A Concrete Naming Certificate for $\mathsf{ApophaticTLoop}^{\uparrow}$

The $\mathsf{ApophaticTLoop}^{\uparrow}$ packet realizes the apophatic T-loop discipline of subsection 9462.25.12 as finite NameCert data. It sits beside the host-source refusal of chapter 1157, the export refusal gate of chapter 1319, the claim-entry layer of chapter 1209, the external supply boundary of section 9395.1, and the negative certificate boundary of chapter 630. The packet names the records-side return through a gap inscription while keeping the far-end supply position outside the carrier.

Definition 6380.1 (Apophatic T-loop carrier)**.** *An* $\mathsf{ApophaticTLoop}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (H, K, M, R, G, I, L, E, N, H_s, C, P, Q)$$

with the following displayed rows:

1. *H is the records-side history row from which the loop read begins.*
2. *K is the classifier row naming the displayed commitment consumed by the history.*
3. *M is the reality-constrained meaning row attached to that classifier read.*
4. *R is the reality-constraint row whose source is not discharged by the closed records.*
5. *G is the gap row exposing the unclosed GAP_T question without internalizing its far end.*
6. *I is the inscription row, recording the local records-side return point.*
7. *L is the loop ledger, recording that the return reaches a successor or refinement of the records-side history rather than T itself.*
8. *E is the external-supply-boundary row, tying the unclosed source to an accepted boundary form without importing an external primitive.*
9. *N is the negative-certificate-boundary row, recording the cannot-internalize and cannot-export refusals.*
10. *H_s records componentwise* hsame *transport for $H, K, M, R, G, I, L, E, N$ and the local naming row.*
11. *C records displayed* Cont *replay from records through classifier, meaning, reality constraint, gap exposure, inscription, loop ledger, boundary rows, provenance, and local naming.*

12. *P is the* Pkg *provenance over* $\mathsf{ApophaticTLoop}^{\uparrow}$, $\mathsf{HostPrimitiveLeakage}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{NegativeCertificateBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
13. *Q is the local* $\mathsf{NameCert}_{\mathsf{ApophaticTLoop}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for the far-end supply position, host primitive content, total truth, object-layer T*, exportable cannot-claim discharge, or an erased gap.*

Theorem 6380.2 (Apophatic T-loop NameCert obligations)**.** *For every accepted* $\mathsf{ApophaticTLoop}^{\uparrow}$ *carrier*

$$T = (H, K, M, R, G, I, L, E, N, H_s, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{ApophaticTLoop}^{\uparrow}}$ *surface consists exactly of records-side history exposure through H, classifier exposure through K, reality-constrained meaning exposure through M, reality-constraint exposure through R, gap exposure through G, local inscription exposure through I, loop-ledger exposure through L, external-supply-boundary exposure through E, negative-certificate-boundary exposure through N, componentwise* hsame *transport through H_s, displayed* Cont *replay through C, package provenance through P, and local naming through Q.*

Proof. Project the carrier of Definition 6380.1. Its content rows are the records-side history, classifier, reality-constrained meaning, reality constraint, gap, inscription, loop ledger, external boundary, and negative boundary.

The records-facing route follows Definition 9462.746. A history read may return through classifier use, meaning, reality constraint, gap exposure, and local inscription, but the return is a records-side successor or refinement rather than an object-layer copy of T.

The refusal rows fix the boundary. $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ blocks imported host primitives, $\mathsf{CannotClaimExportGate}^{\uparrow}$ blocks overstrong export, $\mathsf{ClaimRegistryLayer}^{\uparrow}$ stores the bounded claim row, and $\mathsf{NegativeCertificateBoundary}^{\uparrow}$ records the cannot-internalize certificate. These rows name the boundary without discharging the far-end supply position.

Finally H_s, C, P, Q transport, replay, source, and name the same finite packet. Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6380.3 (Apophatic T-loop gap inscription handoff)**.** *Every accepted* $\mathsf{ApophaticTLoop}^{\uparrow}$ *consumer that reads the loop ledger L must pass through the gap row G, the local inscription row I, the external-supply-boundary row E, and the negative-certificate-boundary row N. The handoff records a records-side return; it does not internalize the far-end supply position, import host primitive leakage, export an overstrong claim, erase the claim registry, or close the negative certificate boundary.*

Proof. Begin with Definition 6380.2. The loop ledger is exposed only after the records-side history, classifier, meaning, reality constraint, gap, inscription, and boundary rows are visible.

Read the gap and inscription rows together. The gap row G names the unclosed question, while I names the local records-side return point. Thus the handoff is a visible inscription in the history, not a carrier field for the far-end supply position.

Now inspect the refusal siblings. The external-supply-boundary row E keeps the source outside the generated packet, and the negative-certificate-boundary row N records the cannot-internalize refusal. Host primitive leakage and cannot-claim export are therefore blocked by the same route that names the loop.

The structural rows H_s, C, P, Q preserve this ordering. They can replay the displayed handoff, but they cannot add a host primitive, erase the claim registry, close the gap, or turn the inscription into T itself. □

Falsifiable prediction: An accepted $\mathsf{ApophaticTLoop}^{\uparrow}$ packet is refuted if a records-side return is read without the displayed classifier, reality-constrained meaning, reality constraint, gap, local inscription, loop ledger, external-supply boundary, negative-certificate boundary, transport, replay, provenance, and local NameCert rows.

Independence witness: hostprimitiveleakage, cannotclaimexportgate, claimregistrylayer, external-supply-boundary, negativecertificateboundary: none is bijective to $\mathsf{ApophaticTLoop}^{\uparrow}$ because only the present carrier jointly records records-side history, classifier use, meaning, reality constraint, gap inscription, loop return, external boundary, negative certificate, transport, replay, provenance, and local naming.

The Lean follow-up obligation is a real $\mathsf{Nontrivial\ ApophaticTLoop}^{\uparrow}$ instance and a $\mathsf{FieldFaithful\ ApophaticTLoop}^{\uparrow}$ instance in `lean4/BEDC/Derived/ApophaticTLoopUp/TasteGate.lean`. Those instances must distinguish $H, K, M, R, G, I, L, E, N, H_s, C, P, Q$ and must keep the gap row, inscription row, external-supply boundary, and negative-certificate boundary as separate fields.

Closure status for $\mathsf{NameCert}_{\mathsf{ApophaticTLoop}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApophaticTLoop}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6380.1, Definition 6380.2, and Definition 6380.3 seed the finite gap-inscription route for the apophatic T-loop without internalizing the far-end supply position.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApophaticTLoop}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a carrier for the far-end supply position, host primitive content, total truth, object-layer T, exportable cannot-claim discharge, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gap-inscription handoff, external-supply boundary, negative-certificate boundary, Nontrivial instance, FieldFaithful instance, transport, replay, provenance, and local naming for BEDC.Derived.ApophaticTLoopUp.

Constructive story: An $\mathsf{ApophaticTLoop}^{\uparrow}$ packet is generated from records-side history, classifier, reality-constrained meaning, reality constraint, gap, inscription, loop ledger, external-supply boundary, negative-certificate boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6381

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$ packet records the regular Cauchy envelope by which rational schedules enter the public real-name boundary without a quotient stream or choice-selected limit. It sits after the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, and the dyadic tolerance core of chapter 291. The packet names only finite windows, regularity witnesses, dyadic tolerances, terminal sealing, transport, replay, provenance, and a local certificate; it does not allocate quotient streams, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient completeness.

Definition 6381.1 (Bishop regular Cauchy envelope carrier)**.** *A* $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the rational observations available to the envelope.*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational schedule row attached to the same displayed windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic precision and comparison budget consumed by* R*.*
4. S *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* W, R, D *have all been displayed.*
5. H *stores componentwise* hsame *transport for the window, regular schedule, dyadic tolerance, terminal seal, replay, provenance, and local naming rows.*
6. C *stores displayed* Cont *replay from finite window inspection through regularity, tolerance discharge, and terminal sealing.*
7. P *is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. N *is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through W, R, D, S, H, C, P, N. It has no coordinate for a quotient stream, selected representative, host limit, countable-choice schedule, trichotomy decision, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Theorem 6381.2 (Bishop regular Cauchy envelope obligation surface)**.** *For every accepted* BishopRegularCauchyEn *carrier $E = (W, R, D, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}}$ *surface consists exactly of finite window exposure through W, regular rational schedule admission through R, dyadic tolerance discharge through D, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. No obligation row exports a quotient stream, selected representative, selected limit, countable-choice schedule, trichotomy decision, host real equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 6381.1. The analytic rows are exactly the finite windows, regular rational schedule, dyadic tolerance ledger, and terminal real seal.

The finite route begins at W. A consumer may inspect only the displayed stream windows before any regular schedule row is available, and the regular schedule R remains attached to those same windows.

The tolerance row D supplies the comparison budget for R, while the terminal seal S is downstream of both the schedule and the dyadic ledger. Thus the real-facing boundary cannot be read before the finite Cauchy envelope has been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since none of those rows adds a quotient, selector, host limit, countable-choice schedule, trichotomy decision, host equality, or completeness witness, the listed rows exhaust the local obligation surface. □

Theorem 6381.3 (Bishop regular Cauchy envelope Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exposes window inspection, regular rational scheduling, dyadic tolerance, terminal sealing, transport, replay, provenance, and local naming only; it exports no quotient stream, selected representative, selected limit, countable-choice schedule, trichotomy decision, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 6381.2. It identifies W, R, D, S as the only analytic rows available to a real-facing consumer.

The regular schedule cannot be detached from the displayed windows. Row R is read after W, and the dyadic tolerance row D supplies the precision budget used by that same schedule.

The terminal seal is therefore forced through the finite Cauchy route. A $\mathsf{Real}^{\uparrow}$ or Completion consumer may read S only after the window, schedule, and tolerance rows have been exposed.

The structural rows preserve the same handoff. Transport, replay, provenance, and local naming add no quotient stream, selected representative, host limit, countable-choice schedule, trichotomy decision, host equality, or completeness principle, so the stated route is the complete export surface. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$ read exposes StreamName windows, RegSeqRat regular schedules, DyadicRatCore tolerances, RealUp sealing, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any Real or Completion consumer receives the packet.

Independence witness: streamname, regseqrat, dyadicratcore, real: none is bijective with $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$ because this packet alone binds finite windows, regular rational schedules, dyadic tolerance discharge, terminal Real sealing, transport, replay, provenance, and local naming without quotient streams or selected limits.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat regular schedules, DyadicRatCore tolerance rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6381.1, Definition 6381.2, and Definition 6381.3 seed the finite regular Cauchy envelope from displayed windows and tolerances to the public Real boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{BishopRegularCauchyEnvelope}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, regular schedule routing, dyadic tolerance exactness, Real boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyEnvelopeUp.

Chapter 6382

A Concrete Naming Certificate for $\mathsf{CompletionDenseExtension}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Mac Lane's universal mapping language, the $\mathsf{CompletionDenseExtension}^{\uparrow}$ packet records the finite route by which a uniformly continuous map on a dense metric source is extended across a displayed completion boundary. It sits after the Cauchy completion functor of chapter 423, the completion universal property of chapter 397, the metric completion dense embedding of chapter 3351, the finite StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, and the terminal Real seal of chapter 38. The packet exposes a dense-extension theorem surface as finite NameCert data; it does not import quotient completion equality, selected limits, countable choice, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6382.1 (Completion dense extension carrier)**.** *A* $\mathsf{CompletionDenseExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, D, Q, M, F, U, W, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric row whose dense subcarrier supplies the domain of the initial map.*
2. *D is the dense embedding row, read through the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *surface before any completion value is inspected.*
3. *Q is the completion seal row supplied by the Cauchy completion functor and completion universal-property route.*
4. *M is the uniform-continuity modulus row for the source map on displayed source histories.*
5. *F is the extension candidate row, carrying only the completion-facing value histories generated from dense source approximants.*
6. *U is the uniqueness ledger row comparing two extension candidates after they agree on the displayed dense embedding and modulus data.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for dense approximants and target observations.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for those windows.*
9. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, Q, M, F, U, W, R have been displayed.*

10. *H records componentwise* hsame *transport for source, dense embedding, completion seal, modulus, extension, uniqueness, readback, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a dense-source request through completion sealing, modulus transport, extension-candidate construction, uniqueness comparison, finite readback, and terminal Real sealing.*
12. *P is the* Pkg *provenance over* $\mathsf{CompletionDenseExtension}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, CompletionUniversalPrope $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionDenseExtension}^{\uparrow}}$ *row.*

Accepted packets are compared only through the displayed source, density, completion, modulus, extension, uniqueness, readback, seal, transport, replay, provenance, and naming rows.

Lean4 ✓ `BEDC.Derived.CompletionDenseExtensionUp.CompletionDenseExtensionTasteGate single carrier alignment`

Theorem 6382.2 (Completion dense extension NameCert obligations)**.** *For every accepted* CompletionDenseExtens *carrier $E = (S, D, Q, M, F, U, W, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionDenseExtension}^{\uparrow}}$ *surface consists exactly of source metric exposure, dense embedding exposure, completion-seal exposure, uniform-continuity modulus exposure, extension-candidate exposure, uniqueness-ledger exposure, StreamName finite windows, RegSeqRat readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming. Every completion-extension consumer must read S, D, Q, M, F, U before it can consume W, R, A, H, C, P, N.*

Proof. Project the carrier of Definition 6382.1. The rows S, D, Q expose the source metric, dense embedding, and completion seal, while M, F, U expose the modulus, extension candidate, and uniqueness ledger.

The finite readback remains downstream of those analytic rows. StreamName windows and RegSeqRat readback in W, R can be read only after the dense source, completion seal, and modulus route have been displayed, and the terminal Real seal A is reached only after the same route is visible.

Finally H, C, P, N transport, replay, source, and name that packet. Since none of the rows stores quotient completion equality, a selected limit, countable choice, host function equality, or ambient Real completeness, the local NameCert obligations are exhausted by the listed finite rows. □

Falsifiable prediction: Every accepted $\mathsf{CompletionDenseExtension}^{\uparrow}$ reader that claims a completion-extension handoff while omitting source metric exposure, dense embedding exposure, completion sealing, uniform-continuity modulus data, extension-candidate data, uniqueness ledger, StreamName windows, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, or local naming refutes the packet.

Independence witness: cauchycompletionfunctor, completionuniversalproperty, metric-completion-dense-embedding, streamname, regseqrat, real: $\mathsf{CompletionDenseExtension}^{\uparrow}$ is not bijective with any listed sibling because it joins dense source exposure, completion sealing, modulus transport, extension candidates, uniqueness comparison, finite readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionDenseExtension}^{\uparrow}}$.

