers; it is not trichotomy, quotient real equality, countable choice, a selected limit, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 6333.1 (Regular Cauchy located split carrier)**.** *A* $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the regular Cauchy source row, recording the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *name whose split boundary is being read.*
2. *L is the located interval evidence row, recording the* $\mathsf{LocatedReal}^{\uparrow}$ *lower and upper side data used by the split request.*
3. *D is the positive dyadic split budget row, recording the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, slack, and positive-gap budget inspected at the split.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite observation windows at which Q, L, and D are compared.*
5. *R is the regular readback row, recording the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite readback after the split budget has been applied to the visible windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the source, located evidence, dyadic budget, stream window, and regular readback rows have been displayed.*
7. *H records componentwise* hsame *transport for Q, L, D, W, R, E and the local certificate rows.*
8. *C records displayed* Cont *replay from a split request through the same source, located, dyadic, window, readback, Real-seal, transport, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedSplit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, L, D, W, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality of completed reals, countable choice, an unbounded split search, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.RegularCauchyLocatedSplitUp`

Theorem 6333.2 (Regular Cauchy located split NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$ *carrier $S = (Q, L, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedSplit}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular Cauchy source row, located interval evidence row, positive dyadic split budget, stream window, regular readback, Real seal, componentwise transport, displayed replay, provenance, and local naming. Every split read must expose $Q, L, D, W, R, H, C, P, N$ before the terminal Real seal row E is public.*

Proof. Project the carrier of Definition 6333.1. The source row is Q, the located evidence row is L, the positive dyadic budget is D, the finite observation row is W, the regular readback is R, and the Real seal is E.

The local certificate orders those rows. A split request first reads the regular Cauchy source, then the located interval evidence and dyadic budget at the finite windows where the readback is inspected.

Finally transport, replay, provenance, and local naming are supplied by H, C, P, N. Since the carrier has no trichotomy coordinate, quotient real equality, countable-choice schedule, selected limit, or ambient completeness row, the listed projections exhaust the NameCert obligations. □

Theorem 6333.3 (Regular Cauchy located split Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{LocatedReal}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exposes the regular Cauchy source, located interval evidence, positive dyadic split budget, finite stream window, regular readback, componentwise transport, replay, provenance, and local naming before the Real seal may be consumed.

Proof. Start from Definition 6333.1. The Real seal row E is downstream of the source Q, located evidence L, dyadic budget D, finite windows W, and regular readback R.

Apply the NameCert obligations of Definition 6333.2. They require any public Real-facing read to keep the same $Q, L, D, W, R, H, C, P, N$ rows visible before E is opened.

Thus the L10 handoff is a finite generator-internal split witness in the sense of chapter 9389. A consumer that asks for trichotomy, quotient real equality, countable choice, selected limits, or ambient completeness must leave this packet and cite a downstream certificate. □

Falsifiable prediction: Deleting the positive dyadic split budget row while keeping the source and Real seal rows leaves no accepted $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$ route from $\mathsf{RegSeqRat}^{\uparrow}$ finite windows to a located Real handoff.

Independence witness: regseqrat, locatedreal, dyadicratcore, streamname, real: no listed sibling is bijective with $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$ because the packet jointly binds a source regular

Cauchy name, located interval evidence, positive dyadic budget, finite windows, regular readback, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedSplit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$ packet is generated from a regular Cauchy source row, located interval evidence, positive dyadic split budget, finite StreamName windows, regular readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedSplit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6333.1, Definition 6333.2, and Definition 6333.3 seed the finite located-split handoff from regular Cauchy names through dyadic and stream windows to Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedSplit}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyLocatedSplitUp`

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, countable choice, selected limits, ambient Real completeness, theorem-level Lean verification, or bridge checking for $\mathsf{RegularCauchyLocatedSplit}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, positive dyadic split exactness, located evidence stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedSplitUp.

Chapter 6334

A Concrete Naming Certificate for $\mathsf{RegularRealCauchySelector}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularRealCauchySelector}^{\uparrow}$ packet records the finite selector surface by which an explicit regular-Cauchy Real read exposes its source, modulus, dyadic tolerance ledger, finite windows, regular-rational handoff, and terminal Real seal. It sits after the StreamName windows of chapter 126, the dyadic arithmetic ledger of chapter 291, the regular-rational route of chapter 301, the Cauchy-modulus discipline of chapter 292, and the terminal Real naming surface of chapter 38. The selector names one displayed read path; it does not choose a quotient-stream representative, select a host Real limit, invoke countable choice, or import ambient Real completeness.

Definition 6334.1 (Regular Real Cauchy selector carrier)**.** *A* $\mathsf{RegularRealCauchySelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R_0, M, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *is the regular Real source row, recording the named Real-facing request before any terminal seal is consumed.*
2. M *is the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *row for the regular-Cauchy read, including the visible request-to-window schedule.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same modulus request.*
4. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by* M *and read against* D*.*
5. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed windows and dyadic tolerance data.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after* R_0, M, D, W, Q *have been displayed.*
7. H *records componentwise* hsame *transport for the regular source, modulus, dyadic ledger, finite windows, regular-rational handoff, Real seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from the source and modulus rows through dyadic tolerance, finite windows, regular-rational handoff, the Real seal, provenance, and local naming.*
9. P *is the* Pkg *provenance over* $\mathsf{RegularRealCauchySelector}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularRealCauchySelector}^{\uparrow}}$ *row.*
The classifier compares accepted selectors only through $R_0, M, D, W, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6334.2 (Regular Real Cauchy selector NameCert obligations)**.** *For every accepted* $\mathsf{RegularRealCauchySelector}^{\uparrow}$ *carrier $S = (R_0, M, D, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularRealCauchySelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular Real source, explicit Cauchy modulus, dyadic tolerance ledger, finite StreamName windows, RegSeqRat handoff, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real-facing selector read must expose $R_0, M, D, W, Q, H, C, P, N$ before it may consume E as Real seal data.*

Lean4 ✓ `BEDC.Derived.RegularRealCauchySelectorUp.RegularRealCauchySelectorCarrier namecert obligation surface`

Proof. Project the carrier of Definition 6334.1. The source row is R_0, the explicit schedule is M, the dyadic tolerance ledger is D, the finite observation surface is W, and the regular-rational handoff is Q.

The certificate orders those rows before the terminal seal. A consumer first reads the regular source and modulus request, then the dyadic tolerance ledger, then the StreamName windows, then the RegSeqRat handoff generated by those displayed rows.

The structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming. Since no quotient stream, selected representative, host real equality, countable-choice schedule, or ambient completeness coordinate is present, the listed rows exhaust the local certificate obligations. □

Lean4 ✓ `BEDC.Derived.RegularRealCauchySelectorUp.RegularRealCauchySelectorTasteGate single carrier alignment`

Theorem 6334.3 (Regular Real Cauchy selector Real seal boundary)**.** *Any* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularRealCauchySelector}^{\uparrow}$ *packet reads the terminal seal only after the regular source, explicit Cauchy modulus, dyadic tolerance ledger, finite StreamName windows, RegSeqRat handoff, transport, replay, provenance, and local naming rows have been displayed. Thus the selector cannot be used as a hidden choice of representative, a host Real limit, a quotient stream equality, or an ambient completeness principle.*

Proof. Use Definition 6334.2. It places the Real seal row E downstream of R_0, M, D, W, Q and downstream of the structural rows H, C, P, N.

The StreamName and RegSeqRat rows are therefore not optional evidence. They are the visible finite readback through which the explicit Cauchy modulus and dyadic tolerance ledger become Real-facing data.

All excluded objects would require a carrier coordinate absent from Definition 6334.1. The consumer receives only the displayed selector route, so the Real seal remains a terminal named row rather than a hidden representative, selected limit, quotient equality, or completeness claim. □

Falsifiable prediction: Every accepted $\mathsf{RegularRealCauchySelector}^{\uparrow}$ read exposes the regular source row, explicit $\mathsf{CauchyModulus}^{\uparrow}$ row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any $\mathsf{Real}^{\uparrow}$ seal is public.

Independence witness: cauchymodulus, dyadicratcore, streamname, regseqrat, real: no listed sibling is bijective with $\mathsf{RegularRealCauchySelector}^{\uparrow}$ because the packet jointly binds the regular source, explicit modulus, dyadic tolerance ledger, finite windows, regular-rational handoff, terminal Real seal, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealCauchySelector}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularRealCauchySelector}^{\uparrow}$ packet is generated from a regular Real source row, explicit Cauchy modulus row, DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat handoff, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRealCauchySelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6334.1, Definition 6334.2, and Definition 6334.3 seed the explicit regular-Cauchy Real selector surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularRealCauchySelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, selected Real limits, countable choice, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{RegularRealCauchySelector}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, explicit modulus exactness, dyadic tolerance stability, StreamName window readback, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularRealCauchySelectorUp.

Chapter 6335

A Concrete Naming Certificate for $\mathsf{LocalInterHistRateComparison}^{\uparrow}$

The $\mathsf{LocalInterHistRateComparison}^{\uparrow}$ packet realizes the local comparison surface of chapter 9419 as finite configuration, causal-witness, maximum-rate, no-global-sync, observer-local transport, provenance, and NameCert rows. It sits after the multi-history configuration of chapter 474, the cross-history causal witness surface of chapter 478, the unary maximum-rate packet of chapter 594, the no-global synchronization boundary of chapter 1003, and the observer-local transport route of chapter 889. The packet compares finite causal-rate rows without a synchronized frame, real-valued speed, metric tensor, Lorentz coordinate, or global observer chart.

Definition 6335.1 (Local inter-Hist rate comparison carrier)**.** *A* $\mathsf{LocalInterHistRateComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, X, R, B, G, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathrm{MultiHistConfig}^{\uparrow}$ *row displaying the finite family of observer histories and their local ledgers.*
2. *X is the finite* $\mathsf{CrossHistCausal}^{\uparrow}$ *witness-family row over selected ordered pairs and local slots from M.*
3. *R is the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row recording the shared unary bound and finite comparison ledger for the selected causal witnesses.*
4. *B is the local comparison row, recording which displayed causal-rate reads are compared and in which local order.*
5. *G is the* $\mathsf{NoGlobalSyncBoundary}^{\uparrow}$ *refusal row excluding synchronized clocks, privileged frames, and all-observer global charts.*
6. *T is the* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *row transporting the comparison through observer-local reindexings without changing the displayed configuration, causal witnesses, or bound row.*
7. *H records componentwise* hsame *transport for configuration, causal witnesses, maximum-rate data, comparison, refusal, observer-local transport, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the multi-Hist configuration through causal witnesses, maximum-rate comparison, no-global-sync refusal, observer-local transport, provenance, and local naming.*

9. *P is the* Pkg *provenance over* LocalInterHistRateComparison$^{\uparrow}$, MultiHistConfig$^{\uparrow}$, CrossHistCausal$^{\uparrow}$, MaxCausalRate$^{\uparrow}$, NoGlobalSyncBoundary$^{\uparrow}$, ObserverLocalityTransport$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{LocalInterHistRateComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, X, R, B, G, T, H, C, P, N$. It has no coordinate for a synchronized frame, real-valued speed, metric tensor, Lorentz geometry, global chart, quotient of histories, or host equality of observers.

Theorem 6335.2 (Local inter-Hist rate comparison NameCert obligations)**.** *For every accepted* LocalInterHistRateComparison$^{\uparrow}$ *carrier $L = (M, X, R, B, G, T, H, C, P, N)$, the local* NameCert$_{\text{LocalInterHistRateCompariso}}$ *surface consists exactly of multi-Hist configuration admission, cross-Hist causal-witness admission, maximum-rate bound readback, local comparison admission, no-global-sync refusal, observer-local transport, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every comparison read must expose $M, X, R, G, T, H, C, P, N$ before it may consume B as local rate-comparison data.*

Proof. Project the carrier of Definition 6335.1. The configuration row M supplies the observer-history family, X supplies selected causal witnesses over that family, and R supplies the maximum-rate bound and finite comparison ledger attached to those witnesses.

The comparison row B is local because it is read only after the no-global-sync refusal row G and observer-local transport row T are displayed. Thus the comparison cannot appeal to a hidden synchronized clock or global observer frame.

The structural rows H, C, P, N preserve exactly the same finite route under transport, replay, provenance, and local naming. Since no real-valued speed, metric tensor, Lorentz coordinate, global chart, quotient of histories, or host observer equality is a carrier coordinate, the listed rows exhaust the local certificate obligations. □

Theorem 6335.3 (Local inter-Hist rate comparison no-frame boundary)**.** *Any consumer of an accepted* LocalInterHistRateComparison$^{\uparrow}$ *packet reads rate comparison only as a finite row over* MultiHistConfig$^{\uparrow}$, CrossHistCausal$^{\uparrow}$, MaxCausalRate$^{\uparrow}$, NoGlobalSyncBoundary$^{\uparrow}$, *and* ObserverLocalityTransport$^{\uparrow}$. *The consumer cannot turn the comparison into a synchronized frame, global clock, real-valued speed, Lorentz geometry, or global observer chart.*

Proof. Use Definition 6335.2. It forces the comparison read through the displayed configuration, causal-witness family, maximum-rate bound, refusal row, observer-local transport, and structural rows.

The refusal row G keeps the comparison from becoming a global synchronization datum, while the transport row T keeps observer-local reindexing attached to the same visible configuration and causal witnesses.

The carrier contains no coordinate from which to build a metric tensor, Lorentz chart, real-valued speed, global clock, or quotient of histories. Therefore every accepted comparison remains a finite local BEDC row and nothing outside the listed surface is exported. □

Falsifiable prediction: Every accepted LocalInterHistRateComparison$^{\uparrow}$ read exposes the MultiHistConfig$^{\uparrow}$ configuration, CrossHistCausal$^{\uparrow}$ witness family, MaxCausalRate$^{\uparrow}$ bound row, NoGlobalSyncBoundary$^{\uparrow}$ refusal, ObserverLocalityTransport$^{\uparrow}$ route, transport, replay, provenance, and local NameCert before any local comparison row is public.

Independence witness: multihistconfig, crosshistcausal, maxcausalrate, noglobalsyncboundary, observerlocalitytransport: no listed sibling is bijective with LocalInterHistRateComparison$^{\uparrow}$ because

the packet jointly binds finite configuration, causal witnesses, maximum-rate bound, local comparison, no-global-sync refusal, observer-local transport, replay, provenance, and local NameCert.

The TasteGate file for $\mathsf{LocalInterHistRateComparison}^{\uparrow}$ must require Lean 'Nontrivial' and 'FieldFaithful' instances before any positive discovery or classifier-shift gate is recorded in BEDC.Derived.LocalInterHistR Without those instances, this chapter records a finite NameCert packet and not a field-sensitive discovery claim.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalInterHistRateComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalInterHistRateComparison}^{\uparrow}$ packet is generated from MultiHistConfig rows, CrossHistCausal witness rows, MaxCausalRate bound rows, a local comparison row, a NoGlobalSyncBoundary refusal row, ObserverLocalityTransport rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalInterHistRateComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6335.1, Definition 6335.2, and Definition 6335.3 seed the finite local causal-rate comparison surface without a synchronized frame.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalInterHistRateComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close synchronized frames, global clocks, real-valued speeds, metric tensors, Lorentz geometry, host observer equality, Lean verification, or bridge checking for $\mathsf{LocalInterHistRateComparison}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, configuration locality, causal-witness handoff, maximum-rate bound readback, local comparison exactness, no-global-sync refusal, observer-local transport, replay, provenance, and local naming for BEDC.Derived.LocalInterHistRateComparisonUp.

Chapter 6336

A Concrete Naming Certificate for $\mathsf{CATZeroMetric}^{\uparrow}$

Following the Cartan–Alexandrov–Toponogov comparison tradition and the metric treatment of Bridson–Haefliger, the $\mathsf{CATZeroMetric}^{\uparrow}$ packet records a finite nonpositive-curvature comparison surface inside BEDC. It sits over the metric carrier of chapter 57, the finite segment witness of chapter 2213, the convex subset rows of chapter 208, and the completion handoff of chapter 128. The packet names comparison-triangle data for displayed geodesic windows; it is not a host path space, not a selected geodesic object, not a quotient path-equality principle, and not an ambient Hadamard-space theorem.

Definition 6336.1 (CAT(0) metric carrier)**.** *A* $\mathsf{CATZeroMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (M, G, V, E, A, Q, D, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, carrying only the displayed point classifier, distance rows, and metric-law ledger.*
2. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *row that names the finite segment windows used by the comparison request.*
3. *V is the finite vertex triple row (x, y, z), with each vertex admitted through the point classifier of M.*
4. *E is the edge-segment row, displaying the three geodesic windows between x, y, z through G.*
5. *A is the Alexandrov comparison-triangle row. It records the Euclidean side-length readback and the comparison point parameters for the displayed edge windows.*
6. *Q is the CAT(0) comparison ledger. For each displayed pair of comparison parameters on the triangle edges, it stores the finite inequality saying that the metric distance in M is bounded by the corresponding Euclidean comparison distance.*
7. *D is the* $\mathsf{ConvexSet}^{\uparrow}$ *domain row for each displayed convex window on which the comparison read is consumed.*
8. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row. It exposes the completion-facing read of the same finite comparison window without asserting that the ambient space is complete.*

9. *H records componentwise* hsame *transport for the metric row, geodesic row, vertex triple, edge windows, comparison-triangle row, inequality ledger, convex window, completion handoff, continuation replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a finite comparison request through*

$$M, G, V, E, A, Q, D, L \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CATZeroMetric}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global CAT(0) existence theorem, selected geodesics, host Euclidean realization, quotient path equality, full convex projection operator, or ambient completeness.

Theorem 6336.2 (CAT(0) metric comparison obligations)**.** *For every accepted* $\mathsf{CATZeroMetric}^{\uparrow}$ *carrier*

$$Z = (M, G, V, E, A, Q, D, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CATZeroMetric}^{\uparrow}}$ *surface consists exactly of metric-source admission, geodesic segment-window admission, displayed vertex-triple admission, comparison-triangle readback, CAT(0) inequality ledger exactness, convex-window handoff, complete-metric handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming over the rows of Definition 6336.1.*

Proof. Carrier admission is projection from Definition 6336.1. The accepted packet displays exactly the metric source, geodesic row, vertex triple, edge windows, comparison-triangle row, inequality ledger, convex handoff, completion handoff, transport, replay, provenance, and naming coordinates.

The comparison obligation is the role of A and Q. Row A gives the Euclidean side-length and parameter readback for the displayed triangle, while Q records only the finite distance inequalities requested by the CAT(0) comparison.

Rows D and L keep downstream consumers attached to the displayed convex and complete-metric surfaces. The structural rows H, C, P, N transport, replay, source, and name the same finite data, so no obligation row can be read as a selected geodesic, host Euclidean construction, quotient path equality, or ambient completeness theorem. □

Theorem 6336.3 (CAT(0) metric projection non-escape)**.** *Every convex-projection or completion-facing consumer of an accepted* $\mathsf{CATZeroMetric}^{\uparrow}$ *packet must factor through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{GeodesicMetric}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

It may consume displayed comparison-triangle inequalities for the named convex window, but it cannot infer a global nearest-point projection map, a general Hadamard-space theorem, selected geodesics, quotient path equality, or ambient completeness.

Proof. Use Definition 6336.2. It exposes a convex-projection-facing or completion-facing read only after the metric source, geodesic windows, vertex triple, comparison-triangle row, and CAT(0) inequality ledger have all been displayed.

The displayed continuation route then passes through D and L. Thus a convex consumer reads the comparison ledger as finite certificate data for the shown window, and a completion

consumer reads the same window through the complete-metric handoff rather than through a global completeness assertion.

Inspecting the carrier definition gives the exclusion. There is no coordinate for a full projection operator, selected geodesic family, host Hadamard-space theorem, quotient path equality, or ambient completeness, so any consumer requiring one of those objects is outside the local classifier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CATZeroMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CATZeroMetric}^{\uparrow}$ packet is generated from a MetricUp source, a GeodesicMetricUp segment-window row, a displayed vertex triple, comparison edge rows, an Alexandrov comparison-triangle readback, a finite CAT(0) inequality ledger, ConvexSetUp and CompleteMetricUp handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CATZeroMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6336.1, Definition 6336.2, and Definition 6336.3 seed the finite CAT(0) comparison route from displayed metric and geodesic data through convex and complete-metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CATZeroMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global Hadamard-space theorem, selected geodesics, quotient path equality, a full nearest-point projection operator, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison-triangle readback exactness, CAT(0) inequality-ledger stability, convex-window handoff, completion handoff, and BEDC.Derived.CatZeroMetricUp formalization.

Chapter 6337

Rising Sun Lemma NameCert Construction

Following Riesz's rising sun lemma, the $\mathsf{RisingSunLemma}^{\uparrow}$ packet records the finite BEDC surface for decomposing a located real interval into exposed and shaded subinterval windows for an upper-envelope comparison. It is a neighbour of the real-name boundary of chapter 38, the located-real route of **??**, the dyadic interval rows of chapter 306, and the compact interval maximum route of chapter 3907. The chapter isolates only the finite interval-decomposition certificate consumed by later $\mathsf{Real}^{\uparrow}$ analysis; it does not import a host measurable decomposition, selected family of open intervals, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6337.1 (RisingSunLemma carrier)**.** *A* $\mathsf{RisingSunLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{RisingSunLemma}(I, F, E, M, S, T, H, C, P, N)$$

with the following rows:

1. *I is the compact located interval row, read through the displayed* $\mathsf{Real}^{\uparrow}$ *endpoint names and the dyadic-interval subdivision ledger;*
2. *F is the located upper-envelope observation row on the interval;*
3. *E is the exposed-window ledger, listing finite dyadic subintervals on which the observation sits below a later envelope read;*
4. *M is the compact interval maximum handoff row used to certify the local envelope bound on each displayed closed window;*
5. *S is the shaded-window complement ledger, recording the remaining finite interval pieces after the exposed windows are read;*
6. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *handoff row through which downstream consumers read the endpoint and envelope seals;*
7. *H is the componentwise* hsame *transport over the interval, observation, maximum, exposed-window, shaded-window, and terminal rows;*
8. *C is the displayed* Cont *replay route for the same rows;*
9. *P is the* Pkg *provenance over* $\mathsf{RisingSunLemma}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{CompactIntervalMaximum}^{\uparrow}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{RisingSunLemma}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.RisingSunLemmaUp.RisingSunLemmaTasteGate single carrier alignment`

Theorem 6337.2 (RisingSunLemma NameCert obligations)**.** *For every accepted* $\mathsf{RisingSunLemma}^{\uparrow}$ *carrier*

$$R = \mathsf{RisingSunLemma}(I, F, E, M, S, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RisingSunLemma}^{\uparrow}}$ *surface consists exactly of compact located interval admission through I, located upper-envelope readback through F, exposed-window visibility through E, compact interval maximum handoff through M, shaded-window complement visibility through S, terminal* $\mathsf{Real}^{\uparrow}$ *seal readback through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

The obligation rows are finite. The BHist *row stores only displayed dyadic subinterval packets and real-name observations; the* hsame *row transports the interval, envelope, maximum, exposed-window, shaded-window, and terminal rows componentwise; the* Cont *row replays the same finite inspection route; the* Pkg *row records provenance through the Real, located-real, dyadic-interval, and compact-maximum siblings; and the* NameCert *row admits no extra decomposition datum outside these rows.*

Proof. Start from the carrier rows in Definition 6337.1. The interval and endpoint data are already displayed as $\mathsf{Real}^{\uparrow}$ and located-real rows, while the subdivision data are finite dyadic interval rows.

Apply the compact interval maximum handoff to each displayed closed window in the finite dyadic ledger. This binds the envelope comparison to M before the exposed and shaded ledgers are consumed by any downstream real-analysis route.

The remaining structural rows are bookkeeping over the same finite packet. Componentwise hsame transport preserves each displayed interval and envelope row, Cont replay keeps the finite inspection order, Pkg records the sibling provenance, and N names the resulting local surface. Since the carrier contains no selected open family, no quotient real equality, no countable-choice row, and no ambient completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6337.3 (RisingSunLemma stopping-time handoff)**.** *Every downstream stopping-time or finite-sweep consumer of an accepted* $\mathsf{RisingSunLemma}^{\uparrow}$ *carrier factors through the exposed-window ledger E, the compact interval maximum handoff M, the shaded-window complement ledger S, and the terminal* $\mathsf{Real}^{\uparrow}$ *row T before it can read an interval-decomposition result. The handoff is therefore a finite interval decomposition over* BHist, hsame, Cont, Pkg, *and* NameCert *rows, not a selected countable union of open intervals, not quotient equality of real endpoints, and not an appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the accepted carrier in the order displayed by the packet. A stopping-time consumer first sees the compact located interval row and the finite dyadic subdivision ledger, so every candidate exposed window is already a finite interval row.

The envelope comparison is then routed through the compact interval maximum handoff. This supplies the local maximum row used to certify whether a window is exposed or remains in the shaded complement, without selecting an external family of intervals.

Finally the downstream consumer reads the terminal $\mathsf{Real}^{\uparrow}$ handoff through the displayed transport, replay, provenance, and naming rows. Thus every stopping-time read is a finite handoff through E, M, S, T, H, C, P, N, and no unlisted choice, quotient, bridge, or completeness datum can supply an alternate decomposition. □

Chapter 6338

A Concrete Naming Certificate for $\mathsf{RegularCauchyNet}^{\uparrow}$

Following Kelley, Bourbaki, and Moore–Smith on directed nets, the $\mathsf{RegularCauchyNet}^{\uparrow}$ packet records the directed-tail form of a regular Cauchy real-seal route as finite NameCert data. It refines the generic Cauchy-net carrier of chapter 589, the net/filter comparison of chapter 1789, and the separated completion surface of chapter 4066. It also keeps the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38 visible before any completion consumer reads the route.

Definition 6338.1 (Regular Cauchy net carrier)**.** *A* $\mathsf{RegularCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed-index row, recording the finite directed preorder requests, comparison witnesses, and cofinal refinements used by the net route.*
2. *T is the tail-filter row, recording the finite tail neighborhoods and tail-containment reads induced by the directed indices.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite observation windows inspected after a tail request has been fixed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the accepted window observations as regular rational Cauchy data.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row, visible only after D, T, W, R have displayed the directed tail, filter read, window, and regular readback.*
6. *H stores componentwise* hsame *transport for directed indices, tail filters, StreamName windows, RegSeqRat readback, Real sealing, replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay from a Real-facing precision request through the directed tail, tail-filter row, finite window, regular readback, and terminal seal.*
8. *P records* Pkg *provenance over* $\mathsf{RegularCauchyNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetFilterCorrespondence}^{\uparrow}$, $\mathsf{SeparatedCauchyNetCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *data.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyNet}^\uparrow}$ *row.*

Accepted carriers are compared only through $D, T, W, R, E, H, C, P, N$. There is no coordinate for a quotient of nets, a selected subnet, a selected limit, countable choice, ambient separated completion, or host equality of real names.

Theorem 6338.2 (Regular Cauchy net NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyNet}^\uparrow$ *carrier $G = (D, T, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyNet}^\uparrow}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the directed index row D, tail-filter row T, finite window row W, regular rational readback R, Real seal E, transport H, replay C, provenance P, and local naming N;*
2. *directed-tail exactness, requiring every tail refinement read to use the same finite directed-index witnesses in D and the same tail-filter row T;*
3. *regular readback, requiring each* $\mathsf{RegSeqRat}^\uparrow$ *observation in R to be downstream of the displayed* $\mathsf{StreamName}^\uparrow$ *windows W and the dyadic tolerance comparisons carried by the route;*
4. *Real-seal nonescape, requiring the* $\mathsf{Real}^\uparrow$ *handoff E to expose only the displayed directed-tail, window, readback, transport, replay, provenance, and naming rows;*
5. *completion-consumer provenance, requiring every downstream completion read to cite the same packet G rather than a quotient net, selected subnet, selected limit, countable-choice schedule, or host completion theorem.*

No other NameCert obligation is available from the regular Cauchy net packet.

Proof. Carrier admission is the projection of Definition 6338.1. The tuple lists the directed index, tail filter, finite window, regular rational readback, Real seal, transport, replay, provenance, and naming rows.

Directed-tail exactness is carried by D and T. A consumer first fixes the finite directed comparison witnesses, then reads the induced tail-filter row before asking for window or Real-facing data.

Regular readback is downstream of W and the tolerance data cited in the route. The row R repacks only those displayed observations as $\mathsf{RegSeqRat}^\uparrow$ data, while E seals the resulting Real-facing row without adding a completion principle.

Finally H, C, P, N transport, replay, cite, and name the same packet. Since no carrier coordinate stores quotient nets, selected subnets, selected limits, countable choice, or ambient separated completion, none of those objects can be exported by the local NameCert surface. □

Theorem 6338.3 (Regular Cauchy net tail stability)**.** *Let $G = (D, T, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyNet}^\uparrow$ *carrier. If a directed-tail refinement replaces the active tail request by a cofinal tail still recorded in D and T, then every public completion read of the refined packet factors through the same* $\mathsf{StreamName}^\uparrow$ *windows, the same* $\mathsf{RegSeqRat}^\uparrow$ *readback route, and the same terminal* $\mathsf{Real}^\uparrow$ *seal handoff. Thus directed-tail refinement preserves the regular rational readback and Real-facing seal route of G.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNetUp.RegularCauchyNetCarrier tail stability`

Proof. Start with the refined tail request. By directed-tail exactness in Definition 6338.2, the refinement is still read through D and T, so it has not left the accepted directed-index and tail-filter rows.

The window row W is downstream of those rows. The refined request therefore uses the same displayed finite StreamName windows, and the regular readback row R can only repack observations from that window surface.

The Real seal E is terminal for the displayed route through D, T, W, R. Componentwise transport H, replay C, provenance P, and local naming N preserve that same packet. Hence the refinement keeps both the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{Real}^{\uparrow}$ seal handoff on the original finite route. □

Falsifiable prediction: Every $\mathsf{RegularCauchyNet}^{\uparrow}$ Real-facing read factors through directed index rows, tail-filter rows, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchynet, cauchy-net-filter-correspondence, separated-cauchy-net-completion, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyNet}^{\uparrow}$ binds directed-tail refinements, induced tail filters, finite observation windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming in one packet; each named sibling lacks at least one of these rows as a local directed-tail coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyNet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6338.1, Definition 6338.2, and Definition 6338.3 seed the finite directed-tail route from CauchyNet data through regular rational readback and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient nets, selected subnets, selected limits, countable choice, ambient separated completion, host equality of real names, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail exactness, regular readback, Real-seal nonescape, completion-consumer provenance, and tail-stability for BEDC.Derived.RegularCauchyNetUp.

Constructive story: A $\mathsf{RegularCauchyNet}^{\uparrow}$ packet is generated from directed index rows, tail-filter rows, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6339

A Concrete Naming Certificate for $\mathsf{BesicovitchCovering}^{\uparrow}$

Following Besicovitch's covering theorem and Bishop-style finite covering practice, the $\mathsf{BesicovitchCovering}^{\uparrow}$ packet records the finite-multiplicity ball-selection route used before differentiation, maximal-function, and metric-dimension consumers read a metric cover. It sits after the disjoint interval ledger of chapter 2184, the finite shadow-cover route of chapter 2166, the scale-control packet of chapter 2035, the gauge-cover surface of chapter 4119, and the domination surface of chapter 3581. The packet names only displayed metric balls, finite chosen subfamilies, bounded-overlap ledgers, transport, replay, provenance, and local naming; it does not import a host covering theorem, selected countable subfamilies, measure completion, quotient point equality, or ambient compactness.

Definition 6339.1 (Besicovitch finite-multiplicity covering carrier)**.** *A* $\mathsf{BesicovitchCovering}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, M, R, Q, S, O, V, F, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the point-history carrier and classifier row for the metric source.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *distance row over X, supplying ball membership and distance comparisons.*
3. *R is the positive-radius ledger, read through* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *rows before any ball is admitted.*
4. *Q is the finite request bundle of target points and admissible ball candidates.*
5. *S is the finite selected subfamily of balls, stored as a closed* $\mathsf{ProbeBundle}$ *over the same source.*
6. *O is the bounded-overlap ledger, recording the finite multiplicity bound for the selected balls at every displayed inspection point.*
7. *V is the* $\mathsf{VitaliCover}^{\uparrow}$ *handoff row, exposing the disjoint-selection discipline that the request bundle may cite.*
8. *F is the* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *handoff row, exposing finite shadow coverage and enlargement control for the selected subfamily.*
9. *D is the* $\mathsf{DoublingMetric}^{\uparrow}$ *handoff row, making the local finite-growth bound available when a dimension or maximal-function consumer asks for uniform multiplicity.*

10. *H records componentwise* hsame *transport for $X, M, R, Q, S, O, V, F, D$ and the structural rows.*
11. *C records displayed* Cont *replay from the ball requests through selection, bounded overlap, and the sibling handoff rows.*
12. *P is the* Pkg *provenance over* BesicovitchCovering$^{\uparrow}$, VitaliCover$^{\uparrow}$, FiniteVitaliCover$^{\uparrow}$, DoublingMetric$^{\uparrow}$, HausdorffDimension$^{\uparrow}$, HardyLittlewoodMaximal$^{\uparrow}$, Met$^{\uparrow}$, Met$^{\uparrow}$, Rat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{BesicovitchCovering}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient locally finite cover, a selected countable subcover, a host differentiation theorem, measure completion, quotient point equality, open-cover compactness, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6339.2 (Besicovitch covering NameCert obligations)**.** *For every accepted* BesicovitchCovering$^{\uparrow}$ *carrier*

$$B = (X, M, R, Q, S, O, V, F, D, H, C, P, N),$$

the local NameCert$_{\text{BesicovitchCovering}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source, positive-radius ledger, finite request bundle, selected ball subfamily, bounded-overlap ledger, Vitali handoff, finite Vitali shadow-cover handoff, doubling-metric handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $X, M, R, Q, S, O, V, F, D, H, C, P, N$.*

Proof. Project the carrier of Definition 6339.1. The source rows X and M provide the metric points, distances, and ball-membership reads, while R supplies the positive-radius data used by every candidate ball.

Open the covering rows. The request bundle Q names the finite ball candidates, S names the selected subfamily, and O records the finite multiplicity bound visible at each displayed inspection point.

The sibling handoffs are then exhausted rowwise. The row V exposes only the Vitali disjoint-selection route, F exposes only finite shadow coverage, and D exposes only the doubling-metric finite-growth route.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains none of the excluded host-cover, choice, measure-completion, quotient, compactness, differentiation, or ambient-completeness coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 6339.3 (Besicovitch covering finite-multiplicity route)**.** *Every* HausdorffDimension$^{\uparrow}$ *or* HardyLittlewoodMaximal$^{\uparrow}$ *consumer reading an accepted* BesicovitchCovering$^{\uparrow}$ *packet factors through the finite route*

Met$^{\uparrow}$, VitaliCover$^{\uparrow}$, FiniteVitaliCover$^{\uparrow}$, DoublingMetric$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, N

Dimension-facing consumers receive only displayed ball radii, selected finite subfamilies, and multiplicity bounds before comparing with gauge-cover data. Maximal-function consumers receive only the same finite multiplicity ledger before using domination rows. The route exports no selected countable cover, no measure-completion theorem, no host differentiation argument, no quotient point equality, and no ambient compactness principle.

Proof. Start with a dimension-facing consumer. It can enter the packet only through the metric and radius rows X, M, R, then through the finite request and selection rows Q, S before the multiplicity ledger O is visible.

Next compare with the dimension surface. The $\mathsf{HausdorffDimension}^{\uparrow}$ consumer may read O as a finite overlap bound for gauge-cover bookkeeping, but it receives no Hausdorff-measure construction or selected countable family from the Besicovitch packet.

Now inspect a maximal-function consumer. The $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ route may cite the same selected balls and bounded overlap through S, O, F, while the Vitali and finite Vitali handoffs V, F keep the domination step inside displayed finite data.

The doubling row D supplies only local finite-growth control, and H, C, P, N preserve the route under transport, replay, provenance, and local naming. Therefore every dimension or maximal-function use remains a finite-multiplicity handoff rather than an ambient covering theorem. □

Falsifiable prediction: Every accepted $\mathsf{BesicovitchCovering}^{\uparrow}$ consumer read displays one metric source, one positive-radius ledger, one finite ball-request bundle, one selected finite subfamily, one bounded-overlap ledger, Vitali and finite Vitali handoff rows, one doubling-metric handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: vitali-cover, finite-vitali-cover, doubling-metric, hausdorff-dimension, hardy-littlewood-maximal: $\mathsf{BesicovitchCovering}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite ball requests, selected subfamilies, bounded multiplicity, Vitali selection, finite shadow coverage, doubling control, and downstream dimension or maximal-function handoff rows in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BesicovitchCovering}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BesicovitchCovering}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6339.1, Definition 6339.2, and Definition 6339.3 seed the finite-multiplicity covering packet over displayed metric balls, Vitali and finite Vitali handoffs, doubling control, Hausdorff-dimension consumers, and Hardy–Littlewood maximal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BesicovitchCovering}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full Besicovitch covering theorem, exact Euclidean multiplicity constants, differentiation theorems, measure completion, selected countable subcovers, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius exactness, selected-subfamily admission, bounded-overlap exactness, Vitali handoff, finite Vitali handoff, doubling-metric handoff, transport, replay, provenance, and local NameCert rows for BEDC.Derived.BesicovitchCoveringUp.

Constructive story: A $\mathsf{BesicovitchCovering}^{\uparrow}$ packet is generated from a metric source row, positive-radius ledger, finite ball-request bundle, selected finite subfamily, bounded-overlap ledger, Vitali and finite Vitali handoff rows, doubling-metric handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6340

A Concrete Naming Certificate for $\mathsf{ReducedProduct}^{\uparrow}$

Following Chang and Keisler on reduced products in model theory, the $\mathsf{ReducedProduct}^{\uparrow}$ packet records the finite BEDC naming surface for a family of first-order models read through a displayed filter. It sits after the membership discipline of $\mathsf{SetLike}^{\uparrow}$, the carrier discipline of $\mathsf{TypeLike}^{\uparrow}$, the syntactic rows of chapter 197, the satisfaction rows of chapter 198, and the local $\mathsf{NameCert}$ carrier discipline. The packet exposes model-family rows, a filter row, pointwise formula reads, a filter-visible agreement classifier, transport, replay, provenance, and local naming; it does not assert an ultrafilter choice, quotient equality of functions, Los theorem, compactness, or any host model product.

Definition 6340.1 (Reduced product carrier)**.** *A* $\mathsf{ReducedProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, F, \Phi, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the model-family source row, naming the finite family window and the associated* $\mathsf{ModelTheory}^{\uparrow}$ *structure rows available to a consumer.*
2. *F is the displayed filter row, recording the finite filter tokens, containment reads, and meet-closure witnesses used by the reduced-product route.*
3. *Φ is the pointwise formula row, reading* $\mathsf{FirstOrder}^{\uparrow}$ *formula endpoints and their coordinatewise* $\mathsf{ModelTheory}^{\uparrow}$ *satisfaction rows before any agreement comparison is public.*
4. *A is the filter-visible agreement classifier: two pointwise reads classify together only when the displayed filter row F marks the coordinate set on which the pointwise formula rows agree.*
5. *H stores componentwise* hsame *transport for the model-family source, displayed filter, formula row, agreement classifier, replay row, provenance row, and local naming row.*
6. *C stores displayed* Cont *replay from a reduced-product consumer through M, F, Φ, A, H before any local name is exported.*
7. *P records* Pkg *provenance over* $\mathsf{ReducedProduct}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{ModelTheory}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ReducedProduct}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $M, F, \Phi, A, H, C, P, N$. There is no coordinate for a chosen ultrafilter, quotient equality of functions, Los theorem, host compactness, or an ambient product model outside the displayed rows.

Lean4 (definition) `BEDC.Derived.ReducedProductUp`

Theorem 6340.2 (Reduced product NameCert obligations)**.** *For every accepted* $\mathsf{ReducedProduct}^{\uparrow}$ *carrier* $Q = (M, F, \Phi, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ReducedProduct}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed model-family source M, filter row F, pointwise formula row Φ, agreement classifier A, transport H, replay C, provenance P, and local naming N;*
2. *displayed filter exposure, requiring every reduced-product agreement read to expose F before the classifier A is read;*
3. *pointwise model-row stability, requiring every formula read in Φ to remain attached to the* $\mathsf{FirstOrder}^{\uparrow}$ *and* $\mathsf{ModelTheory}^{\uparrow}$ *rows named by M;*
4. *classifier transport, requiring filter-visible agreement to move only through componentwise* hsame *transport H and displayed replay C;*
5. *replay and provenance, requiring every downstream consumer to cite P and N after the route M, F, Φ, A, H, C has been displayed;*
6. *refusal of ultrafilter choice, quotient equality, Los theorem, and host compactness, because none of these objects appears as a carrier coordinate.*

Proof. Carrier admission is projection from Definition 6340.1. The tuple lists exactly the model-family source, displayed filter, pointwise formula row, agreement classifier, transport, replay, provenance, and local naming rows.

Displayed filter exposure is the second projection step. A consumer cannot read the agreement classifier A until the filter row F has named the finite coordinate set on which the pointwise formula rows are compared.

Pointwise model-row stability follows from the source row M and formula row Φ. Formula endpoints are read through $\mathsf{FirstOrder}^{\uparrow}$, and their satisfaction rows are read through $\mathsf{ModelTheory}^{\uparrow}$, so the reduced-product packet has no separate syntax or satisfaction source.

Finally use H, C, P, N. The transport and replay rows preserve the same displayed route, while provenance and local naming attach the route to the BEDC carrier. Since no coordinate stores an ultrafilter choice, quotient equality, Los theorem, host compactness, or an ambient product model, the local certificate cannot export those principles. □

Falsifiable prediction: Every accepted $\mathsf{ReducedProduct}^{\uparrow}$ agreement read exposes a model-family source row, displayed filter row, pointwise formula row, filter-visible classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: setlike, typelike, firstorder, modeltheory: $\mathsf{ReducedProduct}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a displayed filter row and a filter-visible pointwise agreement classifier over model-family and formula rows. SetLikeUp supplies membership without model satisfaction, TypeLikeUp supplies fiber transport without the filter-visible classifier, FirstOrderUp supplies syntax without model-family satisfaction, and ModelTheoryUp supplies satisfaction without the reduced-product filter row.

Closure status for $\mathsf{NameCert}_{\mathsf{ReducedProduct}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\mathsf{ReducedProduct}^{\uparrow}}$, seed)

Scope closed: Definition 6340.1 and Definition 6340.2 seed the finite model-family, displayed-filter, pointwise-formula, agreement-classifier, transport, replay, provenance, and local-name rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ReducedProduct}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ultrafilter choice, quotient equality of functions, Los theorem, compactness, host model products, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displayed filter exposure, pointwise model-row stability, classifier transport, replay, provenance, and refusal boundaries for BEDC.Derived.ReducedProductUp.

Constructive story: A ReducedProduct$^{\uparrow}$ packet is generated from a model-family source row, displayed filter row, pointwise formula row, filter-visible agreement classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6341

A Concrete Naming Certificate for $\mathsf{AronszajnTree}^{\uparrow}$

Following Aronszajn, the $\mathsf{AronszajnTree}^{\uparrow}$ packet records the classical height-ω_1 tree obstruction as finite BEDC order data. It sits over the $\mathsf{Tree}^{\uparrow}$ source of chapter 119, the $\mathsf{POSet}^{\uparrow}$ comparison surface of chapter 53, the unary $\mathsf{Order}^{\uparrow}$ read of chapter 1378, the membership discipline of chapter 111, the countable-selection boundary of chapter 1872, and the ordinal-analysis ledger of chapter 6247. The packet names countable displayed levels, a no-uncountable-branch boundary, and finite branch-height readback; it does not assert Suslinness, Kurepa splitting, a club selector, or a host set-theoretic construction of ω_1.

Definition 6341.1 (Aronszajn tree carrier)**.** *An* $\mathsf{AronszajnTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, O, L, B, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Tree}^{\uparrow}$ *source row, read through the same graph and incidence surface as chapter 119.*
2. *O is the* $\mathsf{POSet}^{\uparrow}$ *tree-order row, including parent-extension comparisons, initial-segment comparability, and the inherited* $\mathsf{Order}^{\uparrow}$ *comparison route.*
3. *L is the countable-level ledger. For each displayed height request it records a finite membership window in the level and a countability witness boundary, without selecting a global enumeration of all levels.*
4. *B is the branch-height boundary row. It records that every displayed branch read is routed through a finite height window and cannot be consumed as an ω_1-long branch.*
5. *H records componentwise* hsame *transport for the tree source, order row, level ledger, branch-height boundary, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from tree incidence reads through order comparison, level membership, countability, and branch-height boundary rows.*
7. *P is the* Pkg *provenance over* $\mathsf{AronszajnTree}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, $\mathsf{POSet}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{Set}^{\uparrow}$, $\mathsf{CountableChoiceBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{AronszajnTree}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite Aronszajn-tree packet. It has no coordinate for a Suslin antichain theorem, Kurepa-many branches, a club subset of ω_1, a global choice selector, or a host-level ordinal construction.

Theorem 6341.2 (Aronszajn tree NameCert obligations)**.** *For every accepted* $\mathsf{AronszajnTree}^{\uparrow}$ *carrier* $A = (T, O, L, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AronszajnTree}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed tree source, tree-order row, countable-level ledger, branch-height boundary, transport, replay, provenance, and local naming rows;*
2. *order-source discipline, requiring every branch and level read to use the same* $\mathsf{Tree}^{\uparrow}$ *source* T *and the same* $\mathsf{POSet}^{\uparrow}$ *comparison row* O*;*
3. *countable-level visibility, requiring each displayed level request to pass through the finite ledger* L *and the countable-choice boundary before any consumer reads level data;*
4. *branch-height nonescape, requiring every displayed branch request to pass through* B *before it can be consumed by order, set, or ordinal-analysis consumers;*
5. *set-theoretic boundary discipline, excluding Suslinness, Kurepa splitting, club selectors, host well-order construction, and unrecorded choice from the packet.*

No Aronszajn-tree obligation is stored outside these rows.

Proof. Project the carrier of Definition 6341.1. The projection exposes exactly the tree source T, tree-order row O, countable-level ledger L, branch-height boundary B, and structural rows H, C, P, N.

The order-source and countable-level obligations are tied to the same displayed route. A level read first sees the tree incidence data in T, then the order comparison in O, and only then the countable-level ledger L with its finite membership window.

The branch-height obligation is separate from the level ledger. The row B is reached only after the tree and order rows have been read, and it records a boundary on displayed branch consumption rather than a host proof about all branches.

The remaining exclusions follow from the carrier shape. None of the rows stores a Suslin antichain theorem, Kurepa splitting family, club selector, host well-order construction, or unrecorded choice row, so the listed obligations exhaust the local NameCert surface. □

Theorem 6341.3 (Aronszajn tree branch-height nonescape)**.** *Every order, set, or ordinal-analysis consumer of an accepted* $\mathsf{AronszajnTree}^{\uparrow}$ *carrier* $A = (T, O, L, B, H, C, P, N)$ *reads branch information through the finite route*

$$\mathsf{Tree}^{\uparrow} \longmapsto \mathsf{POSet}^{\uparrow} \longmapsto L \longmapsto B \longmapsto H, C, P, N.$$

Thus a branch-height read exposes the tree source, partial-order comparison, countable-level ledger, branch-height boundary, transport, replay, provenance, and local naming before any consumer-facing conclusion is exported. It cannot be replaced by an ω_1-long branch, a global level enumeration, a club selector, a Suslin antichain claim, or a Kurepa branch family.

Proof. Begin with the tree source. The carrier admits a branch read only after T displays the incidence and tree rows inherited from $\mathsf{Tree}^{\uparrow}$.

Read the order row next. The row O supplies parent-extension and initial-segment comparison through $\mathsf{POSet}^{\uparrow}$ and $\mathsf{Order}^{\uparrow}$, so branch comparability is a displayed finite order route rather than host membership in an ambient tree.

Now inspect the countable-level ledger. The row L records the finite level window and countability boundary needed before a branch-height request reaches B.

Finally the boundary row B and the structural rows H, C, P, N package the same route for downstream consumers. Since the carrier has no coordinate for an ω_1-long branch, global enumeration, club selector, Suslin antichain theorem, or Kurepa family, no such object can be read from the packet. □

Theorem 6341.4 (Aronszajn tree sibling route)**.** *The* $\mathsf{AronszajnTree}^{\uparrow}$ *packet is read by sibling consumers only through the displayed route*

$$\mathsf{Tree}^{\uparrow}, \quad \mathsf{POSet}^{\uparrow}, \quad \mathsf{Order}^{\uparrow}, \quad \mathsf{Set}^{\uparrow}, \quad \mathsf{CountableChoiceBoundary}^{\uparrow}, \quad \mathsf{OrdinalAnalysis}.$$

The first four rows supply tree incidence, order comparison, unary comparison, and membership visibility; the countable-choice boundary restricts level reads; the ordinal-analysis ledger records height requests. The packet does not collapse these sibling reads into a host set-theoretic object.

Proof. Use Definition 6341.2. It fixes the carrier, order-source, countable-level, and branch-height rows as the complete local obligation surface.

Use Definition 6341.3. It places every branch-height consumer behind the same tree, order, level, and boundary rows.

The provenance row P then names the sibling sources and the replay row C preserves their order. Therefore any consumer must read the displayed sibling route rather than an external tree, set, choice, or ordinal object. □

Falsifiable prediction: Every accepted $\mathsf{AronszajnTree}^{\uparrow}$ branch-height read factors through the displayed $\mathsf{Tree}^{\uparrow}$, $\mathsf{POSet}^{\uparrow}$, countable-level, branch-boundary, transport, replay, provenance, and local NameCert rows before any order, set, or ordinal-analysis consumer reads it.

Independence witness: tree, poset, order, set, countable-choice-boundary, ordinal-analysis: $\mathsf{AronszajnTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a tree source, tree-order comparison, countable-level ledger, branch-height boundary, componentwise transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{AronszajnTree}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AronszajnTree}^{\uparrow}$ packet is generated from a displayed TreeUp source, POSetUp tree-order row, countable-level ledger, branch-height boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AronszajnTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6341.1, Definition 6341.2, Definition 6341.3, and Definition 6341.4 seed the finite tree-obstruction NameCert route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AronszajnTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, Suslinness, Kurepa splitting, a club selector, host construction of omega-one, global level enumeration, or uncountable-choice principles.

Upgrade path: Obligation closure requires checked carrier admission, order-source discipline, countable-level visibility, branch-height nonescape, sibling route readback, and ledger exhaustion for BEDC.Derived.AronszajnTreeUp.

Chapter 6342

A Concrete Naming Certificate for $\mathsf{ExtFunctor}^{\uparrow}$

Following Cartan–Eilenberg and Weibel on derived functors over abelian categories, the $\mathsf{ExtFunctor}^{\uparrow}$ packet names the boundary where right-derived Hom data becomes a finite BEDC NameCert surface. It sits after the abelian-category carrier of chapter 176, the derived-functor spine of chapter 177, and the cycle-boundary readback of chapter 99 and chapter 98. The packet records Ext as a displayed derived-functor route through resolution, Hom-row, cohomology, transport, replay, provenance, and local naming rows; it is not a host quotient of complexes, not a chosen injective or projective resolution outside the ledger, not an abelian-category oracle, and not a classical exactness theorem hidden behind the name.

Definition 6342.1 (ExtFunctor carrier)**.** *An* $\mathsf{ExtFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (A, X, Y, R, \mathcal{H}, C^{\bullet}, Z, B, D, H, T, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *source row naming the abelian-category carrier in which objects, morphisms, kernels, cokernels, and exactness reads are interpreted.*
2. *X and Y are the two object rows for the traditional* $\mathrm{Ext}^n(X, Y)$ *request.*
3. *R is the displayed resolution row. It may be read as an injective resolution of Y or a projective resolution of X, but the carrier records the chosen side explicitly as finite* BHist *data.*
4. *$\mathcal{H}$ is the displayed Hom-complex row obtained by applying the Hom request to the resolution row inside the same abelian-category source.*
5. *$C^{\bullet}$ is the cochain ledger whose differential and degree rows are consumed by* $\mathsf{Cohomology}^{\uparrow}$*.*
6. *Z and B are the cycle and boundary rows at the displayed degree.*
7. *D is the* $\mathsf{DerivedFunctor}^{\uparrow}$ *handoff row identifying the Ext read as the right-derived Hom route rather than as a separate quotient object.*
8. *H records componentwise* hsame *transport for the abelian source, object rows, resolution row, Hom-complex row, cochain ledger, cycle-boundary rows, derived-functor handoff, continuation rows, provenance, and local naming.*
9. *T records displayed* Cont *replay from the Ext request through $A, X, Y, R, \mathcal{H}, C^{\bullet}, Z, B, D, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{ExtFunctor}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{DerivedFunctor}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ExtFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, X, Y, R, \mathcal{H}, C^{\bullet}, Z, B, D, H, T, P, N$. It has no coordinate for host quotient equality of complexes, unrecorded resolution replacement, selected representatives of cohomology classes, global abelian-category exactness, countable choice, or an ambient derived-category oracle.

Theorem 6342.2 (ExtFunctor NameCert obligations)**.** *For every accepted* $\mathsf{ExtFunctor}^{\uparrow}$ *carrier $E = (A, X, Y, R, \mathcal{H}, C^{\bullet}, Z, B, D, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ExtFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission for the abelian source A, object rows X, Y, displayed resolution row R, Hom-complex row $\mathcal{H}$, cochain ledger $C^{\bullet}$, cycle and boundary rows Z, B, derived-functor handoff D, componentwise transport H, displayed replay T, package provenance P, and local naming row N.*

Every Ext consumer reads the public class through the displayed chain

$$\mathsf{AbelianCat}^{\uparrow} \longmapsto (X, Y, R) \longmapsto \mathcal{H} \longmapsto C^{\bullet} \longmapsto (Z, B) \longmapsto \mathsf{DerivedFunctor}^{\uparrow}.$$

The certificate exports no quotient complex, unrecorded resolution, selected cohomology representative, global exactness oracle, countable-choice schedule, or ambient derived-category equality.

Proof. Project the carrier of Definition 6342.1. The first visible rows are the abelian source, the two object rows, and the resolution row, so any Hom-complex request is already tied to displayed abelian-category data.

Read the Hom-complex row $\mathcal{H}$ and the cochain ledger $C^{\bullet}$ next. The cycle and boundary rows Z, B are consumed by the cohomology or homology certificate at the displayed degree, and the handoff row D records that the resulting class is the right-derived Hom read inside $\mathsf{DerivedFunctor}^{\uparrow}$.

Finally H, T, P, N transport, replay, source, and name exactly those rows. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface and no hidden quotient, selected representative, exactness oracle, choice object, or ambient derived-category equality can enter the Ext read. □

Theorem 6342.3 (ExtFunctor derived-functor handoff)**.** *Every* $\mathsf{DerivedFunctor}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, *or* $\mathsf{Homology}^{\uparrow}$ *consumer of an accepted* $\mathsf{ExtFunctor}^{\uparrow}$ *packet receives only the displayed abelian source A, object rows X, Y, resolution row R, Hom-complex row $\mathcal{H}$, cochain ledger $C^{\bullet}$, cycle-boundary rows Z, B, derived-functor handoff D, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

In particular, a consumer may change from an injective-resolution presentation to a projective-resolution presentation only by displaying a finite comparison ledger through $R, \mathcal{H}, C^{\bullet}, Z, B, D, H, T, P, N$. Such a comparison is a BEDC route equivalence; it is not host equality of resolutions, not a selected quasi-isomorphism inverse, and not an imported derived-category isomorphism.

Proof. Begin with Definition 6342.2. It places the Ext read behind the abelian-category source, object rows, displayed resolution, Hom-complex row, cochain ledger, cycle-boundary rows, and derived-functor handoff.

For the ordinary derived-functor direction, project D. This row identifies the accepted packet as the derived Hom route and hands the same cycle-boundary data to the downstream $\mathsf{DerivedFunctor}^{\uparrow}$ consumer.

For a change of resolution side, the carrier must expose the comparison as finite data in the resolution, Hom-complex, cochain, cycle-boundary, and replay rows. The comparison can therefore be consumed by $\mathsf{Cohomology}^{\uparrow}$ or $\mathsf{Homology}^{\uparrow}$ only after those rows are displayed.

Thus every downstream consumer sees the same finite ledger and no hidden resolution equality, selected inverse, quotient complex, global exactness theorem, countable-choice schedule, or ambient derived-category oracle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ExtFunctor}\uparrow}$.

Constructive story: An $\mathsf{ExtFunctor}^{\uparrow}$ packet is generated from an AbelianCat source row, two object rows, a displayed resolution row, a Hom-complex row, a cochain ledger, cycle and boundary rows, a DerivedFunctor handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExtFunctor}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6342.1, Definition 6342.2, and Definition 6342.3 seed the finite Ext derived-functor boundary over abelian, cohomology, homology, and derived-functor rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExtFunctor}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host quotient equality of complexes, unrecorded resolution comparison, selected cohomology representatives, global abelian-category exactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, resolution-side comparison coverage, Hom-complex ledger exactness, cycle-boundary classifier stability, derived-functor handoff confinement, transport stability, replay, and provenance nonescape for BEDC.Derived.ExtFunctorUp.

Chapter 6343

A Concrete Naming Certificate for $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completion, the $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$ packet records the finite realizer surface that turns a uniform completion datum into a real-name seal. It sits after the functorial completion route of chapter 1892, the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a displayed modulus-governed realizer for L10 completion reads without importing quotient completions, selected limits, host complete spaces, choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6343.1 (UniformCauchyCompletionRealizer carrier)**.** *A* $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, D, W, R, M, E, H, C, P, N)$$

with the following visible rows:

1. *F is the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *source row, naming the displayed completion datum and its finite functorial handoff;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to state all precision requests;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the finite prefixes inspected at each tolerance;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplying regular rational approximants for those windows;*
5. *M is the modulus row, recording that a dyadic tolerance request selects a displayed finite window before the completion-facing read is exported;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the regular rational readback and the modulus ledger;*
7. *H records componentwise* hsame *transport for F, D, W, R, M, E;*
8. *C records displayed* Cont *replay from the uniform completion datum through the dyadic, stream, regular, modulus, and real-seal rows;*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, a selected limit point, a host complete metric space, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 6343.2 (UniformCauchyCompletionRealizer NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$ *carrier*

$$U = (F, D, W, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}}$ *surface consists exactly of carrier admission for* U*, uniform completion datum exposure through* F*, dyadic tolerance visibility through* D*, finite stream-window visibility through* W*, regular rational readback through* R*, modulus selection through* M*, terminal* $\mathsf{Real}^{\uparrow}$ *seal readback through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Every completion-facing consumer must therefore read the displayed finite rows before it can use the realizer as a Real-facing output.

Proof. Project the accepted carrier through Definition 6343.1. The packet displays the rows $F, D, W, R, M, E, H, C, P, N$, and each row has a fixed local role in the carrier.

Read the analytic route first. The row F supplies the uniform completion datum, D states dyadic precision, W exposes the finite stream window requested by that precision, R supplies the regular rational readback, M records the modulus selecting the window, and E is the resulting Real seal.

The support rows do not add analytic content. Componentwise hsame transport preserves the same displayed rows, Cont replay keeps their inspection order, Pkg records the cited sibling provenance, and N names the local certificate. Since the carrier contains no additional coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6343.3 (UniformCauchyCompletionRealizer modulus stability)**.** *Let* $U = (F, D, W, R, M, E, H, C, P, N)$ *and* $U' = (F', D', W', R', M', E', H', C', P', N')$ *be accepted* $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$ *carriers. If the dyadic tolerance rows* D, D'*, stream-window rows* W, W'*, regular readback rows* R, R'*, and modulus rows* M, M' *agree under the displayed componentwise* hsame *transport, then every completion-facing consumer reads the same finite modulus route before reaching the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

In particular, transport cannot replace the displayed modulus by a selected limit, a quotient-completion equality, or a host completeness argument.

Proof. Begin with the rows controlled by the hypothesis. Agreement of D, D' fixes the dyadic precision ledger, agreement of W, W' fixes the finite windows, agreement of R, R' fixes the regular rational readbacks, and agreement of M, M' fixes the modulus row that sends each precision request to its displayed window.

Apply componentwise transport through H and H'. These rows preserve the analytic coordinates already named and do not introduce a new completion object or a selector for limits.

Finally replay the route through C and C'. A completion-facing consumer reaches E or E' only after the same tolerance, window, readback, and modulus rows have been inspected. Therefore the consumer sees the same finite modulus route, and the excluded quotient, selection, host-space, and completeness readings remain outside the packet. □

Theorem 6343.4 (UniformCauchyCompletionRealizer Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$ *carrier*

$$U = (F, D, W, R, M, E, H, C, P, N)$$

reaches the terminal seal E only through the route

$$F \longmapsto D \longmapsto W \longmapsto R \longmapsto M \longmapsto E$$

and then through the structural rows H, C, P, N. The handoff exports a finite Real-facing seal from the uniform completion datum; it exports no selected limit, no quotient completion equality, no host complete-space object, no choice principle, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.UniformCauchyCompletionRealizerUp.UniformCauchyCompletionRealizerCarrier real seal handoff`

Proof. Read the carrier rows in their displayed order. The uniform completion datum F is not itself a Real seal; it must first expose the dyadic tolerance row D, the finite stream window W, the regular rational readback R, and the modulus row M.

Only after those rows are visible does the consumer reach E. The continuation row C records exactly this replay order, while H preserves it under componentwise transport and P, N package and name the same local surface.

The carrier definition supplies no coordinate for a host completed object, quotient equality of completion names, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence the Real-facing output is precisely the displayed finite seal handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}$ packet is generated from uniform completion data, dyadic tolerance rows, finite stream windows, regular rational readback, a modulus row, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6343.1, Definition 6343.2, Definition 6343.3, and Definition 6343.4 bind the finite carrier, NameCert obligation surface, modulus stability, and Real-seal handoff for the L10 completion realizer route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionRealizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient completion equality, host complete spaces, choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, modulus-row stability, Real-seal handoff coverage, and a Lean realization for BEDC.Derived.UniformCauchyCompletionRealizerUp.

Chapter 6344

A Concrete Naming Certificate for $\mathsf{GateauxDerivative}^{\uparrow}$

Following Gateaux, Bourbaki, and Bishop–Bridges constructive analysis, the $\mathsf{GateauxDerivative}^{\uparrow}$ packet records directional differentiability as a finite NameCert surface. It sits between the pointwise derivative interface of chapter 122 and the full linear approximation interface of chapter 3634. Its displayed route consumes the linear direction row of chapter 48, the norm comparison row of chapter 89, and the real-tolerance seal of chapter 38. The packet names a derivative read in one displayed direction; it is not a host function-extensionality principle, not a chosen limit, not quotient equality of germs, and not ambient completeness of the real line.

6344.1 Directional carrier

Definition 6344.1 (Gateaux derivative carrier)**.** *A* $\mathsf{GateauxDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, A, V, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the normed source-and-target row through which points, steps, and error sizes are read.*
2. *A records the base point and the finite admissible window in which directional probes are accepted.*
3. *V is the displayed direction row. It names one admissible direction over X and exposes no global tangent bundle.*
4. *Q is the directional difference-quotient row. It records the finite quotients obtained by probing the function along the displayed direction V inside the window A.*
5. *T is the* $\mathsf{Real}^{\uparrow}$ *tolerance-agreement row. It compares accepted quotient reads against one candidate directional derivative value by finite real-name tolerance data.*
6. *H records componentwise* hsame *transport for X, A, V, Q, T and the structural rows.*
7. *C records displayed* Cont *replay from a directional derivative request through the source, point-window, direction, quotient, and tolerance rows.*
8. *P is the* Pkg *provenance over* $\mathsf{GateauxDerivative}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{GateauxDerivative}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the displayed direction row V and the real-tolerance agreement row T, together with the structural transport and replay rows. It has no coordinate for host function equality, unrecorded limits, quotient equality of directional germs, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6344.2 (Gateaux derivative classifier adequacy)**.** *For accepted* $\mathsf{GateauxDerivative}^{\uparrow}$ *carriers*

$$G = (X, A, V, Q, T, H, C, P, N) \quad \textit{and} \quad G' = (X', A', V', Q', T', H', C', P', N'),$$

the public classifier identifies G with G' exactly when the source rows, point-window rows, displayed direction rows, directional quotient rows, real-tolerance rows, transport rows, replay rows, provenance rows, and local naming rows are componentwise hsame*-stable, and the direction read V and tolerance agreement T transport to V' and T' over the same source row. The comparison does not inspect host functions, chosen limits, quotient germs, or completeness witnesses outside the packet.*

Proof. Project the two carrier tuples. Every accepted row is displayed in the finite packet, so componentwise hsame transport gives the only data available to the public classifier.

The direction clause is read from V and V'. Because these rows are attached to the same transported source row, a classifier equality can compare the direction displays without importing a tangent-space quotient or a host vector equality.

The tolerance clause is read from T and T'. It compares the quotient rows against the candidate derivative values only through $\mathsf{Real}^{\uparrow}$ tolerance data, so the classifier remains finite and local.

Conversely, the listed componentwise transport data reconstructs the accepted packet row by row. The provenance row records that no additional host coordinate is part of the name, hence the displayed rows exhaust the classifier. □

Theorem 6344.3 (Gateaux derivative NameCert obligations)**.** *For every accepted* $\mathsf{GateauxDerivative}^{\uparrow}$ *carrier $G = (X, A, V, Q, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GateauxDerivative}^{\uparrow}}$ *surface consists exactly of carrier admission for the normed source row, point-window row, displayed direction row, directional difference-quotient row,* $\mathsf{Real}^{\uparrow}$ *tolerance-agreement row, componentwise transport, displayed replay, provenance, and local naming; classifier stability under* hsame *transport of all displayed rows; direction-row exposure before any derivative read is public; tolerance agreement through the same* $\mathsf{Real}^{\uparrow}$ *row for every accepted quotient request; and ledger non-escape from host function extensionality, chosen limits, quotient equality, and ambient real completeness.*

Proof. Read the carrier of Definition 6344.1. The tuple $X, A, V, Q, T, H, C, P, N$ is the whole accepted packet, so the carrier-admission obligations are direct projections.

The direction exposure clause is the read of V over the source row X and point window A. This keeps the Gateaux derivative directional: no Frechet-style full linear approximation is exported unless a separate $\mathsf{FrechetDerivative}^{\uparrow}$ packet supplies it.

The quotient and tolerance clauses are the reads of Q and T. The quotient row records finite directional probes, while the tolerance row compares them through $\mathsf{Real}^{\uparrow}$ data already present in the packet.

Classifier stability is the componentwise transport row H, replay is the continuation row C, and source accounting is the package row P. Since no coordinate names any excluded host object, the local certificate exports only the displayed directional derivative route. □

Theorem 6344.4 (Gateaux derivative local non-escape)**.** *An accepted* $\mathsf{GateauxDerivative}^{\uparrow}$ *packet cannot be used to read host function extensionality, a chosen limiting value, quotient equality of directional germs, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any consumer of the packet must first pass through the finite route*

$$\mathsf{Derivative}^{\uparrow},\ \mathsf{FrechetDerivative}^{\uparrow},\ \mathsf{LinMap}^{\uparrow},\ \mathsf{Norm}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Within that route, $\mathsf{GateauxDerivative}^{\uparrow}$ *contributes only the displayed direction row, finite directional difference quotients, and real-tolerance agreement.*

Proof. Read a consumer request through the continuation row C. The replay exposes the source row X, the point-window row A, and the displayed direction row V before any quotient or derivative value is visible.