Constructive story: A CompletionDenseExtension$^{\uparrow}$ packet is generated from source metric rows, dense embedding rows, completion seal rows, uniform-continuity modulus rows, extension-candidate rows, uniqueness ledgers, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompletionDenseExtension}\uparrow}$, seed)

Scope closed: Definition 6382.1 and Definition 6382.2 seed the dense-source completion-extension route.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompletionDenseExtension}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient completion equality, selected limits, countable choice, host function equality, ambient Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense embedding exposure, completion-seal exposure, modulus transport, extension-candidate exactness, uniqueness-ledger exactness, finite readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionDenseExtensionUp.

Chapter 6383

A Concrete Naming Certificate for $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$

Following the constructive Heine–Cantor proof through finite covers, the $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$ packet records the finite compact-cover modulus functional that turns displayed local continuity radii into a tolerance-only uniform-modulus handoff. It sits after the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the uniform-modulus consumer of chapter 369, the dyadic tolerance core of chapter 291, and the terminal Real seal of chapter 38. The packet is finite ProbeBundle and rational-radius data; it does not select a Lebesgue number outside the carrier, assert open-cover compactness, use quotient map equality, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6383.1 (Finite cover modulus functional carrier)**.** *A* $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, G, B, L, D, U, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover source row, exposing only the displayed ProbeBundle cover data.*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus row for the map being read.*
3. *B is the finite cover cell row carrying centers, local radii, and membership witnesses.*
4. *L is the finite lower-bound fold row over the displayed radius candidates.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison row for radius and oscillation checks.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from the finite fold.*
7. *W is the finite StreamName window row for source and target observations.*
8. *R is the RegSeqRat readback row for the same windows.*
9. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, G, B, L, D, U, W, R have been displayed.*
10. *H records componentwise* hsame *transport for compact-cover, continuous-map, radius, fold, tolerance, uniform-modulus, readback, seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a compact-cover request through local modulus rows, dyadic radius comparison, finite lower-bound folding, uniform-modulus handoff, and terminal Real sealing.*
12. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverModulusFunctional}^{\uparrow}}$ *row.*

Accepted packets are compared only through the displayed compact-cover, continuous-map, radius, fold, tolerance, uniform-modulus, readback, seal, transport, replay, provenance, and naming rows.

Theorem 6383.2 (Finite cover modulus functional NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$ *carrier* $F = (K, G, B, L, D, U, W, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverModulu}}$ *surface consists exactly of CompactMetric finite-cover exposure, ContinuousMap pointwise-modulus exposure, finite cover-cell radius exposure, finite lower-bound folding, DyadicRatCore tolerance accounting, UniformModulus handoff, finite observation windows, RegSeqRat readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming. Every compact-uniform-continuity consumer must read K, G, B, L, D, U before it consumes W, R, S, H, C, P, N.*

Proof. Project the carrier of Definition 6383.1. Rows K, G, B expose the compact source, continuous graph, and finite cover cells, while L, D, U expose the lower-bound fold, dyadic comparison ledger, and uniform-modulus handoff.

The finite readback stays downstream of the cover route. StreamName windows and RegSeqRat readback in W, R only observe the displayed compact-cover and continuous-map data, and the terminal Real seal S is reached after the dyadic tolerance row and uniform-modulus row are already visible.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row carries an external Lebesgue-number selector, open-cover compactness theorem, quotient map equality, countable-choice schedule, or ambient Real-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$ reader that claims a uniform-modulus handoff while omitting CompactMetric finite-cover exposure, ContinuousMap pointwise-modulus exposure, finite cover-cell radii, finite lower-bound folding, DyadicRatCore tolerance accounting, StreamName windows, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, or local naming refutes the packet.

Independence witness: compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$ is not bijective with any listed sibling because it joins compact finite covers, pointwise continuous-map moduli, radius lower-bound folding, dyadic tolerance accounting, uniform-modulus handoff, finite readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverModulusFunctional}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverModulusFunctional}^{\uparrow}$ packet is generated from CompactMetric finite-cover rows, ContinuousMap pointwise-modulus rows, finite cover-cell radius rows, lower-bound fold rows, DyadicRatCore tolerance rows, UniformModulus handoff rows, finite observation windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCoverModulusFunctional}^{\uparrow}}$, seed)

Scope closed: Definition 6383.1 and Definition 6383.2 seed the compact finite-cover modulus-functional route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCoverModulusFunctional}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, external Lebesgue-number selection, open-cover compactness, quotient map equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-cover exposure, continuous-map pointwise-modulus exposure, cover-cell radius exposure, finite lower-bound folding, dyadic tolerance accounting, uniform-modulus handoff, finite readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverModulusFunctionalUp.

Chapter 6384

A Concrete Naming Certificate for $\mathsf{ChoiceSequenceRealizability}^{\uparrow}$

Following Bishop and Kleene–Vesley on choice sequences and realizability, the $\mathsf{ChoiceSequenceRealizability}^{\uparrow}$ packet records finite-prefix evidence for a choice-sequence computation as BEDC NameCert data. It sits beside the finite stream-window carrier of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names only inspected prefixes, local realizers, compatibility rows, replay, provenance, and local naming; it is not a countable-choice selector, quotient stream, selected real, or $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6384.1 (Choice-sequence realizability carrier)**.** *A* $\mathsf{ChoiceSequenceRealizability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, R, F, D, H, T, P, N)$$

whose rows display a $\mathsf{StreamName}^{\uparrow}$ *finite prefix schedule* S*, a realizability row* R *for the inspected prefix, a finite prefix-extension ledger* F*, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-read row* D *when the prefix is consumed by a regular-rational route, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and a local* $\mathsf{NameCert}_{\mathsf{ChoiceSequenceRealizability}^{\uparrow}}$ *row* N*.*

The carrier may be read by a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer only through the displayed finite prefix schedule and tolerance rows. It exports no infinite sequence selector, quotient equality of choice sequences, host real endpoint, unrestricted bar induction, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6384.2 (Choice-sequence realizability prefix stability)**.** *Let* $C = (S, R, F, D, H, T, P, N)$ *be an accepted* $\mathsf{ChoiceSequenceRealizability}^{\uparrow}$ *carrier. If a longer inspected prefix refines* S *through the same finite extension ledger* F *and preserves the displayed realizability row, dyadic tolerance-read row, componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *support, then every RegSeqRat or Real-facing read of the refined prefix factors through the original finite prefix route before it consumes downstream rows.*

The stable read exports no choice function, quotient stream equality, selected real value, host completeness fact, or terminal $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with the finite prefix schedule S and the extension ledger F. The accepted carrier displays the only rows that may be inspected: prefix data, realizability evidence, tolerance readback, transport, replay, provenance, and local naming.

Refine the prefix by reading the longer schedule through F. The hypotheses preserve R, D, H, T, P, N, so the refined route keeps the same BEDC-visible realizability and tolerance surface.

Finally hand the refined packet to the RegSeqRat or Real-facing consumer. Since the consumer can read only the displayed prefix and tolerance rows, it cannot introduce a selector for the whole choice sequence, a quotient stream equality, a selected real endpoint, or a completeness coordinate. The refined read therefore factors through the original finite prefix route. □

Theorem 6384.3 (Choice-sequence realizability NameCert obligations)**.** *For every accepted* ChoiceSequenceRealiza *carrier, the local* $\mathsf{NameCert}_{\mathsf{ChoiceSequenceRealizability}^{\uparrow}}$ *surface consists exactly of the finite prefix schedule, prefix realizability row, extension ledger, dyadic tolerance-read row when present, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. The certificate is consumed through the L10 route from* $\mathsf{StreamName}^{\uparrow}$ *to* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, but it does not assert countable choice, quotient sequence equality, selected representatives, host real equality, metric completeness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6384.1. Its rows are finite prefix data S, realizability evidence R, extension ledger F, tolerance-read data D, and the support rows H, T, P, N.

Use Definition 6384.2 to compare any accepted longer prefix with the displayed finite route. The stability theorem keeps the RegSeqRat and Real-facing reads inside the same prefix and tolerance support.

The excluded objects are not coordinates of the carrier and are not produced by the stability argument. Hence the local NameCert obligations are exactly the listed finite rows and no stronger choice-sequence or Real-completeness surface is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceSequenceRealizability}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChoiceSequenceRealizability}^{\uparrow}}$, seed)

Scope closed: Definition 6384.1, Definition 6384.2, and Definition 6384.3 seed finite-prefix choice-sequence realizability as displayed StreamName, RegSeqRat, DyadicRatCore, support, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChoiceSequenceRealizability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient sequence equality, selected representatives, host real equality, metric completeness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix realizability exposure, prefix-refinement stability, L10 consumer handoff, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.ChoiceSequenceRealizabilityUp.

Constructive story: A $\mathsf{ChoiceSequenceRealizability}^{\uparrow}$ packet is generated from finite StreamName prefix rows, prefix realizability evidence, finite extension ledgers, optional DyadicRatCore tolerance reads, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6385

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$

The $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ packet realizes the closed-loop transport reading of chapter 9463 as finite NameCert data. It sits beside the Poincare disk phase-transport route of chapter 3455, the observer phase groupoid of chapter 6146, the Mobius-invariant transport surface of chapter 6237, and the hyperbolic geodesic-flow packet of chapter 3856. The carrier records closed reversible phase transport through displayed disk, boundary, classifier, replay, provenance, and local naming rows; it is not a host holonomy group, an unlogged geometric law, a selected orbit, or global hyperbolic completeness.

Definition 6385.1 (Hyperbolic phase holonomy carrier)**.** *A* $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (D, L, B, C, R, V, P, N)$$

whose rows display a Poincare disk readout D*, a closed loop transport ledger* L*, a boundary-stable transport row* B*, a phase classifier row* C*, displayed replay* R*, local reversible-transport verification* V*,* Pkg *provenance* P*, and a local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}}$ *row* N*.*

The carrier may export holonomy only after the closed loop, boundary row, classifier row, replay row, provenance row, and local naming row are all displayed. It exports no ambient disk automorphism group, unbounded geodesic flow, hidden phase law, selected endpoint, host smooth connection, or global hyperbolic-completeness claim.

Theorem 6385.2 (Hyperbolic phase holonomy NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseHolonom}$ *carrier* $H = (D, L, B, C, R, V, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}}$ *surface consists only of the displayed disk row, closed-loop transport ledger, boundary-stable transport row, phase classifier row, replay row, local reversible-transport verification, provenance row, and local naming row. The holonomy export is accepted only as a finite packet over those rows and cannot be replaced by a host holonomy group, global flow, selected orbit, or geometry-level completeness principle.*

Proof. Project the carrier of Definition 6385.1. The disk row D, loop ledger L, boundary row B, and classifier row C are the only phase-holonomy-facing coordinates, while R, V, P, N provide replay, reversible-transport verification, provenance, and local naming.

Read the transport through the sibling phase routes. The Poincare disk phase-transport packet supplies finite disk transport, the observer phase groupoid supplies inverse and composition bookkeeping, Mobius-invariant transport supplies boundary-stable disk action, and geodesic flow supplies the finite flow-facing ledger.

These sibling rows jointly determine the accepted holonomy surface. None of them adds a host holonomy group, unbounded geometric law, selected orbit, smooth connection, or global completeness coordinate, so the NameCert obligations are exactly the finite rows listed above. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ route exposes disk row, loop transport row, boundary row, phase classifier row, replay row, provenance row, and local naming before exporting holonomy.

Independence witness: poincare-disk-phase-transport, observer-phase-groupoid, hyperbolic-mobius-invariant, hyperbolic-geodesic-flow: no sibling is bijective because holonomy jointly carries a closed loop, boundary-stable transport, phase classifier, replay, provenance, and local NameCert rows.

Lean TasteGate.lean will provide Nontrivial and FieldFaithful instances for $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ once the finite carrier and obligation rows are registered under BEDC.Derived.HyperbolicPhaseHolonomyUp.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6385.1 and Definition 6385.2 seed finite hyperbolic phase holonomy over disk, closed-loop transport, boundary, classifier, replay, reversible-verification, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host holonomy groups, global geodesic flow, selected orbits, smooth connections, geometry-level completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk row exposure, loop and boundary transport exposure, classifier and replay exactness, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.HyperbolicPhaseHolonomy

Constructive story: A $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ packet is generated from finite Poincare disk rows, closed-loop transport ledgers, boundary-stable transport, phase classifiers, displayed replay, reversible-transport verification, Pkg provenance, and a local NameCert row.

Chapter 6386

A Concrete Naming Certificate for $\mathsf{FiniteVariationPartition}^{\uparrow}$

Following Jordan's finite-partition account of bounded variation and the Bishop–Bridges treatment of regulated integration, the $\mathsf{FiniteVariationPartition}^{\uparrow}$ packet records the partition ledger that a variation or Riemann–Stieltjes consumer must inspect before reading a bounded-variation handoff. It sits between the bounded-variation certificate of chapter 398, the total-variation functional of chapter 2257, the Riemann-sum row of chapter 1615, and the regulated-integral route of chapter 1557. The certificate is finite: it names endpoints, mesh order, edge-difference rows, transport, replay, provenance, and local naming rows, not an ambient partition lattice or a host-level variation supremum.

Falsifiable prediction: If a $\mathsf{FiniteVariationPartition}^{\uparrow}$ packet is accepted, every bounded-variation or Riemann–Stieltjes consumer must read the displayed finite partition ledger before it can cite a variation bound; a route from a host partition selector directly to variation control refutes the packet.

Independence witness: boundedvariation, totalvariationfunction, riemannsum, regulatedintegral: none is bijective because $\mathsf{FiniteVariationPartition}^{\uparrow}$ names a finite ordered ledger of partition points, endpoint rows, mesh comparisons, edge-difference rows, transport, replay, provenance, and local NameCert rows. $\mathsf{BoundedVariation}^{\uparrow}$ names the boundedness claim, $\mathsf{TotalVariationFunction}^{\uparrow}$ names the accumulated variation functional, $\mathsf{RiemannSum}^{\uparrow}$ names tagged summation data, and $\mathsf{RegulatedIntegral}^{\uparrow}$ names the integral-facing route. None alone carries the finite partition ledger required here.

Definition 6386.1 (Finite variation partition carrier)**.** *A* $\mathsf{FiniteVariationPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, E, P, M, D, S, T, H, C, Q, N)$$

with the following displayed rows:

1. *I is the interval or domain row on which variation is measured, exposing the endpoint type and order comparison used by the packet.*
2. *E is the endpoint row, naming the left and right boundary points and their admitted order.*
3. *P is the finite partition row, listing the accepted ordered points between the endpoints.*
4. *M is the mesh-comparison row, recording adjacent-point order and the finite successor relation inside P.*

5. *D is the edge-difference row, naming the finite family of adjacent absolute differences or metric differences attached to P.*
6. *S is the finite sum or ledger row that accumulates the entries of D without taking an ambient supremum.*
7. *T is the sibling handoff row to* $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, *or* $\mathsf{RegulatedIntegral}^{\uparrow}$, *with an explicit empty row when no such consumer is claimed.*
8. *H records componentwise* hsame *transport for I, E, P, M, D, S, T and the local naming row.*
9. *C records displayed* Cont *replay from endpoint admission through partition ordering, edge-difference summation, sibling handoff, provenance, and local naming.*
10. *Q is the* Pkg *provenance over* $\mathsf{FiniteVariationPartition}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteVariationPartition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eleven rows. It has no coordinate for a host-selected partition family, a supremum over all partitions, open-cover compactness, countable choice, quotient equality, or ambient real completeness.