Next read the quotient row Q and the tolerance row T. These rows provide finite directional probes and $\mathsf{Real}^{\uparrow}$ tolerance agreement, not a selected limit object.

Finally read the provenance row P and the local naming row N. Their dependency route lists the neighbouring derivative, Frechet derivative, linear-map, norm, real, history, transport, continuation, package, and NameCert rows. Since host function extensionality, quotient-germ equality, chosen limits, and ambient completeness do not occur in that route, they are not exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{GateauxDerivative}^{\uparrow}$ packet must expose a displayed direction row, a directional difference-quotient row, and a $\mathsf{Real}^{\uparrow}$ tolerance-agreement row before any directional derivative read is public.

Independence witness: derivative, frechet, linearmap, norm, real: $\mathsf{GateauxDerivative}^{\uparrow}$ is not bijective to any listed sibling because it binds one displayed direction and finite real-tolerance agreement without requiring a full Frechet linear approximation or a host derivative operator.

Closure status for $\mathsf{NameCert}_{\mathsf{GateauxDerivative}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GateauxDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6344.1, Definition 6344.2, Definition 6344.3, and Definition 6344.4 seed the finite Gateaux directional-derivative route over Derivative, FrechetDerivative, LinearMap, Norm, Real, BHist, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GateauxDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host differentiability, full Frechet differentiability, global tangent bundles, quotient germ equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, direction-row exposure, directional quotient readback, real-tolerance agreement, classifier stability, local non-escape, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.GateauxDerivativeUp.

Constructive story: A $\mathsf{GateauxDerivative}^{\uparrow}$ packet is generated from a normed source row, a point-window row, a displayed direction row, a directional quotient row, a Real tolerance-agreement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6345

A Concrete Naming Certificate for $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$ packet records the finite-net Lebesgue-number data needed before compact-metric finite-modulus consumers read a cover-stability tolerance. It sits over the compact metric source of chapter 129, the total-bounded refinement surface of chapter 127, the finite epsilon-net handoff of chapter 1767, the finite-net compactness route of chapter 3471, and the Real-facing tolerance surface of chapter 38. The packet records finite centers, cover-stability rows, tolerance comparisons, and replay provenance without claiming open-cover compactness, selected subcovers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6345.1 (Lebesgue-number finite-net carrier)**.** *A* $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, U, \delta, E, P, C, D, T, H, R, S, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the point classifier, metric-distance classifier, compact-metric ledger, and finite-modulus consumer surface read by the packet.*
2. *U is the cover-stability request row. It records the finite family of named cover cells inspected by the packet, not an arbitrary host open cover.*
3. *δ is the positive tolerance row, read through* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *only as displayed tolerance data.*
4. *E is the imported* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *handoff row, exposing center rows, membership rows, dyadic or rational tolerance rows, and the* $\mathsf{TotallyBounded}^{\uparrow}$ *refinement surface.*
5. *P is the closed* ProbeBundle *of finite-net centers read from E.*
6. *C records center admission and cover-cell assignment for every center in P.*
7. *D records the finite coverage ledger from each inspected point to an admitted center, together with the displayed distance comparison bounded by δ.*
8. *T records the finite cover-stability tolerance comparison: if an inspected point is δ-close to an admitted center, the point remains inside the cover cell assigned by C.*
9. *H records componentwise* hsame *transport for $X, U, \delta, E, P, C, D, T, R, S, N$.*

10. *R records displayed* Cont *replay for finite cover-stability requests.*
11. *S is the* Pkg *provenance over* $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteNet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these finite rows. It has no coordinate for an arbitrary open cover, a selected finite subcover, a host compactness theorem, countable choice, or ambient Real completeness.

Theorem 6345.2 (Lebesgue-number finite-net NameCert obligations)**.** *For every accepted* LebesgueNumberFiniteN *carrier $L = (X, U, \delta, E, P, C, D, T, H, R, S, N)$, the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteNet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, cover-stability request, positive tolerance, finite epsilon-net handoff, center bundle, center-cover assignment ledger, coverage-distance ledger, stability-tolerance ledger, transport, replay, provenance, and local naming rows;*
2. *finite-net support, requiring the center rows, membership rows, tolerance rows, and* $\mathsf{TotallyBounded}^{\uparrow}$ *refinement surface of E to be exposed before any cover-stability tolerance is read;*
3. *center assignment, requiring every center used by the stability ledger to be admitted through P and assigned a displayed cover cell by C;*
4. *coverage transport, requiring every inspected point to reach an assigned center through D and to preserve the same tolerance row under H;*
5. *local stability, requiring T to certify the displayed cover-cell containment after the inspected point is compared with its admitted center;*
6. *ledger nonescape, excluding arbitrary open covers, selected finite subcovers, host compactness theorems, countable choice, host* $\mathsf{Real}^{\uparrow}$ *equality, and ambient completeness as local certificate data.*

No Lebesgue-number finite-net obligation is stored outside these rows.

Proof. Project the carrier of Definition 6345.1. The analytic surface consists of the compact metric source X, cover-stability request U, tolerance row δ, finite epsilon-net handoff E, center bundle P, assignment ledger C, coverage ledger D, and stability ledger T.

Use Definition 1767.6. The imported row E exposes center rows, membership rows, rational or dyadic tolerance rows, and the $\mathsf{TotallyBounded}^{\uparrow}$ refinement surface before this packet reads a cover-stability tolerance.

The center assignment and coverage transport rows are then forced locally. A center can be used only after it is visible in P and assigned by C, and an inspected point can use the assigned cell only after D supplies a displayed distance comparison to that center.

Finally apply the stability ledger T and replay it through H and R. The replay remains inside the finite request surface, and S, N record provenance and local naming without adding any selected subcover, open-cover compactness theorem, countable-choice row, host Real equality, or ambient completeness principle. □

Theorem 6345.3 (Lebesgue-number finite-net nonescape)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteModulusReal}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$ *carrier reads a finite route*

$$X, U, \delta, E, P, C, D, T \longmapsto H, R, S, N$$

before it may use a cover-stability tolerance. The route may be combined with the finite-net compactness surface of $\mathsf{HeineBorelFiniteNet}^{\uparrow}$*, but it does not export open-cover compactness, selected subcovers, countable choice, host Real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a downstream consumer of L. By Definition 6345.1, the consumer enters through X, U, δ and the finite epsilon-net row E, not through an ambient cover or host compactness theorem.

Apply Definition 6345.2. The packet opens the center bundle, center-cover assignment, coverage-distance ledger, stability-tolerance ledger, transport, replay, provenance, and local naming rows in that order.

The optional $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ sibling route is only a finite-net compactness surface. It can align named finite-net rows with compact-metric consumers, but it supplies no selected subcover and no open-cover compactness principle to this packet.

Thus every consumer read factors through the displayed finite route before any cover-stability tolerance is available. Since the carrier lacks coordinates for selected subcovers, countable choice, host Real equality, and ambient completeness, none of those objects escapes through the consumer boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteNet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6345.1, Definition 6345.2, and Definition 6345.3 seed the finite-net Lebesgue-number packet over compact metric sources, cover-stability requests, tolerance rows, finite epsilon-net handoffs, center bundles, assignment ledgers, coverage ledgers, stability ledgers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, host Real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net support, center assignment, coverage transport, local stability, ledger nonescape, and compact-metric finite-modulus consumer handoff for BEDC.Derived.LebesgueNumberFiniteNet

Constructive story: A $\mathsf{LebesgueNumberFiniteNet}^{\uparrow}$ packet is generated from a CompactMetricUp source row, a finite cover-stability request, a positive tolerance row, a FiniteEpsilonNetUp handoff, a closed ProbeBundle of centers, center-cover assignment rows, coverage-distance rows, stability-tolerance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6346

A Concrete Naming Certificate for $\mathsf{DunfordPettis}^{\uparrow}$

Following Dunford and Pettis on weak compactness in L^1 spaces, the $\mathsf{DunfordPettis}^{\uparrow}$ packet records the finite BEDC surface on which weak compactness is handed to uniform integrability before any selected weakly compact subsequence, countable-choice schedule, quotient almost-everywhere equality, or ambient Banach-space compactness theorem is public. It sits beside the measure and integral sources of chapter 92 and chapter 123, the tail-budget packet of chapter 6228, the functional-analysis carrier of chapter 94, and the bounded-operator surface of chapter 1644.

Definition 6346.1 (Dunford-Pettis carrier)**.** *A* $\mathsf{DunfordPettis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (U, M, I, F, B, R, W, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformIntegrability}^{\uparrow}$ *source row naming the family-level tail budget.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row through which measurable domains, measurable sets, and finite-measure windows are read.*
3. *I is the* $\mathsf{Integral}^{\uparrow}$ *readback row for displayed L^1 bounds and tail integrals.*
4. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *row naming the weak topology, dual-pairing probes, and finite neighborhood tests visible to the packet.*
5. *B is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row for bounded linear probes used to inspect weak images.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *budget row storing scalar tolerances, norm bounds, and finite comparison windows.*
7. *W is the weak-compactness handoff row. It records only the finite implication route from uniform-integrability evidence through weak-probe tests to the consumer-visible compactness request.*
8. *H records componentwise* hsame *transport for U, M, I, F, B, R, W and the local structural rows.*
9. *C records displayed* Cont *replay from weak-compactness requests through $U, M, I, F, B, R, W, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{DunfordPettis}^{\uparrow}$, $\mathsf{UniformIntegrability}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DunfordPettis}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected weakly compact subsequence, countable choice, quotient almost-everywhere equality, ambient Banach-space compactness, a host dual-ball compactness theorem, or an unbounded family of weak probes.

Theorem 6346.2 (Dunford-Pettis NameCert obligations)**.** *For every accepted* $\mathsf{DunfordPettis}^{\uparrow}$ *carrier*

$$D = (U, M, I, F, B, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DunfordPettis}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, uniform-integrability source compatibility through* U*, measure source compatibility through* M*, integral readback through* I*, weak-test visibility through* F*, bounded-probe visibility through* B*, scalar-budget visibility through* R*, weak-compactness handoff through* W*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*.*

Every weak-compactness-facing consumer must read the same rows before using the handoff. It receives no selected subsequence, no countable-choice schedule, no quotient almost-everywhere equality, no ambient Banach-space compactness theorem, no host dual-ball compactness theorem, and no infinite probe family.

Proof. Carrier admission is projection from Definition 6346.1. The accepted packet displays exactly $U, M, I, F, B, R, W, H, C, P, N$.

The analytic source rows U, M, I fix the uniform-integrability, measure, and integral surfaces. The weak-facing rows F and B then limit the consumer to the displayed weak topology tests and bounded linear probes, while R supplies only the scalar budgets visible in the packet.

The handoff row W is downstream of those rows. It records the finite implication route from uniform integrability to weak compactness, but it does not choose a subsequence, quotient representatives, or a host compactness theorem.

The structural rows H, C, P, N preserve that same packet under transport, replay, provenance, and naming. Since every excluded object has no carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6346.3 (Dunford-Pettis uniform-integrability handoff)**.** *Every weak-compactness consumer of an accepted* $\mathsf{DunfordPettis}^{\uparrow}$ *carrier reaches the Dunford-Pettis handoff only through the displayed route*

$$U \longmapsto M, I \longmapsto F, B, R \longmapsto W \longmapsto H, C, P, N.$$

Thus the consumer may read the uniform-integrability budget, measure and integral evidence, finite weak-test and bounded-probe rows, scalar bounds, the weak-compactness handoff, transport, replay, provenance, and local naming, and it may not read selected weakly compact subsequences, countable choice, quotient almost-everywhere equality, ambient Banach-space compactness, host dual-ball compactness, or unbounded weak-probe families.

Proof. Begin with a weak-compactness-facing read. By Definition 6346.1, the only tail-control source is U, and it is interpreted only through the displayed measure and integral rows M and I.

The weak tests then pass through F and B. These rows expose finite dual-pairing and bounded-operator probes, while R records the scalar comparison budgets needed by those probes.

The consumer reaches weak compactness only at W. That row is a handoff from the already displayed uniform-integrability data to the public weak-compactness request, not an extraction of a subsequence or a compactness theorem from an ambient Banach space.

Finally H, C, P, N transport, replay, package, and name the same route. Because the carrier lacks coordinates for the refused objects, no consumer can recover them from the Dunford-Pettis packet. □

Falsifiable prediction: Any $\mathsf{DunfordPettis}^{\uparrow}$ read that claims weak compactness while bypassing the displayed $\mathsf{UniformIntegrability}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 6346.1.

Independence witness: uniform-integrability, measure, integral, functional-analysis, bounded-linear-operator: $\mathsf{DunfordPettis}^{\uparrow}$ is not bijective to any listed sibling because it stores the finite weak-compactness handoff row over the shared tail-control and weak-probe sources without storing selected subsequences, countable choice, quotient almost-everywhere equality, or ambient compactness.

Closure status for $\mathsf{NameCert}_{\mathsf{DunfordPettis}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DunfordPettis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6346.1, Definition 6346.2, and Definition 6346.3 seed the finite handoff from uniform integrability to weak compactness over measure, integral, weak-test, bounded-probe, scalar-budget, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DunfordPettis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected weakly compact subsequences, countable choice, quotient almost-everywhere equality, ambient Banach-space compactness, host dual-ball compactness, unbounded weak-probe families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-integrability source compatibility, measure and integral readback, weak-test visibility, bounded-probe visibility, scalar-budget visibility, handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DunfordPettisUp.

Constructive story: A $\mathsf{DunfordPettis}^{\uparrow}$ packet is generated from UniformIntegrability, Measure, Integral, FunctionalAnalysis, BoundedLinearOperator, Real scalar-budget, weak-compactness handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6347

A Concrete Naming Certificate for $\mathsf{LocatedOrderInterval}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedOrderInterval}^{\uparrow}$ packet names the finite order-facing interval data needed to compare located lower and upper boundary evidence before a real-completion consumer reads a terminal real seal. It sits between the interval carrier of chapter 1709 and the two-sided cut surface of chapter 2087: the packet records lower-bound and upper-bound rows, a located-gap row, dyadic tolerance data, finite stream windows, regular-rational readback, and a terminal $\mathsf{Real}^{\uparrow}$ seal without importing trichotomy, a Dedekind construction of $\mathsf{Real}^{\uparrow}$, quotient real equality, selected representatives, countable choice, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6347.1 (Located order interval carrier)**.** *A* $\mathsf{LocatedOrderInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, U, G, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower-bound row. It records the finite lower observations and the order-facing comparison requests visible to a completion route.*
2. *U is the upper-bound row. It records the finite upper observations and the matching comparison requests.*
3. *G is the located-gap row. It binds the lower and upper observations to one displayed apartness or overlap request before any real-facing seal is read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores the dyadic endpoints, slack, radius, and comparison budget used by L, U, G.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It schedules the visible lower and upper reads without selecting an infinite name.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It translates the scheduled windows into regular-rational comparison evidence.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It is available only after L, U, G, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the lower-bound row, upper-bound row, located-gap row, dyadic tolerance row, stream window, regular-rational readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay for each order, interval, or real-completion request through* $L, U, G, D, S, R, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{LocatedOrderInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LowerUpperRealCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedOrderInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, G, D, S, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, selected representatives, countable choice, open-cover compactness, a Dedekind construction of $\mathsf{Real}^{\uparrow}$*, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6347.2 (Located order interval NameCert obligations)**.** *For an accepted* $\mathsf{LocatedOrderInterval}^{\uparrow}$ *carrier*

$$O = (L, U, G, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedOrderInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the lower-bound row, upper-bound row, located-gap row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, replay, provenance, and local naming row;*
2. *lower-bound stability, requiring every lower observation to be read through L, D, S, R, H, C, P, N before a completion-facing consumer may inspect it;*
3. *upper-bound stability, requiring every upper observation to be read through U, D, S, R, H, C, P, N by the same finite route;*
4. *located-gap exactness, requiring G to bind the displayed lower and upper rows to one located request before the regular-rational readback and real seal are consumed;*
5. *tolerance-window compatibility, requiring D and S to expose the same finite comparison budget that R reads back;*
6. *real-seal non-escape, requiring E to remain downstream of L, U, G, D, S, R and to export no trichotomy, quotient real equality, selected representative, countable-choice schedule, open-cover compactness witness, Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 6347.1. The accepted packet displays exactly the lower-bound row, upper-bound row, located-gap row, dyadic tolerance row, stream window, regular-rational readback, real seal, and structural rows.

Lower-bound and upper-bound stability are componentwise. The row D supplies the shared dyadic tolerance budget, S schedules the finite windows, and R reads the same windows back as regular-rational comparison evidence.

Located-gap exactness is read from G against L and U. The gap row binds the two order-facing ledgers to one displayed located request before any terminal real seal can be consumed.

The structural tail H, C, P, N transports, replays, sources, and locally names the same packet. Since the carrier has no coordinate for trichotomy, quotient real equality, selected representatives, countable choice, open-cover compactness, a Dedekind construction of $\mathsf{Real}^{\uparrow}$, or ambient completeness, the listed obligation rows are exhaustive. □

Theorem 6347.3 (Located order interval real-completion route)**.** *Every completion-facing read of an accepted* $\mathsf{LocatedOrderInterval}^{\uparrow}$ *carrier factors through the displayed route*

$$L, U, G \longmapsto D, S, R \longmapsto E, H, C, P, N.$$

The route first exposes lower-bound, upper-bound, and located-gap evidence, then consumes the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *finite window, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then reaches the* $\mathsf{Real}^{\uparrow}$ *seal. Thus it gives Real and Completion consumers a finite comparison packet between located interval data and lower/upper real cut boundaries without asserting trichotomy, quotient real equality, selected representatives, countable choice, open-cover compactness, a Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $O = (L, U, G, D, S, R, E, H, C, P, N)$. The order-facing evidence is exactly the lower-bound row L, upper-bound row U, and located-gap row G.

Read the tolerance and name rows next. The dyadic row D records the finite comparison budget, the stream row S schedules the visible lower and upper windows, and the regular-rational row R reads those windows back for the real-completion route.

Only after those rows are present may the terminal seal E be consumed. The structural rows H, C, P, N preserve the same finite packet under transport, replay, provenance, and local naming. No further carrier coordinate exists, so the route cannot export any of the excluded order, quotient, choice, compactness, or completeness principles. □

Falsifiable prediction: Every accepted $\mathsf{LocatedOrderInterval}^{\uparrow}$ completion-facing read factors through lower-bound, upper-bound, located-gap, dyadic tolerance, stream-window, regular-rational readback, $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and local naming rows.

Independence witness: locatedrealinterval, loweruppperrealcut, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedOrderInterval}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries order-facing lower and upper boundary rows, a located-gap row, dyadic tolerance data, stream-window scheduling, regular-rational readback, a terminal real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedOrderInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedOrderInterval}^{\uparrow}$ packet is generated from lower-bound and upper-bound rows, a located-gap row, DyadicRatCore tolerance data, a StreamName finite window, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedOrderInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6347.1, Definition 6347.2, and Definition 6347.3 seed the finite order-facing comparison packet between located interval data and lower-upper real cut boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedOrderInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, a Dedekind construction of $\mathsf{Real}^{\uparrow}$, quotient real equality, selected representatives, countable choice, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier exposure, lower-bound stability, upper-bound stability, located-gap exactness, tolerance-window compatibility, and real-seal non-escape for BEDC.Derived.LocatedOrderIntervalUp.

Chapter 6348

A Concrete Naming Certificate for $\mathsf{NagataSmirnovMetrization}^{\uparrow}$

Following Nagata and Smirnov on metrization, the $\mathsf{NagataSmirnovMetrization}^{\uparrow}$ packet records the finite BEDC route by which a regular topological source with a displayed locally finite σ-cover basis exposes a metric handoff. It sits between the topology carrier of chapter 88, the metric consumer surface of chapter 57, the uniform-entourage handoff of chapter 4226, and the normal second-countable route of chapter 3337. The packet names only the displayed cover-family route to metric data; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, choice-selected covers, host topology equality, or arbitrary point-set metrizability.

Definition 6348.1 (Nagata–Smirnov metrization carrier)**.** *A* $\mathsf{NagataSmirnovMetrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, R, L, S, B, E, D, M, F, U, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, recording the open-set classifier and finite neighbourhood requests read by the packet.*
2. *R is the regularity row for closed-neighbourhood separation requests presented by the topology source.*
3. *L is the locally finite cover-family ledger. It lists the inspected cover layers and the finite star-neighbourhood checks used by the metric route.*
4. *S is the σ-layer schedule row. It records the finite layer window through which cover-family requests are replayed.*
5. *B is the base-refinement row, tying each inspected neighbourhood request in T to a displayed cover member in the locally finite schedule.*
6. *E is the entourage-shrink row exported to the* $\mathsf{FrinkMetrization}^{\uparrow}$ *route after the local cover checks have been displayed.*
7. *D is the dyadic radius ledger used by the downstream metric handoff.*
8. *M is the* $\mathsf{Met}^{\uparrow}$ *handoff row. It is available only after T, R, L, S, B, E, D have been exposed.*
9. *F records finite compatibility between the metric-ball rows from M and the source topology windows from T.*

10. *U records the comparison with the* $\mathsf{UrysohnMetrization}^{\uparrow}$ *route on packets that also expose normal second-countable data.*
11. *H records componentwise* hsame *transport for all displayed rows.*
12. *C records displayed* Cont *replay from a topology request through regularity, locally finite cover layers, entourage shrink, dyadic radius data, metric handoff, compatibility, provenance, and local naming.*
13. *P is the* Pkg *provenance over* $\mathsf{NagataSmirnovMetrization}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FrinkMetrization}^{\uparrow}$, $\mathsf{UrysohnMetrization}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{NagataSmirnovMetrization}^{\uparrow}}$ *row.*

The carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, choice-selected covers, host topology equality, arbitrary refinements, quotient point equality, or an ambient metric oracle.*

Lean4 (statement) `BEDC.Derived.NagataSmirnovMetrizationUp`

Theorem 6348.2 (Nagata–Smirnov metrization NameCert obligations)**.** *For every accepted* NagataSmirnovMetriza *carrier $G = (T, R, L, S, B, E, D, M, F, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NagataSmirnovMetrization}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the topology source, regularity row, locally finite cover-family ledger, layer schedule, base-refinement row, entourage-shrink row, dyadic radius ledger, metric handoff, compatibility rows, transport, replay, provenance, and local naming row;*
2. *cover-family readability, requiring every cover request to start at T and pass through the locally finite ledger L and layer schedule S before any metric row is consumed;*
3. *regularity and base-refinement compatibility, requiring R and B to expose the finite closed-neighbourhood and cover-refinement checks used by the shrink row E;*
4. *metric handoff stability, requiring E, D, M, F to keep the* $\mathsf{Met}^{\uparrow}$ *ball rows downstream of the displayed cover-family route and comparable with the* $\mathsf{FrinkMetrization}^{\uparrow}$ *and* $\mathsf{UrysohnMetrization}^{\uparrow}$ *dependency anchors;*
5. *refusal, requiring P and N to name only this finite packet and to refuse* $\mathsf{Real}^{\uparrow}$ *completeness, choice-selected covers, host topology equality, arbitrary refinements, quotient point equality, and ambient metric oracles.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 6348.1. The projection exposes exactly the topology source, regularity row, locally finite cover ledger, layer schedule, base-refinement row, shrink row, dyadic ledger, metric handoff, compatibility rows, and the structural rows H, C, P, N.

The cover-family route is forced by row order. A metric-facing request first reads neighbourhood data from T, then the locally finite cover ledger L, and then the finite layer schedule S before a base-refinement row B or shrink row E can be inspected.

The metric handoff is therefore downstream of R, L, S, B, E, D. The rows F and U only compare the resulting metric windows with the topology source and the neighbouring metrization packets; they do not supply a host metric or a new topology equality principle.

Since the tuple contains no $\mathsf{Real}^{\uparrow}$ completeness, choice-selected cover, host topology equality, arbitrary refinement, quotient point equality, or ambient metric coordinate, the local NameCert cannot export those principles. □

Theorem 6348.3 (Nagata–Smirnov metric handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$ *consumer of an accepted* NagataSmirnovMetrizati *packet receives the finite route*

$$\mathsf{Topology}^{\uparrow},\ R,\ L,\ S,\ B,\ E,\ D,\ M,\ F,\ U,\ H,\ C,\ P,\ N.$$

The metric row M is consumed as a downstream handoff tied to the displayed locally finite cover family and its topology compatibility windows. It is not a host metric, not a selected cover metric, and not a claim that the source topology equals an external topology.

Proof. Read the carrier rows in order. The topology source, regularity row, locally finite cover ledger, layer schedule, base-refinement row, entourage shrink, and dyadic radius ledger are displayed before M is available.

The compatibility row F binds the handoff back to finite topology windows, and U records only the comparison with the Urysohn-style route when that sibling data is also present. Thus the metric consumer receives a named finite route from the original topology surface to the displayed metric row.

Finally use the refusal surface in P and N. Since no row stores $\mathsf{Real}^{\uparrow}$ completeness, selected covers, host topology equality, arbitrary refinements, quotient point equality, or an ambient metric oracle, the handoff remains the finite BEDC route named above. □

Closure status for $\mathsf{NameCert}_{\mathsf{NagataSmirnovMetrization}^{\uparrow}}$.

Constructive story: A $\mathsf{NagataSmirnovMetrization}^{\uparrow}$ packet is generated from a topology source row, regularity row, locally finite cover-family ledger, layer schedule, base-refinement row, entourage shrink, dyadic radius ledger, metric handoff, topology compatibility row, sibling metrization comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NagataSmirnovMetrization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6348.1, Definition 6348.2, and Definition 6348.3 seed the finite regular locally finite cover-family route to a displayed metric handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NagataSmirnovMetrization}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, choice-selected covers, host topology equality, arbitrary refinements, quotient point equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover-family readability, regularity and base-refinement compatibility, entourage-shrink exactness, metric handoff stability, transport, replay, provenance, and local naming for BEDC.Derived.NagataSmirnovMetrizationUp.

Chapter 6349

A Concrete Naming Certificate for PicardCompletionResidualCauchyRealizer$^{\uparrow}$

Following Bishop–Bridges constructive analysis and Banach's fixed-point route, the PicardCompletionResidualCauchy packet records the finite residual-to-completion realizer that a Picard orbit exposes before endpoint consumers read a completed value. It refines the iteration ledger of chapter 2359 through the completion side of chapter 1691, the complete-metric source of chapter 128, the Cauchy-modulus budget of chapter 292, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the residual Cauchy route consumed by Banach fixed-point and Picard–Lindelof surfaces; it does not select a fixed point, identify quotient reals, invoke countable choice, assume host function extensionality, or assert ambient Real$^{\uparrow}$ completeness.

Definition 6349.1 (Picard completion residual Cauchy realizer carrier)**.** *A* PicardCompletionResidualCauchyRealize *carrier is a finite packet*

$$P = (X, T, I, D, M, F, R, E, H, C, Q, N)$$

with the following displayed rows.

1. *X is the* CompleteMetric$^{\uparrow}$ *source row, including the metric carrier and distance-read boundary used by the residual comparisons.*
2. *T is the contraction and* PicardIteration$^{\uparrow}$ *ledger row, recording the self-map graph, initial point, finite orbit, and Picard replay data read before any completion handoff.*
3. *D is the residual-distance row, storing the adjacent distance comparisons and contraction-ratio bounds extracted from T inside the complete metric source X.*
4. *M is the* CauchyModulus$^{\uparrow}$ *row generated from the displayed residual-distance schedule.*
5. *F is the* FastCauchyCompletion$^{\uparrow}$ *handoff row, exposing the modulus-controlled completion route read from M and the finite Picard residual ledger.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row available to consumers that inspect the completion realizer as a regular rational Cauchy name.*
7. *E is the* Real$^{\uparrow}$ *seal row, marking the terminal real-facing boundary after F and R have been displayed.*
8. *H records componentwise* hsame *transport for the complete-metric source, contraction/Picard ledger, residual-distance row, CauchyModulus row, FastCauchyCompletion handoff, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the complete metric and contraction rows through the residual schedule, modulus extraction, completion handoff, regular readback, Real seal, transport, provenance, and local naming.*

10. *Q is the* Pkg *provenance over* $\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{FastCauchyCompletion}^{\uparrow}$ $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, D, M, F, R, E, H, C, Q, N$. It has no coordinate for selected fixed points, quotient equality, countable choice, host function extensionality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 6349.2 (Picard completion residual Cauchy realizer NameCert obligations)**.** *For every accepted* $\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}$ *carrier $P = (X, T, I, D, M, F, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed complete-metric source, contraction/Picard ledger, finite iterate row, residual-distance row, CauchyModulus row, FastCauchyCompletion handoff, RegSeqRat readback, Real seal, and structural rows H, C, Q, N;*

2. *residual discipline, requiring every completion-facing read to inspect the Picard ledger and residual-distance row before any Cauchy modulus or completion row is exposed;*

3. *modulus extraction, requiring M to be generated from the displayed residual schedule rather than from an endpoint selector or ambient completeness theorem;*

4. *completion handoff, requiring F to read the same modulus route before the regular readback row R or terminal Real seal E may be consumed;*

5. *transport and replay stability, requiring H and C to preserve the ordered route under componentwise sameness and displayed continuation replay;*

6. *ledger non-escape, requiring Q and N to name only the displayed rows and to export no selected fixed point, quotient equality, countable choice, host function extensionality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6349.1. The visible packet consists of the complete-metric source X, contraction/Picard ledger T, finite iterate row I, residual-distance row D, modulus row M, completion handoff F, regular readback R, Real seal E, and structural rows H, C, Q, N.

Residual discipline follows from the placement of X, T, I, D at the front of the route. A completion-facing consumer first reads the metric and contraction data, then the finite Picard ledger and the residual comparisons extracted from it.

Modulus extraction and completion handoff are downstream. The row M is generated only after the residual schedule is displayed, and F is the only completion row exposed after M. Thus R and E remain attached to the residual-to-modulus route.

Finally, H, C, Q, N transport, replay, source, and name exactly the same rows. Since selected fixed points, quotient equality, countable choice, host function extensionality, and ambient Real completeness are absent from the carrier, no local NameCert obligation can export them. □

Theorem 6349.3 (Picard completion residual Cauchy realizer handoff)**.** *Every completion-facing read of an accepted* $\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{FastCauchyCompletion}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Consequently Banach fixed-point and Picard–Lindelof consumers receive a complete-metric source, contraction/Picard ledger, residual-distance row, CauchyModulus schedule, FastCauchyCompletion handoff, RegSeqRat readback, terminal Real seal, transport, replay, provenance, and local naming before they can read the completion endpoint boundary.

Proof. Start with a completion-facing read of P. By Definition 6349.1, the only completion handoff is F, and it is downstream of the complete-metric row X, contraction/Picard ledger T, finite iterate row I, residual row D, and modulus row M.

The first part of the route is fixed by the Picard data. The complete metric supplies the distance-read boundary, the contraction/Picard ledger supplies the finite orbit, and the residual row supplies the adjacent-distance schedule used by the modulus row.

The second part is fixed by the completion and readback rows. The FastCauchyCompletion handoff F is read only after M, the regular rational row R is read only after F, and the Real seal E is terminal for the displayed route.

The structural rows H, C, Q, N preserve and name the same order. Because the excluded objects have no coordinate in the carrier and no replay edge in the displayed route, every completion-facing read factors through the route shown in the statement. □

Falsifiable prediction: Every accepted $\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}$ completion-facing read factors through a CompleteMetric source, contraction/Picard ledger, residual-distance row, CauchyModulus schedule, FastCauchyCompletion handoff, RegSeqRat readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any fixed-point or ODE endpoint boundary is consumed.

Independence witness: picard-iteration, fast-cauchy-completion, completemetric, cauchymodulus, regseqrat, real: $\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the complete-metric source, contraction/Picard ledger, residual-distance row, modulus extraction, completion handoff, regular readback, real-seal boundary, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6349.1, Definition 6349.2, and Definition 6349.3 seed the finite residual Cauchy realizer route from Picard residuals to completion-facing Real reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, quotient equality, countable choice, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, residual discipline, modulus extraction, completion handoff, transport and replay stability, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.PicardCompletionResidualCau

Constructive story: A $\mathsf{PicardCompletionResidualCauchyRealizer}^{\uparrow}$ packet is generated from a CompleteMetric source, contraction/Picard ledger, residual-distance row, CauchyModulus schedule, FastCauchyCompletion handoff, RegSeqRat readback, RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6350

A Concrete Naming Certificate for $\mathsf{CoreCompact}^{\uparrow}$

Following Isbell, Johnstone, and constructive locale practice, the $\mathsf{CoreCompact}^{\uparrow}$ packet records a core-compact neighbourhood relation as finite BEDC data. It sits between the topology carrier of chapter 88, the local compact-neighbourhood certificate of chapter 1726, the compact metric witness surface of chapter 129, and the located compact handoff of chapter 1488. The packet names one displayed way-below neighbourhood route and its compact witness support; it does not assert open-cover compactness, a host basis selector, countable choice, quotient opens, or ambient Real completeness.

Definition 6350.1 (CoreCompact carrier)**.** *A* $\mathsf{CoreCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, U, V, W, K, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Topology}^{\uparrow}$ *source row whose opens and incidence data are already admitted as finite BEDC carrier rows.*
2. *U is the inspected open-neighbourhood row requested by a consumer.*
3. *V is the displayed core row, read as a neighbourhood that is way below U in the finite inspection order carried by the packet.*
4. *W is the way-below witness row, recording the finite containment and directed-cover test by which the packet justifies $V \ll U$ for the displayed request.*
5. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *or compact-window witness attached to the displayed core neighbourhood when a metric compact witness is available.*
6. *L is the optional* $\mathsf{LocatedCompact}^{\uparrow}$ *handoff row for the same core neighbourhood, or an explicit empty handoff row when no located boundary is claimed.*
7. *H records componentwise* hsame *transport for topology source, inspected open, core row, way-below witness, compact witness, located handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite neighbourhood request through X, U, V, W, K, L, H and into local compactness, compact metric, located compact, or completion-facing consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{CoreCompact}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{LocallyCompact}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{LocatedCompact}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CoreCompact}^\uparrow}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for arbitrary open covers, a host-selected basis, quotient-open equality, countable choice, all-neighbourhood local compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CoreCompactUp.CoreCompactTasteGate single carrier alignment`

Theorem 6350.2 (CoreCompact way-below neighbourhood route)**.** *Let $Q = (X, U, V, W, K, L, H, C, P, N)$ be an accepted* $\mathsf{CoreCompact}^\uparrow$ *packet. Every* $\mathsf{LocallyCompact}^\uparrow$ *or* $\mathsf{Topology}^\uparrow$ *consumer that reads a core-compact neighbourhood must first display the topology source X, the inspected open row U, the core row V, and the way-below witness W. Only after those rows are present may the consumer inspect the compact witness K, the optional located compact handoff L, and the structural rows H, C, P, N. The route supplies a finite way-below neighbourhood certificate and does not export arbitrary open-cover compactness, a host basis selector, quotient-open equality, countable choice, all-centres/all-radii properness, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 6350.1. The first public rows are the topology source, the inspected open, the displayed core neighbourhood, and the way-below witness.

Read the local compactness sibling through chapter 1726. That sibling supplies compact neighbourhood data only after an inspected point and displayed compact window are named; here the analogous route is U, V, W before compact support is read.

The compact support is therefore downstream. The row K records the compact metric or compact-window witness for the displayed core, and the optional row L can refine the same neighbourhood only when located compact data are shown.

Finally use the structural rows. Componentwise transport and replay preserve the same finite route, while provenance and local naming identify the sibling surfaces. Since no excluded open-cover, basis-selector, quotient, choice, properness-family, or ambient-completeness coordinate occurs in Q, no consumer can recover such data from the way-below route. □

Theorem 6350.3 (CoreCompact located compact handoff)**.** *Let $Q = (X, U, V, W, K, L, H, C, P, N)$ be an accepted* $\mathsf{CoreCompact}^\uparrow$ *packet. A* $\mathsf{LocatedCompact}^\uparrow$ *or* $\mathsf{CompactMetric}^\uparrow$ *consumer may read L or K only as support for the same displayed core neighbourhood $V \ll U$. The handoff factors through the* $\mathsf{Topology}^\uparrow$ *source row, the* $\mathsf{LocallyCompact}^\uparrow$ *compact-neighbourhood route, the* $\mathsf{CompactMetric}^\uparrow$ *witness row, the optional* $\mathsf{LocatedCompact}^\uparrow$ *row, and then the* BHist, hsame, Cont, Pkg, *and* NameCert *rows H, C, P, N. It exports no independent located compact object, no open-cover compactness theorem, no countable choice, and no ambient completeness principle.*

Proof. Begin with Definition 6350.2. It forces every consumer to expose X, U, V, W before compact or located support is available.

Use the compact metric sibling of chapter 129. The compact row K is read only for the displayed core neighbourhood; it is not a host compactness theorem and not a compact object detached from $V \ll U$.

Use the located compact sibling of chapter 1488. The row L is optional and exact: when present it refines the same compact neighbourhood, and when absent the packet makes no locatedness claim.

The remaining rows bind the handoff. Transport, replay, provenance, and local naming pass through H, C, P, N, so the located or compact consumer receives one displayed core-neighbourhood route and none of the excluded open-cover, choice, quotient, independent located-object, or ambient-completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CoreCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{CoreCompact}^{\uparrow}$ packet is generated from a topology source row, an inspected open row, a displayed core neighbourhood row, a way-below witness row, a compact metric or compact-window witness, an optional located compact handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoreCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6350.1, Definition 6350.2, and Definition 6350.3 seed the constructive core-compact interface between topology, local compactness, compact metric witnesses, and located compact handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoreCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, host basis selection, quotient-open equality, countable choice, all-neighbourhood local compactness, global properness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, way-below neighbourhood routing, compact witness projection, located compact handoff exactness, componentwise transport, replay stability, provenance, and local NameCert exactness for BEDC.Derived.CoreCompactUp.

Chapter 6351

A Concrete Naming Certificate for BoundedRiemannConvergence$^{\uparrow}$

Following Bishop and Bridges, the BoundedRiemannConvergence$^{\uparrow}$ packet records the finite BEDC surface by which a uniformly bounded row of regulated functions, a displayed pointwise limit row, and a Riemann/Darboux comparison ledger are handed to a Riemann-integral consumer. It sits after the regulated-function carrier of chapter 1906, the Riemann-integral boundary of chapter 1526, the Darboux-sum comparison route of chapter 1880, the bounded-variation real-function control surface of chapter 3654, and the real-equality naming boundary of chapter 1636. The packet names only the bounded finite handoff rows needed for constructive Riemann convergence; it does not import measure integration, host function quotients, selected limits, choice, or ambient Real$^{\uparrow}$ completeness.

Definition 6351.1 (Bounded Riemann convergence carrier)**.** *A* BoundedRiemannConvergence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, F, A, T, S, B, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the common compact interval and Darboux partition row, read through the accepted* DarbouxSum$^{\uparrow}$ *comparison surface.*
2. *F is the regulated-function family row, recording the displayed approximating functions over the same interval.*
3. *A is the pointwise approach row, listing the finite observation windows by which the family is compared with its named limit row.*
4. *T is the tagged Riemann readback row for the displayed members of the family.*
5. *S is the lower/upper Darboux bracket ledger associated to the same partition and tolerance rows.*
6. *B is the uniform bound row, exposing a common finite bound before any convergence consumer reads the integral handoff.*
7. *E is the terminal real-equality row used only to compare the named integral readbacks after D, F, A, T, S, B have been displayed.*
8. *H records componentwise* hsame *transport for the interval, family, approach, Riemann readback, Darboux bracket, bound, real-equality, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from regulated-function reads through pointwise approach windows, tagged sums, Darboux brackets, the uniform bound, and terminal real-equality comparison.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedRiemannConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRiemannConvergence}^{\uparrow}}$ *row.*

Accepted packets are compared only by these displayed rows.

Theorem 6351.2 (Bounded Riemann convergence NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRiemannConvergence}^{\uparrow}$ *carrier* $R = (D, F, A, T, S, B, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedRiemannConverge}}$ *surface consists exactly of common interval and Darboux partition admission through D, regulated-family exposure through F, pointwise approach windows through A, tagged Riemann readback through T, lower/upper Darboux bracket visibility through S, uniform boundedness through B, terminal real-equality comparison through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6351.1. The interval and partition data are opened by D, the regulated family by F, and the finite approach windows by A.

The Riemann/Darboux rows then supply the analysis handoff. Tagged Riemann reads pass through T, lower and upper Darboux brackets pass through S, and the common boundedness coordinate is visible as B before any terminal comparison is read.

Finally E, H, C, P, N compare, transport, replay, source, and name the same packet. Since the carrier contains no measure-integration row, no quotient-function equality row, no selected limit row, no choice row, and no ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6351.3 (Bounded Riemann convergence Darboux handoff)**.** *Every Riemann-integral consumer of an accepted* $\mathsf{BoundedRiemannConvergence}^{\uparrow}$ *carrier must first read the route*

$$\mathsf{RegulatedFunction}^{\uparrow},\ A,\ \mathsf{RiemannIntegral}^{\uparrow},\ \mathsf{DarbouxSum}^{\uparrow},\ B,\ \mathsf{RealEquality}^{\uparrow} \longmapsto H, C, P, N.$$

Thus the bounded convergence handoff is exposed as finite regulated-function observations, tagged Riemann readbacks, Darboux brackets, a common bound, and terminal real-equality comparison, not as measure integration, host function quotients, selected limits, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 6351.2. It makes the regulated-family row, pointwise approach windows, Riemann readback, Darboux bracket, uniform bound, and terminal real-equality comparison the entire consumer-facing route.

The Darboux handoff is finite. A consumer may inspect the tagged Riemann row T only together with the lower/upper bracket row S over the same displayed interval and partition row D, and it may use the common bound only through B.

The structural rows H, C, P, N preserve that route for later integral readers. They do not add measure-theoretic integration, quotient equality of host functions, a selected limiting function, a choice principle, or ambient completeness of $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: A purported $\mathsf{BoundedRiemannConvergence}^{\uparrow}$ consumer that reads a bounded convergence conclusion while omitting the regulated-family row, pointwise approach windows, tagged Riemann readback, Darboux bracket, common bound, real-equality comparison, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: regulated-function, riemannintegral, darboux-sum, bounded-variation-real-function, real-equality: $\mathsf{BoundedRiemannConvergence}^{\uparrow}$ is not bijective with any listed sibling because it joins the regulated-family source, pointwise approach windows, tagged Riemann readback, Darboux brackets, common bound, real-equality comparison, transport, replay, provenance, and local naming as one bounded convergence packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRiemannConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRiemannConvergence}^{\uparrow}$ packet is generated from a common interval and Darboux partition row, a regulated-function family row, finite pointwise approach windows, tagged Riemann readback, lower/upper Darboux brackets, a uniform bound row, terminal real-equality comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRiemannConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6351.1, Definition 6351.2, and Definition 6351.3 seed the finite bounded Riemann convergence route for regulated functions, Darboux brackets, Riemann-integral consumers, real-equality comparison, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRiemannConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure integration, host function quotients, selected limits, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family exposure, pointwise approach windows, tagged Riemann readback, Darboux bracket exactness, uniform-bound visibility, real-equality comparison, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.BoundedRiemannConvergenceUp.

Chapter 6352

A Concrete Naming Certificate for $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ packet records the finite NameCert form of the constructive Dini theorem: a monotone continuous family on a compact metric source reaches a uniform limit through displayed finite modulus, window, rational readback, and Real-seal rows. It consumes the compact-uniform sibling chapter 4213, the modulus sibling chapter 3454, the uniform-limit sibling chapter 5795, the compact metric source of chapter 129, the continuous-map rows of chapter 130, the uniform-limit handoff of chapter 463, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite theorem carrier; it does not assert open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of functions, countable choice, or hidden limiting values.

Definition 6352.1 (Constructive Dini theorem carrier)**.** *A* $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, F, M, D, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the finite compact-metric source and probe rows used by the theorem route.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, naming the displayed continuous maps and the target* $\mathsf{Real}^{\uparrow}$ *value rows inspected by the packet.*
3. *M is the monotone ledger, recording the pointwise order route and the visible approach of F toward its limiting row.*
4. *D is the* $\mathsf{ConstructiveDiniModulus}^{\uparrow}$ *row, carrying the finite Dini modulus extracted from compact finite-net data, dyadic tolerances, pointwise windows, and finite maximum rows.*
5. *U is the combined* $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$ *and* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *handoff row, exposing the compact-uniform route and the resulting* $\mathsf{UniformLimit}^{\uparrow}$ *row.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, scheduling function values, limit values, finite net centers, and consumer precision requests.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from W before the terminal real-name seal is exposed.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the uniform-limit read. It names the displayed real values without adding ambient real completeness.*
9. *H records componentwise* hsame *transport for the compact source, continuous family, monotone ledger, Dini modulus, uniform-limit handoff, stream windows, regular rational readback, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a theorem request through $K, F, M, D, U, W, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$, $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$, $\mathsf{ConstructiveDiniModulu}$ $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveDiniTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, M, D, U, W, R, E, H, C, P, N$. It has no coordinate for general open-cover compactness, arbitrary subcover selection, quotient function equality, countable choice, hidden limit selectors, host suprema, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ConstructiveDiniTheoremUp.TasteGate.ConstructiveDiniTheoremTasteGate`
`single carrier alignment`

Theorem 6352.2 (Constructive Dini theorem NameCert obligations)**.** *For every accepted* ConstructiveDiniTheorem *carrier*

$$T = (K, F, M, D, U, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveDiniTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, continuous-map family, monotone ledger, Dini modulus row, uniform-limit row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming rows.*

The obligation surface requires the compact source and continuous family through K, F, monotone visibility through M, finite Dini modulus extraction through D, compact-uniform and uniform-limit handoff through U, L10 finite real-readback through W, R, E, transport and replay stability through H, C, provenance through P, and local naming through N.

Proof. Project the carrier of Definition 6352.1. The analytic rows are K, F, M, D, U, W, R, E, while H, C, P, N are the structural certificate rows.

The compact metric source and continuous family are admitted first. The monotone ledger then fixes which pointwise comparisons may be inspected, so the Dini modulus row D is downstream of displayed compact finite-net data and not of an external compactness principle.

The handoff row U consumes D together with the compact-uniform sibling route and exposes the $\mathsf{UniformLimit}^{\uparrow}$ read. The L10 boundary is then read only through the $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Finally H, C, P, N preserve, replay, source, and name the same route. Since no excluded object is a carrier coordinate, none is a NameCert obligation of the theorem packet. □

Theorem 6352.3 (Constructive Dini monotone uniform route)**.** *Every uniform-limit consumer of an accepted* $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ *carrier must factor through the displayed route*

$$K, F, M \longmapsto D \longmapsto U \longmapsto W, R, E \longmapsto H, C, P, N.$$

Thus the theorem export is the finite BEDC route from compact metric source and monotone continuous family data through $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$, $\mathsf{ConstructiveDiniModulus}^{\uparrow}$, $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *It exports no open-cover compactness, quotient function equality, countable choice, hidden limiting values, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ConstructiveDiniTheoremUp.ConstructiveDiniTheoremMonotoneUniformRoute`

Proof. Begin with the NameCert obligations of Definition 6352.2. They place the compact source K, continuous family F, and monotone ledger M before the theorem can expose any uniform conclusion.

The row D is the finite Dini modulus row. It reads the compact finite-net and pointwise monotone data already displayed by the source and family rows, and it supplies the modulus object consumed by the compact-uniform handoff.

The row U composes the compact-uniform sibling and the uniform-limit-modulus sibling. Hence a uniform-limit consumer receives a single handoff produced by finite modulus extraction, not a selected open cover or a host-level supremum.

The terminal real-readback rows W, R, E keep the exported conclusion inside finite stream windows, regular rational readback, and a displayed Real seal. The structural rows H, C, P, N then transport, replay, source, and name the same route for downstream consumers. □

Theorem 6352.4 (Constructive Dini L10 seal nonescape)**.** *For an accepted* $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ *carrier, the terminal* $\mathsf{Real}^{\uparrow}$ *values used by the uniform-limit conclusion are reachable only after the compact source row K, continuous-map family row F, monotone ledger M, Dini modulus row D, uniform-limit handoff row U,* $\mathsf{StreamName}^{\uparrow}$ *window row W, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R have been displayed. The* $\mathsf{Real}^{\uparrow}$ *seal row E therefore exports the finite L10 readback route and no ambient completeness, quotient stream equality, hidden host limit, countable choice, or real trichotomy coordinate.*

Proof. Use Definition 6352.3. It places every terminal read downstream of the compact metric source, continuous family, monotone ledger, finite Dini modulus, and uniform-limit handoff rows.

The L10 readback portion is visible in W, R, E. The stream row W schedules the finite observations, the regular rational row R reads those observations at the requested precision, and E seals the displayed real values only after that readback has occurred.

Transport and replay do not create another analytic route. The rows H, C, P, N preserve the same carrier coordinates, so the terminal seal cannot export any object absent from T.

The excluded principles have no row in the carrier. Thus the theorem packet gives a finite Real-seal boundary for the constructive Dini route without importing ambient completion, quotient equality, hidden host limits, countable choice, or trichotomy. □

Theorem 6352.5 (Constructive Dini finite-net monotone-window route)**.** *Every uniform-limit consumer of an accepted* $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ *carrier*

$$T = (K, F, M, D, U, W, R, E, H, C, P, N)$$

must expose the compact finite-net source and monotone window before the Dini modulus and $\mathsf{UniformLimit}^{\uparrow}$ *row are public. Equivalently, the consumer read factors through*

$$K, F, M \longmapsto D \longmapsto U \longmapsto W, R, E \longmapsto H, C, P, N,$$

with K providing the finite compact-metric net source, F the displayed continuous family, M the monotone comparison window, D the Dini modulus row, and U the uniform-limit handoff.

Lean4 ✓ `BEDC.Derived.ConstructiveDiniTheoremUp.ConstructiveDiniTheoremFiniteNetMonotoneWindowRoute`

Proof. Project the carrier rows $K, F, M, D, U, W, R, E, H, C, P, N$ from Definition 6352.1. The compact source, continuous family, and monotone ledger are the only rows available before the Dini modulus is inspected.

Use Definition 6352.3. It already forces every uniform-limit consumer through K, F, M, then D, then U, and finally the L10 readback and structural rows.

The finite-net source is part of the compact metric row K, while the monotone window is the public comparison data in M. Thus the modulus row D cannot be read as an ambient supremum or open-cover compactness principle; it is downstream of the displayed finite compact-metric and monotone data.

Apply Definition 6352.4. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows W, R, E keep the resulting uniform-limit read inside finite L10 windows, and H, C, P, N transport, replay, source, and name only that route. □

Theorem 6352.6 (Constructive Dini theorem obligation-closure package)**.** *The carrier, NameCert obligation, monotone-uniform route, L10 seal nonescape, and finite-net monotone-window route assemble the full obligation surface for* $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ *over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ConstructiveDiniModulus}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The assembled package excludes open-cover compactness, countable choice, hidden limiting values, quotient function equality, host suprema, real trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier of Definition 6352.1. Its rows name the compact metric source, continuous family, monotone ledger, Dini modulus, uniform-limit handoff, finite stream windows, regular-rational readback, Real seal, transport, replay, provenance, and local naming surface.

Apply Definition 6352.2. The listed carrier admission, theorem-route, modulus extraction, uniform-limit handoff, finite readback, transport, replay, provenance, local naming, and ledger exhaustion rows give the NameCert obligation frame for the packet.

Use Definition 6352.3, Definition 6352.4, and Definition 6352.5. These route the public consumer through the compact source and monotone window, then through the Dini modulus and uniform-limit handoff, and finally through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the $\mathsf{Real}^{\uparrow}$ seal.

The carrier has no remaining analytic coordinate. Therefore the displayed rows close the paper-side obligation surface while the excluded principles remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ read must expose a compact metric source, continuous-map family, monotone ledger, Dini modulus row, uniform-limit row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-monotone-compact-uniform, constructive-dini-modulus, dini-uniform-limit-modulus, compactmetric, continuousmap, uniformlimit, streamname, regseqrat, real: ConstructiveDiniTheorem is not bijective to any listed sibling because it binds the monotone compact-uniform theorem route to the L10 finite real-readback boundary in one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveDiniTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveDiniTheorem}^{\uparrow}$ packet is generated from compact metric source rows, continuous-map family rows, monotone ledger rows, ConstructiveDiniModulus rows, DiniMonotoneCompactUniform and DiniUniformLimitModulus handoff rows, UniformLimit rows, StreamName finite windows, RegSeqRat readbacks, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveDiniTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6352.1, Definition 6352.2, Definition 6352.3, and Definition 6352.4 seed the finite NameCert form of the constructive Dini theorem over compact metric, continuous-map, uniform-limit, StreamName, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{ConstructiveDiniTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, ambient Real$^{\uparrow}$ completeness, quotient equality of functions, countable choice, hidden limiting values, host suprema, or real trichotomy.

Upgrade path: Obligation closure requires checked carrier admission, monotone compact-uniform route exactness, Dini modulus extraction, uniform-limit handoff, StreamName and RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveDiniTheoremUp.

Chapter 6353

A Concrete Naming Certificate for $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$

Following Banach and Rudin on closed operators between Banach spaces, the $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$ packet records the graph norm of a displayed operator as finite NameCert data. It sits over the Banach carrier of chapter 90, the public bounded-linear-operator surface of chapter 1644, the closed-graph route of chapter 1537, the metric rows of chapter 57, the complete-metric witness rows of chapter 128, and the real-name seal of chapter 38. The packet names the displayed domain graph and its norm-sum route without replacing the graph by a quotient carrier or a host function-space object.

Definition 6353.1 (Banach operator graph-norm carrier)**.** *A* $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, T, \Gamma, A, M, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Banach}^{\uparrow}$ *row, including the source norm, metric, complete-metric, and real-seal reads.*
2. *Y is the target* $\mathsf{Banach}^{\uparrow}$ *row, including the target norm, metric, complete-metric, and real-seal reads.*
3. *T is the operator action row, read either through a displayed* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *packet or through a graph-closed operator row whose closedness is audited by* $\mathsf{ClosedGraphTheorem}^{\uparrow}$*.*
4. *Γ is the graph row, recording source endpoints, target endpoints, and graph-membership witnesses for the displayed action.*
5. *A is the graph-admission row, stating that only source endpoints whose graph membership is displayed in Γ are admitted to the graph-norm domain.*
6. *M is the metric readback row, routing source and target distance requests through* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *data.*
7. *Q is the norm-sum row, recording the exact graph-norm expression $\|x\|_X + \|Tx\|_Y$ as a displayed* $\mathsf{Real}^{\uparrow}$ *read.*
8. *L is the completion handoff row, recording the Cauchy-to-limit route for graph-norm Cauchy data through X, Y, Γ, M, and Q.*

9. *H records componentwise* hsame *transport for source, target, operator, graph, admission, metric, norm-sum, completion handoff, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from graph admission through metric readback, norm-sum exactness, graph-closedness stability, and completion handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{ClosedGraphTheorem}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachOperatorGraphNorm}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotienting the graph, selecting host representatives, importing an ambient operator space, or replacing the displayed norm-sum by an external equality theorem.

Lean4 ✓ `BEDC.Derived.BanachOperatorGraphNormUp.TasteGate.BanachOperatorGraphNormTasteGate single carrier alignment`

Theorem 6353.2 (Banach operator graph-norm obligations)**.** *For every accepted* $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$ *carrier* $G = (X, Y, T, \Gamma, A, M, Q, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BanachOperatorGraphNorm}^{\uparrow}}$ *surface consists exactly of graph-norm carrier admission, graph-closedness stability, norm-sum exactness, completion handoff, and refusal of quotient graph export.*

Lean4 ✓ `BEDC.Derived.BanachOperatorGraphNormUp.BanachOperatorGraphNormCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 6353.1. The accepted graph-norm domain is read through A and Γ, so a source endpoint is admitted only when its graph-membership row is displayed.

Graph-closedness stability is read through T, Γ, L, H, C. The operator action is either already bounded-linear through chapter 1644 or is routed through the closed-graph certificate of chapter 1537; in both cases transport by H and replay by C preserve the same graph rows.

Norm-sum exactness is the role of Q. The source and target norm reads are measured through the metric and complete-metric rows M and sealed as $\mathsf{Real}^{\uparrow}$ data, so the graph norm is exactly the displayed sum $\|x\|_X + \|Tx\|_Y$.

Completion handoff is the role of L. A graph-norm Cauchy read supplies compatible Cauchy data in X and Y, replays graph membership through Γ, and returns a displayed graph limit through the complete-metric rows.

Finally, the carrier inventory rules out quotient graph export. No row of G stores a graph quotient, selected representative, ambient operator-space point, or host equality theorem, so every consumer remains inside the displayed NameCert surface. □

Theorem 6353.3 (Banach operator graph-norm completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$ *packet factors through*

$$X, Y, T, \Gamma, A, M, Q, L, H, C, P, N.$$

The handoff reads source completeness, target completeness, graph membership, the exact norm-sum row, and the graph-closedness row before exporting graph-norm completion data.

Lean4 ✓ `BEDC.Derived.BanachOperatorGraphNormUp.BanachOperatorGraphNormCompletionHandoff`

Proof. Start with the Banach source and target rows X and Y. Their metric and complete-metric data provide the only Cauchy and limit witnesses available to the graph-norm packet.

Next read the graph rows T, Γ, A. The action row and graph-membership row determine which source endpoints are in the graph-norm domain, and the admission row prevents a consumer from reading outside the displayed graph.

Use M and Q for the graph norm itself. Metric readback supplies the source and target distances, while the norm-sum row records the exact real-valued graph-norm expression.

Finally apply L, H, C, P, N. The completion handoff replays graph-closedness through the same rows, then transport, continuation, provenance, and local naming preserve the packet. No quotient graph or external selector is exported. □

Theorem 6353.4 (Banach operator graph-norm no quotient graph)**.** *No accepted* $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$ *consumer can replace the displayed graph row* Γ *by a quotient graph, host function graph, or selected representative while retaining the local* $\mathsf{NameCert}_{\mathsf{BanachOperatorGraphNorm}^{\uparrow}}$ *read.*

Lean4 ✓ `BEDC.Derived.BanachOperatorGraphNormUp.BanachOperatorGraphNorm no quotient graph`

Proof. Project an accepted carrier $G = (X, Y, T, \Gamma, A, M, Q, L, H, C, P, N)$. The only graph coordinate is Γ, and graph-domain admission is mediated by A.

The metric and completion rows do not add another graph object. They only measure source and target reads, seal the norm-sum value, and replay graph-closedness through the completion handoff.

Transport, continuation, provenance, and local naming preserve the same displayed coordinates. Since the carrier contains no quotient graph, host function graph, or selected representative row, replacing Γ by such an object leaves the accepted NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachOperatorGraphNorm}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachOperatorGraphNorm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6353.1, Definition 6353.2, Definition 6353.3, and Definition 6353.4 seed the graph-norm packet over displayed Banach source and target rows, operator graph rows, metric readback, exact norm-sum data, and completion handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachOperatorGraphNorm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, closed-operator calculus, inverse mapping, quotient graph equality, host operator spaces, or selected representatives.

Upgrade path: Obligation closure requires checked carrier admission, graph-closedness stability, norm-sum exactness, completion handoff, and no-quotient-graph nonescape for BEDC.Derived.BanachOperatorGraphNormUp.

Constructive story: A $\mathsf{BanachOperatorGraphNorm}^{\uparrow}$ packet is generated from Banach source and target rows, an operator action row, displayed graph membership, graph-domain admission, metric readback, an exact RealUp norm-sum row, completion handoff, componentwise transport, continuation replay, provenance, and local naming.

Chapter 6354

A Concrete Naming Certificate for $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$

Following Krantz and Parks and Bishop–Bridges constructive analysis, the $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ packet records the finite route by which a local equation solve may be read from displayed derivative, invertibility, Newton, completion, and real-name data. It sits beside the Newton iteration route of chapter 223, the derivative source of chapter 122, the real-name surface of chapter 38, the completion boundary of chapter 95, and the metric context of chapter 57. The chapter does not assert a host implicit-function theorem; it names the finite NameCert carrier a later constructive calculus consumer must inspect.

Definition 6354.1 (Implicit function theorem carrier)**.** *An* $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (E, D, I, N, K, R, H, C, P, L)$$

with the following displayed rows:

1. *E is the equation packet, recording the finite source variables, target variable, base point, local equation value, and classifier for the read $F(x, y) = 0$.*
2. *D is the* $\mathsf{Derivative}^{\uparrow}$ *row for the equation packet at the displayed base point, including the partial derivative history read by the target coordinate.*
3. *I is the invertibility window, naming the displayed inverse witness, local radius, and tolerance budget in the same* $\mathsf{Met}^{\uparrow}$ *context as E and D.*
4. *N is the* $\mathsf{NewtonIteration}^{\uparrow}$ *route, recording the correction step, residual budget, nonescape window, and finite stopping schedule used by the local solve.*
5. *K is the* $\mathsf{Completion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal, requiring every limiting or real-facing read to pass through the displayed completion row before the Real name is exposed.*
6. *R is the transport row from the solved Newton endpoint to the local graph read, keeping the equation packet, derivative row, invertibility window, Newton route, completion seal, and Real seal componentwise aligned.*
7. *H records componentwise* hsame *transport for equation packets, derivative histories, invertibility witnesses, Newton schedules, Completion and Real seals, transport rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a local solve request through $E, D, I, N, K, R, H, P, L$.*

9. *P is the* Pkg *provenance over* $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *L is the local* $\mathsf{NameCert}_{\mathsf{ImplicitFunctionTheorem}^{\uparrow}}$ *row binding the packet to the displayed route.*

The classifier compares accepted packets only through $E, D, I, N, K, R, H, C, P, L$. The carrier has no coordinate for a host implicit function, a selected germ, global inverse theorem, quotient function equality, ambient choice, or an untracked completeness principle.

Lean4 (statement) `BEDC.Derived.ImplicitFunctionTheoremUp`

Theorem 6354.2 (Implicit function theorem NameCert obligations)**.** *For every accepted* $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ *carrier*

$$T = (E, D, I, N, K, R, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{ImplicitFunctionTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed equation packet, derivative row, invertibility window, Newton route, Completion and Real seal, transport, replay, provenance, and local name;*
2. *derivative-invertibility compatibility, requiring D and I to display the same target-coordinate approximation inside the same* $\mathsf{Met}^{\uparrow}$ *window;*
3. *Newton residual replay, requiring N and C to keep every correction step downstream of E, D, I and inside the named nonescape window;*
4. *Completion and Real sealing, requiring K to be the only route from the Newton residual schedule to a real-facing endpoint;*
5. *graph transport, requiring R, H to preserve the equation packet, derivative row, invertibility window, Newton route, and seal rows componentwise;*
6. *provenance exactness, requiring P and L to name only the listed rows and no host implicit function theorem or selected germ.*

No local NameCert obligation is stored in an ambient function space or external completeness theorem.

Proof. Carrier admission is projection from Definition 6354.1. The packet lists exactly the equation, derivative, invertibility, Newton, seal, transport, replay, provenance, and local naming rows.

The analytic obligations are internal to D, I, N. The derivative and invertibility rows name the same local approximation, while the Newton row records the displayed correction schedule and residual budget.

The endpoint obligations are downstream of that schedule. The Completion and Real seal row K is reached only after the Newton route has been replayed, and R, H transport the resulting local graph read without replacing it by a host solution object.

Finally the provenance and local naming rows bind the same finite route. Since the carrier contains no selected germ, quotient function equality, global inverse theorem, ambient choice, or untracked completeness coordinate, these rows exhaust the NameCert surface. □

Theorem 6354.3 (Implicit function theorem Newton-completion handoff)**.** *Every* $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ *local-solve read factors through the displayed finite route*

$$\mathsf{Derivative}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{NewtonIteration}^{\uparrow}, \mathsf{Completion}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

In the notation of Definition 6354.1, the consumer must open $E, D, I, N, K, R, H, C, P, L$ before it can export a local graph endpoint.

Proof. Project the accepted carrier. The local-solve request has no available coordinate except the equation packet, derivative row, invertibility window, Newton route, Completion and Real seal, transport, replay, provenance, and local naming rows.

The derivative and metric rows provide the local analytic source. The Newton route consumes that source through the invertibility window and records the finite correction schedule together with the residual nonescape budget.

The handoff to Completion and Real data is then forced through K. The transport and replay rows preserve the same displayed endpoint before provenance and local naming expose it as a local graph read, so no host implicit-function theorem or selected germ is read. □

Falsifiable prediction: Every $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ local-solve read opens one equation packet, one Derivative row, one invertibility window in a MetricSpace context, one NewtonIteration route, one Completion and Real seal, graph transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before exporting a graph endpoint.

Independence witness: newtoniteration, derivative, real, completion, metricspace: $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries equation data, derivative data, an invertibility window, Newton residual replay, Completion and Real sealing, transport, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ImplicitFunctionTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ packet is generated from an equation packet, derivative row, invertibility window, NewtonIteration route, Completion and Real seal, graph transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ImplicitFunctionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6354.1, Definition 6354.2, and Definition 6354.3 seed the finite implicit-function-theorem certificate over equation, derivative, invertibility, Newton, Completion, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ImplicitFunctionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.ImplicitFunctionTheoremUp`

Bridge status: none

Not claimed: This chapter does not close host implicit functions, selected germs, quotient function equality, global inverse theorem packages, ambient choice, full analytic existence, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-invertibility compatibility, Newton residual replay, Completion and Real sealing, graph transport, provenance exactness, and local naming for BEDC.Derived.ImplicitFunctionTheor

Chapter 6355

Picard Iteration Budget NameCert Construction

Following Picard's successive approximations and Banach's contraction principle in Bishop–Bridges constructive analysis, the $\mathsf{PicardIterationBudget}^{\uparrow}$ packet records the finite budget surface that a contraction orbit must expose before endpoint-facing completion data are read. It sits between the Cauchy contraction orbit of chapter 2350, the Banach contraction row of chapter 3529, the Picard ledger of chapter 2359, and the terminal real-name seal of chapter 38. The packet names the finite means of an iteration budget; it does not assert a general completeness theorem, choose an endpoint, identify quotient reals, or import countable choice.

Definition 6355.1 (Picard iteration budget carrier)**.** *A* $\mathsf{PicardIterationBudget}^{\uparrow}$ *carrier is a finite packet*

$$B = (S, K, W, D, E, H, C, P, N)$$

with the following displayed rows.

1. *S is the seed row, naming the initial point, accepted metric source, and contraction orbit entry used by the budget.*
2. *K is the contraction-modulus row, storing the displayed contraction comparison and the finite modulus read from the Banach contraction surface.*
3. *W is the iterate-window row, listing the finite interval of Picard iterates inspected by the budget request.*
4. *D is the dyadic error-budget row, recording the requested tolerance, the residual comparison, and the finite arithmetic certificate that the window is long enough.*
5. *E is the endpoint-handoff row, exposing only the completion-facing or Real-facing boundary available after S, K, W, D have been displayed.*
6. *H records componentwise* hsame *transport for the seed, modulus, window, dyadic error budget, endpoint handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the seed row through the contraction modulus, iterate window, dyadic budget, endpoint handoff, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{PicardIterationBudget}^{\uparrow}$, $\mathsf{CauchyContractionOrbit}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{PicardIterationBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, K, W, D, E, H, C, P, N$. It has no coordinate for a hidden infinite orbit, a selected fixed point, quotient equality of endpoint names, countable choice, host function extensionality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6355.2 (Picard iteration budget NameCert obligations)**.** *For every accepted* $\mathsf{PicardIterationBudget}^{\uparrow}$ *carrier $B = (S, K, W, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardIterationBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for the seed row, contraction-modulus row, iterate-window row, dyadic error-budget row, endpoint-handoff row, componentwise transport, displayed replay, provenance, and local naming.*

The classifier agreement obligation requires two accepted packets to agree precisely when these rows agree componentwise through the displayed hsame *route. The stability obligation requires the same row order to be preserved by* hsame *transport and* Cont *replay before any endpoint handoff is consumed.*

Proof. Project the carrier of Definition 6355.1. The analytic part is S, K, W, D, E; the structural certificate part is H, C, P, N.