Theorem 6386.2 (Finite variation partition NameCert obligations)**.** *For every accepted* $\mathsf{FiniteVariationPartition}^{\uparrow}$ *carrier $V = (I, E, P, M, D, S, T, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteVariationPartition}^{\uparrow}}$ *surface consists exactly of carrier admission, endpoint exposure, finite partition ordering, mesh comparison, edge-difference exposure, finite-sum ledger exposure, sibling handoff to the bounded-variation, total-variation, Riemann-sum, or regulated-integral rows when T is present, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation in the packet asserts a host partition selector, a global total-variation supremum, countable choice, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. Its visible rows are the domain row, endpoint row, finite partition row, mesh-comparison row, edge-difference row, finite-sum ledger, sibling handoff, transport, replay, provenance, and local name.

The partition obligation is finite. The row P supplies only the displayed list of partition points, while M records adjacent order and successor comparisons inside that list. No row ranges over all possible partitions.

The variation obligation is ledgered through D and S. A bounded-variation or total-variation consumer may read the adjacent edge differences and their finite sum, but the packet does not identify this finite ledger with a supremum over every refinement.

The sibling handoff is exact. When T cites $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, or $\mathsf{RegulatedIntegral}^{\uparrow}$, the read passes through H, C, Q, N; when T is empty, the packet makes no downstream variation or integration claim. □

Theorem 6386.3 (Finite variation partition bounded-variation handoff)**.** *Every* $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, *or* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteVariationPartition}^{\uparrow}$ *packet must first read*

$$I, E, P, M, D, S, T, H, C, Q, N.$$

It receives the displayed endpoint, ordered finite partition, mesh-comparison, edge-difference, finite-sum, sibling handoff, transport, replay, provenance, and local NameCert rows. It receives no host-level partition choice, no hidden variation supremum, no unledgered refinement family, no countable choice, and no ambient completeness theorem.

Proof. Begin with the carrier of Definition 6386.1. The bounded-variation and integration-facing data occur only in the finite rows P, M, D, S, T over the endpoint data I, E.

Apply the NameCert obligations of Definition 6386.2. They require every downstream handoff to expose the finite partition ordering, mesh comparison, edge-difference ledger, and finite sum before the sibling row T is read.

The structural rows preserve the same finite route. Transport H is componentwise, replay C follows the displayed ledger, provenance Q names the sibling certificates, and N names the local packet.

Therefore a bounded-variation, total-variation, Riemann-sum, or regulated-integral consumer receives only the finite partition ledger. The absent coordinates for host partition choice, global supremum, refinement-family choice, and ambient completeness cannot be recovered from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteVariationPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteVariationPartition}^{\uparrow}$ packet is generated from endpoint rows, a finite ordered partition row, mesh-comparison rows, edge-difference rows, a finite-sum ledger, a bounded-variation or integration-facing handoff, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteVariationPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6386.1, Definition 6386.2, and Definition 6386.3 seed the finite partition ledger for bounded-variation, total-variation, Riemann-sum, and regulated-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteVariationPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, host-selected partition families, global variation suprema, countable choice, quotient equality, or ambient Real completeness.

Upgrade path: A formal route can encode the eleven-row carrier obligations and prove the finite bounded-variation handoff for BEDC.Derived.FiniteVariationPartitionUp.

Chapter 6387

A Concrete Naming Certificate for $\mathsf{BishopLocatedZero}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopLocatedZero}^{\uparrow}$ packet records a constructive located zero witness over the L10 real-name substrate. It sits over the real-name seal of chapter 38, the regular-rational readback of chapter 301, the finite stream-window route of chapter 126, and the located interval oscillation surface of chapter 6364. The packet names the finite sign-change and bisection rows that later interval-search consumers may inspect; it is not a host intermediate-value theorem, quotient real equality, selected global root, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6387.1 (Bishop located zero carrier)**.** *A* $\mathsf{BishopLocatedZero}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (B, M, S, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the sign-change bracket row, recording lower and upper rational endpoint windows, the two displayed sign reads, and the non-overlap evidence that the bracket remains located.*
2. *M is the uniform modulus row for the displayed function route, translating a requested sign tolerance into a finite source-window budget.*
3. *S is the bisection schedule row, carrying the finite midpoint sequence and the chosen retained half at each displayed stage.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the midpoint and endpoint windows produced by S.*
5. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after the bracket, modulus, schedule, and readback rows have been displayed.*
6. *H records componentwise* hsame *transport for brackets, moduli, schedules, readbacks, seals, and local naming rows.*
7. *C records displayed* Cont *replay through the route B, M, S, Q, A, H.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedZero}^{\uparrow}$, $\mathsf{BishopLocatedIntervalOscillation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedZero}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host real equality, a selected global root, quotient stream equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6387.2 (Bishop located zero NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedZero}^{\uparrow}$ *carrier* $Z = (B, M, S, Q, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedZero}^{\uparrow}}$ *surface is exhausted by sign-change bracket admission through* B*, uniform modulus exposure through* M*, bisection schedule exposure through* S*, RegSeqRat readback through* Q*, Real sealing through* A*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6387.1. The analytic input is not a host function equality claim; it is the displayed bracket row B together with the modulus row M.

The finite bisection data is then forced. The schedule row S records the retained half at each displayed stage, Q reads the same midpoint and endpoint windows as regular-rational data, and A seals the resulting real-name boundary only after those rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since the carrier has no selected-root, quotient, choice, compactness, host-equality, or completeness coordinate, no such object can become a local NameCert obligation. □

Theorem 6387.3 (Bishop located zero bisection soundness)**.** *Let* $Z = (B, M, S, Q, A, H, C, P, N)$ *be an accepted* $\mathsf{BishopLocatedZero}^{\uparrow}$ *carrier. Every zero-witness read produced by the displayed bisection schedule factors through the sign-change bracket* B*, uniform modulus* M*, retained-half schedule* S*, regular-rational readback* Q*, and terminal Real seal* A *before it reaches transport, replay, provenance, and naming rows. The read is therefore a constructive located zero surface inside the L10 real-name route, not a host intermediate-value theorem or a selected global root.*

Proof. Start with the sign-change bracket. The row B is the only source for the two sign reads and the located endpoint comparison, so a bisection consumer cannot begin from an ambient real interval.

Next use the modulus and schedule rows. The row M gives the finite tolerance-to-window budget, and S records each retained half by displayed midpoint data. The readback row Q then supplies the regular-rational midpoint and endpoint route consumed by the terminal seal A.

Finally attach the structural rows. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row preserve the same finite packet. Thus bisection soundness is a row-exhaustion statement for $B, M, S, Q, A, H, C, P, N$, with no host equality, quotient stream, selected limit, countable choice, compactness, or ambient completeness imported. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedZero}^{\uparrow}$ consumer that reads a zero witness while omitting one of the sign-change bracket, uniform modulus, bisection schedule, RegSeqRat readback, Real seal, hsame, Cont, Pkg, or NameCert rows has left the packet.

Independence witness: bishoplocatedintervaloscillation, streamname, regseqrat, real: $\mathsf{BishopLocatedZero}^{\uparrow}$ is not bijective with any listed sibling because it joins sign-change bracket data, a uniform modulus, a finite bisection schedule, regular-rational readback, Real sealing, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedZero}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedZero}^{\uparrow}$ packet is generated from a sign-change bracket, a uniform modulus, a finite bisection schedule, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BishopLocatedZero}^{\uparrow}}$, seed)

Scope closed: Definition 6387.1, Definition 6387.2, and Definition 6387.3 seed the finite located zero witness surface for L10 Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopLocatedZero}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host intermediate-value theorem, selected global root, quotient real equality, quotient stream equality, countable choice, open-cover compactness, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bracket admission, modulus exposure, bisection schedule exposure, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedZeroUp

Chapter 6388

Constructive Cauchy-Filter Boundary NameCert Construction

Following Bishop and Bridges, the $\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}$ packet records the finite boundary surface through which Cauchy-filter completion reads enter the Real and Completion route. It is deliberately placed between the Cauchy-filter carrier of chapter 333, the finite StreamName observation windows of chapter 126, the regular rational schedules of chapter 301, the dyadic tolerance arithmetic of chapter 291, and the terminal Real seal of chapter 38. The packet gives completion consumers a finite boundary object without importing quotient streams, countable choice, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6388.1 (Constructive Cauchy-filter boundary)**.** *A* $\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, S, R, D, Q, H, C, P, N)$$

with the following rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row. It records the accepted filter request, its directed finite neighbourhood ledger, and the displayed Cauchy-filter admission data.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed when a completion consumer asks for a named finite observation of the filter.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational schedule read from the finite StreamName windows before any Real-facing seal is consumed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the dyadic precision, radius, and comparison data used by the RegSeqRat readback.*
5. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, S, R, D have been displayed.*
6. *H records componentwise* hsame *transport for F, S, R, D, Q and the structural rows.*
7. *C records displayed* Cont *replay of the route*

$$F \longmapsto S, D \longmapsto R \longmapsto Q, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, S, R, D, Q, H, C, P, N$. It has no coordinate for quotient stream equality, countable choice, a selected limit, host real equality, real trichotomy, or ambient Real completeness.

Lean4 (statement) `BEDC.Derived.ConstructiveCauchyFilterBoundaryUp`

Theorem 6388.2 (Constructive Cauchy-filter boundary NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}$ *carrier $B = (F, S, R, D, Q, H, C, P, N)$, Cauchy-filter completion reads are exhausted by the displayed route*

$$F \longmapsto S, D \longmapsto R \longmapsto Q.$$

The source row F is read through the Cauchy-filter packet of chapter 333; finite observations pass through the StreamName window row of chapter 126; regular rational schedules pass through the RegSeqRat readback row of chapter 301; dyadic tolerances pass through the DyadicRatCore row; and the Real-facing boundary is sealed only by Q. The structural rows H, C, P, N preserve that route and do not export quotient streams, countable choice, a selected limit, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6388.1. The only source-facing row is F, so the completion request first exposes the accepted Cauchy-filter ledger and cannot begin from a quotient stream or a selected limit.

The finite observation stage is routed through S, D, R. The StreamName row supplies the finite window, the DyadicRatCore row supplies the precision and radius comparisons, and the RegSeqRat row supplies the regular rational readback consumed by a Real-facing route.

Finally project Q, H, C, P, N. The terminal Real seal is downstream of the finite rows, while componentwise transport, continuation replay, provenance, and local naming preserve the same carrier. Since none of the excluded coordinates occurs in the packet, the boundary cannot be used as an ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}$ packet is generated from CauchyFilter source rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 6388.1 and Definition 6388.2 seed the finite Cauchy-filter boundary carrier for Real and Completion reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ConstructiveCauchyFilterBoundary}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window routing, RegSeqRat readback, DyadicRatCore tolerance ordering, Real seal nonescape, provenance, and local naming for BEDC.Derived.ConstructiveCauchyFilterBoundaryUp

Chapter 6389

A Concrete Naming Certificate for $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$ packet records the finite-window handoff used when regular Cauchy data enter the Real-completion route. It realizes the regular-Cauchy vision of section 9238.1 as concrete NameCert data over the finite StreamName window of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet does not import quotient streams, selected limits, countable choice, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6389.1 (Finite-window RegSeqRat handoff carrier)**.** *A* $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, D, R, Q, H, C, P, N)$$

with the following rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing the inspected source indices and observation schedule.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radius, common-scale comparison, and requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite window and tolerance row.*
4. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after S, D, R have been displayed.*
5. *H records componentwise* hsame *transport for the StreamName, DyadicRatCore, RegSeqRat, Real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the finite route*

$$S, D \longmapsto R \longmapsto Q, H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, D, R, Q, H, C, P, N. It has no coordinate for quotient stream equality, a selected limit, a countable-choice schedule, metric completeness, or ambient real completeness.

Lean4 (statement) `BEDC.Derived.FiniteWindowRegSeqRatHandoffUp`

Theorem 6389.2 (Finite-window RegSeqRat handoff NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$ *carrier* $W = (S, D, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}}$ *surface consists exactly of finite StreamName window exposure through* S*, dyadic tolerance ordering through* D*, regular rational readback through* R*, terminal Real sealing through* Q*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*. Every Real-completion consumer must read these rows in that order, and no obligation row exports quotient streams, selected limits, countable choice, metric completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 6389.1. The finite observation surface is S, and the requested tolerance is recorded by D, so a consumer first sees an explicit window and dyadic precision row.

The regular rational readback is R. It is attached to the same finite window and tolerance row, so the handoff cannot replace the displayed data by quotient stream equality or by a selected limiting representative.

The Real-facing boundary is terminal. Row Q can be consumed only after S, D, R have been projected, while H, C, P, N transport, replay, source, and name the same finite packet.

Since the carrier has no coordinate for choice, completeness, quotient equality, or selected limits, the listed rows exhaust the NameCert obligations and define the finite-window handoff used by Real-completion consumers. □

Falsifiable prediction: Every accepted $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$ read exposes one StreamName finite window, one DyadicRatCore tolerance row, one RegSeqRat readback row, one RealUp seal, componentwise hsame, Cont replay, Pkg provenance, and a local NameCert row before any Real-completion consumer receives the packet.

Independence witness: streamname, dyadicratcore, regseqrat, real: $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the finite observation window, tolerance row, regular readback, terminal Real seal, transport, replay, provenance, and local naming as one handoff packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}$ packet is generated from StreamName finite windows, DyadicRatCore tolerance rows, RegSeqRat readback, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}}$, seed)

Scope closed: Definition 6389.1 and Definition 6389.2 seed the finite-window RegSeqRat handoff over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatHandoff}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.FiniteWindowRegSeqRatHandoffUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, metric completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-window exposure, dyadic tolerance ordering, regular rational readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWindowRegSeqRatHandoffUp.

Chapter 6390

A Concrete Naming Certificate for $\mathsf{PrueferSequence}^{\uparrow}$

Following Cayley and Pruefer, the $\mathsf{PrueferSequence}^{\uparrow}$ packet records a finite labelled-tree code object as a BEDC NameCert row. It reads label lists from chapter 36, vertex counters from $\mathsf{Nat}^{\uparrow}$, and finite tree-code rows from chapter 119; the packet is meant for finite tree enumeration and graph-code consumers, not for quotient graph isomorphism or an ambient set-theoretic tree space.