The seed row and contraction-modulus row determine what orbit may be inspected. The iterate-window row then restricts the read to finitely many Picard rows, and the dyadic error-budget row records the tolerance comparison attached to that window.

Endpoint handoff is terminal for the budget route. Since E is downstream of S, K, W, D, no consumer can read endpoint data without first exposing the finite seed, modulus, iterate window, and dyadic budget rows.

Finally H, C, P, N transport, replay, source, and name the same rows. No excluded object is a carrier coordinate, so no hidden infinite orbit, selected fixed point, quotient endpoint equality, choice principle, host extensionality rule, or ambient Real-completeness theorem is a local obligation. □

Theorem 6355.3 (Picard iteration budget exactness)**.** *Every endpoint-facing read of an accepted* $\mathsf{PicardIterationBudget}^{\uparrow}$ *carrier factors through*

$$\mathsf{CauchyContractionOrbit}^{\uparrow} \longmapsto \mathsf{BanachContraction}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The finite budget is exact in the following sense: it exposes the seed row, contraction modulus, iterate window, dyadic error budget, and endpoint handoff as displayed rows, and it exports no additional infinite orbit data beyond those rows.

Proof. Begin with the NameCert obligations of Definition 6355.2. They place the seed row, contraction-modulus row, iterate-window row, and dyadic budget row before the endpoint handoff.

The Cauchy contraction orbit and Banach contraction rows supply the visible contraction data. The Picard iteration row supplies only the finite window requested by W, while D checks the requested dyadic tolerance against that finite window.

The endpoint handoff row E is reached only after those rows have been displayed. It may feed completion-facing or Real-facing consumers, but it does not add a selected endpoint, quotient equality, host extensionality, countable choice, hidden tail stream, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Thus the budget route is exact for finite inspection: every exported endpoint read is tied to the displayed rows of B, and no unlisted orbit data can be consumed by the local certificate. □

Theorem 6355.4 (Picard iteration budget Cauchy-tail handoff)**.** *Let $B = (S, K, W, D, E, H, C, P, N)$ be an accepted* $\mathsf{PicardIterationBudget}^{\uparrow}$ *carrier whose displayed rows include a contraction row, a finite Picard iteration ledger, a ratio-tail budget, a* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary, and a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff. For every tolerance history accepted by the dyadic error-budget row, the packet exports a unary stage after which every displayed pair of Picard iterates in the window is within the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance read by the handoff row.*

The exported tail ledger is finite. It is transported componentwise by hsame*, replayed only through the displayed* Cont *rows, and consumed by completion and Banach fixed-point chapters without selected endpoints, host functions, quotient equality of completed names, or countable choice.*

Proof. Project the carrier rows. The seed row S and contraction row K fix the accepted orbit and the displayed contraction comparison; the window row W names the finite Picard rows that may be inspected.

Use the contraction row to shrink adjacent residuals inside the displayed window. The ratio-tail part of D then dominates the finite sum of those residuals for the requested tolerance history, so the same row supplies a unary stage for the whole tail comparison.

Route this finite comparison through the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{CompleteMetric}^{\uparrow}$ boundary named by the endpoint handoff row E. The structural rows H, C, P, N transport, replay, source, and name the same ledger, and no selected endpoint or quotient equality is introduced after the finite tail stage has been exposed. □

Theorem 6355.5 (Picard iteration budget ledger nonescape)**.** *For an accepted* $\mathsf{PicardIterationBudget}^{\uparrow}$ *carrier, the ledger visible to downstream consumers is exhausted by the seed, contraction modulus, iterate window, dyadic error budget, endpoint handoff, transport, replay, provenance, and local naming rows. In particular, a downstream consumer cannot recover a hidden infinite orbit, a selected fixed point, quotient equality of completed endpoints, countable choice, host function extensionality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the budget packet.*

Proof. Use Definition 6355.1. The carrier lists exactly $S, K, W, D, E, H, C, P, N$.

The analytic ledger is exhausted by S, K, W, D, E. These rows record the seed, contraction comparison, finite iterate window, dyadic tolerance comparison, and endpoint handoff.

The structural ledger is exhausted by H, C, P, N. These rows preserve and name the analytic route, but they do not introduce another endpoint source or an infinite-orbit coordinate.

The excluded objects are absent from both ledgers. Therefore they cannot be recovered from the local NameCert surface of the accepted packet. □

Falsifiable prediction: Every accepted $\mathsf{PicardIterationBudget}^{\uparrow}$ endpoint-facing read must expose a seed row, contraction-modulus row, finite iterate-window row, dyadic error-budget row, endpoint-handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a completion or Real-facing consumer reads endpoint data.

Independence witness: cauchy-contraction-orbit, banach-contraction, picard-iteration, real: $\mathsf{PicardIterationBudget}^{\uparrow}$ is not bijective to any listed sibling because it binds a seed row, contraction modulus, finite iterate window, dyadic error budget, endpoint handoff, transport, replay, provenance, and local naming in one finite budget packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardIterationBudget}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardIterationBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6355.1, Definition 6355.2, Definition 6355.3, and Definition 6355.5 seed the finite budget interface from contraction orbit data to endpoint-facing reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardIterationBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general completeness, selected fixed points, quotient endpoint equality, countable choice, host function extensionality, hidden infinite orbit data, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, classifier agreement, hsame and Cont stability, ledger nonescape, finite budget exactness, and local naming for BEDC.Derived.PicardIterationBudgetUp.

Constructive story: A PicardIterationBudget$^{\uparrow}$ packet is generated from a seed row, contraction modulus, finite Picard iterate window, dyadic error budget, endpoint handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6356

Kernel Budget Flow NameCert Construction

The $\mathsf{KernelBudgetFlow}^{\uparrow}$ packet realizes the finite kernel-budget flow suggested by the kernel vision hub Definition 9350.3 as concrete NameCert rows. It sits beside the governance route of chapter 9467, the kernel audit witness of chapter 546, the kernel acceptance witness of chapter 549, the finite multihist packet of chapter 468, and the kernel inductive acceptance row of chapter 915. The packet exposes BMark, BHist, Cont, Pkg, Gap, ledger, and NameCert rows as a finite flow boundary; it does not certify the host kernel, assert global soundness, hide an acceptance trace, or supply a theorem proof.

Definition 6356.1 (Kernel budget flow carrier)**.** *A* $\mathsf{KernelBudgetFlow}^{\uparrow}$ *carrier is a finite packet*

$$F = (B, H, K, G, L, C, P, N)$$

with the following displayed rows.

1. *B is the* BMark *budget row, naming the finite kernel-facing request and the bounded inspection scope.*
2. *H is the* BHist *flow row, recording the ordered budget events accepted by the packet.*
3. *K is the kernel-scope row, naming the accepted kernel witness or audit witness that the flow is allowed to inspect.*
4. *G is the* Gap *row, recording refused, absent, or not-yet-certified budget edges without erasing them.*
5. *L is the ledger row, pairing every visible budget event with the source, acceptance, gap, and consumer rows it may reach.*
6. *C is the displayed* Cont *replay row from budget request through history, kernel scope, gap accounting, ledger readback, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{KernelBudgetFlow}^{\uparrow}$*,* $\mathsf{KernelAuditWitness}^{\uparrow}$*,* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$*,* $\mathsf{KernelInductiveAcceptance}^{\uparrow}$*,* $\mathsf{FiniteMultiHistPacket}^{\uparrow}$*,* BMark*,* BHist*,* Gap*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{KernelBudgetFlow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, H, K, G, L, C, P, N. It has no coordinate for host-kernel soundness, unrestricted proof checking, hidden traces, unbounded fuel, erased gap rows, or theorem-proof evidence.

Theorem 6356.2 (Kernel budget flow NameCert obligations)**.** *For every accepted* $\mathsf{KernelBudgetFlow}^{\uparrow}$ *carrier* $F = (B, H, K, G, L, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KernelBudgetFlow}^{\uparrow}}$ *surface consists exactly of carrier admission for the BMark budget row, BHist flow row, kernel-scope row, Gap row, ledger row, displayed Cont replay, Pkg provenance, and local naming.*

The flow obligation requires each budget event in H *to be accounted for by* L *before a downstream consumer reads it. The gap obligation requires refused or unavailable edges to remain visible in* G *rather than being reclassified as accepted kernel evidence.*

Proof. Project the carrier of Definition 6356.1. The rows B, H, K, G, L are the budget-flow data, while C, P, N replay, source, and name the same data.

The BMark row bounds the request, and the BHist row orders the events. The kernel-scope row says which accepted witness may be inspected, while the Gap row keeps unavailable or refused edges visible.

The ledger row is the exact accounting surface. Every downstream read of a budget event must pass through L, so the packet cannot replace the ledger by a hidden trace or a host-kernel endorsement.

Finally, C, P, N preserve and name the displayed route. Since no excluded object is a carrier coordinate, no local NameCert obligation can export unrestricted proof checking, host soundness, unbounded fuel, or theorem-proof evidence. □

Theorem 6356.3 (Kernel budget flow finite realization)**.** *Every accepted* $\mathsf{KernelBudgetFlow}^{\uparrow}$ *read factors through displayed*

$$\mathsf{BMark},\ \mathsf{BHist},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Gap},\ L,\ \mathsf{NameCert}$$

rows, with L *the finite ledger of budget-event accountability. Thus the packet realizes kernel-budget flow as finite BEDC data rather than as an ambient kernel theorem, an untracked execution trace, or a hidden proof object.*

Proof. Start from the NameCert obligations of Definition 6356.2. They expose the BMark request, BHist flow, kernel-scope witness, Gap row, ledger, replay, provenance, and local naming.

The budget and history rows fix the finite event surface. The kernel-scope row restricts which accepted witness the flow may inspect, and the gap row preserves refused or missing edges.

The ledger row L is then the only route from events to consumers. The replay and provenance rows do not create additional events; they preserve the finite route already displayed.

Therefore the realization is finite and row-local. It exports no ambient kernel theorem, hidden trace, theorem proof, or unbounded budget source. □

Falsifiable prediction: Every accepted $\mathsf{KernelBudgetFlow}^{\uparrow}$ read must expose BMark budget data, BHist event flow, kernel-scope evidence, Gap accounting, finite ledger rows, displayed Cont replay, Pkg provenance, and a local NameCert row; Lean TasteGate work must later supply Nontrivial and FieldFaithful instances for this carrier.

Independence witness: kernel-audit-witness, kernelacceptancewitness, kernelinductiveacceptance, finite-multihist-packet, metacicclosuretrace: $\mathsf{KernelBudgetFlow}^{\uparrow}$ is not bijective to any listed sibling because it binds bounded kernel request data, event history, accepted-witness scope, gap accounting, finite ledger readback, replay, provenance, and local naming in one flow packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KernelBudgetFlow}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KernelBudgetFlow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6356.1, Definition 6356.2, and Definition 6356.3 seed finite kernel-budget flow as displayed BMark, BHist, Cont, Pkg, Gap, ledger, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{KernelBudgetFlow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host-kernel soundness, unrestricted proof checking, hidden acceptance traces, unbounded fuel, erased gap rows, theorem-proof evidence, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, flow accountability, gap visibility, finite ledger exactness, Nontrivial and FieldFaithful TasteGate instances, and local naming for BEDC.Derived.KernelBudgetFlowUp.

Constructive story: A KernelBudgetFlow$^{\uparrow}$ packet is generated from BMark budget rows, BHist event flow, kernel-scope evidence, Gap accounting, finite ledger rows, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6357

A Concrete Naming Certificate for CompactMetricContinuousImageCompact$^{\uparrow}$

Following Bishop-style compact metric analysis, the continuous image of compact metric data is compact only after two finite rows are visible: total bounded image nets and completeness for the target image route. The CompactMetricContinuousImageCompact$^{\uparrow}$ packet records that theorem-facing route as finite BEDC data. It consumes the compact metric source of chapter 129, the continuous-map graph of chapter 130, the tolerance routing of chapter 369, the finite image-net packet of chapter 3605, the total-bounded image carrier of chapter 3924, and the complete-metric handoff of chapter 128. The packet names a compact-metric image row; it does not assert open-cover compactness, selected inverse images, quotient equality of target names, or ambient Real$^{\uparrow}$ completeness.

Definition 6357.1 (Compact metric continuous-image compact carrier)**.** *A* CompactMetricContinuousImageCompa *carrier is a finite* BHist *packet*

$$J = (K, F, U, I, T, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing finite source-net and compact-metric provenance.*
2. *F is the* ContinuousMap$^{\uparrow}$ *graph row from the source carrier to the target metric carrier.*
3. *U is the* UniformModulus$^{\uparrow}$ *tolerance route used by the same displayed map row.*
4. *I is the* CompactMetricContinuousImage$^{\uparrow}$ *finite image-net route from source nets to target image centers.*
5. *T is the* CompactContinuousImageTotalBounded$^{\uparrow}$ *row that packages those image centers as total-bounded target-image data.*
6. *E is the* CompleteMetric$^{\uparrow}$ *row available for the displayed target-image route.*
7. *H records componentwise* hsame *transport for the compact source, map row, modulus row, finite image-net row, total-bounded row, complete-metric row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-image request through $K, F, U, I, T, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactMetricContinuousImageCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactMetricContinuousImage}^{\uparrow}$, $\mathsf{CompactContinuousImageTotalBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImageCompact}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, U, I, T, E, H, C, P, N$. It has no coordinate for open-cover compactness, a host image subset, selected preimages, quotient equality of target names, choice-selected target centers, or ambient real completeness.

Theorem 6357.2 (Compact metric continuous-image compact obligations)**.** *For every accepted* $\mathsf{CompactMetricContinuousImageCompact}^{\uparrow}$ *carrier $J = (K, F, U, I, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactMetricC}}$ *surface consists exactly of carrier admission, compact source-net accountability, continuous-map graph routing, uniform-modulus compatibility, finite image-net exactness, image total-bounded export, complete-metric handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6357.1. The source, map, and tolerance rows are K, F, U, while the image-facing compactness route is I, T, E.

The finite image-net row I may be read only after the source compact metric row and the displayed modulus row have routed a target tolerance to a source-net request. The total-bounded row T repackages those image centers without adding a host image set.

The complete-metric row E is read after the total-bounded image row. Transport, replay, provenance, and local naming are supplied by H, C, P, N, so the compact-metric image row is assembled from displayed finite data.

Since the carrier has no open-cover, selected-preimage, quotient-equality, choice, or ambient-completeness coordinate, the local NameCert surface cannot export those principles. □

Theorem 6357.3 (Compact metric continuous-image compact route)**.** *Every compact-image consumer of an accepted* $\mathsf{CompactMetricContinuousImageCompact}^{\uparrow}$ *packet receives only the finite BEDC route*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactMetricContinuousImage}^{\uparrow}$, CompactContinuous

The exported compactness row is a $\mathsf{CompactMetric}^{\uparrow}$*-style row for the displayed image route, assembled from image nets plus completeness, not an open-cover compactness theorem, not a selected inverse-image construction, not quotient target equality, and not ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a compact-image request. The request first reads the compact source row K, the continuous-map graph row F, and the uniform-modulus row U.

Next apply the finite image-net route I. It reads source nets and displayed graph values to produce target image centers. Apply the total-bounded image row T to expose those centers as total-bounded target-image data.

Finally read the complete-metric row E for the same displayed target-image route. The structural rows H, C, P, N transport, replay, source, and name this route componentwise.

The construction is exhausted by $K, F, U, I, T, E, H, C, P, N$. Therefore a consumer receives compact-metric image data from finite image nets plus completeness, with none of the excluded open-cover, selected-preimage, quotient, choice, or ambient-completeness objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImageCompact}^{\uparrow}}$ **·**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactMetricContinuousImageCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6357.1, Definition 6357.2, and Definition 6357.3 seed the compact-metric continuous-image compact route from finite image nets and complete-metric handoff to a compact-metric image row.

Formal verification: FormalStatus(NameCert$_{\text{CompactMetricContinuousImageCompact}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected inverse images, quotient target equality, choice-selected image centers, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, image-net exactness, total-bounded image export, complete-metric handoff, transport, replay, provenance, and local NameCert registration for BEDC.Derived.CompactMetricContinuousIma

Constructive story: A CompactMetricContinuousImageCompact$^{\uparrow}$ packet is generated from CompactMetric source nets, ContinuousMap graph rows, UniformModulus tolerance routing, CompactMetricContinuousImage image-net data, CompactContinuousImageTotalBounded total-bounded rows, CompleteMetric handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6358

A Concrete Naming Certificate for $\mathsf{TheoremGenomeEvolution}^{\uparrow}$

The $\mathsf{TheoremGenomeEvolution}^{\uparrow}$ packet realizes the theorem-genome evolution audit of chapter 9409 as finite NameCert data. It reads theorem-flow recognition through the recognizer-flow carrier of chapter 1048, theorem-DNA scoring through chapter 6243, classifier-level information through chapter 9366, and the theorem-DNA scoring taste gate through chapter 9460. The packet exists so discovery classifiers can inspect genome flow, mutation, selection, classifier shift, transport, provenance, and local naming rows rather than relying on narrative methodology.

Definition 6358.1 (Theorem genome evolution carrier)**.** *A* $\mathsf{TheoremGenomeEvolution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, R, D, Q, M, S, L, H, C, P, N)$$

with the following displayed rows:

1. *F is the theorem-flow row, recording source theorem objects, proof loci, statement loci, certificate loci, and consumer-facing theorem roles.*
2. *R is the recognizer row, recording which theorem-flow entries are admitted as genome-bearing theorem records.*
3. *D is the theorem-DNA row, recording role-complete feature, circuit, classifier, stability, intervention, ledger, and seal surfaces.*
4. *Q is the classifier-shift row, recording the before and after classifier phenotype when a mutation claims discovery-facing movement.*
5. *M is the mutation row, recording compression, recombination, certificate insertion, ledger exposure, and classifier-shifting genome moves.*
6. *S is the selection row, recording the score, taste-gate, novelty, reuse, and downstream-consumer coordinates used to rank genome moves.*
7. *L is the ledger row, recording which mutation or selection reads are admitted, refused, or held as obligations.*
8. *H records componentwise* hsame *transport for theorem-flow, recognizer, theorem-DNA, classifier-shift, mutation, selection, ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a theorem-genome audit request through $F, R, D, Q, M, S, L, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{TheoremGenomeEvolution}^{\uparrow}$*, theorem-flow recognition, classifier-level information, theorem-DNA scoring, theorem-DNA scoring taste gate, mutation, selection, transport,* BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{TheoremGenomeEvolution}^{\uparrow}}$ *row.*

The carrier contains no coordinate for unledgered discovery, score-only discovery, theorem sentence identity as genome identity, proof compression as classifier shift, or a mutation whose before and after classifier rows are not displayed.

Theorem 6358.2 (Theorem genome evolution NameCert obligations)**.** *For every accepted* TheoremGenomeEvolutio *carrier $G = (F, R, D, Q, M, S, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TheoremGenomeEvolution}^{\uparrow}}$ *surface consists exactly of carrier admission, theorem-flow exposure, recognizer admission, theorem-DNA exactness, classifier-shift visibility, mutation classification, selection accounting, ledger non-escape, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6358.1. The theorem-facing rows are F, R, D, Q, M, S, L, and the structural rows are H, C, P, N.

The theorem-flow and recognizer rows identify the genome-bearing theorem records. The theorem-DNA row supplies the role-complete loci before any mutation or selection row can be inspected.

Classifier-shift visibility is supplied by Q. A mutation row M may be read as discovery-facing only when its before and after classifier phenotypes are displayed there; compression or recombination without Q remains a genome move but not a classifier-shift claim.

Selection accounting is supplied by S and bounded by the ledger row L. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route, so no unledgered discovery or score-only discovery can escape. □

Theorem 6358.3 (Theorem genome evolution audit route)**.** *Every discovery-classifier consumer of an accepted* $\mathsf{TheoremGenomeEvolution}^{\uparrow}$ *packet must read*

$$F, \quad R, \quad D, \quad Q, \quad M, \quad S, \quad L, \quad H, \quad C, \quad P, \quad N.$$

Thus theorem-genome evolution is a finite NameCert packet over theorem-flow, recognizer, theorem-DNA, classifier-shift, mutation, selection, transport, provenance, and local naming rows, not a prose-only discovery claim.

Proof. Begin with a discovery-classifier request. The theorem-flow row F and recognizer row R identify the theorem objects that can carry genome data.

Read the theorem-DNA row D next. It fixes the displayed role loci, so a later mutation cannot replace a theorem genome by a sentence-only surface.

Then read the classifier-shift row Q, mutation row M, and selection row S. The ledger row L records whether that route is admitted, refused, or left as an obligation.

Finally transport and replay the route through H and C, and source and name it through P and N. These rows exhaust the accepted carrier, so the consumer receives finite audit data rather than an uninspected methodology claim. □

The Lean follow-up file for $\mathsf{TheoremGenomeEvolution}^{\uparrow}$ must provide explicit Nontrivial $\mathsf{TheoremGenomeEvolution}^{\uparrow}$ and FieldFaithful $\mathsf{TheoremGenomeEvolution}^{\uparrow}$ TasteGate instances, preserving $F, R, D, Q, M, S, L, H, C, P, N$ as separate displayed fields.

Falsifiable prediction: Deleting the classifier-shift row Q while retaining theorem-flow, theorem-DNA, mutation, and selection rows leaves a genome move but invalidates a discovery-facing theorem-genome evolution carrier.

Independence witness: theorem-dna-complexity-scoring, classifier-level-information, theorem-dna-scoring-taste-gate, theorem-genome-evolution: none is bijective because this packet uniquely binds theorem flow, recognizer admission, theorem-DNA rows, classifier-shift evidence, mutation classes, selection accounting, ledger verdicts, transport, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{TheoremGenomeEvolution}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TheoremGenomeEvolution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6358.1, Definition 6358.2, and Definition 6358.3 seed the theorem-genome evolution packet as finite theorem-flow, recognizer, theorem-DNA, classifier-shift, mutation, selection, ledger, transport, provenance, and NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TheoremGenomeEvolution}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim positive discovery without classifier shift, score-only discovery, proof compression as discovery, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, theorem-flow exposure, recognizer admission, theorem-DNA exactness, classifier-shift visibility, mutation classification, selection accounting, ledger non-escape, transport, replay, provenance, and local NameCert registration for BEDC.Derived.TheoremGenomeEvolutionUp.

Constructive story: A $\mathsf{TheoremGenomeEvolution}^{\uparrow}$ packet is generated from theorem-flow rows, recognizer rows, theorem-DNA rows, classifier-shift rows, mutation rows, selection rows, ledger verdicts, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6359

A Concrete Naming Certificate for $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$

Following Bourbaki–Kelley on uniform spaces and Bishop–Bridges constructive completion, the $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ packet records the finite NameCert surface of a completion read that is uniform, regular, and selection-free. It sits after the uniform source of chapter 339, the completion boundary of chapter 1473, the filter and net Cauchy routes of chapter 333 and chapter 589, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the constructive completion route as displayed rows rather than as a quotient completion, chosen limit, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 6359.1 (Constructive uniform completion carrier)**.** *A* $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ *carrier is a finite packet*

$$U = (S, F, T, W, R, D, E, H, C, P, N)$$

with the following displayed rows.

1. *S is the uniform-source row naming the accepted* $\mathsf{UniformSpace}^{\uparrow}$ *surface, entourage ledger, and separatedness data visible to the completion request.*
2. *F is the Cauchy-filter row read through* $\mathsf{CauchyFilter}^{\uparrow}$*, including the finite filter-basis observations used by the completion route.*
3. *T is the Cauchy-net row read through* $\mathsf{CauchyNet}^{\uparrow}$*, including the directed finite comparison windows paired with the filter row.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposed before any regular readback is consumed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the finite stream windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the positive dyadic scales used by the uniform Cauchy comparison.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, F, T, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the source, filter, net, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the uniform source through the Cauchy rows, finite windows, regular readback, dyadic tolerance ledger, Real seal, transport, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveUniformCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, T, W, R, D, E, H, C, P, N$. It has no coordinate for quotient completion classes, selected representatives, arbitrary choice of Cauchy subdata, host real equality, or ambient completeness.

Theorem 6359.2 (Constructive uniform completion NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ *carrier $U = (S, F, T, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveUniformCon}}$ *surface consists exactly of carrier admission for the uniform-source row, Cauchy-filter row, Cauchy-net row, finite stream-window row, regular rational readback row, dyadic tolerance ledger, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming.*

The classifier agreement obligation requires two accepted packets to agree precisely when these displayed rows agree componentwise through hsame*. The stability obligation requires* hsame *transport and* Cont *replay to preserve the same row order before any completion-facing or Real-facing consumer reads the terminal seal.*

Proof. Project the carrier of Definition 6359.1. The analytic completion route is S, F, T, W, R, D, E, and the structural certificate route is H, C, P, N.

The uniform-source row fixes the entourage surface. The Cauchy-filter and Cauchy-net rows then expose the two finite Cauchy presentations that the completion request may compare.

The finite stream window, regular rational readback, and dyadic tolerance ledger form the computational readback route. The terminal Real seal is downstream of those rows, so it cannot be consumed before the finite Cauchy and tolerance data have been displayed.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no excluded object is present as a coordinate, no quotient completion class, selected representative, arbitrary choice schedule, host equality, or ambient completeness theorem is a local obligation. □

Theorem 6359.3 (Constructive uniform completion uniform route)**.** *Every completion-facing read of an accepted* $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow}, \mathsf{CauchyNet}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exports a finite uniform Cauchy readback and terminal seal, not a host quotient completion, selected completed representative, countable-choice schedule, detached equality of completed names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the NameCert obligations of Definition 6359.2. They place the uniform-source row and the two Cauchy presentation rows before finite stream windows and regular rational readback.

Read the completion request through chapter 1473. In the present packet, the completion boundary receives only S, F, T, W, R, D, E as its analytic rows.

The dyadic tolerance ledger gives the positive scales used by the uniform comparison, and the Real seal is terminal for the read. Because the carrier has no coordinate for quotient completion classes, selected representatives, choice schedules, detached host equality, or ambient Real completeness, those objects cannot be exported by the route. □

Theorem 6359.4 (Constructive uniform completion nonescape)**.** *Every downstream consumer of an accepted* $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ *packet receives only the uniform source, Cauchy-filter row, Cauchy-net row, finite stream window, regular rational readback, dyadic tolerance ledger, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. In particular, the packet supplies no quotient completion class, selected limit, countable-choice schedule, host equality of completed representatives, compactness principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Use Definition 6359.1. The displayed analytic rows are exactly S, F, T, W, R, D, E, and the structural rows are exactly H, C, P, N.

Apply the uniform route of Definition 6359.3. It forces completion-facing reads through the uniform source, Cauchy presentations, finite window, regular readback, dyadic tolerance ledger, and terminal Real seal.

The structural rows preserve and name that route, but they do not add another completion object or equality source. Therefore every downstream read is exhausted by the listed rows and cannot escape to quotient completions, selected limits, choice schedules, host equality, compactness, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ completion-facing read must expose the uniform source, Cauchy-filter row, Cauchy-net row, finite stream window, regular rational readback, dyadic tolerance ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a consumer reads completed data.

Independence witness: uniformspace, uniformcompletion, cauchyfilter, cauchynet, streamname, regseqrat, dyadicratcore, real: $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ is not bijective to any listed sibling because it binds a uniform source, two finite Cauchy presentations, finite stream windows, regular rational readback, dyadic tolerance data, terminal Real seal, transport, replay, provenance, and local naming in one completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveUniformCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveUniformCompletion}^{\uparrow}$ packet is generated from a uniform source row, Cauchy-filter row, Cauchy-net row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveUniformCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6359.1, Definition 6359.2, Definition 6359.3, and Definition 6359.4 seed the finite constructive uniform-completion interface from uniform Cauchy data to Real-facing reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveUniformCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, compactness, host equality of completed representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, classifier agreement, hsame and Cont stability, finite uniform-route support, ledger nonescape, and local naming for BEDC.Derived.ConstructiveUniformCompletionUp.

Chapter 6360

A Concrete Naming Certificate for KalmanBucyFilter$^{\uparrow}$

Following Kalman and Bucy's continuous-time filtering theory, the KalmanBucyFilter$^{\uparrow}$ packet records the finite BEDC certificate rows for a state estimator whose prediction, observation, covariance, gain, and replay data are all displayed before any downstream control consumer reads the filter. It sits beside the discrete KalmanFilter$^{\uparrow}$ packet of chapter 5102, the regulator rows of LQR$^{\uparrow}$ in chapter 296, the Gramian rows of ObservabilityGramian$^{\uparrow}$ in chapter 5787, and the finite observation and reachability certificates of ControlObservability$^{\uparrow}$ and ControlControllability$^{\uparrow}$ in chapter 294 and chapter 297. The packet names only the displayed finite ledger used by continuous-time estimator consumers; it does not claim a host stochastic process, analytic convergence theorem, or infinite-dimensional filtering semantics.

Definition 6360.1 (KalmanBucyFilter carrier)**.** *A* KalmanBucyFilter$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, A, C, Q, R, P, L, \widehat{x}, \Phi, \Omega, G, E, T, H, Pkg, N)$$

with the following visible rows:

1. *X is the state row and Y is the observation row, each read through displayed* VecSpace$^{\uparrow}$ *and* Mat$^{\uparrow}$ *coordinates;*
2. *A is the state-flow row and C is the observation-flow row consumed from finite* DynSystem$^{\uparrow}$ *and* ControlObservability$^{\uparrow}$ *packets;*
3. *Q and R are the displayed process and observation covariance rows, and P is the Riccati covariance ledger row;*
4. *L is the gain row determined by the covariance, observation, and measurement-covariance ledgers;*
5. *$\widehat{x}$ is the estimator row, Φ is the state-flow replay row, Ω is the observation-flow replay row, and G is the innovation replay row;*
6. *E records estimator readback through the sibling* KalmanFilter$^{\uparrow}$ *and* LQR$^{\uparrow}$ *consumer surfaces without identifying the continuous-time packet with either one;*
7. *T records componentwise* hsame *transport for state-flow, observation-flow, covariance, gain, estimator, and replay rows;*
8. *H records displayed* Cont *replay for finite time slices and accepted row concatenation;*

9. *Pkg is the* Pkg *provenance naming* $\mathsf{KalmanBucyFilter}^{\uparrow}$, $\mathsf{KalmanFilter}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{ObservabilityGramian}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KalmanBucyFilter}^{\uparrow}}$ *row.*

No host Brownian motion, selected sample path, analytic stochastic integral, convergence rate, or external observer object is part of the carrier.

Theorem 6360.2 (KalmanBucyFilter NameCert obligations)**.** *For the carrier of Definition 6360.1, the local* $\mathsf{NameCert}_{\mathsf{KalmanBucyFilter}^{\uparrow}}$ *surface consists exactly of state-flow admission through X, A, Φ, observation-flow admission through Y, C, Ω, covariance and Riccati-ledger admission through Q, R, P, gain admission through L, estimator replay through $\widehat{x}$ and G, sibling readback through the* $\mathsf{KalmanFilter}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{ObservabilityGramian}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, *and* $\mathsf{ControlControllability}^{\uparrow}$ *package rows, componentwise* hsame *transport through T, displayed* Cont *replay through H, package provenance through Pkg, and local naming through N.*

Proof. Project the accepted carrier of Definition 6360.1. The state-flow and observation-flow rows are displayed finite coordinates, so their reads pass through the same matrix, vector-space, dynamic-system, and observability certificates named by the package row.

The covariance and gain rows are the Riccati-style ledger face of the packet. They are consumed as finite BHist data: Q, R, P expose the covariance route, while L exposes the gain row read by the estimator replay.

The estimator replay rows $\widehat{x}, \Phi, \Omega, G$ are then transported by T and replayed by H. The sibling package rows identify exactly which $\mathsf{KalmanFilter}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{ObservabilityGramian}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, and $\mathsf{ControlControllability}^{\uparrow}$ surfaces are available to downstream readers, so no hidden stochastic process or analytic filtering object can be recovered from the certificate. □

Falsifiable prediction: An accepted $\mathsf{KalmanBucyFilter}^{\uparrow}$ packet is refuted by any estimator consumer that reads a gain or covariance row while bypassing the displayed Riccati ledger Q, R, P, the observation-flow row C, Ω, the estimator replay rows $\widehat{x}, \Phi, G$, or the package provenance naming the sibling Kalman, regulator, Gramian, observability, and controllability certificates.

Independence witness: kalman-filter, lqr, observability-gramian, controlobservability, control-controllability: none is bijective to $\mathsf{KalmanBucyFilter}^{\uparrow}$ because the continuous-time filter packet jointly carries state-flow, observation-flow, covariance/Riccati ledger, gain, estimator replay, transport, continuation replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{KalmanBucyFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KalmanBucyFilter}^{\uparrow}$ packet is generated from finite state-flow, observation-flow, covariance, Riccati, gain, estimator replay, transport, continuation, provenance, and local naming rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KalmanBucyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 6360.1, Definition 6360.2, the displayed falsifiable prediction, and the displayed independence witness seed the finite continuous-time filtering NameCert surface over Kalman, regulator, Gramian, observability, controllability, matrix, vector-space, and dynamic-system rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KalmanBucyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, stochastic integral semantics, analytic convergence, infinite-horizon optimality, or host continuous-time probability semantics.