Definition 6390.1 (Pruefer sequence carrier)**.** *A* $\mathsf{PrueferSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (n, V, L, S, D, E, T, H, C, G, N)$$

with the following displayed rows:

1. *n is the* $\mathsf{Nat}^{\uparrow}$ *vertex-count row for a labelled finite tree with labels in the visible interval* $1, \ldots, n$*;*
2. *V is the* $\mathsf{List}^{\uparrow}$ *row listing the displayed labels without importing an ambient finite set;*
3. *L is the length row certifying that the code list has length $n - 2$ when the two-leaf boundary is active;*
4. *S is the* $\mathsf{List}^{\uparrow}$ *code row whose entries are labels from V;*
5. *D is the finite degree ledger obtained by scanning S and the two remaining labels;*
6. *E is the edge-row ledger produced by the leaf-deletion reconstruction route;*
7. *T is the* $\mathsf{Tree}^{\uparrow}$ *tree-code row carrying the displayed vertex and edge rows after reconstruction;*
8. *H records componentwise* hsame *transport for n, V, L, S, D, E, T and the naming support rows;*
9. *C records the displayed* Cont *replay from list scan to degree ledger, leaf deletion, edge ledger, and tree-code readback;*
10. *G is the* Pkg *provenance over* $\mathsf{Nat}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrueferSequence}^{\uparrow}}$ *row.*

The carrier stores no quotient by relabelling, no selected representative of a graph-isomorphism class, and no infinite tree object.

Theorem 6390.2 (Pruefer sequence NameCert obligations)**.** *For every accepted* $\mathsf{PrueferSequence}^{\uparrow}$ *carrier*

$$P = (n, V, L, S, D, E, T, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrueferSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the vertex-count row, visible label list, code-length row, code list, degree ledger, edge ledger, reconstructed tree-code row, componentwise transport, replay routes, provenance, and local naming row. The obligation route is finite list admission, natural-number length admission, degree-ledger scan, leaf-deletion edge construction, tree-code readback, and then the* hsame*,* Cont*,* Pkg*, and* NameCert *packaging rows.*

Proof. Project the carrier of Definition 6390.1. The tuple lists the vertex-count row, label list, code length, code list, degree ledger, edge ledger, tree-code readback, transport, replay, provenance, and local name; there is no further coordinate for graph isomorphism, relabelling, or an infinite object.

Read the code list through chapter 36. Each entry of S is checked against the visible label list V, and L records the finite length boundary determined by n.

Next scan S to form D. The scan raises the displayed degree counter for each listed label and leaves the two-leaf boundary as finite counter data, so the reconstruction route has only displayed Nat and List rows to inspect.

Finally replay the leaf-deletion construction. At each finite step the least available leaf in the displayed label list pairs with the next code entry, producing one edge row in E; the remaining two labels produce the terminal edge. Repacking E as the $\mathsf{Tree}^{\uparrow}$ row T and transporting it through H, C, G, N gives exactly the stated NameCert surface. □

Theorem 6390.3 (Pruefer sequence tree-code route)**.** *Every accepted* $\mathsf{PrueferSequence}^{\uparrow}$ *carrier determines its downstream finite tree-code read solely from*

$$n, \quad V, \quad L, \quad S, \quad D, \quad E, \quad T.$$

The read consumes the $\mathsf{List}^{\uparrow}$ *code row and* $\mathsf{Nat}^{\uparrow}$ *counters first, then exports the* $\mathsf{Tree}^{\uparrow}$ *edge ledger through the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. It does not export a host graph, an isomorphism class, or a chosen representative outside the displayed labels.*

Proof. Begin with the list spine. The row S supplies a finite sequence of labels and L supplies its length boundary, both over the visible label list V.

Use the degree ledger D to drive the finite reconstruction. Every deletion step reads the next code entry and the least currently available displayed leaf, so each edge added to E is determined by finite rows already present in the carrier.

The terminal two-label edge completes the edge ledger. The tree-code row T is then a repacking of the same displayed labels and edges through the sibling $\mathsf{Tree}^{\uparrow}$ surface, and H, C, G, N preserve this read under transport, replay, provenance, and local naming. □

Theorem 6390.4 (Pruefer sequence Cayley consumer boundary)**.** *A finite enumeration consumer that uses* $\mathsf{PrueferSequence}^{\uparrow}$ *for Cayley's labelled-tree count may consume the packet only through the visible list-code and tree-code rows of Definition 6390.1. The consumer may count the* n^{n-2} *code rows by reading* $\mathsf{Nat}^{\uparrow}$ *exponent data and* $\mathsf{List}^{\uparrow}$ *spines, then hand the reconstructed edge ledgers to* $\mathsf{Tree}^{\uparrow}$ *or* $\mathsf{Graph}^{\uparrow}$ *consumers. It may not identify trees up to relabelling, import a quotient classifier, or replace the displayed reconstruction route with an ambient bijection proof.*

Proof. The consumer first reads n, V, L, S. These rows expose exactly the finite label interval, the visible list spine, and the code-length boundary used to count code rows.

It then invokes Definition 6390.3. The reconstruction route supplies D, E, T as displayed rows, so the consumer receives a tree-code ledger rather than a host graph object.

The remaining rows H, C, G, N preserve the same dependency boundary. Since the carrier has no quotient, relabelling representative, or ambient bijection coordinate, the Cayley-facing consumer boundary is exactly the finite code-to-tree route described above. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrueferSequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrueferSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6390.1, Definition 6390.2, Definition 6390.3, and Definition 6390.4 seed the finite labelled-tree code packet over displayed Nat, List, degree-ledger, edge-ledger, Tree, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrueferSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient graph isomorphism, relabelling invariance, unlabelled tree enumeration, a host bijection proof, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, code-length exactness, degree-ledger scan, leaf-deletion reconstruction, tree-code readback, and Cayley-facing consumer boundary for the same finite packet.

Constructive story: A $\mathsf{PrueferSequence}^{\uparrow}$ packet is generated from a displayed vertex count, visible label list, finite code list, degree counters, reconstructed edge rows, a tree-code row, componentwise transports, replay routes, provenance, and local NameCert evidence.

Chapter 6391

A Concrete Naming Certificate for $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$ packet records the endpoint seal that a displayed interval contraction must expose before downstream fixed-point consumers may read a Real endpoint. It sits after the interval-contraction route of chapter 5867, the general contraction-mapping surface of chapter 1418, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the stability consumer of chapter 5856. The packet names the endpoint handoff as finite BEDC data; it does not assert a host Banach fixed-point theorem, select a completed limit, use quotient real equality, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6391.1 (Bishop contraction endpoint-seal carrier)**.** *A* $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (I, F, Q, R, X, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *row exposing the located interval, contraction witness, dyadic shrinkage ledger, finite windows, regular-rational readback, and Real seal already certified by the interval-contraction packet.*
2. *F is the* $\mathsf{ContractionMapping}^{\uparrow}$ *row recording that the same displayed map is read as a contraction before an endpoint consumer may inspect it.*
3. *Q is the endpoint-request row, naming the requested fixed-point endpoint handoff and the shrinkage budget that routes it to the readback row.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the interval-contraction windows and endpoint request.*
5. *X is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal consumed by fixed-point consumers.*
6. *H records componentwise* hsame *transport for I, F, Q, R, X, P, N.*
7. *C records displayed* Cont *replay from the endpoint request through I, F, Q, R, X, H.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$, $\mathsf{BishopIntervalContraction}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BanachFixedPointStability}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopContractionEndpointSeal}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a selected fixed point, quotient real equality, a host convergence theorem, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6391.2 (Bishop contraction endpoint-seal NameCert obligations)**.** *For every accepted* $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$ *carrier* $E = (I, F, Q, R, X, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopContractionEndpointSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed interval-contraction row, contraction-mapping row, endpoint request, regular rational readback, Real endpoint seal, transport, replay, provenance, and local naming rows; contraction-route compatibility between I and F; endpoint-budget exactness through Q and R; Real-seal ordering through X; and downstream stability handoff for* $\mathsf{BanachFixedPointStability}^{\uparrow}$ *consumers. No NameCert obligation is stored outside* $I, F, Q, R, X, H, C, P, N$.

Proof. Carrier admission is projection from Definition 6391.1. The tuple lists the interval-contraction source, contraction-mapping row, endpoint request, regular readback, Real seal, transport, replay, provenance, and local name as the only available coordinates.

Contraction-route compatibility reads I and F together. The $\mathsf{BishopIntervalContraction}^{\uparrow}$ row supplies the located interval, dyadic shrinkage ledger, finite windows, and readback route, while the $\mathsf{ContractionMapping}^{\uparrow}$ row records the displayed map as the contraction consumed by the endpoint request.

Endpoint-budget exactness is then read through Q and R. The request row names the endpoint budget, and the $\mathsf{RegSeqRat}^{\uparrow}$ row receives only the scheduled readback exported by the interval-contraction packet.

Finally the Real handoff row X and the structural rows H, C, P, N preserve the same route for $\mathsf{BanachFixedPointStability}^{\uparrow}$ consumers. Since the carrier contains no selected fixed point, quotient real equality, host convergence theorem, countable-choice row, or ambient Real-completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 6391.3 (Bishop contraction endpoint-seal Real handoff)**.** *Every fixed-point stability consumer that reads the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal X from an accepted* $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$ *carrier* $E = (I, F, Q, R, X, H, C, P, N)$ *must first read*

$$\mathsf{BishopIntervalContraction}^{\uparrow} \longmapsto \mathsf{ContractionMapping}^{\uparrow} \longmapsto Q \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows I, F, Q, R, X, and then read the structural rows H, C, P, N for hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. The handoff may be consumed by* $\mathsf{BanachFixedPointStability}^{\uparrow}$*, but it exports no selected fixed point, quotient completion, host Banach theorem, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the endpoint request. The carrier exposes the source interval-contraction route only through I and the displayed contraction row only through F, so a consumer cannot begin from an external fixed-point theorem or an unrecorded self-map.

Read the endpoint budget through Q. By the NameCert obligations of Definition 6391.2, this budget is the only route from the contraction data to the $\mathsf{RegSeqRat}^{\uparrow}$ readback R.

The terminal Real endpoint seal is then X. It is downstream of I, F, Q, R, so a fixed-point stability consumer receives a displayed regular-rational-to-Real handoff rather than a chosen limit or quotient real equality.

Finally replay the route through H, C, P, N. Componentwise transport, displayed continuation, provenance, and local naming preserve the same endpoint-seal packet before $\mathsf{BanachFixedPointStability}^{\uparrow}$ consumes it, and no excluded host fixed-point or completeness data is present in the carrier. □

Falsifiable prediction: An accepted $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$ consumer that reaches the $\mathsf{Real}^{\uparrow}$ endpoint seal or a $\mathsf{BanachFixedPointStability}^{\uparrow}$ handoff without reading $I, F, Q, R, X, H, C, P, N$ refutes the carrier surface.

Independence witness: bishop-interval-contraction, contraction-mapping, regseqrat, real, banach-fixed-point-stability: no listed sibling supplies the joint endpoint-seal packet containing an interval-contraction source, displayed contraction map, endpoint request budget, regular rational readback, terminal Real endpoint seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopContractionEndpointSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopContractionEndpointSeal}^{\uparrow}$ packet is generated from a BishopIntervalContraction row, a ContractionMapping row, an endpoint request budget, RegSeqRat readback, a Real endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopContractionEndpointSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6391.1, Definition 6391.2, and Definition 6391.3 seed the finite endpoint-seal route from interval contraction and contraction-mapping data to RegSeqRat, Real, and BanachFixedPointStability consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopContractionEndpointSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a selected fixed point, quotient real equality, host Banach fixed-point theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, contraction-route compatibility, endpoint-budget exactness, Real handoff ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopContractionEndpointSealUp

Chapter 6392

A Concrete Naming Certificate for $\mathsf{CompactDyadicGridRefinement}^{\uparrow}$

The $\mathsf{CompactDyadicGridRefinement}^{\uparrow}$ packet realizes the finite grid-refinement route of chapter 9237 as concrete NameCert data. It sits over the compact finite-net surface of chapter 129, the dyadic tolerance ledger of chapter 291, the uniform-modulus consumer of chapter 369, and the terminal real-name boundary of chapter 38. The packet records compact-net rows, dyadic-radius refinements, and tolerance-only handoff data; it does not import open-cover compactness, a host grid topology, selected mesh limits, or ambient completeness.

Definition 6392.1 (Compact dyadic grid-refinement carrier)**.** *A* $\mathsf{CompactDyadicGridRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Q, \Delta, \Gamma, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the consumed* $\mathsf{CompactMetric}^{\uparrow}$ *row, including the displayed compact finite-net and located metric support;*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the input dyadic radius, half-radius, and comparison budget;*
3. *Δ is the finite dyadic grid row, listing cells whose centers are read from the compact finite-net surface of X;*
4. *Γ is the refinement ledger, recording which dyadic child cells refine which parent cells and which compact-net probes they cover;*
5. *R is the finite-net coverage row saying that every inspected source point is routed through one displayed grid cell and one compact-net center;*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff row, available only after Q, Δ, Γ, R have been projected;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the displayed dyadic tolerance and uniform-modulus route;*
8. *H records componentwise* hsame *transport for $X, Q, \Delta, \Gamma, R, U, E$ and the support rows;*
9. *C records the displayed* Cont *replay from compact-net readback to dyadic subdivision, coverage, uniform-modulus handoff, and real seal;*

10. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactDyadicGridRefinement}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows and stores no open-cover proof, external grid space, quotient real equality, selected mesh limit, or ambient completeness principle.

Theorem 6392.2 (Compact dyadic grid-refinement NameCert obligations)**.** *For every accepted* $\mathsf{CompactDyadicGridRefinement}^{\uparrow}$ *carrier*

$$G = (X, Q, \Delta, \Gamma, R, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactDyadicGridRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric row, dyadic tolerance row, finite grid row, refinement ledger, coverage row, uniform-modulus handoff, real seal, componentwise transport, replay routes, provenance, and local naming row. The obligation route is compact finite-net readback, dyadic-radius admission, finite grid subdivision, parent-child refinement coverage, uniform-modulus consumer handoff, real-seal nonescape, and then the* hsame, Cont, Pkg, *and* NameCert *packaging rows.*

Proof. Project the carrier of Definition 6392.1. The displayed tuple is the full public surface, so an open-cover proof, host grid topology, selected mesh limit, quotient real equality, and ambient completeness are not available as extra coordinates.

Read X and Q first. The compact metric row supplies finite-net centers and located metric support, while the dyadic tolerance row supplies the visible radius, half-radius, and comparison budget used by every grid cell.

Next build Δ, Γ, R. The finite grid row lists dyadic cells, the refinement ledger ties each child to a parent and to the compact-net probes it covers, and the coverage row records the inspected source-point route through one displayed cell and one compact-net center.