Upgrade path: Obligation closure requires checked carrier admission, state-flow and observation-flow replay, covariance and Riccati-ledger exactness, gain admission, estimator replay, componentwise transport, continuation replay, package provenance, and local NameCert exhaustion for BEDC.Derived.KalmanBucyFilterUp.

Chapter 6361

A Concrete Naming Certificate for $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$ packet records the finite modulus object used by constructive Cauchy convergence arguments before any Real-facing seal is consumed. It binds the dyadic tolerance rows of chapter 291, the finite stream windows of chapter 126, the regular readback rows of chapter 301, the terminal seal boundary of chapter 38, and the monotone convergence ledger of chapter 2074. The packet is a NameCert reconstruction of an effective Cauchy-modulus surface; it is not a Real completeness theorem, not a quotient of streams, and not a source of selected limits.

Definition 6361.1 (Effective Cauchy convergence modulus carrier)**.** *An* $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, W, R, S, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the dyadic precision request and the comparison budget used by the modulus read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the bounded observations inspected at that precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row attached to D and W.*
4. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, W, R have been displayed.*
5. *M is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *monotone ledger row, recording that later dyadic requests read weakly later finite windows without shortening the accepted tail.*
6. *H records componentwise* hsame *transport for the tolerance, window, readback, seal, modulus ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an effective Cauchy-modulus request through D, W, R, S, M, H.*
8. *P is the* Pkg *provenance over* $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, S, M, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, selected representatives, selected limits, countable choice, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6361.2 (Effective Cauchy modulus carrier admission)**.** *Every accepted* $\mathsf{EffectiveCauchyConvergenceModul}$ *packet exposes exactly the rows $D, W, R, S, M, H, C, P, N$ of Definition 6361.1 before any Real or Completion consumer may use its convergence claim. The admitted surface contains dyadic tolerances, finite stream windows, regular readback, a terminal Real seal, a monotone convergence ledger, componentwise transport, continuation replay, package provenance, and local naming, and nothing else.*

Proof. Project the finite carrier. The rows D, W, R, S, M are the only analytic rows, while H, C, P, N transport, replay, source, and name that same route.

Since the classifier compares packets only through these coordinates, a consumer cannot read a hidden quotient stream, host equality, selected representative, selected limit, choice schedule, metric-completeness row, or ambient completeness row from the carrier. □

Theorem 6361.3 (Effective Cauchy monotone tail-window stability)**.** *Let $E = (D, W, R, S, M, H, C, P, N)$ be an accepted* $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$ *packet. If a later dyadic tolerance request is transported through the monotone ledger M, then the accepted read moves only to a weakly later* $\mathsf{StreamName}^{\uparrow}$ *finite window, preserves the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route, and reaches the same terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary before the convergence claim is consumed.*

Proof. Read the tolerance request through D and the finite observation through W. The monotone ledger M is the only row allowed to compare an earlier tolerance request with a later one.

Apply the Real-modulus tail-stability route of Definition 2074.4. The later request must remain on a weakly later finite window and on the same regular readback path.

The seal row S is downstream of D, W, R, M. Thus the later-tail read cannot introduce a separate selected tail, quotient equality, countable-choice schedule, or ambient completeness witness. □

Theorem 6361.4 (Effective Cauchy RegSeqRat handoff)**.** *Every accepted* $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$ *consumer that asks for a regular Cauchy read must pass through*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}$$

before the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger or the terminal* $\mathsf{Real}^{\uparrow}$ *seal can be used. The handoff exports no quotient stream equality, selected representative, host real equality, selected limit, or countable-choice schedule.*

Proof. Project the carrier rows $D, W, R, S, M, H, C, P, N$. The dyadic row D supplies the precision budget, the stream row W supplies only a finite observation window, and the regular readback row R is the first row that can present the data as a regular Cauchy request.

Use Definition 2074.5. The Real-modulus ledger consumes the same dyadic tolerance, finite window, and regular readback surface before reaching a Real-facing seal.

Therefore any regular Cauchy consumer must read D, W, R first. The carrier contains no coordinate that could supply quotient stream equality, selected representatives, host equality, selected limits, or countable choice outside that route. □

Theorem 6361.5 (Effective Cauchy Real seal nonescape)**.** *For every accepted* $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$ *packet* $E = (D, W, R, S, M, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* S *is reachable only after the dyadic tolerance row, finite stream window, regular readback row, and monotone convergence ledger have been displayed. The packet exports no Real completeness theorem, quotient stream equality, host real equality, selected limit, metric-completeness assertion, or countable-choice schedule.*

Proof. Carrier admission gives the displayed order of rows. The seal row S is not an independent coordinate: it is listed after the dyadic, window, and regular readback rows and is controlled by the monotone ledger.

Apply Definition 38.867. Any accepted Real terminal seal read on the L10 route factors through the displayed dyadic, stream, regular readback, and Real faces.

The structural rows H, C, P, N preserve that finite route. Since neither the carrier nor the Real L10 route contains a completeness coordinate, quotient stream, host equality row, selected limit, metric-completeness row, or choice schedule, the seal cannot export one. □

Theorem 6361.6 (Effective Cauchy Bishop interface consumer route)**.** *Every* $\mathsf{BishopRealLineInterface}^{\uparrow}$ *consumer of an accepted* $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$ *packet must read*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{RealModulusOfConvergence}^{\uparrow}$$

before using the effective modulus as real-line interface data. The route reaches the Bishop interface only as a finite tolerance, finite-window, regular-readback, Real-seal, and monotone-ledger surface; it does not assert quotient equality, trichotomy, selected limits, countable choice, host real equality, metric completeness, or ambient Real completeness.

Proof. Start with the carrier admission theorem. It exposes the dyadic tolerance row, finite window row, regular readback row, Real seal row, and monotone modulus ledger before any structural row can be used by a downstream consumer.

Apply Definition 6361.4 and Definition 6361.5. These two routes force the regular readback and terminal seal to remain on the displayed L10 surface.

Now use the Bishop interface route of Definition 2062.11. A Bishop real-line consumer may compare convergence-modulus data only after the dyadic, stream, regular readback, Real seal, and Cauchy-equivalence boundary are visible, and it receives the downstream $\mathsf{RealModulusOfConvergence}^{\uparrow}$ ledger as finite evidence.

Combining the routes gives the stated consumer surface. The exclusion clauses are inherited from the effective carrier, the Real seal nonescape theorem, and the Bishop interface handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, finite StreamName windows, RegSeqRat readback, a terminal Real seal, a monotone RealModulusOfConvergence ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}}$, obligation)

Scope closed: Definition 6361.1, Definition 6361.2, Definition 6361.3, Definition 6361.4, Definition 6361.5, and Definition 6361.6 seed the effective Cauchy-modulus boundary over the displayed dyadic, stream, regular-readback, Real-seal, monotone-ledger, transport, continuation, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EffectiveCauchyConvergenceModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected representatives, selected limits, metric completeness, or bridge checking.

Upgrade path: Scoped closure requires binding the listed obligations to DyadicRatCore, StreamName, RegSeqRat, RealUp, RealModulusOfConvergence, BHist, hsame, Cont, Pkg, and NameCert rows for BEDC.Derived.EffectiveCauchyConvergenceModulusU

Chapter 6362

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$

Following Bishop–Bridges on regular Cauchy reals and constructive algebra, the $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$ packet records the finite modulus surface that lets algebraic operations on regular Cauchy representatives be replayed as named BEDC data. It sits over the dyadic tolerance ledger of chapter 291, the finite StreamName windows of chapter 126, the regular rational sequence rows of chapter 301, and the terminal Real seal rows of chapter 38. The packet is an L10 completion-facing algebra ledger: it packages sum and product stability for displayed representatives, not Real completeness, quotient equality of real names, open-cover compactness, or host real algebra.

Definition 6362.1 (RegularCauchyModulusAlgebra carrier)**.** *A* $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, W, Q, E, S, M, U, V, H, T, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *modulus ledger, exposing dyadic tolerances, comparison rows, and arithmetic tolerance requests used by every operation row;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, giving the finite input windows inspected before a tolerance request is answered;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *sequence row, carrying the regular rational representatives, their window readback, and the local regularity witnesses consumed by the operation rows;*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational readback is replayed through the displayed modulus rows;*
5. *S is the sum-stability row, recording a dyadic output tolerance, the two displayed input windows selected for that tolerance, the regular rational sum readback, and the resulting Real seal handoff;*
6. *M is the product-stability row, recording the bounded window data, dyadic tolerance split, rational product readback, and Real seal handoff required for multiplication of displayed regular representatives;*
7. *U is the transport row, recording componentwise* hsame *for D, W, Q, E, S, M and for the replay, provenance, and naming rows;*

8. *V is the replay row, recording displayed* Cont *routes from dyadic tolerance requests through StreamName windows, RegSeqRat readback, sum stability, product stability, and Real seal rows;*
9. *H is the operation-history row, collecting the finite* BHist *traces for the input representatives, selected windows, rational operation rows, and output seals;*
10. *T is the provenance row, a* Pkg *ledger over* $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows;*
11. *P is the local operation package row, exposing the accepted sum and product packets as downstream consumable BEDC objects;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, quotient equality of Real names, open-cover compactness, a selected Cauchy limit, countable choice, or host real algebra.

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusAlgebraUp.RegularCauchyModulusAlgebraTasteGate single carrier alignment`

Theorem 6362.2 (RegularCauchyModulusAlgebra NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$ *carrier*

$$A = (D, W, Q, E, S, M, U, V, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}}$ *surface consists exactly of carrier admission for A, dyadic modulus admission through D, finite StreamName window admission through W, RegSeqRat sequence admission through Q, Real seal admission through E, sum-stability admission through S, product-stability admission through M, componentwise* hsame *transport through U, displayed* Cont *replay through V, operation history through H,* Pkg *provenance through T, operation package export through P, and local naming through N.*

Consequently a downstream algebra consumer may use the packet only after reading the finite dyadic modulus rows, StreamName windows, RegSeqRat sequence rows, Real seal rows, sum and product operation-stability rows, transport, replay, provenance, and local NameCert data displayed in the carrier.

Proof. Project the accepted carrier of Definition 6362.1. The rows $D, W, Q, E, S, M, U, V, H, T, P, N$ are the only coordinates exposed by the packet.

The analytic part is finite. Dyadic tolerance requests enter through D, are answered by StreamName windows in W, are read as regular rational representatives through Q, and reach the Real-facing seal row E only after those displayed reads have occurred.

The operation rows preserve the same discipline. The sum row S records its selected input windows and rational sum readback before exporting an output seal, while the product row M records bounded window data, tolerance split, and rational product readback before exporting its seal.

The structural rows do not add external algebraic content. Componentwise hsame transport in U, displayed Cont replay in V, operation histories in H, Pkg provenance in T, operation package export in P, and the local naming row N package the same finite surface. Since no other carrier coordinate is present, Real completeness, quotient equality, open-cover compactness, selected limits, choice, and host real algebra remain outside the NameCert obligations. □

Theorem 6362.3 (RegularCauchyModulusAlgebra operation replay)**.** *Every accepted* RegularCauchyModulusAlgeb *carrier*

$$A = (D, W, Q, E, S, M, U, V, H, T, P, N)$$

exports sum and product data only through the finite route

$$D, W, Q \longmapsto S, M \longmapsto E \longmapsto U, V, H, T, P, N.$$

Thus operation stability is a replayable BEDC obligation over dyadic modulus rows, StreamName windows, RegSeqRat sequence rows, Real seal rows, transport, replay, provenance, and local NameCert data. It is not a claim of Real completeness, quotient equality, open-cover compactness, or host real algebra.

Proof. Read the carrier rows in operation order. The dyadic row D states the output precision request, W selects the finite input windows, and Q supplies the regular rational representatives visible in those windows.

For addition, the row S records the selected windows and rational sum readback before the output seal can be read through E. For multiplication, the row M records the bounded window data, tolerance split, and rational product readback before its output seal can be read through E.

The rows U, V, H, T, P, N then transport, replay, remember, package, export, and name the same operation traces. Because the route never opens a completeness theorem, quotient equality relation, open-cover argument, or host algebra object, the exported stability remains finite BEDC replay data. □

Falsifiable prediction: A consumer that claims $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$ operation stability while omitting the dyadic modulus row, StreamName window row, RegSeqRat sequence row, Real seal row, sum-stability row, product-stability row, hsame transport, Cont replay, Pkg provenance, operation package export, or NameCert row refutes the carrier of Definition 6362.1.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$ binds dyadic modulus requests, finite stream windows, regular rational readback, Real seal handoff, and explicit sum/product stability in one local NameCert packet; each named sibling lacks at least one of these operation-stability rows as a local algebra coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}$ packet is generated from dyadic modulus rows, StreamName windows, RegSeqRat sequence rows, Real seal rows, sum and product stability rows, componentwise hsame transport, displayed Cont replay, operation histories, Pkg provenance, operation package export, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6362.1, Definition 6362.2, and Definition 6362.3 seed the finite modulus algebra packet for regular Cauchy representative sum and product stability.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, quotient equality of Real names, open-cover compactness, selected Cauchy limits, countable choice, or host real algebra.

Upgrade path: Obligation closure requires checked carrier admission, sum-stability replay, product-stability replay, Real seal handoff, and a Lean realization for BEDC.Derived.RegularCauchyModulusAlgebraUp.

Chapter 6363

A Concrete Naming Certificate for $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$

Following Heine, Borel, and Bishop–Bridges constructive analysis, the $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$ packet records the finite-subcover boundary available for a displayed located real interval after the cover has already been reduced to finite dyadic interval data. It sits beside the compact interval route of chapter 3986, the dyadic interval-cover packet of chapter 1428, the finite closed-bounded interval compactness surface of chapter 3969, and the L10 Real and Completion route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The packet names a constructive finite interval subcover interface; it does not claim general open-cover compactness, a choice-selected subcover, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6363.1 (Heine–Borel finite-interval carrier)**.** *A* $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, B, C, S, Q, T, E, H, R, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row, exposing lower and upper endpoint names, locatedness data, and interval-radius requests;*
2. *D is the* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *finite cover row, recording dyadic cells, mesh scale, membership checks, and cover-read witnesses;*
3. *B is the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *compact-interval boundary row used only as the finite constructive interval route of chapter 3986;*
4. *C is the* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *row, supplying the closed-bounded interval compactness handoff after finite cover data is displayed;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row attached to endpoint and cover observations;*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same observed windows;*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and mesh-refinement ledger;*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the interval, cover, mesh, window, and readback rows have been projected;*
9. *H records componentwise* hsame *transport for all displayed rows;*

10. *R records displayed* Cont *replay for interval admission, cover readback, dyadic refinement, finite subcover witness, and Real-seal handoff;*
11. *P is the* Pkg *provenance over* $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for arbitrary open covers, countable choice, selected host representatives, quotient equality of real names, or ambient real completeness.

Theorem 6363.2 (Heine–Borel finite-interval NameCert obligations)**.** *For every accepted* $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$ *carrier $K = (I, D, B, C, S, Q, T, E, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteInterval}^{\uparrow}}$ *surface consists exactly of five finite rows: interval-source admission through I; finite cover admission through D; dyadic mesh refinement through T with the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows S, Q; finite subcover witness readback through the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *and* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *rows B, C; and Real-seal nonescape through E, H, R, P, N. No row exports general open-cover compactness, a choice-selected subcover, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The source interval row is exactly I, so endpoint, radius, locatedness, and containment requests begin with the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$ packet rather than with a host interval.

The finite cover and mesh rows are D and T. The cover cells, mesh scale, and membership checks are therefore read through $\mathsf{DyadicIntervalCover}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$, with S, Q supplying only the finite window and regular-rational readback needed to inspect the same observations.

The finite subcover witness is obtained only after the compact-interval boundary rows B, C have been displayed. These rows are the constructive compact interval surfaces cited above; they do not add an arbitrary open cover or a choice functional.

Finally read the seal and structural rows. The terminal $\mathsf{Real}^{\uparrow}$ row E is reached only after I, D, B, C, S, Q, T have been projected, and H, R, P, N transport, replay, provenance, and name that same finite packet. Since the carrier has no coordinate for the excluded principles, the five listed rows exhaust the local NameCert obligations. □

Theorem 6363.3 (Heine–Borel finite-interval dyadic mesh obligation)**.** *For every accepted* $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$ *carrier $K = (I, D, B, C, S, Q, T, E, H, R, P, N)$, the interval-cover mesh obligation is read only through the displayed located interval endpoints in I, the finite dyadic cover cells in D, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh ledger T. The* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows S, Q may report the endpoint windows used by the mesh, but the obligation exports no arbitrary open-cover refinement, no host interval cover, no quotient real equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project I first. The closed interval endpoints are available only as displayed located real names, so every endpoint read begins inside the $\mathsf{LocatedRealInterval}^{\uparrow}$ row rather than in a host interval object.

Next project D and T. The cover cells, mesh scale, and dyadic comparisons are finite rows, and the mesh refinement is certified by the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger attached to those rows.

Finally use S, Q only as the observation route for the same endpoint and cell windows. Because the carrier contains no coordinate for an arbitrary open cover or quotient real equality, the mesh obligation remains a finite dyadic-cover obligation over the displayed interval. □

Theorem 6363.4 (Heine–Borel finite-interval subcover witness obligation)**.** *For every accepted* $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$ *carrier* $K = (I, D, B, C, S, Q, T, E, H, R, P, N)$*, a finite subcover witness may be consumed only after the finite cover row* D*, the compact-interval handoff rows* B, C*, and the displayed witness rows carried through* $\mathsf{ProbeBundle}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, and* $\mathsf{TotallyBounded}^{\uparrow}$*-style finite data have been exposed by the same* BHist *packet. The witness is a finite row selection inside the packet, not a countable-choice selector, not an arbitrary open-cover subcover, and not a host compactness theorem.*

Proof. Start with the finite cover row D. It lists the cover cells and membership checks already reduced to finite dyadic interval data, so the witness has a finite source to inspect.

Read the compact-interval handoff rows B, C next. These rows provide the constructive compact and closed-bounded interval surfaces used by the carrier, and they keep the witness attached to the same interval packet.

The probe, compact-metric, and totally-bounded reads are therefore finite rows inside the displayed BHist. The structural rows H, R, P, N transport, replay, source, and name that finite witness, while the carrier still lacks any coordinate for countable choice or arbitrary open-cover compactness. □

Theorem 6363.5 (Heine–Borel finite-interval Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$ *carrier must display* $I, D, B, C, S, Q, T, H, R, P, N$ *before it reads the terminal seal row* E*. The seal records that the finite interval subcover route is Real-facing, but it does not claim arbitrary subset Heine–Borel compactness, general open-cover compactness, choice-selected subcovers, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier in the order of Definition 6363.1. The interval, cover, compact handoff, window, readback, and dyadic mesh rows are all displayed before E is available.

The transport and replay rows preserve that same finite route. They allow the interval-cover and subcover-witness rows to be moved componentwise, but they do not create an arbitrary cover family or a selected subcover functional.

Finally inspect the provenance and local certificate. The Pkg and $\mathsf{NameCert}$ rows name only the displayed finite interval packet, so the terminal $\mathsf{Real}^{\uparrow}$ seal is a nonescape boundary rather than a completeness or open-cover compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteInterval}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6363.1, Definition 6363.2, Definition 6363.3, Definition 6363.4, and Definition 6363.5 seed the finite interval subcover boundary over $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general open-cover compactness, arbitrary Heine–Borel compactness for subsets of $\mathsf{Real}^{\uparrow}$, choice-selected subcovers, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked interval-source admission, finite cover admission, dyadic mesh refinement, finite subcover witness readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HeineBorelFiniteIntervalUp.

Constructive story: A $\mathsf{HeineBorelFiniteInterval}^{\uparrow}$ packet is generated from a LocatedRealInterval row, a DyadicIntervalCover finite cover row, BishopCompactInterval and ClosedBoundedIntervalCompact handoff rows, StreamName windows, RegSeqRat readback, a DyadicRatCore mesh ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6364

A Concrete Naming Certificate for BishopLocatedIntervalOscillation$^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the BishopLocatedIntervalOscillation$^{\uparrow}$ packet records finite located-interval oscillation data for the L10 Real and Completion route. It sits over the located interval surface of chapter 394, the graph-read surface of chapter 130, the finite window route of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names noncompact located-interval oscillation rows; it does not claim open-cover compactness, selected extrema, quotient function equality, or ambient Real$^{\uparrow}$ completeness.

Definition 6364.1 (Bishop located interval oscillation carrier)**.** *A* BishopLocatedIntervalOscillation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (I, F, W, R, D, B, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the* LocatedInterval$^{\uparrow}$ *source row, read as a located interval rather than as a compact interval object.*
2. *F is the* ContinuousMap$^{\uparrow}$ *graph row whose values are inspected only through displayed finite windows.*
3. *W is the* StreamName$^{\uparrow}$ *finite observation row for source and target probes.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the same finite windows.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, carrying the interval radius, value tolerance, and visible comparison budget.*
6. *B is the oscillation-bound row recording the accepted dyadic upper bound for the displayed interval probe.*
7. *S is the terminal* Real$^{\uparrow}$ *seal consumed only after I, F, W, R, D, B have been displayed.*
8. *H records componentwise* hsame *transport for the analytic rows and local naming rows.*
9. *C records displayed* Cont *replay through the finite route I, F, W, R, D, B, S, H.*
10. *P is the* Pkg *provenance over* BishopLocatedIntervalOscillation$^{\uparrow}$, LocatedInterval$^{\uparrow}$, ContinuousMap$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for compactness, selected suprema, host real equality, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6364.2 (Bishop located interval oscillation NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}$ *carrier* $O = (I, F, W, R, D, B, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalO}}$ *surface is exhausted by located-interval admission through* I*, continuous graph exposure through* F*, finite StreamName window exposure through* W*, RegSeqRat readback through* R*, DyadicRatCore tolerance exactness through* D*, oscillation-bound exposure through* B*, Real sealing through* S*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6364.1. The source row is the located interval I, and the function row is the displayed continuous graph F.

The finite readback route is then forced. A probe opens the StreamName windows W, reads them through the RegSeqRat row R, applies the dyadic tolerance row D, and records the oscillation bound in B before the Real seal S can be consumed.

The structural rows H, C, P, N transport, replay, source, and name only that displayed route. Since the carrier has no compactness, selected-extremum, quotient, choice, host-equality, or completeness coordinate, no such object can become a local NameCert obligation. □

Theorem 6364.3 (Bishop located interval oscillation L10 route)**.** *Every L10 Real and Completion consumer of an accepted* $\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}$ *packet receives a noncompact located-interval oscillation surface through*

$$\mathsf{LocatedInterval}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N.$$

The route displays finite interval probes, continuous graph observations, regular rational readback, dyadic tolerances, and a terminal Real seal. It exports no open-cover compactness, selected maximum, quotient stream equality, selected limit, countable choice, or ambient completeness theorem.

Proof. Start with the NameCert obligations. They require the consumer to read I, F, W, R, D, B, S before transport, replay, provenance, or local naming can be used.

The route is noncompact because I is only a located interval source. The oscillation row B records a displayed dyadic bound for the accepted probe, not a finite-subcover or extremum principle.

Finally the Real-facing endpoint is the seal row S behind the same finite route. Thus an L10 consumer receives a certificate-local oscillation surface and none of the excluded compactness, quotient, selection, choice, host-equality, or completeness data. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}$ consumer that reads an oscillation bound while omitting one of the LocatedInterval, ContinuousMap, StreamName, RegSeqRat, DyadicRatCore, Real seal, hsame, Cont, Pkg, or NameCert rows has left the packet.

Independence witness: locatedinterval, continuousmap, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}$ is not bijective with any listed sibling because it joins a noncompact located interval source, continuous graph observations, finite windows, regular rational readback, dyadic tolerances, oscillation bounds, Real sealing, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}$ packet is generated from a LocatedInterval source row, a ContinuousMap graph row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, an oscillation-bound row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6364.1, Definition 6364.2, and Definition 6364.3 seed the finite noncompact located-interval oscillation surface for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected extrema, quotient function equality, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-interval admission, continuous graph exposure, StreamName window replay, RegSeqRat readback, DyadicRatCore tolerance exactness, oscillation-bound exposure, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedIntervalOscillationUp.

Chapter 6365

A Concrete Naming Certificate for $\mathsf{LocatedDyadicCompletion}^{\uparrow}$

Following Bishop–Bridges constructive completion practice, the $\mathsf{LocatedDyadicCompletion}^{\uparrow}$ packet records the finite BEDC route from located dyadic tolerance data to regular rational streams and the terminal real-name seal. It sits over the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the real-name boundary of chapter 38. The packet names a displayed completion interface for the current L10 Real and Completion phase; it does not import quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6365.1 (Located dyadic completion carrier)**.** *A* $\mathsf{LocatedDyadicCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, common refinements, and positive located gaps;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by each tolerance request;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed;*
4. *L is the located split row, answering each dyadic comparison request before any real seal is exposed;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, read only after D, S, R, L have been projected;*
6. *H records componentwise* hsame *transport for the displayed dyadic, stream, regular, locatedness, and real rows;*
7. *C records displayed* Cont *replay for tolerance admission, finite-window readback, regular-sequence handoff, located split, and real sealing;*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedDyadicCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, L, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected completion limit, countable choice, detached order trichotomy, or ambient real completeness.

Theorem 6365.2 (Located dyadic completion NameCert obligations)**.** *For every accepted* $\mathsf{LocatedDyadicCompletio}$ *carrier* $K = (D, S, R, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicCompletion}^{\uparrow}}$ *surface consists exactly of five finite rows: dyadic tolerance admission through* D*; finite stream-window inspection through* S*; regular rational readback through* R*; located comparison discharge through* L*; and real-seal nonescape through* E, H, C, P, N*. No obligation row exports quotient streams, selected limits, countable choice, detached trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The dyadic tolerance ledger is exactly D, so every radius, refinement, and positive-gap request begins inside $\mathsf{DyadicRatCore}^{\uparrow}$.

The finite observation route is S followed by R. Thus a completion-facing consumer reads only displayed stream windows and their $\mathsf{RegSeqRat}^{\uparrow}$ readback before it can ask for a real boundary.

The located split row is L. It answers the comparison request associated with the displayed dyadic budget, but it is not a detached trichotomy principle and it does not select a global representative.

Finally inspect E, H, C, P, N. The terminal $\mathsf{Real}^{\uparrow}$ seal is reached only after the four rows D, S, R, L have been projected, while the structural rows transport, replay, source, and name that same finite packet. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6365.3 (Located dyadic completion Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedDyadicCompletion}^{\uparrow}$ *carrier factors through the route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the Cauchy handoff from dyadic tolerance data to a real-name boundary is mediated by displayed finite windows and regular rational readback, not by quotienting Cauchy streams or selecting a limit object.

Proof. Start with the accepted carrier $K = (D, S, R, L, E, H, C, P, N)$. A regular rational consumer can inspect the readback row only after D supplies the tolerance ledger and S supplies the finite stream windows.

A real-name consumer reaches E only after R and L have been read. The located row L supplies the comparison response attached to the same dyadic budget, so the handoff carries the Cauchy information already displayed by D, S, R.

The structural rows H, C, P, N preserve this order under transport, replay, provenance, and local naming. Hence the only exported route is the displayed dyadic-to-stream-to-regular-to-real chain, with no quotient stream or selected limit coordinate available. □

Theorem 6365.4 (Located dyadic completion nonescape)**.** *No accepted* $\mathsf{LocatedDyadicCompletion}^{\uparrow}$ *carrier can be used as evidence for quotient stream equality, countable choice, a choice-selected completion limit, detached trichotomy of real names, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*. Any downstream claim using the carrier must consume the displayed rows* $D, S, R, L, E, H, C, P, N$*.*

Proof. The carrier definition lists every exported coordinate. The computational rows are D, S, R, L, E, and the structural rows are H, C, P, N.

Quotient stream equality and selected limits would require a coordinate identifying arbitrary Cauchy names or choosing a representative beyond the displayed stream windows. No such coordinate appears in the carrier.

Countable choice, detached trichotomy, and ambient real completeness would require a global principle independent of the finite dyadic ledger. The carrier instead routes comparison through L and real sealing through E after D, S, R have already been displayed.

Therefore any downstream use must consume the listed rows, and the excluded principles cannot escape from the local $\mathsf{NameCert}_{\mathsf{LocatedDyadicCompletion}^{\uparrow}}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDyadicCompletion}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedDyadicCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 6365.1, Definition 6365.2, Definition 6365.3, and Definition 6365.4 seed the finite located dyadic completion route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedDyadicCompletion}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.LocatedDyadicCompletionUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, detached trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic tolerance admission, finite stream-window inspection, regular rational readback, located comparison discharge, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedDyadicCompletionUp.

Constructive story: A $\mathsf{LocatedDyadicCompletion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a located comparison row, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Lean4 (statement) `BEDC.Derived.LocatedDyadicCompletionUp`

Chapter 6366

Sequentially Located Real NameCert Construction

Following Bishop and Bridges on constructive real sequences and locatedness, the $\mathsf{SequentiallyLocatedReal}^{\uparrow}$ packet records a sequence-indexed family of $\mathsf{Real}^{\uparrow}$ names whose finite observations carry an explicit locatedness witness at each inspected unary index. It sits after the $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback surface of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the located real sequence packet of chapter 1984. The packet is a choice-free sequential locatedness carrier: every visible coordinate is finite, named, and ledgered before any downstream Real or Completion consumer may read it.

Definition 6366.1 (Sequentially located real carrier)**.** *A* $\mathsf{SequentiallyLocatedReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, S, E, L, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the unary index-window row, naming the finite initial segment of sequence indices that a consumer may inspect.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, displaying the finite stream windows attached to the indices in I.*
3. *E is the pointwise* $\mathsf{Real}^{\uparrow}$ *name row, recording the real-name packet exposed at each inspected index.*
4. *L is the locatedness-witness row, assigning to each unary index in I the finite locatedness evidence used to compare the corresponding real-name observation with rational bounds.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows, pointwise real names, and locatedness witnesses.*
6. *Q is the finite request ledger, recording which indices, stream windows, rational bounds, and locatedness witnesses were exposed.*
7. *H records componentwise* hsame *transport for index windows, stream observations, pointwise real names, locatedness witnesses, regular rational readback, ledger rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an index request through $I, S, E, L, R, Q, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{SequentiallyLocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentiallyLocatedReal}^{\uparrow}}$ *row.*

The carrier exposes sequence-indexed $\mathsf{Real}^{\uparrow}$ *packets only through finite* $\mathsf{StreamName}^{\uparrow}$ *observations and a locatedness witness for each inspected unary index.*

Theorem 6366.2 (Sequentially located real NameCert obligations)**.** *For every accepted* $\mathsf{SequentiallyLocatedReal}^{\uparrow}$ *carrier*

$$X = (I, S, E, L, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentiallyLocatedReal}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed* BHist *packet X with unary index windows, finite stream observations, pointwise real-name rows, locatedness witnesses, regular rational readback, request ledger, transport, replay, provenance, and local naming rows;*
2. *pointwise classifier stability: classified replacement of an inspected index, stream window, real-name row, or locatedness witness is transported componentwise through H and replayed only along the displayed route in C;*
3. *locatedness transport: the witness row L moves with its unary index in I and with its pointwise* $\mathsf{Real}^{\uparrow}$ *row in E, so no downstream read may detach a locatedness decision from the coordinate that generated it;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *readback: the row R is readable only after the corresponding I, S, E, L rows have been displayed, matching the regular rational handoff of chapter 301;*
5. *ledger nonescape: the request ledger Q records every exposed index, stream observation, rational bound, and locatedness witness before the packet reaches P and N, and the packet exports no quotient stream, countable-choice selector, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or unchecked bridge data.*

These rows are the whole sequential locatedness surface consumed by the sibling sequence route of chapter 1984.

Falsifiable prediction: Every accepted $\mathsf{SequentiallyLocatedReal}^{\uparrow}$ read displays a finite unary index window, finite $\mathsf{StreamName}^{\uparrow}$ observations, pointwise $\mathsf{Real}^{\uparrow}$ names, locatedness witnesses, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a request ledger, and local transport, replay, provenance, and naming rows before any Real or Completion consumer reads the packet.

Independence witness: streamname, regseqrat, real, located-real-sequence: $\mathsf{SequentiallyLocatedReal}^{\uparrow}$ is not bijective to any listed sibling because it binds sequence-indexed $\mathsf{Real}^{\uparrow}$ names to per-index locatedness witnesses and a request ledger before the regular rational readback.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentiallyLocatedReal}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentiallyLocatedReal}^{\uparrow}$ packet is generated from unary index windows, finite StreamName observations, pointwise Real names, per-index locatedness witnesses, RegSeqRat readback, a request ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentiallyLocatedReal}^{\uparrow}}$, seed)

Scope closed: Definition 6366.1 and Definition 6366.2 seed the choice-free sequential locatedness carrier over StreamName, RegSeqRat, Real, and located-real-sequence consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentiallyLocatedReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not assert Real completeness, any choice principle, a selected limit, quotient stream equality, Lean verification, or checked bridge data.

Upgrade path: Lean closure requires checked carrier admission, pointwise classifier stability, locatedness transport, RegSeqRat readback, and ledger nonescape for BEDC.Derived.SequentiallyLocatedRealUp.