Finally expose U and E. The uniform-modulus handoff consumes only the compact-net, dyadic-radius, grid, refinement, and coverage rows, and the real seal is placed after that handoff. Repacking through H, C, P, N gives exactly the NameCert surface stated above. □

Theorem 6392.3 (Compact dyadic grid-refinement finite-net route)**.** *Every finite-net read of an accepted* $\mathsf{CompactDyadicGridRefinement}^{\uparrow}$ *packet factors through*

$$X, \quad Q, \quad \Delta, \quad \Gamma, \quad R.$$

The route first consumes the compact finite-net row of X, then reads dyadic radii from Q, then exposes the displayed grid cells and refinement ledger. No consumer receives a standalone grid topology, an untracked mesh parameter, or a selected cover outside the finite BEDC rows.

Proof. Start with the compact source row. The only centers available to the packet are the finite-net centers carried by X.

Use the dyadic tolerance row Q to size the cells. Each grid cell in Δ is therefore a finite dyadic-radius row, and each parent-child relation in Γ is checked against the same comparison budget.

The coverage row R ties every inspected source point to one displayed cell and compact-net center. Since H, C, P, N only transport, replay, package, and name these same rows, the finite-net read cannot escape to a host grid or selected cover. □

Theorem 6392.4 (Compact dyadic grid-refinement uniform-modulus consumer)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactDyadicGridRefinement}^{\uparrow}$ *packet reads the compact-net coverage, dyadic radius, grid subdivision, and refinement rows before it may consume the uniform-modulus handoff row* U*. The subsequent* $\mathsf{Real}^{\uparrow}$ *seal* E *is available only downstream of* U *and the displayed* hsame, Cont, Pkg*, and local* NameCert *rows. Thus the consumer receives finite compact-net, dyadic-radius, and uniform-modulus handoff data, not an ambient Heine–Cantor theorem or host real-completeness argument.*

Proof. Apply Definition 6392.3. It fixes the finite route through X, Q, Δ, Γ, R before any uniform-modulus read is exposed.

The row U is downstream of that route in the carrier. It therefore reads a tolerance-only modulus handoff from displayed compact-net and dyadic-grid data rather than from a selected external modulus.

The real seal E comes after U. Transport and replay through H and C, together with provenance P and local naming N, preserve that order, so no consumer can bypass the finite grid-refinement packet to reach ambient completeness or host real equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactDyadicGridRefinement}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactDyadicGridRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6392.1, Definition 6392.2, Definition 6392.3, and Definition 6392.4 seed the finite compact-net, dyadic-radius, grid-refinement, coverage, uniform-modulus, real-seal, transport, replay, provenance, and local naming packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactDyadicGridRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host grid topology, selected mesh limits, quotient real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net readback, dyadic-radius exactness, grid-refinement coverage, uniform-modulus consumer handoff, and real-seal nonescape for the same finite packet.

Constructive story: A $\mathsf{CompactDyadicGridRefinement}^{\uparrow}$ packet is generated from a compact metric finite-net row, dyadic tolerance data, finite grid cells, refinement coverage, a uniform-modulus handoff, a RealUp seal, componentwise transports, replay routes, provenance, and local NameCert evidence.

Chapter 6393

A Concrete Naming Certificate for $\mathsf{LocatedCantorBendixson}^{\uparrow}$

Following Cantor and Bendixson, the $\mathsf{LocatedCantorBendixson}^{\uparrow}$ packet records the constructive derived-set route for a compact located real subset as finite derivative rows and perfect-kernel boundary data. It sits over the Cantor-set prefix surface of chapter 1530, the compact metric carrier of chapter 129, the closed-set boundary of chapter 4229, the finite intersection discipline of chapter 1792, and the real-name seal of chapter 38. The certificate names the located derivative search and residual perfect-kernel rows; it does not assert a host transfinite rank, a powerset decomposition, countable choice, or a classical isolated-point selector.

Definition 6393.1 (Located Cantor–Bendixson carrier)**.** *A* $\mathsf{LocatedCantorBendixson}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, C, D, I, P, R, H, Q, S, N)$$

with the following displayed rows:

1. *K is the compact located metric row, naming the compact metric presentation, its located distance read, and the finite cover budgets available to the derivative search.*
2. *C is the closed real-set row, recording closedness tests through displayed complements and* $\mathsf{Real}^{\uparrow}$ *seals.*
3. *D is the finite derived-set ledger, listing inspected neighborhoods, witnessed isolated exclusions, and the residual closed rows generated by the displayed search depth.*
4. *I is the finite isolated-point ledger, carrying the local separation witness for each isolated read admitted by D.*
5. *P is the residual perfect-kernel row, recording the no-isolated-point boundary for the remaining displayed closed subpacket.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *membership and distance handoff row consumed only after K, C, D, I, P have been displayed.*
7. *H records componentwise* hsame *transport for compact metric data, closed-set tests, derivative ledgers, isolated witnesses, residual rows, real handoff, continuation replay, provenance, and local naming.*
8. *Q records displayed* Cont *replay from finite neighborhood requests to derivative rows and from residual rows to the perfect-kernel boundary.*

9. *S is the* Pkg *provenance over* $\mathsf{LocatedCantorBendixson}^{\uparrow}$, $\mathsf{CantorSet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{FiniteIntersectionProperty}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCantorBendixson}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host ordinal rank, ambient powersets, a selected enumeration of all isolated points, quotient real equality, countable choice, or a classical Cantor–Bendixson theorem outside the displayed compact located route.

Theorem 6393.2 (Located Cantor–Bendixson NameCert obligations)**.** *For every accepted* LocatedCantorBendixson *carrier $L = (K, C, D, I, P, R, H, Q, S, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCantorBendixson}^{\uparrow}}$ *surface is exhausted by the following five obligation rows:*

1. *compact located admission through K, exposing only displayed finite cover and distance data;*
2. *closed real-set boundary through C, exposing only displayed complement and seal tests;*
3. *derived-set ledger exactness through D, relating every inspected neighborhood to the finite derivative row;*
4. *isolated-point separation through I, naming each admitted isolated read by a displayed local witness;*
5. *residual perfect-kernel stability through P, R, H, Q, S, N, keeping every surviving membership read inside the real handoff, transport, replay, provenance, and local naming route.*

Proof. Project the carrier of Definition 6393.1. The compact and closed inputs are rows K and C, so the certificate starts from displayed located metric and closed-set data rather than from a host powerset.

The derivative work is finite at the named surface. Row D records the inspected neighborhoods and residual closed rows, while I stores only those isolated reads that come with displayed local separation evidence.

The residual row P binds the remaining perfect-kernel boundary. The real handoff R, transport H, continuation replay Q, provenance S, and local naming row N preserve the same route, so the five obligation rows exhaust the NameCert surface without importing an ordinal rank, a global isolated-point enumeration, quotient real equality, countable choice, or a classical decomposition theorem. □

Theorem 6393.3 (Located Cantor–Bendixson derivative stability)**.** *Let $L = (K, C, D, I, P, R, H, Q, S, N)$ be an accepted* $\mathsf{LocatedCantorBendixson}^{\uparrow}$ *carrier. Every derivative read produced from the displayed compact located closed set factors through*

$$K \longmapsto C \longmapsto D \longmapsto I \longmapsto P \longmapsto R$$

before it reaches transport, replay, provenance, and local naming rows. The residual closed packet is therefore stable under the displayed derived-set route, not under a host transfinite decomposition or a selected classical isolated-point enumeration.

Proof. Start with the compact located row K and closed row C. Together they provide the only admissible neighborhoods, distance reads, finite cover budgets, complement tests, and real seals available to the derivative search.

Next read the derivative and isolated ledgers. The row D records which neighborhoods have been inspected at the displayed depth, and I attaches local separation evidence to the isolated reads admitted there. No row supplies a global enumeration of all isolated points.

Finally pass through the residual row and structural rows. The perfect-kernel boundary P is consumed before the real handoff R, and H, Q, S, N transport, replay, source, and name that same finite route. Hence derivative stability is a row-exhaustion statement for the displayed compact located closed packet. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCantorBendixson}^{\uparrow}$ consumer that reads a derivative or residual perfect-kernel witness while omitting one of the compact located admission, closed real-set boundary, derivative ledger, isolated separation, residual kernel, Real handoff, hsame, Cont, Pkg, or NameCert rows has left the packet.

Independence witness: cantorset, compactmetric, closedset, finiteintersectionproperty, real: $\mathsf{LocatedCantorBendixson}^{\uparrow}$ is not bijective with any listed sibling because it joins compact located admission, closed real-set tests, finite derived-set rows, isolated separation, residual perfect-kernel stability, real handoff, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCantorBendixson}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCantorBendixson}^{\uparrow}$ packet is generated from compact located metric data, closed real-set tests, finite derived-set ledgers, isolated-point separation witnesses, residual perfect-kernel rows, Real handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCantorBendixson}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6393.1, Definition 6393.2, and Definition 6393.3 seed the constructive derived-set decomposition route for compact located closed real subsets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCantorBendixson}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host transfinite rank, ambient powerset decomposition, a selected enumeration of all isolated points, quotient real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact located exactness, closed-set boundary exactness, derivative ledger exactness, isolated separation, residual perfect-kernel stability, route replay, provenance, local naming, and non-escape for BEDC.Derived.LocatedCantorBendixsonUp.

Chapter 6394

A Concrete Naming Certificate for $\mathsf{NetConvergenceCriterion}^{\uparrow}$

Following Kelley, Moore–Smith, and Bourbaki, the $\mathsf{NetConvergenceCriterion}^{\uparrow}$ packet records the directed-net convergence test as finite L10 NameCert data rather than as an ambient filter or topological limit assertion. It reads directed indices from chapter 1607, net windows from chapter 3403, eventual-tail comparison through chapter 1601, uniform entourage control through chapter 339, and Cauchy-tail consumers through chapter 589. The packet is a nonquotient criterion surface for directed convergence; it is not a selected subnet, a host limit point, countable choice, quotient net equality, or ambient compactness.

Definition 6394.1 (Net convergence criterion carrier)**.** *A* $\mathsf{NetConvergenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, N, F, U, T, E, H, C, P, L)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index row, carrying the finite comparison and upper-bound witnesses that a tail request may inspect.*
2. *N is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *observation row, recording the source net values opened at the displayed directed indices.*
3. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *eventual-tail row, translating a neighborhood or entourage request into a displayed tail base.*
4. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *control row, exposing the entourage ledger against which the net values are compared.*
5. *T is the convergence-test row, pairing every accepted entourage request with a tail base and the finite net windows required on that tail.*
6. *E is the* $\mathsf{CauchyNet}^{\uparrow}$ *handoff row, available only after the directed, net, filter-base, uniform-space, and convergence-test rows have all been displayed.*
7. *H records componentwise* hsame *transport for D, N, F, U, T, E and the structural rows.*
8. *C records displayed* Cont *replay from a convergence request through directed indices, net windows, filter-base tails, uniform entourages, and the Cauchy-net handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{NetConvergenceCriterion}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. L is the local $\mathsf{NameCert}_{\mathsf{NetConvergenceCriterion}^{\uparrow}}$ *row.*

Accepted packets are compared only through $D, N, F, U, T, E, H, C, P, L$. No coordinate stores a host limit, a selected subnet, quotient equality of nets, countable choice, or an ambient compactness principle.

Theorem 6394.2 (Net convergence criterion NameCert obligations)**.** *For every accepted* $\mathsf{NetConvergenceCriterion}^{\uparrow}$ *carrier $Q = (D, N, F, U, T, E, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{NetConvergenceCriterion}^{\uparrow}}$ *surface consists exactly of directed-index admission, Moore–Smith net window exposure, filter-base eventual-tail exposure, uniform-space entourage accounting, convergence-test exactness, Cauchy-net handoff admission, componentwise transport, displayed replay, provenance, and local naming for the same displayed rows.*

Proof. Project the carrier of Definition 6394.1. The convergence request first exposes the directed index row D and the Moore–Smith net row N, so every later tail read is tied to displayed directed data.

The eventual and uniform parts are then fixed. The filter-base row F supplies the admitted tail base, while U supplies the entourage ledger against which the net windows are compared. The test row T records only those paired tail and entourage checks.

The handoff E is downstream of those rows and may be consumed by Cauchy-net readers only after the criterion surface is visible. The structural rows H, C, P, L transport, replay, source, and name the same finite packet. Since no carrier row stores a host limit, selected subnet, quotient equality, choice schedule, or compactness witness, the listed rows exhaust the local NameCert obligations. □

Theorem 6394.3 (Net convergence criterion filter handoff)**.** *Every* $\mathsf{FilterBase}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *consumer of an accepted* $\mathsf{NetConvergenceCriterion}^{\uparrow}$ *packet must read the route*

$$D, N \longmapsto F, U \longmapsto T \longmapsto E, H, C, P, L$$

before it may inspect the convergence result. Thus the criterion hands off a displayed eventual-tail test over directed Moore–Smith net data, not a quotient filter, selected convergent subnet, host limit point, countable-choice schedule, or ambient compactness theorem.

Proof. Start with the directed and net rows. The consumer can inspect only the index comparisons and finite net windows exposed by D and N.

Next read the filter and uniform rows. The row F gives the tail base used for the request, and U gives the entourage ledger. The convergence-test row T binds those two rows to the same net windows.

Finally the Cauchy-net handoff E and the structural rows H, C, P, L preserve that route for downstream readers. Because every public read factors through the displayed packet, the handoff cannot be replaced by a quotient filter, selected subnet, host limit, choice principle, or ambient compactness assertion. □

Falsifiable prediction: Every accepted $\mathsf{NetConvergenceCriterion}^{\uparrow}$ reader that claims directed convergence while omitting the DirectedSet index row, Moore–Smith net windows, FilterBase tail row, UniformSpace entourage ledger, convergence-test row, CauchyNet handoff, hsame transport, Cont replay, Pkg provenance, or local NameCert has left the packet surface.

Independence witness: directedset, mooresmithnet, filterbase, uniformspace, cauchynet: $\mathsf{NetConvergenceCriterio}$ is not bijective with any listed sibling because it joins directed index comparison, net observation,

eventual-tail filtering, entourage control, convergence testing, Cauchy-net handoff, transport, replay, provenance, and local naming as one finite criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{NetConvergenceCriterion}\uparrow}$.

Constructive story: A $\mathsf{NetConvergenceCriterion}^{\uparrow}$ packet is generated from DirectedSet index rows, Moore–Smith net windows, FilterBase eventual-tail rows, UniformSpace entourage ledgers, a convergence-test row, a CauchyNet handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NetConvergenceCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6394.1, Definition 6394.2, and Definition 6394.3 seed the displayed directed-net convergence criterion for completion and uniform-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NetConvergenceCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host topological limit, selected subnet, quotient filter, quotient net equality, countable choice, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-index exactness, Moore–Smith net window replay, filter-base tail exactness, uniform entourage accounting, convergence-test exactness, Cauchy-net handoff, transport, replay, provenance, and local naming for BEDC.Derived.NetConvergenceCriterionUp.

Chapter 6395

A Concrete Naming Certificate for $\mathsf{CompactRadiusChain}^{\uparrow}$

Following the Bishop–Heine–Cantor finite-cover proof, the $\mathsf{CompactRadiusChain}^{\uparrow}$ packet records the radius ledger that is read before a compact-continuity consumer reaches a $\mathsf{UniformModulus}^{\uparrow}$ row. It sits after the compact metric finite data of chapter 129, the ProbeBundle lower-bound fold of chapter 4118, the continuous-map pointwise radius route of chapter 130, the rational comparison surface of chapter 291, and the uniform-modulus consumer of chapter 369. The packet is the finite radius-chain component of the compact-uniform route; it is not an external Lebesgue-number selector, open-cover compactness, quotient map equality, countable choice, or ambient Real completeness.

Definition 6395.1 (Compact radius-chain carrier)**.** *A* $\mathsf{CompactRadiusChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, G, B, A, F, D, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-data row, exposing the compact source only as displayed ProbeBundle cover information.*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-radius row for the map whose compact-uniform handoff is being read.*
3. *B is the finite ProbeBundle cell row, carrying centers, local membership witnesses, and the radius candidates attached to each cell.*
4. *A is the positive-radius admission row, requiring every local radius candidate to be visible as finite rational or dyadic comparison data.*
5. *F is the finite lower-bound fold row over the displayed radius candidates.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the folded radius with the requested tolerance budget.*
7. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *placeholder row, available only as a handoff after K, G, B, A, F, D have been displayed.*
8. *H records componentwise* hsame *transport for compact source rows, pointwise-radius rows, bundle cells, radius admissions, folds, dyadic comparisons, and the handoff row.*

9. *C records displayed* Cont *replay from compact finite data through pointwise radii, ProbeBundle folding, dyadic comparison, and uniform-modulus handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactRadiusChain}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRadiusChain}^{\uparrow}}$ *row.*

Accepted packets are compared only through $K, G, B, A, F, D, U, H, C, P, N$ and never through an external radius selector, an open cover, a quotient map, countable choice, or ambient completeness.

Theorem 6395.2 (Compact radius-chain NameCert obligations)**.** *For every accepted* $\mathsf{CompactRadiusChain}^{\uparrow}$ *carrier $R = (K, G, B, A, F, D, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactRadiusChain}^{\uparrow}}$ *surface consists exactly of compact finite-data admission, continuous-map pointwise-radius admission, ProbeBundle cell exposure, positive-radius admission, finite lower-bound folding, DyadicRatCore tolerance accounting, UniformModulus handoff admission, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6395.1. The compact source and pointwise-radius rows K, G are visible before any radius fold can be read.

The finite chain is then displayed by B, A, F, D. The ProbeBundle cells name the finite family, the radius admission row exposes each positive candidate, the fold row records the lower-bound construction, and the dyadic ledger records the tolerance comparison.

Only after those rows are visible may the handoff row U be consumed by a uniform-modulus reader. The rows H, C, P, N transport, replay, source, and name the same packet. Since no row stores an external selector, open cover, quotient equality, choice schedule, or ambient completeness witness, these rows exhaust the local NameCert obligations. □

Theorem 6395.3 (Compact radius-chain uniform-modulus handoff)**.** *Every compact-uniform-continuity consumer that reads a* $\mathsf{CompactRadiusChain}^{\uparrow}$ *packet reaches* $\mathsf{UniformModulus}^{\uparrow}$ *only through*

$$K, G \longmapsto B, A, F, D \longmapsto U, H, C, P, N.$$

The handoff exposes a finite ProbeBundle lower-bound chain before the uniform-modulus row is consumed; it does not export a selected Lebesgue number, open-cover compactness, quotient map equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the compact and pointwise rows first. The consumer receives compact finite data from K and local radius information from G, not an ambient compactness theorem.

Next read the ProbeBundle radius chain. The cells B, admissions A, fold F, and dyadic ledger D display the lower-bound route that binds all local radii to one finite tolerance comparison.

Finally consume the handoff row U and the structural rows H, C, P, N. Because the uniform-modulus read is downstream of the displayed chain, it cannot be replaced by a selected Lebesgue number, an open-cover proof, quotient equality, choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CompactRadiusChain}^{\uparrow}$ reader that claims a compact uniform-modulus handoff while omitting compact finite data, pointwise-radius data, ProbeBundle cells, positive-radius admission, lower-bound folding, DyadicRatCore comparison, hsame transport, Cont replay, Pkg provenance, or local NameCert has left the packet.

Independence witness: compactmetric, continuousmap, uniformmodulus, dyadicratcore, probebundle-finite-minimum-fold: $\mathsf{CompactRadiusChain}^{\uparrow}$ is not bijective with any listed sibling because

it joins compact finite data, pointwise local radii, finite bundle cells, positive-radius admission, lower-bound folding, dyadic tolerance comparison, uniform-modulus handoff, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRadiusChain}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRadiusChain}^{\uparrow}$ packet is generated from CompactMetric finite data, ContinuousMap pointwise-radius rows, ProbeBundle cell rows, positive-radius admissions, a finite lower-bound fold, DyadicRatCore tolerance comparison, a UniformModulus handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRadiusChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6395.1, Definition 6395.2, and Definition 6395.3 seed the finite radius-chain surface for compact-uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRadiusChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an external Lebesgue-number selector, open-cover compactness, quotient map equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-data admission, pointwise-radius admission, ProbeBundle cell exposure, positive-radius admission, lower-bound folding, dyadic tolerance accounting, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactRadiusChainUp.

Chapter 6396

A Concrete Naming Certificate for $\mathsf{FreudenthalCompactification}^{\uparrow}$

Following Freudenthal's compactification of locally compact spaces by ends, the $\mathsf{FreudenthalCompactification}^{\uparrow}$ packet records a source space together with a finite end-filter boundary and a compact-boundary admission route as NameCert data. It reads the end carrier of chapter 5998, the one-point boundary discipline of chapter 2049, the compact metric route of chapter 129, the locally compact surface of chapter 1726, the topology carrier of chapter 88, and the metric carrier of chapter 57. The packet names the compactification boundary through displayed finite end filters rather than through an ambient quotient, selected ideal points, open-cover compactness, or choice-selected escaping rays.

Definition 6396.1 (FreudenthalCompactification carrier)**.** *A* $\mathsf{FreudenthalCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, E, B, J, T, H, Q, P, N)$$

with the following displayed rows:

1. *X is the source row, exposing the* $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, *and optional* $\mathsf{ProperMetric}^{\uparrow}$ *support used by the compactification packet.*
2. *E is the* $\mathsf{FreudenthalEnd}^{\uparrow}$ *row. It records compact-exhaustion stages, complement-component rows, tail-comparison data, and escaping-prefix ledgers exactly as in chapter 5998.*
3. *B is the finite end-filter boundary row. Each boundary request names the compact stage, the complement-component identifier, and the tail ledger slice that admits the boundary read.*
4. *J is the source-inclusion row. It records the displayed embedding of the source row into the compactification carrier without adding a quotient host space.*
5. *T is the compact-boundary admission ledger. It compares finite source neighbourhood reads, one-point compactification boundary discipline, and compact metric support rows before any boundary request is public.*
6. *H records componentwise* hsame *transport for the source, end-filter, boundary, inclusion, compact-boundary ledger, provenance, and local naming rows.*
7. *Q records displayed* Cont *replay from a compactification request through X, E, B, J, T, H.*
8. *P is the* Pkg *provenance over* $\mathsf{FreudenthalCompactification}^{\uparrow}$, $\mathsf{FreudenthalEnd}^{\uparrow}$, $\mathsf{OnePointCompactification}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FreudenthalCompactification}^{\uparrow}}$ *row.*
The carrier has no coordinate for an ambient quotient compactification, a selected ideal boundary point, an open-cover compactness proof, a chosen escaping ray, countable-choice enumeration of ends, or a standard bridge.

Theorem 6396.2 (FreudenthalCompactification NameCert obligation surface)**.** *For every accepted* $\mathsf{FreudenthalCompactification}^{\uparrow}$ *carrier* $K = (X, E, B, J, T, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FreudenthalCompactificati}}$ *surface consists exactly of source admission, Freudenthal end admission, finite end-filter boundary display, source-inclusion display, compact-boundary ledger readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A compactification consumer must read E before any boundary row B, must read X, J, B before the compact-boundary ledger T, and must keep the boundary admission route separate from open-cover compactness, quotient equality, selected ideal points, and choice-selected rays.*

Proof. Project the carrier of Definition 6396.1. The source row X supplies only the displayed topological, metric, locally compact, and optional proper metric data, while the end row E supplies the finite Freudenthal end surface.

The boundary row B is therefore readable only through compact stages, complement-component identifiers, and tail ledger slices already exposed by E. The source-inclusion row J records how source points enter the compactification carrier, but it does not create a quotient host space or a selected ideal point.

Next read the compact-boundary ledger T. Its only inputs are X, E, B, J together with the cited one-point, compact metric, locally compact, topological, and metric support rows, so it is a finite boundary-admission ledger rather than an open-cover compactness theorem.

Finally transport and replay through H and Q, then package and name through P and N. Since no displayed coordinate stores quotient compactification equality, selected rays, countable-choice enumeration of ends, or a standard bridge, the listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FreudenthalCompactification}^{\uparrow}}$.

Constructive story: A $\mathsf{FreudenthalCompactification}^{\uparrow}$ packet is generated from a displayed locally compact or metric source, a Freudenthal end row, finite end-filter boundary rows, a source-inclusion row, a compact-boundary admission ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FreudenthalCompactification}^{\uparrow}}$, seed)

Scope closed: Definition 6396.1 and Definition 6396.2 seed the Freudenthal compactification carrier over FreudenthalEnd, OnePointCompactification, CompactMetric, LocallyCompact, TopologicalSpace, MetricSpace, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FreudenthalCompactification}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a quotient compactification, public compact Hausdorff bridge, open-cover compactness theorem, selected boundary points, selected escaping rays, countable-choice enumeration of ends, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, end-filter boundary display, source inclusion, compact-boundary ledger readback, transport, replay, provenance, and local naming for BEDC.Derived.FreudenthalCompactificationUp.

Chapter 6397

A Concrete Naming Certificate for $\mathsf{LocatedZeroUniqueness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedZeroUniqueness}^{\uparrow}$ packet records the uniqueness boundary for two displayed located-zero reads over one shared constructive bracket route. It sits after the located-zero witness surface of chapter 6387, the finite stream and regular-rational readbacks of chapter 126 and chapter 301, the dyadic tolerance core of chapter 291, and the separated comparison boundary of chapter 1636. The packet names classifier equality over a displayed separated-zero route; it is not host equality of roots, a selected root, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6397.1 (Located zero uniqueness carrier)**.** *A* $\mathsf{LocatedZeroUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, M, S, Z_0, Z_1, W_0, W_1, R_0, R_1, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B, M, S are the shared* $\mathsf{BishopLocatedZero}^{\uparrow}$ *bracket, modulus, and bisection-schedule rows, recording that both zero reads come from the same displayed sign-change route.*
2. *Z_0 and Z_1 are the two displayed zero-witness rows, each pointing back to the common B, M, S route before any comparison is read.*
3. *W_0 and W_1 are the two* $\mathsf{StreamName}^{\uparrow}$ *window rows used to expose the finite source observations for the displayed zero reads.*
4. *R_0 and R_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the comparison route.*
6. *E is the* $\mathsf{RealEquality}^{\uparrow}$ *comparison row, or equivalently a separated-metric zero-distance comparison row, read only after $B, M, S, Z_0, Z_1, W_0, W_1, R_0, R_1, D$ have been displayed.*
7. *H records componentwise* hsame *transport for the shared bracket route, the two witness rows, the readback rows, the comparison row, and the local naming row.*
8. *C records displayed* Cont *replay through the route $B, M, S, Z_0, Z_1, W_0, W_1, R_0, R_1, D, E, H$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedZeroUniqueness}^{\uparrow}$, $\mathsf{BishopLocatedZero}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedZeroUniqueness}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the displayed separated-zero route. It has no coordinate for host equality of roots, a selected root, trichotomy, countable choice, open-cover compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.LocatedZeroUniquenessUp`

Theorem 6397.2 (Located zero uniqueness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedZeroUniqueness}^{\uparrow}$ *carrier* $U = (B, M, S, Z_0, Z_1, W_0, W_1, R_0, R_1, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedZeroUniqueness}^{\uparrow}}$ *surface is exhausted by shared located-zero bracket admission through* B, M, S*, two displayed zero-witness rows through* Z_0, Z_1*, StreamName exposure through* W_0, W_1*, RegSeqRat readback through* R_0, R_1*, dyadic tolerance accounting through* D*, separated comparison through* E*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6397.1. The shared data B, M, S is the same displayed located-zero route named in chapter 6387, so the comparison cannot begin from two unrelated host roots.

The two witness rows are then read symmetrically. Rows Z_0, Z_1 display the two zero witnesses, W_0, W_1 expose the finite stream windows, R_0, R_1 give the regular-rational readbacks, and D supplies the dyadic tolerance ledger consumed by the comparison row E.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no root-selection, trichotomy, choice, compactness, host-equality, quotient-equality, or completeness coordinate, none of those objects can become a local NameCert obligation. □

Theorem 6397.3 (Located zero separated comparison envelope)**.** *Let* $U = (B, M, S, Z_0, Z_1, W_0, W_1, R_0, R_1, D, E,$ *be an accepted* $\mathsf{LocatedZeroUniqueness}^{\uparrow}$ *carrier. Every downstream consumer that compares the two displayed zero reads must factor the comparison through the common* $\mathsf{BishopLocatedZero}^{\uparrow}$ *route* B, M, S*, the two displayed zero-witness rows* Z_0, Z_1*, the two* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* W_0, W_1, R_0, R_1*, the dyadic tolerance ledger* D*, and the* $\mathsf{RealEquality}^{\uparrow}$ *or* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row* E *before it reaches transport, replay, provenance, and naming rows. The exported result is classifier equality over this displayed separated-zero route, not host equality of roots or a selected global zero.*

Proof. Start with the shared located-zero route. Rows B, M, S are the only admissible bracket, modulus, and bisection schedule for both displayed witnesses, so a consumer cannot substitute an ambient intermediate-value theorem or a separate root-selection principle.

Next read both witnesses through the same finite observation discipline. The rows Z_0, Z_1 provide the two zero-witness displays, W_0, W_1 and R_0, R_1 expose the finite stream and regular-rational routes, and D records the tolerance ledger.