Chapter 6367

A Concrete Naming Certificate for $\mathsf{UpperLowerRealEnclosure}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UpperLowerRealEnclosure}^{\uparrow}$ packet records a constructive upper/lower rational enclosure for a real name on the L10 Real and Completion path. It sits between the rational tolerance service of chapter 291, the finite observation schedules of chapter 126, the regular rational readback route of chapter 301, the located-name boundary of chapter 1933, and the terminal real-name seal of chapter 38. The packet exposes interval enclosure data as finite BEDC rows; it does not identify quotient real classes, select a completed limit, invoke trichotomy, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6367.1 (Upper/lower real enclosure carrier)**.** *An* $\mathsf{UpperLowerRealEnclosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, U, W, S, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower rational bound row, read through the rational and dyadic tolerance surface used by* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
2. *U is the upper rational bound row for the same inspected real-name window;*
3. *W is the dyadic width row, displaying a tolerance certificate that $U - L$ is bounded by the named dyadic width and can be refined along the same finite schedule;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming exactly the finite observation windows used to inspect the enclosure;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating those observations into regular rational approximants;*
6. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the lower bound, upper bound, width, schedule, and readback rows have been displayed;*
7. *H records componentwise* hsame *transport for L, U, W, S, R, Z;*
8. *C records displayed* Cont *replay for bound inspection, width refinement, regular readback, located-name handoff, and Real sealing;*
9. *P is the* Pkg *provenance over* $\mathsf{UpperLowerRealEnclosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UpperLowerRealEnclosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host real representative, quotient equality of names, selected limits, trichotomy of real order, or unrestricted completeness.

Theorem 6367.2 (Upper/lower real enclosure NameCert obligations)**.** *For every accepted* $\mathsf{UpperLowerRealEnclosur}$ *carrier $E = (L, U, W, S, R, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UpperLowerRealEnclosure}^{\uparrow}}$ *surface consists exactly of five finite rows:*

1. *lower-bound admission, where L is displayed as a rational bound over the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the inspected real-name window;*
2. *upper-bound admission, where U is displayed over the same ledger and is compared with L only through dyadic rational order data;*
3. *width control, where W records the finite dyadic enclosure width and its refinement schedule;*
4. *schedule/readback coherence, where S and R tie the bound rows to the same* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational observations;*
5. *Real-seal nonescape, where Z, H, C, P, N transport, replay, source, and name the displayed enclosure without exporting host representatives, quotient equality, selected limits, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The first two rows are precisely the rational bound rows L and U, and both are read through the displayed dyadic tolerance ledger rather than through a host order on completed reals.

The width row W is part of the same finite packet. Its dyadic comparison is therefore a displayed tolerance certificate attached to L and U, not an external metric completeness assertion.

Next read the schedule and readback rows. The finite windows in S determine which observations may be inspected, and R translates only those observations into regular rational approximants. This keeps the enclosure on the L10 path through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$.

Finally project the seal and structural rows. The $\mathsf{Real}^{\uparrow}$ row Z is reached only after L, U, W, S, R have been displayed, while H, C, P, N transport, replay, source, and name the same finite data. Since the carrier has no coordinate for the excluded principles, the five rows exhaust the local NameCert obligations. □

Theorem 6367.3 (Upper/lower real enclosure width shrink)**.** *Let $E = (L, U, W, S, R, Z, H, C, P, N)$ be an accepted* $\mathsf{UpperLowerRealEnclosure}^{\uparrow}$ *carrier. Any refinement of the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule S that is replayed by C and read back by R may replace W by a smaller displayed dyadic width W' only through the same lower-bound row L, upper-bound row U,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger, and* $\mathsf{Real}^{\uparrow}$ *seal row Z. The shrink route exports a narrower finite enclosure row, but it does not export a selected limit point, quotient real equality, order trichotomy, or ambient completeness.*

Proof. Start with the carrier definition. The only width coordinate is W, and every permitted inspection of W is tied to the bound rows L, U, the finite schedule S, and the regular readback row R.

A refinement of S supplies a smaller finite observation window only when the replay row C displays that refinement inside the same packet. The readback row R then compares the resulting rational approximants through the dyadic ledger, so the proposed W' is a new displayed width row rather than a semantic limit.

The structural rows H, P, N keep the refined enclosure attached to the original packet, and the terminal seal Z is not reread as completeness. Therefore width shrink is a finite dyadic enclosure operation over the displayed rows and cannot yield any of the excluded host principles. □

Theorem 6367.4 (Upper/lower real enclosure Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{UpperLowerRealEnclosure}^{\uparrow}$ *packet must first display the lower rational bound* L*, upper rational bound* U*, dyadic width* W*,* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local name* N *before reading the seal row* Z*. The seal may certify that the displayed enclosure is Real-facing, but it does not identify quotient real representatives, select a completed limit, prove arbitrary locatedness, invoke trichotomy, or supply ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the packet in the order forced by Definition 6367.1. The seal row Z is one coordinate of the carrier and is not available before the bound, width, schedule, and readback rows have been displayed.

The transport and replay rows keep the consumer on the same finite enclosure. They allow the listed rows to be moved and replayed componentwise, but they do not create a new representative of the real name or a completion operation.

Finally inspect the provenance and local certificate. The Pkg row names the dependency corridor through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and the local $\mathsf{NameCert}$ row certifies only that corridor. Thus the Real seal is a nonescape boundary for the displayed enclosure packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UpperLowerRealEnclosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UpperLowerRealEnclosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6367.1, Definition 6367.2, Definition 6367.3, and Definition 6367.4 seed the upper/lower rational enclosure surface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UpperLowerRealEnclosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, selected completed limits, order trichotomy, arbitrary locatedness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked lower-bound admission, upper-bound admission, width control, schedule/readback coherence, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UpperLowerRealEnclosu

Constructive story: An $\mathsf{UpperLowerRealEnclosure}^{\uparrow}$ packet is generated from lower and upper rational bound rows, a dyadic width row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6368

A Concrete Naming Certificate for $\mathsf{FrechetCompleteMetric}^{\uparrow}$

Following Frechet and Bishop on metric completion by Cauchy data, the $\mathsf{FrechetCompleteMetric}^{\uparrow}$ packet records the finite shared-tail route by which a metric Cauchy family exposes a completion-facing real seal. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, the metric carrier of chapter 57, and the complete-metric interface of chapter 128. The packet names a finite shared-tail completion obligation; it does not construct a quotient completion, select a limit representative, assert countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6368.1 (Cauchy-modulus shared-tail carrier)**.** *A* $\mathsf{FrechetCompleteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, S, R, D, T, E, H, C, P, N)$$

with the following displayed rows.

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, naming the distance surface and the finite metric comparison ledger used by the Cauchy request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected tail windows of the candidate Cauchy name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive tolerance ledger consumed by the tail comparison.*
5. *T is the shared-tail modulus row, recording that every displayed tolerance request is answered by one finite tail window accepted by both the stream and regular-readback faces.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after M, S, R, D, T have been displayed.*
7. *H records componentwise* hsame *transport for the metric, stream, regular, tolerance, shared-tail, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from the metric source through the stream windows, regular readback, dyadic tolerance ledger, shared-tail row, Real seal, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{FrechetCompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{FrechetCompleteMetric}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, S, R, D, T, E, H, C, P, N$. It has no coordinate for quotient completion equality, a selected completed point, an infinite choice schedule, host real equality, or an ambient completeness theorem.

Theorem 6368.2 (Cauchy-modulus shared-tail NameCert obligations)**.** *For every accepted* FrechetCompleteMetric *carrier $F = (M, S, R, D, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetCompleteMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric row, finite stream windows, regular rational readback, dyadic tolerance ledger, shared-tail modulus row, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming.*

The classifier agreement obligation requires two accepted packets to agree precisely when these displayed rows agree componentwise through hsame*. The stability obligation requires* hsame *transport and* Cont *replay to preserve the same row order before any completion-facing or Real-facing consumer reads the terminal seal.*

Proof. Project the carrier of Definition 6368.1. The analytic route is M, S, R, D, T, E, and the structural certificate route is H, C, P, N.

The metric row fixes the distance surface. The stream and regular-readback rows expose the finite windows on which the Cauchy request is inspected, while the dyadic tolerance ledger supplies the positive comparison rows.

The shared-tail row is downstream of those rows and upstream of the terminal Real seal. It therefore records one displayed tail window for the two consuming faces without adding quotient equality, selected limits, choice, host equality, or ambient completeness as local certificate data.

Finally H, C, P, N transport, replay, source, and name exactly the same rows. Hence the listed fields exhaust the local NameCert obligations. □

Theorem 6368.3 (Cauchy-modulus shared-tail cofinality)**.** *Every finite family of* $\mathsf{StreamName}^{\uparrow}$ *finite-window requests and* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity checks that consumes a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row through an accepted* $\mathsf{FrechetCompleteMetric}^{\uparrow}$ *carrier has a common shared-tail refinement. The refinement preserves the metric row, finite stream windows, regular readback, dyadic denominator ledger, shared-tail modulus row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *support.*

The common refinement is cofinal among the finite tolerance demands visible to the packet: every listed request factors through its displayed tail window before any completion-facing consumer reaches the Real seal.

Proof. Enumerate the finite StreamName requests and RegSeqRat checks. Starting from the positive dyadic tolerance row, repeatedly read the shared-tail row T of Definition 6368.1 to enlarge the displayed tail window until all listed finite demands are covered.

At each step the metric row M, the stream row S, the regular row R, and the dyadic row D remain the same public source rows. Componentwise hsame transport and displayed Cont replay preserve the accumulated window rather than creating a second tolerance source.

The final window is therefore common to the finite family and is cofinal for the requests named inside the carrier. Since the construction uses only displayed carrier rows, it cannot appeal to quotient completion equality, selected representatives, countable choice, host equality, or ambient Real completeness. □

Theorem 6368.4 (Cauchy-modulus shared-tail Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{FrechetCompleteMetric}^{\uparrow}$ *carrier is reached only through the route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The shared-tail modulus row must be displayed before the seal is visible, and the read exports no quotient completion class, selected completed point, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Begin with the NameCert obligations of Definition 6368.2. They place the metric row, finite stream windows, regular readback, dyadic tolerance ledger, and shared-tail modulus before the Real seal.

Apply the cofinality statement of Definition 6368.3. Any finite completion-facing request is first absorbed into a displayed shared-tail window that both the StreamName and RegSeqRat faces can read.

Only after that finite route is fixed may the consumer read the terminal seal E. The carrier has no coordinate for quotient completion classes, selected completed points, choice schedules, host equality, or ambient completeness, so those objects cannot be exported by the seal route. □

Falsifiable prediction: Every accepted $\mathsf{FrechetCompleteMetric}^{\uparrow}$ completion-facing read must expose the metric row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, shared-tail modulus row, terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert support before a consumer reads completed data.

Independence witness: metric, completemetric, streamname, regseqrat, dyadicratcore, real: $\mathsf{FrechetCompleteMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric source row, finite stream windows, regular rational readback, dyadic tolerance data, one shared-tail modulus row, a terminal RealUp seal, transport, replay, provenance, and local naming in one completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetCompleteMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrechetCompleteMetric}^{\uparrow}$ packet is generated from a metric source row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, a shared-tail modulus row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrechetCompleteMetric}^{\uparrow}}$, seed)

Scope closed: Definition 6368.1, Definition 6368.2, Definition 6368.3, and Definition 6368.4 seed the finite shared-tail completion interface from metric Cauchy data to Real-facing reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrechetCompleteMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected completed representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, classifier agreement, shared-tail cofinality, Real-seal route support, ledger nonescape, and local naming for BEDC.Derived.FrechetCompleteMetricUp.

Chapter 6369

A Concrete Naming Certificate for $\mathsf{DyadicCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicCauchyCriterion}^{\uparrow}$ packet records the finite dyadic criterion bridge from dyadic tolerance data to regular rational readback. It sits between the dyadic endpoint and tolerance rows of chapter 291, the finite stream-window surface of chapter 126, the regular Cauchy readback of chapter 301, the terminal real-name seal of chapter 38, and the equality-facing comparison boundary of chapter 1820. The packet names a criterion route for Real and Completion consumers before any completed real line is assumed.

Definition 6369.1 (Dyadic Cauchy criterion carrier)**.** *A* $\mathsf{DyadicCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger, recording dyadic radii, comparison budgets, and common refinements.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by each tolerance request.*
3. *T is the dyadic Cauchy criterion row, asserting that every requested dyadic tolerance is discharged by some displayed finite window over D and W.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from the criterion row T.*
5. *E is the equality-facing boundary row: it records* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison for the displayed regular readbacks and the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, W, T, R have been projected.*
6. *H records componentwise* hsame *transport for the dyadic, window, criterion, regular-readback, comparison, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for tolerance admission, finite-window inspection, criterion discharge, regular readback, comparison, and sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicCauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, T, R, E, H, C, P, N$. It has no coordinate for quotient equality, selected limits, countable choice, trichotomy, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6369.2 (Dyadic Cauchy criterion NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyCriterion}^{\uparrow}$ *carrier $K = (D, W, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyCriterion}^{\uparrow}}$ *surface consists exactly of five finite obligation rows: dyadic tolerance admission through D; finite stream-window inspection through W; dyadic criterion discharge through T; regular rational readback through R; and comparison, seal, transport, replay, provenance, and local naming through E, H, C, P, N. No obligation row exports quotient equality, selected limits, countable choice, trichotomy, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 6369.1. The first two rows are read through the sibling dyadic and stream surfaces chapter 291 and chapter 126: the dyadic ledger supplies tolerances and common refinements, while the stream row supplies only finite windows.

The criterion row T is therefore local to the displayed finite data. It says that a requested dyadic tolerance has a displayed window witness, not that a global stream quotient or a selected limit has been chosen.

The readback row R is consumed through chapter 301. The equality-facing part of E is read through chapter 1820, and its terminal seal is read only through chapter 38.

The structural rows H, C, P, N transport, replay, source, and name the same displayed packet. Since none of the projected rows contains quotient equality, selected limits, countable choice, trichotomy, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6369.3 (Dyadic Cauchy criterion RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicCauchyCriterion}^{\uparrow}$ *carrier must read the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicCauchyCriterion}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

The handoff packages dyadic tolerance windows as a regular Cauchy readback while retaining only $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison and the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary. It does not export quotient equality, selected limits, countable choice, trichotomy, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the dyadic source and finite-window source. By chapter 291 and chapter 126, the rows D and W expose only dyadic budgets and bounded observations.

Use the criterion row T to bind these two sources. A $\mathsf{RegSeqRat}^{\uparrow}$ consumer may read R only after the tolerance request has been discharged by a displayed finite window, so the handoff lands in chapter 301 without choosing a limit representative.

The comparison and seal remain downstream. The row E cites the comparison boundary of chapter 1820 and reaches the terminal real-name boundary only as in chapter 38.

The transport, replay, provenance, and naming rows preserve this route. They contain no quotient equality, selected limit, countable-choice schedule, trichotomy decision, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness principle, so none is exported by the handoff. □

Theorem 6369.4 (Dyadic Cauchy criterion Real seal boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{DyadicCauchyCriterion}^{\uparrow}$ *carrier reaches* $\mathsf{Real}^{\uparrow}$ *only through the displayed rows $D, W, T, R, E, H, C, P, N$. The consumer may inspect the dyadic source of chapter 291, the finite-window source of chapter 126, the regular readback of chapter 301, the comparison boundary of*

chapter 1820, and the terminal seal of chapter 38; it receives no quotient equality, selected limits, countable choice, trichotomy, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Unpack the accepted carrier. The value-facing route begins at D and W, whose sibling chapters chapter 291 and chapter 126 expose finite dyadic and finite-window data rather than a host real object.

The criterion and readback rows are next. The row T records the finite dyadic Cauchy discharge, and the row R is read through chapter 301 as regular rational data.

The seal row is last. Its comparison part is bounded by chapter 1820, and its terminal real-name reading is the boundary supplied by chapter 38.

Finally inspect H, C, P, N. These structural rows transport, replay, source, and name the same route; they do not add quotient equality, selected limits, countable choice, trichotomy, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness. Hence Real and Completion consumers cannot escape the displayed criterion bridge. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyCriterion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, a dyadic criterion row, RegSeqRat readback, CauchyEquivalenceSetoid comparison, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6369.1, Definition 6369.2, Definition 6369.3, and Definition 6369.4 seed the finite dyadic criterion bridge over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchyCriterion}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.DyadicCauchyCriterionUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality, selected limits, countable choice, trichotomy, host real equality, $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic tolerance admission, finite stream-window inspection, criterion discharge, regular readback, comparison, terminal sealing, transport, replay, provenance, and local naming for BEDC.Derived.DyadicCauchyCriterionUp.

Chapter 6370

A Concrete Naming Certificate for $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Brouwer–Troelstra choice-sequence grounding, the $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$ packet records choice-sequence Cauchy data as finite BEDC rows before it enters the Real and Completion route. It sits after the choice-sequence source of chapter 1482, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the spread-indexed real-name boundary of chapter 4161. The packet also points toward the regular spread sibling chapter 2072. It names a non-quotient Cauchy route; it does not choose an infinite branch, select a Cauchy representative, assert countable choice, identify quotient streams, or add ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6370.1 (Bishop Cauchy choice-sequence carrier)**.** *A* $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, W, D, R, E, S, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *source row, exposing only the inspected finite prefixes of the choice sequence.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the inspected prefixes are scheduled.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed prefix windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite prefix and tolerance data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, W, D, R have been displayed.*
6. *S is the spread-comparison row, recording the compatible* $\mathsf{CauchyRealSpread}^{\uparrow}$ *or* $\mathsf{RegularCauchySpread}^{\uparrow}$ *read when a spread-indexed consumer asks for the same Cauchy data.*
7. *H records componentwise* hsame *transport for the choice-sequence source, window, tolerance, regular readback, real seal, spread-comparison, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for prefix inspection, tolerance discharge, regular readback, spread comparison, and terminal sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealSpread}^{\uparrow}$, $\mathsf{RegularCauchySpread}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyChoiceSequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, W, D, R, E, S, H, C, P, N$. It has no coordinate for a host infinite branch, selected Cauchy representative, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) `BEDC.Derived.BishopCauchyChoiceSequenceUp`

Theorem 6370.2 (Bishop Cauchy choice-sequence NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$ *carrier*

$$K = (Q, W, D, R, E, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyChoiceSequence}^{\uparrow}}$ *surface consists exactly of choice-sequence prefix exposure through Q, finite stream-window scheduling through W, dyadic tolerance exposure through D, regular rational readback through R, terminal real sealing through E, spread-compatible comparison through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. No obligation row exports a host infinite branch, selected Cauchy representative, quotient stream equality, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6370.1. The choice-sequence source Q is visible only through the finite window schedule W, and every tolerance read is mediated by the dyadic ledger D.

The regular and real-facing rows stay downstream of that finite source. Row R records the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to the same prefixes and tolerances, while E is the terminal $\mathsf{Real}^{\uparrow}$ seal reached only after those rows have been displayed.

The spread row S is a comparison route, not a second source of representatives. It records compatibility with the Cauchy-real and regular-Cauchy spread siblings while keeping branch selection, quotient stream equality, countable choice, and ambient completeness outside the carrier.

Finally H, C, P, N transport, replay, source, and name exactly the same packet. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6370.3 (Bishop Cauchy choice-sequence RegSeqRat and Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion consumer of an accepted* $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{ChoiceSequence}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

When a spread-indexed consumer is present, the same read also factors through the displayed $\mathsf{CauchyRealSpread}^{\uparrow}$ *or* $\mathsf{RegularCauchySpread}^{\uparrow}$ *comparison row S. The handoff exports prefix inspection, finite windows, dyadic tolerance, regular readback, real sealing, spread comparison, transport, replay, provenance, and local naming only; it exports no selected infinite branch, selected Cauchy representative, quotient stream equality, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 6370.2. It identifies the only available source rows as the choice-sequence prefix row, the finite window row, and the dyadic tolerance row.

The regular readback is therefore forced through those rows. A $\mathsf{RegSeqRat}^{\uparrow}$ consumer may read R only after the displayed prefix window and tolerance ledger have been consumed, so the route cannot replace the prefix data by a selected infinite branch or a quotient stream representative.

The real seal remains terminal. Row E is consumed only after Q, W, D, R, and any spread-indexed comparison uses S as a displayed compatibility row beside the Cauchy-real or regular-Cauchy spread siblings.

The structural rows preserve the same route under transport and replay. Since H, C, P, N add no selector, quotient, countable-choice schedule, trichotomy decision, host equality, or completeness principle, every downstream read is confined to the stated handoff. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$ read exposes ChoiceSequence prefix rows, StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, RealUp seal, CauchyRealSpread or RegularCauchySpread comparison, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any Real or Completion consumer receives the packet.

Independence witness: choice-sequence, streamname, dyadicratcore, regseqrat, real, cauchy-real-spread, regular-cauchy-spread: none is bijective with $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$ because this packet alone binds a Brouwer-style choice-sequence prefix source to the finite Cauchy tolerance, regular readback, terminal Real seal, and spread-compatible comparison route without a selected branch or quotient stream.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$ packet is generated from ChoiceSequence prefix rows, StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, RealUp seal rows, CauchyRealSpread or RegularCauchySpread comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyChoiceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6370.1, Definition 6370.2, and Definition 6370.3 seed the finite choice-sequence Cauchy route over $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealSpread}^{\uparrow}$, and $\mathsf{RegularCauchySpread}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyChoiceSequence}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.BishopCauchyChoiceSequenceUp`

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, selected Cauchy representatives, quotient stream equality, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-window scheduling, dyadic tolerance exactness, regular readback, RealUp seal nonescape, spread comparison, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyChoiceSequenceUp.

Chapter 6371

A Concrete Naming Certificate for $\mathsf{CauchyModulusDiagonal}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy reals and diagonal arguments for countable families, the $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ packet records the finite schedule that turns a displayed family of Cauchy-modulus requests into one diagonal tail witness. It sits over the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational sequence rows of chapter 301, the terminal Real seal rows of chapter 38, and the modulus algebra surface of chapter 6362. The packet names a local diagonal route for completion-facing consumers; it does not select a global real representative, identify quotient real names, or assert a completed real-line choice principle.

Definition 6371.1 (CauchyModulusDiagonal carrier)**.** *A* $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, S, Q, E, M, T, W, H, C, P, N)$$

with the following displayed rows:

1. *F is a finite family row of* $\mathsf{RegSeqRat}^{\uparrow}$ *names whose members expose regular rational readback only through named windows;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule assigning the finite input windows inspected for each family member and each requested dyadic tolerance;*
3. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic scales consumed by the diagonal comparison;*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed regular readback and dyadic tolerance rows have been replayed;*
5. *M is the family of accepted* $\mathsf{CauchyModulus}^{\uparrow}$ *rows controlling the ordinary tail windows for the displayed regular rational names;*
6. *T is the diagonal threshold row. Given a finite tolerance request and a finite family window, it records one displayed tail index large enough for every modulus row visible in that family window;*
7. *W is the diagonal tail-witness row, storing the finite comparison traces showing that all scheduled members remain within the requested dyadic tolerance after the threshold named by T;*

8. *H records componentwise* hsame *transport for F, S, Q, E, M, T, W and for the replay, provenance, and local naming rows;*
9. *C records displayed* Cont *replay from a requested diagonal tail comparison through S, then through F, Q, M, T, W, and only then into the Real-facing seal row E;*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusDiagonal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusDiagonal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a chosen infinite tail, equality of completed Real names, countable choice over all precision requests, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6371.2 (CauchyModulusDiagonal tail witness)**.** *Let*

$$D = (F, S, Q, E, M, T, W, H, C, P, N)$$

be an accepted $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ *carrier. Every diagonal tail read exported by D factors through the finite route*

$$S, F, Q, M \longmapsto T \longmapsto W \longmapsto E.$$

Thus the witness for a requested dyadic tolerance is a displayed threshold over the scheduled finite family window, read from the existing Cauchy-modulus rows and dyadic tolerance ledger before any $\mathsf{Real}^{\uparrow}$ *seal can be consumed.*

Proof. Project the accepted carrier of Definition 6371.1. The stream schedule S fixes the finite family window and the inspected regular rational windows in F before the dyadic tolerance row Q or any modulus row in M is read.

The threshold row T is downstream of those displayed rows. It records a single finite tail index that dominates the visible modulus thresholds for the requested dyadic tolerance, so the row is a finite maximum over displayed certificate entries rather than a choice over completed sequences.

The witness row W then replays the tail comparisons after that threshold and hands the result to the seal row E. Transport by H, replay by C, provenance by P, and local naming by N preserve the same route, so no consumer can bypass the scheduled family, dyadic tolerance, or Cauchy-modulus coordinates. □

Theorem 6371.3 (CauchyModulusDiagonal NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ *carrier*

$$D = (F, S, Q, E, M, T, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusDiagonal}^{\uparrow}}$ *surface consists exactly of carrier admission for D, regular rational family exposure through F, scheduled window exposure through S, dyadic tolerance exposure through Q, Real seal exposure through E, Cauchy-modulus exposure through M, diagonal threshold exposure through T, tail-witness exposure through W, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Consequently a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion-facing consumer may use the diagonal only after reading the displayed finite family schedule, dyadic tolerance ledger, modulus rows, diagonal threshold, and tail witness. The certificate does not claim completed-stream equality, quotient real equality, countable choice, or ambient completeness.*

Proof. Carrier admission lists exactly the rows $F, S, Q, E, M, T, W, H, C, P, N$. The analytic rows expose the regular rational family, finite stream schedule, dyadic tolerance request, Cauchy-modulus thresholds, diagonal threshold, tail-witness comparisons, and terminal Real-facing seal.

The structural rows do not add analytic content. Componentwise hsame transport keeps the same carrier coordinates, displayed Cont replay preserves the order of reads, Pkg provenance records the dependency ledger, and the local NameCert row names precisely this finite surface.

Apply Definition 6371.2. Any completion-facing read must pass through the finite diagonal route before it reaches a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer. Since the carrier has no coordinate for completed-stream equality, quotient real equality, choice over all requests, or ambient completeness, none of those claims belongs to the local obligation surface. □

Falsifiable prediction: A consumer that claims $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ tail control while omitting the regular rational family row, StreamName schedule, dyadic tolerance ledger, CauchyModulus rows, diagonal threshold, tail witness, hsame transport, Cont replay, Pkg provenance, or NameCert row refutes the carrier of Definition 6371.1.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-modulus-algebra: $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ binds a finite family schedule, dyadic tolerance ledger, existing CauchyModulus rows, one diagonal threshold, and a tail-witness route in one local NameCert packet; each named sibling lacks at least one of these diagonal-tail coordinates as a local carrier field.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ packet is generated from a regular rational family, StreamName schedule, dyadic tolerance ledger, Real seal row, CauchyModulus rows, diagonal threshold, tail witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6371.1, Definition 6371.2, and Definition 6371.3 seed the finite diagonal modulus packet for scheduled regular Cauchy families.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed-stream equality, quotient real equality, selected global real representatives, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, diagonal threshold replay, tail-witness replay, Real seal handoff, and a Lean realization for BEDC.Derived.CauchyModulusDiagonalUp.

Chapter 6372

A Concrete Naming Certificate for $\mathsf{TeichmullerSpace}^{\uparrow}$

Following Teichmuller and Ahlfors-Bers, the $\mathsf{TeichmullerSpace}^{\uparrow}$ packet records a finite moduli-facing NameCert surface for marked conformal structures on a displayed surface. It sits after the charted carrier of chapter 96, the complex-structure rows of chapter 39, the metric-read surface of chapter 3474, and the structural hsame, Cont, Pkg, and NameCert anchors used throughout the concrete-instance corpus. The packet names the finite marking, complex-row, hyperbolic-metric, deformation-ledger, transport, replay, provenance, and local naming data; it does not complete analytic moduli, identify quotient surfaces by host equality, or choose representatives of equivalence classes.

Definition 6372.1 (Teichmuller space carrier)**.** *A* $\mathsf{TeichmullerSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, M, J, G, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the underlying oriented surface row, read through the* $\mathsf{Manifold}^{\uparrow}$ *chart and incidence carrier.*
2. *M is the marking row: a finite boundary, generator, or triangulation comparison that records how the named surface is related to the reference surface.*
3. *J is the* $\mathsf{Complex}^{\uparrow}$ *row carrying the displayed conformal or complex-chart compatibility data.*
4. *G is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row when the finite surface window carries the negative-curvature metric read used by the moduli route.*
5. *D is the deformation ledger. It records displayed Beltrami, quasiconformal, or chart-transition evidence only as finite witness rows attached to S, M, J, G.*
6. *E is the equivalence-facing classifier row. It compares accepted packets by componentwise agreement of the surface, marking, complex row, metric row, and deformation ledger through* hsame*, not by host quotient equality of surfaces.*
7. *H records componentwise* hsame *transport for the surface, marking, complex, hyperbolic-metric, deformation, classifier, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from marked surface data through complex and hyperbolic metric reads to the deformation classifier.*

9. *P is the* Pkg *provenance over* $\mathsf{TeichmullerSpace}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{TeichmullerSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, J, G, D, E, H, C, P, N$. It has no coordinate for analytic moduli completion, quotient surface equality, selected representatives, universal curves, measurable Beltrami class equality, or host Teichmuller metric completion.

Theorem 6372.2 (Teichmuller space NameCert obligations)**.** *For every accepted* $\mathsf{TeichmullerSpace}^{\uparrow}$ *carrier $T = (S, M, J, G, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TeichmullerSpace}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the marked manifold row; complex-structure exposure; hyperbolic-metric readback when present; deformation-ledger admission; equivalence-facing classifier stability through* hsame*; displayed* Cont *replay of the marked complex route;* Pkg *provenance over the sibling certificates; and local naming by N.*

Every consumer of the packet must therefore read the route

$$\mathsf{Manifold}^{\uparrow},\quad \mathsf{Complex}^{\uparrow},\quad \mathsf{HyperbolicMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}$$

through $S, M, J, G, D, E, H, C, P, N$, and no consumer receives analytic moduli completion, quotient surface equality, or choice-selected representatives.

Proof. Project the carrier of Definition 6372.1. The surface row S, marking row M, complex row J, hyperbolic metric row G, deformation ledger D, and classifier row E are displayed before the local naming row is consumed.

The moduli-facing comparison is the row E. It is transported only by H and replayed only by C, so equality-sensitive movement is componentwise over the same finite surface, marking, complex, metric, and deformation rows.

The provenance row P names only the cited sibling packets and N names only the local $\mathsf{TeichmullerSpace}^{\uparrow}$ carrier. Since no excluded analytic or quotient coordinate appears in the carrier, the listed rows exhaust the NameCert obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{TeichmullerSpace}^{\uparrow}$ packet displays a ManifoldUp surface row, marking row, ComplexUp conformal row, HyperbolicMetricUp read when present, deformation ledger, classifier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before a moduli-facing consumer reads it.

Independence witness: manifold, complex, hyperbolicmetric: $\mathsf{TeichmullerSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a marked surface row, complex-structure row, hyperbolic-metric read, deformation ledger, classifier transport, replay, provenance, and local naming in one finite moduli packet.

Closure status for $\mathsf{NameCert}_{\mathsf{TeichmullerSpace}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TeichmullerSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6372.1 and Definition 6372.2 seed the finite Teichmuller-space NameCert surface over marked manifold, complex, hyperbolic-metric, deformation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TeichmullerSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: Analytic moduli completion, quotient surface equality, choice-selected representatives, universal curves, measurable Beltrami class equality, host Teichmuller metric completion, Lean verification, and bridge checking are not claimed.

Upgrade path: Obligation closure requires checked carrier admission, marked-surface classifier stability, complex and hyperbolic metric readback, deformation-ledger exactness, transport, replay, provenance, and local NameCert rows for BEDC.Derived.TeichmullerSpaceUp.

Constructive story: A TeichmullerSpace$^{\uparrow}$ packet is generated from a ManifoldUp surface row, a marking row, ComplexUp conformal data, a HyperbolicMetricUp read when present, a finite deformation ledger, classifier transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6373

A Concrete Naming Certificate for $\mathsf{ClosedObserverAuditTrace}^{\uparrow}$

The $\mathsf{ClosedObserverAuditTrace}^{\uparrow}$ packet realizes the closed observational system and finite verification trace interface of chapter 9393 as finite NameCert data. It sits after the closed-observation rows of chapter 616, the finite trace socket of chapter 4149, the GAP-facing routes of chapter 504, and the structural BHist, hsame, Cont, Pkg, and NameCert anchors. The packet names observable records, monotone trace growth, GAP socket exposure, replay, provenance, and local naming without making a substrate-internal universal quantifier available.

Definition 6373.1 (Closed observer audit trace carrier)**.** *A* $\mathsf{ClosedObserverAuditTrace}^{\uparrow}$ *carrier is a finite packet*

$$A = (O, R, T, G, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the closed observer row: the current observation state and its finite* Obs *records as read from the closed observational system surface.*
2. *R is the record ledger. It lists the finite witness records admitted by closed-generation reasoning before the current audit trace is read.*
3. *T is the monotone trace row. It records that later audit states preserve earlier records and append only displayed finite observations.*
4. *G is the GAP socket row. It tags the unfulfilled promise that cannot be discharged from the finite records, especially any universal or induction-facing claim.*
5. *L is the replay ledger. It stores the finite sequence of record reads, preservation checks, and GAP handoffs that a consumer may audit.*
6. *H records componentwise* hsame *transport for the observer state, record ledger, monotone trace, GAP socket, replay ledger, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from finite observations through monotone preservation, GAP exposure, audit replay, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{ClosedObserverAuditTrace}^{\uparrow}$, $\mathsf{ClosedObservationSystem}^{\uparrow}$, FiniteObservationTraceFilter $\mathsf{FiniteTraceGapSocket}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedObserverAuditTrace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, R, T, G, L, H, C, P, N$. It has no coordinate for substrate-internal induction, a completed universal quantifier, external oracle content, erased observations, altered earlier records, or choice-selected future witnesses.

Theorem 6373.2 (Closed observer audit trace NameCert obligations)**.** *For every accepted* ClosedObserverAuditTrac *carrier $A = (O, R, T, G, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedObserverAuditTrace}^{\uparrow}}$ *surface consists exactly of observer-row admission; finite record-ledger admission; monotone trace preservation; GAP socket exposure; replay-ledger exactness; componentwise* hsame *transport; displayed* Cont *replay;* Pkg *provenance over the closed-observation and finite-trace siblings; and local naming by N.*

Thus a consumer reads finite Obs *records, monotone trace rows, GAP socket rows, replay rows, provenance, and local NameCert rows, but receives no substrate-internal universal quantifier, no induction rule, no external oracle content, no erased-history operation, and no selected future witness.*

Proof. Project the carrier of Definition 6373.1. The observer row O, finite record ledger R, monotone trace row T, GAP socket G, and replay ledger L are the complete audit data.