Finally apply the separated comparison row E and carry the result through H, C, P, N. The comparison is the same kind of displayed equality boundary isolated by chapter 1636 and the separated classifier discipline of chapter 1411; it does not export host root equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{LocatedZeroUniqueness}^{\uparrow}$ consumer that compares two displayed zero reads while omitting the shared BishopLocatedZero bracket route, one of the two zero-witness rows, one of the StreamName or RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the separated comparison row, hsame, Cont, Pkg, or NameCert has left the packet.

Independence witness: bishoplocatedzero, realequality, separatedmetric, streamname, regseqrat, dyadicratcore: $\mathsf{LocatedZeroUniqueness}^{\uparrow}$ is not bijective with any listed sibling because it joins one shared located-zero route, two displayed zero-witness rows, paired readbacks, a dyadic comparison ledger, separated classifier equality, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedZeroUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedZeroUniqueness}^{\uparrow}$ packet is generated from one shared BishopLocatedZeroUp bracket, modulus, and bisection schedule, two displayed zero-witness rows, paired StreamName and RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a RealEqualityUp or SeparatedMetricUp comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedZeroUniqueness}^{\uparrow}}$, seed)

Scope closed: Definition 6397.1, Definition 6397.2, and Definition 6397.3 seed the finite classifier route for comparing two displayed located-zero reads over one shared L10 bracket surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedZeroUniqueness}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.LocatedZeroUniquenessUp`

Bridge status: none

Not claimed: This chapter does not claim host equality of roots, a selected global zero, trichotomy, quotient real equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification of the obligation theorems, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared bracket admission, two zero-witness rows, paired readbacks, dyadic comparison accounting, separated classifier comparison, transport, replay, provenance, and local naming for BEDC.Derived.LocatedZeroUniquenessUp.

Chapter 6398

A Concrete Naming Certificate for $\mathsf{CountablyCompact}^{\uparrow}$

Following Kelley and Bourbaki on countable open-cover compactness, the $\mathsf{CountablyCompact}^{\uparrow}$ packet records the traditional countably compact surface as finite NameCert data. It reads the $\mathsf{Topology}^{\uparrow}$ source row of chapter 88, the compactness boundary of chapter 60, the finite window discipline of chapter 126, the countable-cover consumer surface of chapter 3914, and the basis-counting route of chapter 1901. The packet names the countable-cover interface without making arbitrary open-cover compactness a primitive coordinate.

Definition 6398.1 (Countably compact carrier)**.** *A* $\mathsf{CountablyCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, C, W, S, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the carrier, indexed open rows, finite-intersection read-back, and open-membership classifier used by the packet.*
2. *C is the countable open-cover enumeration row. It records the inspected StreamName schedule of open indices and the displayed statement that the named countable family covers the source row.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite cover-window row, listing finite prefixes and the pointwise cover checks visible inside each prefix.*
4. *S is the finite-subcover ledger. It records the accepted prefix whose listed open rows cover the same source surface, together with the finite witness that no later enumeration row is needed for that cover read.*
5. *H stores componentwise* hsame *transport for topology, countable-cover enumeration, finite windows, finite-subcover ledger, replay, provenance, and local naming rows.*
6. *R stores displayed* Cont *replay from a countable-cover request through T, C, W, S, H.*
7. *P is the* Pkg *provenance over* $\mathsf{CountablyCompact}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{LindelofSpace}^{\uparrow}$, $\mathsf{SecondCountable}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CountablyCompact}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open-cover compactness, selected ultrafilters, countable-choice extraction of subcovers, host powersets, quotient open equality, or a standard bridge.

Lean4 (statement) `BEDC.Derived.CountablyCompactUp`

Theorem 6398.2 (Countably compact NameCert obligations)**.** *For every accepted* $\mathsf{CountablyCompact}^{\uparrow}$ *carrier* $K = (T, C, W, S, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CountablyCompact}^{\uparrow}}$ *surface consists exactly of topology source admission, countable open-cover enumeration, StreamName finite cover windows, finite-subcover ledger readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every countable-cover consumer must read* T, C, W, S *before the structural rows* H, R, P, N *can be consumed.*

Proof. Project the carrier of Definition 6398.1. The topology row T is the only source surface, and the countable cover row C is the only row that records an open-cover enumeration.

The finite evidence is downstream of that enumeration. Row W exposes finite StreamName windows of the countable cover, and S records the finite prefix whose displayed open rows cover the same source row.

Finally H, R, P, N transport, replay, source, and name exactly those rows. Since no field stores arbitrary open covers, ultrafilter convergence, selected subcovers, host powersets, quotient open equality, or a bridge credential, the listed rows exhaust the local NameCert obligations. □

Theorem 6398.3 (Countably compact StreamName cover route)**.** *Every accepted* $\mathsf{CountablyCompact}^{\uparrow}$ *cover read factors through the finite route*

$$\mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{CountablyCompact}^{\uparrow} \longrightarrow \mathsf{LindelofSpace}^{\uparrow} \longrightarrow \mathsf{SecondCountable}^{\uparrow}$$

whenever a downstream countability or basis consumer asks for countable-cover compactness. The route exports only the displayed topology source row, countable open-cover enumeration, finite StreamName windows, finite-subcover ledger, transport, replay, provenance, and local naming rows.

Proof. Start with the accepted packet $K = (T, C, W, S, H, R, P, N)$. A cover read first inspects T and C, so the cover is a displayed countable family over the named topology row rather than an arbitrary host cover.

The StreamName handoff is the finite evidence layer. Row W provides the finite prefix windows, and S records the finite-subcover ledger consumed by countable-cover readers.

The downstream Lindelof and second-countable surfaces receive only that finite ledger through H, R, P, N. Thus the route is a displayed countable-cover compactness packet and not an open-cover compactness primitive. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountablyCompact}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CountablyCompact}^{\uparrow}$ packet is generated from a Topology source row, a countable open-cover enumeration, finite StreamName cover windows, a finite-subcover ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CountablyCompact}^{\uparrow}}$, seed)

Scope closed: Definition 6398.1, Definition 6398.2, and Definition 6398.3 seed the countable-cover compactness carrier over Topology, Compact, StreamName, LindelofSpace, SecondCountable, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CountablyCompact}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, ultrafilter compactness, selected finite subcovers by countable choice, host powerset topology, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, countable-cover enumeration, StreamName finite-window exactness, finite-subcover ledger readback, transport, replay, provenance, and local naming for BEDC.Derived.CountablyCompact

Chapter 6399

A Concrete Naming Certificate for $\mathsf{ObservableOpenFilter}^{\uparrow}$

Following Sierpinski, Kelley, and Bourbaki on observable opens and filters, the $\mathsf{ObservableOpenFilter}^{\uparrow}$ packet records the open-membership data needed by compact-uniform-continuity cover reads as a finite NameCert surface. It consumes the Sierpinski classifier of chapter 1860, the topology source row of chapter 88, the finite StreamName windows of chapter 126, and the uniform-modulus consumer boundary of chapter 369. The packet keeps open membership as displayed observable truth rather than as a host proposition.

Definition 6399.1 (Observable open-filter carrier)**.** *An* $\mathsf{ObservableOpenFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, O, W, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *classifier row, exposing observable truth marks for open-membership reads.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row whose indexed opens are filtered by the packet.*
3. *O is the observable-open filter row. It records the directed finite family of open-index requests, refinement witnesses, and compatibility with the Sierpinski truth row.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite window row, listing the observed open-membership requests available to compact cover readers.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *cover-read handoff row, recording the tolerance-facing consumer that reads the finite open filter before it consumes a compact-uniform modulus route.*
6. *H stores componentwise* hsame *transport for the Sierpinski classifier, topology source, observable-open filter, finite windows, uniform-modulus handoff, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from an open-filter request through S, T, O, W, U, H.*
8. *P is the* Pkg *provenance over* $\mathsf{ObservableOpenFilter}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ObservableOpenFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for host open-membership propositions, excluded middle, selected neighbourhood filters, arbitrary powerset opens, quotient open equality, countable-choice schedules, or bridge credentials.

Lean4 (statement) `BEDC.Derived.ObservableOpenFilterUp`

Theorem 6399.2 (Observable open-filter NameCert obligations)**.** *For every accepted* $\mathsf{ObservableOpenFilter}^{\uparrow}$ *carrier* $F = (S, T, O, W, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ObservableOpenFilter}^{\uparrow}}$ *surface consists exactly of Sierpinski classifier admission, Topology source admission, observable-open filter display, StreamName finite windows, UniformModulus cover-read handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every compact-uniform cover consumer must read* S, T, O, W, U *before it consumes* H, C, P, N*.*

Proof. Project the carrier of Definition 6399.1. Rows S and T supply the only observable-open classifier and topology source visible to the packet.

The filter data are finite and displayed. Row O names the directed open-index requests and refinement witnesses, while W records the finite StreamName windows through which compact cover readers observe those requests.

The uniform-modulus handoff U is downstream of those observable-open rows. The structural rows H, C, P, N then transport, replay, source, and name the same packet. Since no field stores host propositions, selected neighbourhood filters, powerset opens, quotient open equality, countable choice, or a bridge credential, the listed rows exhaust the local NameCert obligations. □

Theorem 6399.3 (Observable open-filter Sierpinski handoff)**.** *Every open-membership read exported by an accepted* $\mathsf{ObservableOpenFilter}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{SierpinskiSpace}^{\uparrow} \longrightarrow \mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{UniformModulus}^{\uparrow}.$$

Thus compact-uniform cover reads receive observable Sierpinski classifier data and finite open windows, not host propositions or selected neighbourhood filters.

Proof. Read the accepted packet $F = (S, T, O, W, U, H, C, P, N)$. The Sierpinski row S classifies each open-membership request before the topology row T is consumed, so the route begins with observable truth data.

The filter row O and finite window row W then display which open-index requests are available to a cover reader. The handoff row U records the uniform-modulus consumer only after those finite observable-open rows have been inspected.

Transport, replay, provenance, and naming through H, C, P, N preserve this dependency order. Therefore no compact-uniform cover read can bypass the Sierpinski classifier by importing host propositions, selected neighbourhood filters, powerset opens, quotient open equality, countable choice, or a bridge credential. □

Theorem 6399.4 (Observable open-filter rounded Cauchy consumption)**.** *Any completion-facing consumer that reads an accepted* $\mathsf{ObservableOpenFilter}^{\uparrow}$ *packet before a* $\mathsf{RoundedCauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *route must expose the* $\mathsf{SierpinskiSpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *rows first. The handoff into the rounded filter base is allowed only through the displayed open-membership windows of that packet. It cannot import host open predicates, selected neighbourhood filters, quotient filter equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 6399.1. The only rows available before the structural transport, replay, provenance, and local naming coordinates are the Sierpinski classifier S, topology source T, observable-open filter row O, StreamName windows W, and UniformModulus handoff U.

Apply Definition 6399.2. It forces every compact-uniform cover consumer to read S, T, O, W, U before it can consume H, C, P, N. Apply Definition 6399.3 to identify the observable route as the displayed Sierpinski-to-uniform-modulus chain.

The downstream completion route is the rounded Cauchy filter packet of chapter 2016. By Definition 2016.4, its completion-facing read consumes only the displayed rounded-base, stream-window, regular-readback, dyadic-ledger, completion-handoff, and real-seal rows. Therefore an $\mathsf{ObservableOpenFilter}^{\uparrow}$ consumer can feed that route only through displayed open-membership windows, not through host open predicates, selected neighbourhood filters, quotient filter equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObservableOpenFilter}^{\uparrow}}$.

Constructive story: An $\mathsf{ObservableOpenFilter}^{\uparrow}$ packet is generated from a SierpinskiSpace observable-open classifier row, a Topology source row, directed observable-open filter data, finite StreamName windows, a UniformModulus cover-read handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservableOpenFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6399.1, Definition 6399.2, Definition 6399.3, and Definition 6399.4 seed the observable-open filter carrier over SierpinskiSpace, Topology, StreamName, UniformModulus, BHist, hsame, Cont, Pkg, NameCert, and rounded Cauchy completion-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservableOpenFilter}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim host open-membership propositions, selected neighbourhood filters, powerset opens, quotient open equality, countable choice, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked classifier admission, topology source admission, observable-open filter exactness, finite-window readback, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.ObservableOpenFilterUp.

Chapter 6400

A Concrete Naming Certificate for $\mathsf{PellEquation}^{\uparrow}$

Following Lagrange's continued-fraction treatment of Pell equations, the $\mathsf{PellEquation}^{\uparrow}$ packet records the finite certificate surface for integer solutions of $x^2 - Dy^2 = 1$ with D a positive nonsquare parameter. It is read against the integer row of chapter 31, the rational row of chapter 37, the quadratic-form surface of chapter 5112, the convergent ledger of chapter 1777, and the period ledger of chapter 1961. The packet names the solution route; it does not choose an infinite continued fraction stream, assert unique minimality from a host theorem, import quotient equality of solution sets, or add an ambient number-theory oracle.

Definition 6400.1 (Pell equation carrier)**.** *A* $\mathsf{PellEquation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (D, X, Y, N, Q, V, L, H, C, K, M)$$

with the following displayed rows:

1. *D is the nonsquare parameter row. It records a positive* $\mathsf{Int}^{\uparrow}$ *value together with a displayed refusal of a square root inside the integer ledger.*
2. *X and Y are integer solution rows, read through chapter 31, carrying the displayed candidate pair for the equation.*
3. *N is the quadratic norm row $x^2 - Dy^2$, read through the* $\mathsf{QuadraticForm}^{\uparrow}$ *surface of chapter 5112.*
4. *Q is the rational comparison row, read through chapter 37, used only to inspect finite convergent quotients and the equation value* 1*.*
5. *V is the* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *row listing the finite convergents inspected by the certificate.*
6. *L is the* $\mathsf{PeriodicContinuedFraction}^{\uparrow}$ *period row displaying the repeated finite block attached to $\sqrt{D}$.*
7. *H records componentwise* hsame *transport for the parameter, integer solution rows, norm row, rational comparison row, convergent ledger, period ledger, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a Pell-equation request through D, X, Y, N, Q, V, L, H.*
9. *K is the* Pkg *provenance over* $\mathsf{PellEquation}^{\uparrow}$*,* $\mathsf{Int}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{QuadraticForm}^{\uparrow}$*,* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$*,* $\mathsf{PeriodicContinuedFraction}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. M is the local $\mathsf{NameCert}_{\mathsf{PellEquation}^\uparrow}$ *row.*

The classifier compares accepted packets only through these rows. The carrier has no coordinate for a host-level solution set, selected infinite period stream, quotient equality of all solutions, or external decidability principle.