Monotonicity is read from T. It states preservation of earlier records and addition of only displayed later records, so no audit step can delete or rewrite R.

The GAP row G records claims not discharged by the finite trace. The replay row L exposes how the consumer reaches that socket, while H and C move and replay the same rows componentwise.

Finally P and N source and name the packet. Since the carrier contains no coordinate for internal induction, completed universals, oracle content, erased observations, or selected future witnesses, the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{ClosedObserverAuditTrace}^{\uparrow}$ packet displays finite Obs records, a monotone trace row, a GAP socket, replay ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data before any closed-observer audit consumer can read the trace.

Independence witness: closedobservationsystem, finite-observation-trace-filter, finite-trace-gap-socket: $\mathsf{ClosedObserverAuditTrace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries observer records, monotone preservation, GAP exposure, replay, transport, provenance, and local naming as one finite audit packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedObserverAuditTrace}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosedObserverAuditTrace}^{\uparrow}}$, seed)

Scope closed: Definition 6373.1 and Definition 6373.2 seed the finite closed-observer audit route over Obs records, monotone trace rows, GAP sockets, replay, transport, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosedObserverAuditTrace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: Substrate-internal induction, completed universal quantification, external oracle content, erased observations, altered earlier records, selected future witnesses, Lean verification, and bridge checking are not claimed.

Upgrade path: Obligation closure requires checked observer-row admission, finite record-ledger exactness, monotone trace preservation, GAP socket exposure, replay exactness, transport, provenance, and local NameCert rows for BEDC.Derived.ClosedObserverAuditTraceUp.

Constructive story: A $\mathsf{ClosedObserverAuditTrace}^{\uparrow}$ packet is generated from finite Obs records, a monotone trace row, a GAP socket, replay ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6374

A Concrete Naming Certificate for $\mathsf{FiniteDiniModulus}^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the $\mathsf{FiniteDiniModulus}^{\uparrow}$ packet records the finite NameCert route from compact finite-net data and monotone pointwise descent to one uniform modulus row over $\mathsf{Real}^{\uparrow}$. It consumes the compact finite-net surface of chapter 4760, the monotone Dini route of chapter 4213, the continuous-map graph rows of chapter 130, the dyadic tolerance ledger of chapter 291, the finite minimum-budget handoff of chapter 5816, and the terminal real-name seal of chapter 38. The chapter names only the finite compact-window modulus route; it does not import arbitrary open-cover compactness, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6374.1 (Finite Dini modulus carrier)**.** *A* $\mathsf{FiniteDiniModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, G, E, R, T, B, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row, exposing the inspected net centers, radius witnesses, and the finite cover ledger consumed by the modulus extraction.*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the monotone family and the displayed limit row over the same compact source.*
3. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for every function value, limit value, and comparison value read by the packet.*
4. *R is the monotone pointwise descent row, recording the displayed order comparisons and pointwise tail windows used at the finite net centers.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing the requested tolerance, comparison slack, and finite dyadic descent used by the route.*
6. *B is the finite minimum-budget row, extracting one displayed index budget from the centerwise Dini comparisons before the uniform-modulus export is available.*
7. *H records componentwise* hsame *transport for the compact net, graph, real seal, monotone descent, tolerance, budget, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact finite-net request through K, G, E, R, T, B, H to the exported modulus route.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteDiniModulus}^{\uparrow}$, $\mathsf{CompactUniformFiniteNet}^{\uparrow}$, $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDiniModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, G, E, R, T, B, H, C, P, N$. It has no coordinate for arbitrary open covers, selected finite subcovers, quotient real equality, hidden limiting values, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6374.2 (Finite Dini modulus obligations)**.** *For every accepted* $\mathsf{FiniteDiniModulus}^{\uparrow}$ *carrier*

$$M = (K, G, E, R, T, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDiniModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *expose the compact finite-net row K before any modulus consumer reads a centerwise comparison;*
2. *display the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row G and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E before any function-value comparison is used;*
3. *route monotone pointwise descent through R and dyadic tolerance descent through T;*
4. *extract the uniform index budget only through the finite minimum-budget row B;*
5. *preserve the same route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
6. *source and name the packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row states arbitrary open-cover compactness, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6374.1. The compact data are exactly the finite net centers and radius witnesses in K, so a modulus consumer cannot inspect an arbitrary open cover or a selected subcover.

Next read the analytic rows. The graph row G supplies the displayed $\mathsf{ContinuousMap}^{\uparrow}$ family and limit graph, while E is the only $\mathsf{Real}^{\uparrow}$ seal for the values compared by the packet.

The Dini part is split into visible finite rows. Monotone pointwise descent is recorded in R, and the requested tolerance plus slack comparisons are recorded in the dyadic row T.

The exported budget is downstream of those rows. The finite minimum-budget row B folds the centerwise comparisons into one displayed index budget, and H, C, P, N transport, replay, source, and name the same packet. Since no excluded coordinate occurs in the carrier, the local obligation surface is exhausted by the listed rows. □

Theorem 6374.3 (Finite Dini uniform modulus route)**.** *Every uniform-modulus consumer of an accepted* $\mathsf{FiniteDiniModulus}^{\uparrow}$ *carrier must factor through the displayed route*

$$\mathsf{CompactUniformFiniteNet}^{\uparrow},\ \mathsf{DiniMonotoneCompactUniform}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{DiniFiniteMi}$$

Thus the packet exports a uniform modulus route for compact finite-net and monotone pointwise-descent data. It does not claim arbitrary open-cover compactness, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the accepted carrier. The finite source row K names the compact net inspected by the route, and the graph plus real-seal rows G, E name the continuous-map values and limit values that can be compared.

Apply Definition 6374.2. The monotone descent row R, dyadic tolerance row T, and finite minimum-budget row B are the only rows from which a uniform index budget can be read.

The structural rows then keep the consumer on the same packet. Componentwise transport in H and replay in C preserve the displayed dependency order, while P, N provide provenance and local naming. Because the carrier has no field for arbitrary open covers, quotient real equality, selected limits, countable choice, or ambient completeness, the exported object is exactly the finite uniform-modulus route. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDiniModulus}^{\uparrow}$ uniform-modulus read first exposes compact finite-net rows, ContinuousMap graph rows, RealUp seals, monotone pointwise descent, DyadicRatCore tolerance cells, a finite minimum budget, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: compact-uniform-finite-net, dini-monotone-compact-uniform, continuousmap, real, dyadicratcore, dini-finite-minimum-budget: $\mathsf{FiniteDiniModulus}^{\uparrow}$ is not bijective to any listed sibling because it binds finite compact-net Dini descent to one uniform-modulus budget route at the RealUp seal.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDiniModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDiniModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6374.1, Definition 6374.2, and Definition 6374.3 seed the finite compact-net Dini modulus route over ContinuousMap, Real, DyadicRatCore, finite budget, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDiniModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, quotient real equality, selected limits, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, ContinuousMap graph visibility, Real seal nonescape, monotone pointwise descent, dyadic tolerance exactness, finite budget extraction, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDiniModulusUp.

Constructive story: A $\mathsf{FiniteDiniModulus}^{\uparrow}$ packet is generated from compact finite-net rows, ContinuousMap graph rows, RealUp seal rows, monotone pointwise descent, DyadicRatCore tolerance rows, a finite minimum-budget row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6375

A Concrete Naming Certificate for $\mathsf{CompactRealUniformModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactRealUniformModulus}^{\uparrow}$ packet records the finite uniform-modulus surface available from compact real data when the compactness evidence is already displayed as metric and finite-net information. It reads metric real distances through chapter 1638, uniform control through chapter 369, compact metric finite data through chapter 129, finite observations through chapter 126, rational readback through chapter 301, and terminal real names through chapter 38. The packet names an L10 adjacent finite-modulus route over compact real sources; it is not an open-cover compactness theorem, a choice-selected finite subcover, quotient real equality, or ambient completeness principle.

Definition 6375.1 (Compact real uniform modulus carrier)**.** *A* $\mathsf{CompactRealUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (R, M, U, K, W, A, S, T, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source row, carrying the real names whose finite compact real data are being read.*
2. *M is the* $\mathsf{RealMetric}^{\uparrow}$ *row, recording the metric distance comparison surface used by the compact real request.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row, exposing the dyadic tolerance budget and response modulus.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row, read only as finite compact metric data for the displayed real source.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the compact real observations requested by R, M, K.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same displayed windows and tolerance budget.*
7. *S is the target* $\mathsf{Real}^{\uparrow}$ *seal row reached after metric comparison, compact metric data, finite windows, readback, and uniform-modulus control have all been displayed.*
8. *T records componentwise* hsame *transport for R, M, U, K, W, A, S.*
9. *C records displayed* Cont *replay through the finite route*

$$R, M, K \longmapsto W, A, U \longmapsto S, T, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{CompactRealUniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $R, M, U, K, W, A, S, T, C, P, N$. It has no coordinate for open-cover compactness, countable choice, selected subcovers, quotient real equality, host real representatives, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.CompactRealUniformModulusUp.CompactRealUniformModulusTasteGate single carrier alignment`

Theorem 6375.2 (Compact real uniform modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealUniformModulus}^{\uparrow}$ *carrier $Q = (R, M, U, K, W, A, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactRealUniformModu}}$ *surface consists exactly of real-source admission, real-metric comparison admission, compact-metric finite-data admission, finite StreamName window exposure, RegSeqRat readback, uniform-modulus tolerance exactness, target Real seal admission, componentwise transport, displayed replay, provenance, and local naming for the same displayed rows.*

Proof. Project the carrier of Definition 6375.1. The projection exposes the real source, real metric, uniform modulus, compact metric, finite windows, rational readback, target seal, and structural rows.

The compact real obligations are upstream of every modulus read. A consumer must first display R, M, K before it can open finite windows W or consume the readback row A.

The uniform-modulus row U then binds all accepted compact real observations to the same dyadic tolerance budget. The seal S is downstream of those rows, while T, C, P, N transport, replay, source, and name the same finite packet.

Since the carrier has no coordinate for open covers, selected subcovers, quotient equality, countable choice, host real representatives, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6375.3 (Compact real uniform modulus finite-net extraction)**.** *Every finite-net extraction from an accepted* $\mathsf{CompactRealUniformModulus}^{\uparrow}$ *carrier factors through*

$$R, M, K \longmapsto W, A, U.$$

The compact metric row K may hand off only the displayed compact real source to finite StreamName windows, RegSeqRat readback, and the exposed uniform-modulus row. It does not export open-cover compactness, a choice-selected subcover, quotient syntax equality for reals, or ambient Real completeness.

Proof. Start from the carrier projection. The extraction request has no source other than the displayed real source, real-metric comparison, and compact-metric finite-data rows R, M, K.

The finite windows W and rational readback A are read at the tolerance governed by U. Thus the extraction is a local finite route through displayed compact real data and the visible uniform-modulus row.

The structural rows preserve the same route. Because no row stores an open cover, selected subcover, quotient equality proof, choice schedule, or ambient completeness witness, the extraction cannot be read as any of the excluded principles. □

Falsifiable prediction: Every $\mathsf{CompactRealUniformModulus}^{\uparrow}$ read that exports a uniform-modulus or finite-net result without first exposing real source data, RealMetric comparison, CompactMetric finite data, StreamName windows, RegSeqRat readback, target Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert is outside the carrier surface.

Independence witness: Nearest siblings: real, real-metric, uniform-modulus, compact-metric, streamname, and regseqrat. $\mathsf{CompactRealUniformModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact real source data, metric comparison, finite compact metric evidence, finite windows, rational readback, uniform-modulus control, target Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealUniformModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRealUniformModulus}^{\uparrow}$ packet is generated from Real source rows, RealMetric comparison rows, a UniformModulus row, CompactMetric finite data, StreamName finite windows, RegSeqRat readback, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6375.1, Definition 6375.2, and Definition 6375.3 seed the finite compact real uniform-modulus route over metric comparison, compact finite data, windows, readback, seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, selected finite subcovers, quotient real equality, host real representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, RealMetric comparison exactness, UniformModulus tolerance exactness, CompactMetric finite-data admission, StreamName window replay, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactRealUniformModulusUp.

Chapter 6376

A Concrete Naming Certificate for $\mathsf{WeylCriterion}^{\uparrow}$

Following Weyl and Kuipers–Niederreiter, the $\mathsf{WeylCriterion}^{\uparrow}$ packet records the finite BEDC surface of the Weyl equidistribution criterion. A sequence in the circle is inspected through finite exponential-sum windows: rational frequency rows, complex phase rows, unit-circle seal rows, finite stream-name schedules, regular rational readback, dyadic tolerance budgets, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows. The packet sits after the natural-number index surface of chapter 28, the complex arithmetic surface of chapter 39, the circle carrier of chapter 58, finite schedules from chapter 126, rational readback from chapter 301, dyadic tolerance arithmetic from chapter 291, and terminal real seals from chapter 38. It names a finite certificate route for equidistribution, not a host integral, countable choice over frequencies, quotient equality of circle points, or ambient Fourier analysis.

Definition 6376.1 (Weyl criterion carrier)**.** *A* $\mathsf{WeylCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (I, F, Z, U, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Nat}^{\uparrow}$ *index-window row naming the finite initial segment being averaged.*
2. *F is the finite nonzero integer-frequency row read through rational and natural-number code rows.*
3. *Z is the* $\mathsf{Complex}^{\uparrow}$ *exponential-phase row for the displayed frequency and circle sample.*
4. *U is the* $\mathsf{S}^{1\uparrow}$ *unit-circle sample row whose points are inspected only through the displayed finite schedule.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row exposing the finite sample windows consumed by the average.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row for the real and imaginary parts of the displayed averages.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row used to compare the finite averages with zero.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row recording the equidistribution-facing zero-limit boundary visible to the packet.*
9. *H records componentwise* hsame *transport for I, F, Z, U, S, R, D, E.*

10. *C records displayed* Cont *replay through the finite route*

$$I, F, U, S \longmapsto Z, R, D \longmapsto E, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{WeylCriterion}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{WeylCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $I, F, Z, U, S, R, D, E, H, C, P, N$. It has no coordinate for a host integral, a completed infinite average, selected limiting subsequences, quotient equality of circle points, or an unrestricted Fourier basis.

Theorem 6376.2 (Weyl criterion NameCert obligations)**.** *For every accepted* $\mathsf{WeylCriterion}^{\uparrow}$ *carrier $W = (I, F, Z, U, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeylCriterion}^{\uparrow}}$ *surface consists exactly of index-window admission, nonzero frequency admission, complex phase admission, unit-circle sample admission, finite schedule exposure, regular rational readback, dyadic tolerance comparison, terminal Real seal admission, componentwise transport, displayed replay, provenance, and local naming for the same displayed rows.*

Proof. Project the carrier of Definition 6376.1. The projection exposes the finite index window, frequency row, circle sample, finite schedule, complex phase, rational readback, dyadic tolerance, terminal seal, and structural rows.

The average can be consumed only after the index and schedule rows have been displayed. The frequency and circle rows then determine the complex phase row, while the rational readback and dyadic tolerance rows expose the finite zero-comparison data visible to the packet.

The terminal Real seal records only the boundary reached through these finite rows. Componentwise transport, replay, provenance, and local naming preserve the same route. Since the carrier has no coordinate for host integrals, completed infinite averages, selected subsequences, quotient circle equality, or unrestricted Fourier analysis, the listed rows exhaust the local NameCert surface. □

Theorem 6376.3 (Weyl criterion equidistribution route)**.** *Every equidistribution-facing read from an accepted* $\mathsf{WeylCriterion}^{\uparrow}$ *carrier factors through*

$$I, F, U, S \longmapsto Z, R, D \longmapsto E.$$

Thus the consumer may read only finite exponential-sum windows, rational readback, dyadic zero-comparison budgets, and the terminal Real seal. It cannot extract a host integral, a choice-selected limiting frequency, quotient equality of circle points, or an ambient Fourier theorem.

Proof. Start with the displayed index, frequency, circle, and schedule rows. These rows are the only entries from which a finite exponential sum can be formed.

The complex phase row Z and the regular rational readback row R expose the finite average through rational real and imaginary coordinates. The dyadic tolerance row D then supplies the visible zero-comparison budget.

Finally the Real seal E is downstream of those finite rows, and H, C, P, N transport, replay, source, and name the same packet. Because no row stores a host integral, a completed infinite average, a selected limiting subsequence, quotient circle equality, or an unrestricted Fourier basis, the factorization is exactly the stated finite BEDC route. □

Falsifiable prediction: Every $\mathsf{WeylCriterion}^{\uparrow}$ equidistribution read that exports a zero-limit or uniform-distribution conclusion without first exposing Nat index windows, nonzero frequency rows, Complex phase rows, SOne sample rows, StreamName schedules, RegSeqRat readback, DyadicRatCore tolerance comparison, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert is outside the carrier surface.

Independence witness: Nearest siblings: nat, complex, sone, streamname, regseqrat, dyadicratcore, and real. $\mathsf{WeylCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite index windows, nonzero frequencies, complex phase rows, unit-circle samples, finite schedules, rational readback, dyadic tolerance comparison, terminal Real sealing, transport, replay, provenance, and local naming as one equidistribution certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{WeylCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{WeylCriterion}^{\uparrow}$ packet is generated from Nat index-window rows, nonzero frequency rows, Complex exponential-phase rows, SOne sample rows, StreamName finite schedules, RegSeqRat rational readback, DyadicRatCore tolerance comparison, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeylCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6376.1, Definition 6376.2, and Definition 6376.3 seed the finite Weyl equidistribution certificate over index windows, frequencies, complex phases, circle samples, schedules, rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeylCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host integrals, unrestricted Fourier analysis, quotient equality of circle points, countable choice over frequencies, completed infinite averages, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, frequency nonzero admission, complex phase exactness, circle sample admission, schedule-window replay, rational readback, dyadic zero-comparison, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.WeylCriterionUp.

Chapter 6377

A Concrete Naming Certificate for $\mathsf{AsymptoticRegularity}^{\uparrow}$

Following Bruck and Reich on nonexpansive mappings and asymptotic regularity, the $\mathsf{AsymptoticRegularity}^{\uparrow}$ packet records orbit-displacement decay as finite NameCert data rather than as a host fixed-point theorem. It sits over the metric-distance surface of chapter 57, the regular rational readback of chapter 301, the Cauchy-modulus ledger of chapter 292, the terminal real-name seal of chapter 38, and the continuous-map route of chapter 130. The packet gives Completion and fixed-point-facing consumers a displayed orbit window before any $\mathsf{Real}^{\uparrow}$ seal is inspected.

Definition 6377.1 (Asymptotic regularity carrier)**.** *An* $\mathsf{AsymptoticRegularity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (O, D, M, E, S, T, H, C, P, N)$$

with the following displayed rows:

1. *O is the orbit-window row, naming the finite iterates and the source map row read by a* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer.*
2. *D is the displacement-metric row, recording the displayed* $\mathsf{Met}^{\uparrow}$ *distances between successive orbit entries.*
3. *M is the Cauchy-modulus row, giving the finite tolerance window through which the displacement sequence is read.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after O, D, M have been displayed.*
5. *S is the map-stability row, recording the nonexpansive or continuity budget used to keep the displayed orbit inside the same metric source.*
6. *T is the transport row binding orbit windows, metric displacements, modulus reads, Real seals, and map-stability data under componentwise* hsame*.*
7. *H records the completion-facing handoff from regular Cauchy readback to the displayed orbit-displacement row.*
8. *C records displayed* Cont *replay through O, D, M, E, S, T, H.*
9. *P is the* Pkg *provenance over* $\mathsf{AsymptoticRegularity}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AsymptoticRegularity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, D, M, E, S, T, H, C, P, N$.

Theorem 6377.2 (Asymptotic regularity NameCert obligations)**.** *For every accepted* $\mathsf{AsymptoticRegularity}^{\uparrow}$ *carrier $A = (O, D, M, E, S, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AsymptoticRegularity}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission through the displayed orbit window O, displacement-metric row D, Cauchy-modulus row M, terminal seal E, map-stability row S, transport row T, handoff row H, replay row C, provenance row P, and local naming row N;*
2. *metric displacement visibility, requiring every orbit-decay read to expose the* $\mathsf{Met}^{\uparrow}$ *distance row D before it can be consumed as a real-valued displacement claim;*
3. *Cauchy-modulus routing, requiring M to give the finite tolerance window through which the displacement sequence is inspected before E is opened;*
4. *map-stability preservation, requiring S, T, C to keep the orbit entries and displacement rows inside the same displayed map and metric source;*
5. *seal non-escape, requiring E, P, N to export no host fixed-point theorem, ambient completeness, quotient orbit equality, selected limit, countable choice, or bridge-checking evidence.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6377.1. Carrier admission lists every row available to a consumer, so the orbit window, metric displacement, modulus, seal, stability, transport, handoff, replay, provenance, and local naming rows are the complete packet surface.

The analytic read begins with O and D. A displacement claim has no separate host metric coordinate; it is read only from the displayed $\mathsf{Met}^{\uparrow}$ row attached to the finite orbit window.

The tolerance step is M. It supplies the finite Cauchy window before the terminal Real seal E is opened, while S, T, C preserve the same map and orbit rows under stability, transport, and replay.

Finally P, N source and name only this route. Since the carrier contains no coordinate for a host fixed point, ambient completeness, quotient orbit equality, selected limit, choice principle, or bridge certificate, the five listed rows exhaust the obligation surface. □

Theorem 6377.3 (Asymptotic regularity Cauchy-orbit handoff)**.** *Every Completion or fixed-point-facing consumer of an accepted* $\mathsf{AsymptoticRegularity}^{\uparrow}$ *carrier must read the displayed orbit-window row O, metric displacement row D, and Cauchy-modulus row M before any terminal* $\mathsf{Real}^{\uparrow}$ *seal E is exposed. The handoff may use* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyModulus}^{\uparrow}$ *tolerance data, and* $\mathsf{ContinuousMap}^{\uparrow}$ *stability, but it exports no host fixed-point theorem, ambient completeness assertion, quotient orbit equality, selected orbit limit, countable-choice schedule, or bridge-checking row.*

Proof. Start from Definition 6377.2. The obligation surface forces carrier admission through $O, D, M, E, S, T, H, C, P, N$ and places the metric displacement and modulus rows before the terminal seal.

A Completion consumer therefore sees the regular Cauchy and modulus rows through the finite handoff H before reading E. A fixed-point-facing consumer sees the same orbit window and map-stability row S before any displacement-decay claim is consumed.

The structural rows T, C, P, N preserve the same displayed route. Because the carrier has no coordinate for fixed points, ambient completeness, quotient orbit equality, selected limits, countable choice, or bridge checking, none of those objects can be read from the handoff. □

Falsifiable prediction: Every accepted $\mathsf{AsymptoticRegularity}^{\uparrow}$ read exposes a finite orbit window, metric displacement row, Cauchy-modulus row, map-stability row, transport, handoff, replay, provenance, and local NameCert before a Real-facing displacement seal is consumed.

Independence witness: metric, regular-Cauchy, Cauchy-modulus, Real, continuous-map: $\mathsf{AsymptoticRegularity}^{\uparrow}$ is not bijective to any listed source because it binds orbit-displacement decay into a finite consumer route while preserving each source as a named sibling row.

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticRegularity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AsymptoticRegularity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6377.1, Definition 6377.2, and Definition 6377.3 seed the constructive orbit-displacement certificate over displayed metric, modulus, Real-seal, map-stability, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AsymptoticRegularity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point theorems, ambient completeness, quotient orbit equality, selected limits, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displacement-metric visibility, Cauchy-modulus routing, map-stability preservation, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.AsymptoticRegula

Constructive story: An $\mathsf{AsymptoticRegularity}^{\uparrow}$ packet is generated from a finite orbit window, displayed metric displacements, a Cauchy-modulus tolerance row, a terminal Real seal, a map-stability row, componentwise hsame transport, completion-facing handoff, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6378

A Concrete Naming Certificate for $\mathsf{PerronIntegral}^{\uparrow}$

Following Perron and the Bishop–Bridges constructive reading of integration, the $\mathsf{PerronIntegral}^{\uparrow}$ packet records an integral value through finite majorant and minorant envelopes before any real seal is exported. It sits beside the gauge-partition route of chapter 1999, the tagged-mesh row of chapter 1526, the upper/lower finite-sum boundary of chapter 1880, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite envelope interface for one displayed integrand window; it is not measure completion, quotient function equality, a selected primitive, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6378.1 (Perron integral carrier)**.** *A* $\mathsf{PerronIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (G, R, D, M, m, U, L, E, H, C, Q, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{GaugeIntegral}^{\uparrow}$ *source row, exposing only the finite gauge-partition request and its tagged subdivision boundary.*
2. *R is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *readback row over the same displayed interval and integrand window.*
3. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *comparison row, carrying finite upper and lower Darboux sums for the displayed partition data.*
4. *M is the finite majorant envelope row. Each entry records a displayed upper control function, its gauge or Riemann readback, and the regular rational upper value by which it bounds the integrand window.*
5. *m is the finite minorant envelope row. Each entry records a displayed lower control function, its gauge or Riemann readback, and the regular rational lower value by which it is bounded by the integrand window.*
6. *U and L are the* $\mathsf{RegSeqRat}^{\uparrow}$ *upper and lower value rows read from the majorant and minorant envelopes.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite upper and lower regular-rational envelopes have been displayed and compared.*
8. *H records componentwise* hsame *transport for gauge, Riemann, Darboux-sum, majorant, minorant, upper value, lower value, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from gauge and Riemann reads through Darboux upper/lower sums, then through the majorant/minorant envelopes, the regular-rational rows, and the terminal real seal.*
10. *Q is the* Pkg *provenance over* $\mathsf{PerronIntegral}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PerronIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for measure completion, quotient equality of functions, selected primitives, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.PerronIntegralUp.PerronIntegralTasteGate single carrier alignment`

Theorem 6378.2 (Perron integral NameCert obligations)**.** *For every accepted* $\mathsf{PerronIntegral}^{\uparrow}$ *carrier* $P = (G, R, D, M, m, U, L, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PerronIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission, gauge and Riemann source visibility, Darboux upper/lower finite-sum compatibility, majorant envelope exposure, minorant envelope exposure, regular-rational upper and lower value readback, terminal real-seal handoff, componentwise transport, displayed replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.PerronIntegralUp.PerronIntegralNamecertObligations`

Proof. Project the carrier of Definition 6378.1. The rows G, R, D make the gauge, Riemann, and Darboux-sum sources visible before any envelope value is read.

The majorant and minorant obligations are finite. The row M lists upper control windows and their regular-rational upper values, while m lists lower control windows and their regular-rational lower values. The rows U and L expose those values as $\mathsf{RegSeqRat}^{\uparrow}$ data before the real seal is available.

Finally E, H, C, Q, N seal, transport, replay, source, and name the same displayed packet. Since no carrier coordinate stores a measure space, quotient function equality, selected primitive, choice principle, or ambient real-completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6378.3 (Perron integral major/minor route)**.** *Every accepted* $\mathsf{PerronIntegral}^{\uparrow}$ *read that reaches a* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite route*

$$\mathsf{GaugeIntegral}^{\uparrow}, \quad \mathsf{RiemannIntegral}^{\uparrow}, \quad \mathsf{DarbouxSum}^{\uparrow}, \quad M, \quad m, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Thus the Perron value is exposed only as a displayed upper/lower envelope comparison over gauge, Riemann, Darboux-sum, regular-rational, transport, replay, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.PerronIntegralUp.PerronIntegralMajorMinorRoute`

Proof. Start with a consumer read of the terminal seal E. By Definition 6378.1, E is downstream of the gauge row G, the Riemann readback R, the Darboux-sum comparison D, and the majorant/minorant envelope rows M, m.

The regular-rational boundary is then forced by U and L. The upper and lower values are not independent real numbers; they are read from the displayed envelope rows and compared only after the finite gauge, Riemann, and Darboux data have been opened.

Componentwise transport through H and replay through C preserve the same order, while Q and N name no additional analytic source. Hence every real-facing Perron read factors through the stated finite major/minor envelope route. □

Falsifiable prediction: A purported $\mathsf{PerronIntegral}^{\uparrow}$ consumer that exports a real-valued integral while omitting the gauge source, Riemann readback, Darboux-sum comparison, majorant envelope, minorant envelope, regular-rational upper and lower rows, terminal real seal, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: gauge-integral, riemannintegral, darboux-sum, regseqrat, real: $\mathsf{PerronIntegral}^{\uparrow}$ is not bijective with any listed sibling because it joins majorant and minorant envelope rows to the gauge, Riemann, Darboux-sum, regular-rational, and real-seal route as one named packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PerronIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{PerronIntegral}^{\uparrow}$ packet is generated from gauge and Riemann source rows, a Darboux upper/lower finite-sum comparison row, finite majorant and minorant envelope rows, upper and lower RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PerronIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6378.1, Definition 6378.2, and Definition 6378.3 seed the finite Perron major/minor envelope route over $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PerronIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure integration, quotient equality of functions, selected primitives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gauge and Riemann source visibility, Darboux-sum compatibility, majorant and minorant envelope exactness, regular-rational readback, real-seal non-escape, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.PerronIntegralUp.

Chapter 6379

A Concrete Naming Certificate for $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completion, the $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$ packet records a rate-bearing completion route for regular rational names as finite BEDC data. It sits after the dyadic tolerance core of chapter 291, the finite stream naming surface of chapter 126, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Bishop regular completion route of chapter 1639. The packet names rates, windows, tolerances, readbacks, and Real-facing seals by displayed rows only; it does not quotient regular sequences, select limits, invoke countable choice, import host real equality, or assume ambient completeness.

Definition 6379.1 (Bishop Cauchy rate completion carrier)**.** *A* $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, D, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected rational stream windows.*
2. *M is the Bishop rate row, recording the displayed modulus request by which later windows are compared with earlier windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same rate request and window family.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback obtained from S, M, D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the stream windows, rate row, dyadic tolerance ledger, and regular-rational readback are displayed.*
6. *B is the Bishop regular Cauchy completion row read from chapter 1639; it records that the rate-bearing readback is a completion-facing regular Cauchy name rather than a host limit.*
7. *H records componentwise* hsame *transport for S, M, D, R, E, B and the local naming row.*
8. *C records displayed* Cont *replay from stream windows through rate requests, dyadic tolerances, regular-rational readback, Bishop completion handoff, terminal Real seal, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyRateCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, M, D, R, E, B, H, C, P, N$. It has no coordinate for quotient stream equality, a selected representative, a chosen limit, countable choice, host real equality, or ambient Real completeness.

Theorem 6379.2 (Bishop Cauchy rate completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$ *carrier*

$$K = (S, M, D, R, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyRateCompletion}^{\uparrow}}$ *surface consists exactly of finite-window exposure through S, rate exposure through M, dyadic tolerance exposure through D, regular-rational readback through R, terminal Real seal exposure through E, Bishop regular completion handoff through B, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6379.1. Its content rows are the finite stream window, rate, dyadic tolerance, regular-rational readback, terminal Real seal, and Bishop completion handoff.

Read the L10 dependency route in order. The $\mathsf{StreamName}^{\uparrow}$ row S exposes the finite observations, M fixes the rate request against those observations, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row D supplies the tolerance ledger used by that rate request.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is downstream of S, M, D, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of R. The Bishop regular completion row B names the completion-facing handoff of the same route, so it cannot replace the displayed windows, rates, tolerances, or readback by a selected limit.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate remains outside $S, M, D, R, E, B, H, C, P, N$, the listed rows exhaust the local NameCert obligations. □

Theorem 6379.3 (Bishop Cauchy rate regular readback)**.** *Every accepted* $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$ *consumer that reads a terminal* $\mathsf{Real}^{\uparrow}$ *seal from the packet must first read the same finite route*

$$\mathsf{StreamName}^{\uparrow}(S), \quad \mathsf{DyadicRatCore}^{\uparrow}(D), \quad \mathsf{RegSeqRat}^{\uparrow}(R)$$

under the displayed Bishop rate row M and the Bishop regular completion handoff B. The route exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness coordinate.

Proof. Start with Definition 6379.2. It places the Real seal E after the stream window S, rate row M, dyadic tolerance row D, regular-rational readback R, and Bishop completion handoff B.

The regular readback is fixed by the displayed window and tolerance route. A consumer therefore cannot read R as an abstract quotient class or choose a representative outside S, M, D; the row R is the named regular-rational readback of those finite observations.

The Real-facing seal is also downstream from the same route. The row E is reachable only after R and B have been exposed, and the structural rows H, C, P, N preserve that ordering. Hence every accepted Real-facing read factors through the displayed rate-completion packet rather than through selected limits, host equality, choice, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$ packet is refuted if a Real-facing completion read reaches the terminal seal without displaying the StreamName window,

Bishop rate row, DyadicRatCore tolerance ledger, RegSeqRat readback, Bishop regular completion handoff, transport, replay, provenance, and local NameCert rows.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-regular-cauchy-completion: none is bijective to $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$ because only the present packet jointly carries finite windows, an explicit Bishop rate row, dyadic tolerances, regular-rational readback, terminal Real seal, Bishop completion handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyRateCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyRateCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6379.1, Definition 6379.2, and Definition 6379.3 seed the finite Bishop rate-completion route over StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seals, and Bishop regular completion handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyRateCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rate exposure, dyadic tolerance exactness, regular-rational readback, terminal Real seal handoff, Bishop completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyRateCompletionUp.

Constructive story: A $\mathsf{BishopCauchyRateCompletion}^{\uparrow}$ packet is generated from finite StreamName windows, a Bishop rate row, DyadicRatCore tolerances, RegSeqRat readback, a terminal RealUp seal, Bishop regular completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6380