Lean4 ✓ `BEDC.Derived.PellEquationUp.PellEquationTasteGate single carrier alignment`

Theorem 6400.2 (Pell equation NameCert obligations)**.** *For every accepted* $\mathsf{PellEquation}^\uparrow$ *carrier*

$$P = (D, X, Y, N, Q, V, L, H, C, K, M),$$

the local $\mathsf{NameCert}_{\mathsf{PellEquation}^\uparrow}$ *surface consists exactly of nonsquare parameter admission through D, integer solution-row admission through X, Y, quadratic norm evaluation through N, rational comparison through Q, finite convergent exposure through V, finite period exposure through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through K, and local naming through M.*

No Pell equation obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.PellEquationUp.PellEquationCarrier namecert obligations`

Proof. Project the accepted carrier. Its analytic rows are exactly the nonsquare parameter, the two integer solution rows, the quadratic norm, the rational comparison row, the convergent ledger, and the period ledger.

The equation check is read from the norm row N. Since N is the displayed quadratic form $x^2 - Dy^2$ and Q compares its value with the rational unit, the certificate verifies the Pell equation only by inspecting rows already present in the packet.

The continued-fraction data is finite. The convergent ledger V and period ledger L record the Lagrange route used to source candidate integer rows, but neither row supplies an infinite stream or a global selector.

Finally, H, C, K, M transport, replay, source, and name the same displayed route. Since the carrier has no remaining coordinate, the local NameCert obligations are exhausted by the listed rows. □

Theorem 6400.3 (Pell equation norm preservation)**.** *Let $P = (D, X, Y, N, Q, V, L, H, C, K, M)$ be an accepted* $\mathsf{PellEquation}^\uparrow$ *carrier. Any* hsame/Cont *replay of the packet that preserves the nonsquare parameter row, the two integer solution rows, the continued-fraction convergent row, and the period row preserves the displayed quadratic norm row N and therefore preserves the public equation witness $x^2 - Dy^2 = 1$.*

The preservation route factors through $\mathsf{Int}^\uparrow$, $\mathsf{Rat}^\uparrow$, $\mathsf{QuadraticForm}^\uparrow$, $\mathsf{ContinuedFractionConvergents}^\uparrow$, *and* $\mathsf{PeriodicContinuedFraction}^\uparrow$ *before the local* $\mathsf{NameCert}_{\mathsf{PellEquation}^\uparrow}$ *row is read. It exports no host solution-set equality, selected infinite continued fraction, quotient class of solutions, or ambient number-theory decision oracle.*

Lean4 ✓ `BEDC.Derived.PellEquationUp.PellEquation norm preservation`

Proof. Start with the carrier projection. The norm row N is tied to the displayed parameter and solution rows D, X, Y, so a replay preserving those rows also preserves the inputs to the quadratic-form evaluation.

Use the finite Lagrange route next. The rows V and L show which finite convergents and period block were inspected before X, Y were accepted. Preserving those rows keeps the same finite source for the solution witness.

The rational comparison row Q reads the displayed norm value against the unit. Since H transports componentwise and C replays the same displayed coordinates, the comparison remains attached to the same norm row.

Thus the public witness $x^2 - Dy^2 = 1$ is preserved as a finite NameCert route. No step introduces a host equality of solution sets, an infinite continued fraction object, a quotient class, or an external decision principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{PellEquation}\uparrow}$.

Constructive story: A $\mathsf{PellEquation}^{\uparrow}$ packet is generated from a nonsquare IntUp parameter row, two IntUp solution rows, a QuadraticFormUp norm row, a RatUp comparison row, ContinuedFractionConvergentsUp and PeriodicContinuedFractionUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PellEquation}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6400.1, Definition 6400.2, and Definition 6400.3 seed the finite Pell-equation certificate surface over integer rows, rational comparison, quadratic norm evaluation, continued-fraction convergents, and periodic continued-fraction data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PellEquation}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host solution-set equality, selected infinite continued fraction, quotient class of all Pell solutions, ambient number-theory decision oracle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked parameter admission, integer solution-row admission, norm evaluation, convergent-period route, transport stability, replay stability, and nonescape for BEDC.Derived.PellEquationUp.

Chapter 6401

A Concrete Naming Certificate for $\mathsf{WeakStarCompactness}^{\uparrow}$

Following Bourbaki and Kelley on locally convex spaces and weak-star compactness, the $\mathsf{WeakStarCompactness}^{\uparrow}$ packet records the finite dual-ball compactness interface that sits between the weak-star observation rows of chapter 5192 and the finite dual-ball handoff of chapter 3420. It is read over the locally convex source of chapter 3386 and the compactness carrier of chapter 60. The chapter names the compactness-facing dual-ball route as finite NameCert data; it does not identify a host dual space, choose cluster points, invoke ultrafilters, or export unrestricted product compactness.

Definition 6401.1 (Weak-star compactness carrier)**.** *A* $\mathsf{WeakStarCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, T, B, A, C, R, H, Q, P, N)$$

with the following displayed rows:

1. *E is the locally convex source row, read through the finite seminorm and convex balanced neighbourhood surface of* $\mathsf{LocallyConvexSpace}^{\uparrow}$*.*
2. *T is the weak-star topology row, exposing only the finite functional observation windows admitted by* $\mathsf{WeakStarTopology}^{\uparrow}$*.*
3. *B is the finite dual-ball row, listing the displayed bounded functionals, source probes, scalar bounds, and tolerance rows inspected by the packet.*
4. *A is the Banach–Alaoglu handoff row, used only as the finite dual-ball window described by* $\mathsf{BanachAlaoglu}^{\uparrow}$*.*
5. *C is the compactness row, read through* $\mathsf{Compact}^{\uparrow}$ *as finite-net or located compactness evidence for the displayed window, not as an unrestricted host compactness predicate.*
6. *R is the scalar readback row for real-valued functional values, bounds, and comparisons.*
7. *H records componentwise* hsame *transport for the locally convex source, weak-star topology window, dual-ball row, Banach–Alaoglu handoff, compactness row, scalar readback, replay, provenance, and naming rows.*
8. *Q records displayed* Cont *replay from a compactness-facing dual-ball request through $E, T, B, A, C, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{WeakStarCompactness}^{\uparrow}$*,* $\mathsf{LocallyConvexSpace}^{\uparrow}$*,* $\mathsf{WeakStarTopology}^{\uparrow}$*,* $\mathsf{BanachAlaoglu}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{WeakStarCompactness}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $E, T, B, A, C, R, H, Q, P, N$. It has no coordinate for a chosen dual element, a selected cluster point, ultrafilter extension, quotient equality of functionals, unrestricted Tychonoff compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.WeakStarCompactnessUp.TasteGate.WeakStarCompactnessTasteGate single carrier alignment`

Theorem 6401.2 (Weak-star compactness NameCert obligations)**.** *For every accepted* $\mathsf{WeakStarCompactness}^{\uparrow}$ *carrier $K = (E, T, B, A, C, R, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakStarCompactness}^{\uparrow}}$ *surface consists exactly of locally convex source admission through E, weak-star observation-window admission through T, finite dual-ball admission through B, Banach–Alaoglu finite-window handoff through A, compactness evidence through C, scalar readback through R, componentwise transport through H, displayed replay through Q, provenance through P, and local naming through N.*

Proof. Project the accepted carrier in Definition 6401.1. The rows $E, T, B, A, C, R, H, Q, P, N$ are the complete displayed inventory of the packet.

The source and topology rows are read first. The locally convex source E fixes the finite seminorm and neighbourhood surface, while T restricts weak-star access to finite functional observation windows.

The compactness-facing data then pass through B, A, C, R. The dual-ball row B lists the bounded functional probes, A cites only the Banach–Alaoglu finite-window handoff, C supplies the displayed compactness evidence for that window, and R records the scalar readbacks.

Transport, replay, provenance, and naming are supplied by H, Q, P, N. Since no other carrier coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 6401.3 (Weak-star compactness finite dual-ball route)**.** *Every compactness export from an accepted* $\mathsf{WeakStarCompactness}^{\uparrow}$ *packet factors through the finite route*

$$E, T, B, A, C, R, H, Q, P, N.$$

Thus a functional-analysis consumer may read weak-star compactness only after exposing the locally convex source, the weak-star observation window, the finite dual-ball row, the Banach–Alaoglu handoff, compactness evidence, scalar readback, transport, replay, provenance, and local NameCert rows. The export carries no chosen dual element, no selected cluster point, no ultrafilter extension, no quotient equality of functionals, no unrestricted Tychonoff compactness, and no ambient completeness coordinate.

Proof. Begin with a compactness-facing export. By Definition 6401.2, the export must expose the locally convex source E and the weak-star observation window T before any dual-ball compactness data can be inspected.

The finite dual-ball row B and Banach–Alaoglu handoff row A then determine the displayed functional probes and scalar bounds. Compactness evidence is read only through C, and scalar values and comparisons are read only through R.

The structural rows H, Q, P, N preserve that same route under transport, replay, provenance, and local naming. Because the carrier contains no selection, ultrafilter, quotient, unrestricted product, or ambient completeness row, none of those data can be exported by projection from the accepted packet. □

Falsifiable prediction: Every public $\mathsf{WeakStarCompactness}^{\uparrow}$ compactness read factors through a displayed $\mathsf{LocallyConvexSpace}^{\uparrow}$ source, a finite $\mathsf{WeakStarTopology}^{\uparrow}$ observation window, a finite dual-ball row, a $\mathsf{BanachAlaoglu}^{\uparrow}$ handoff, a $\mathsf{Compact}^{\uparrow}$ compactness row, scalar readback, BHist transport, hsame, Cont, Pkg, and local NameCert naming. A public read that exports selected dual elements, cluster-point choice, ultrafilters, quotient functional equality, unrestricted product compactness, or ambient completeness from this packet refutes the carrier boundary.

Independence witness: weakstartopology, banachalaoglu, locallyconvexspace, compact: none is bijective with $\mathsf{WeakStarCompactness}^{\uparrow}$ because this carrier binds the locally convex source, weak-star finite observation window, finite dual-ball handoff, compactness evidence, scalar readback, transport, replay, provenance, and local NameCert rows while refusing selection and unrestricted compactness coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakStarCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{WeakStarCompactness}^{\uparrow}$ packet is generated from a locally convex source row, a weak-star finite observation window, a finite dual-ball row, a Banach–Alaoglu handoff, compactness evidence, scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakStarCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6401.1, Definition 6401.2, and Definition 6401.3 seed the finite dual-ball compactness interface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakStarCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected dual elements, cluster-point choice, ultrafilter extension, quotient functional equality, unrestricted Tychonoff compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak-star observation-window admission, finite dual-ball exactness, compactness-row handoff, scalar readback, transport, replay, provenance, and local naming for BEDC.Derived.WeakStarCompactnessUp.

Chapter 6402

A Concrete Naming Certificate for $\mathsf{LocatedDistanceFunction}^{\uparrow}$

Following Bishop and Bridges on located subsets of metric spaces, the $\mathsf{LocatedDistanceFunction}^{\uparrow}$ packet records the standard point-to-set distance function as a finite BEDC NameCert surface. It sits over the metric source of chapter 57, the located-set row of chapter 1541, the point-to-set packet of chapter 4364, the lower-semicontinuity sibling of chapter 1536, the located-real comparison surface of **??**, and the terminal real-name seal of chapter 38. The packet names a reusable real-valued function row for located subsets; it does not assert a host infimum, selected nearest point, quotient real equality, countable-choice selector, or ambient completeness principle.

Definition 6402.1 (Located distance function carrier)**.** *A* $\mathsf{LocatedDistanceFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, A, D, F, R, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row over which point and subset reads are interpreted.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *source row naming the subset by located-radius observations.*
3. *D is the* $\mathsf{DistanceToSet}^{\uparrow}$ *row that supplies the point-to-set distance read for each displayed point request.*
4. *F is the function graph row, recording the finite route from a point row in X through A, D to the exported real-name value.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for each displayed value of the function.*
6. *O is the lower-semicontinuity and* $\mathsf{LocatedReal}^{\uparrow}$ *comparison ledger, recording lower-real threshold reads, located-real value comparison, and sibling handoff to* $\mathsf{LowerSemicontinuous}^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for the metric source, located-set source, distance-to-set row, graph row, Real seal, comparison ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a point request through the metric and located-set rows, the distance-to-set row, the graph row, the Real seal, and the lower-semicontinuity ledger.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedDistanceFunction}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{LocatedSet}^{\uparrow}$*,* $\mathsf{DistanceToSet}^{\uparrow}$*,* $\mathsf{LowerSemicontinuous}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDistanceFunction}^{\uparrow}}$ *row.*

The classifier accepts only packets whose graph values are read through $X, A, D, F, R, O, H, C, P, N$. It has no coordinate for a host function space, selected nearest point, ambient infimum, quotient real equality, or countable-choice schedule.

Theorem 6402.2 (Located distance function NameCert obligations)**.** *For every accepted* $\mathsf{LocatedDistanceFunction}^{\uparrow}$ *carrier $L = (X, A, D, F, R, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedDistanceFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, located-set source, distance-to-set row, function graph, Real seal, lower-semicontinuity and located-real comparison ledger, transport, replay, provenance, and local naming;*
2. *point-request routing, requiring every value read to start in X and pass through the located subset row A;*
3. *distance-to-set handoff, requiring the value row to consume the* $\mathsf{DistanceToSet}^{\uparrow}$ *packet of chapter 4364 before the graph row F is public;*
4. *Real and located-real sealing, requiring R and O to record only displayed values and comparisons;*
5. *lower-semicontinuity exposure, requiring the lower-threshold route to pass through the sibling surface of chapter 1536;*
6. *componentwise transport, displayed replay, package provenance, and local naming for exactly the displayed packet.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 6402.1. The source row X supplies points, the located-set row A supplies located-radius observations, and the distance row D supplies the point-to-set value route.

The graph row F does not introduce a separate host function. It records the replay from point requests to the displayed distance row and then to the Real seal R.

The ledger O records the lower-semicontinuity and located-real comparison data after the value row is sealed. Transport H, replay C, provenance P, and local naming N preserve the same row family, so the listed obligations exhaust the certificate surface. □

Theorem 6402.3 (Located distance function lower semicontinuity)**.** *Every accepted* $\mathsf{LocatedDistanceFunction}^{\uparrow}$ *carrier $L = (X, A, D, F, R, O, H, C, P, N)$ exports lower-semicontinuity only through the displayed route*

$$X, A, D, F, R, O, H, C, P, N.$$

The lower-threshold read consumes the $\mathsf{DistanceToSet}^{\uparrow}$ *value row and the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison ledger before it reaches the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *sibling surface. It cannot be replaced by a host liminf, selected nearest point, quotient real equality, countable-choice selector, or ambient completeness theorem.*

Proof. Start with a lower-threshold request for the function value. By Definition 6402.2, the request first reads the metric source, located subset, distance-to-set row, graph row, and Real seal.

The ledger O then exposes the located-real comparison needed by the lower-semicontinuity sibling. Since O is downstream of D, F, R, the lower-threshold route remains tied to the same displayed point-to-set distance value.

Finally H, C, P, N transport, replay, source, and name that finite route. The carrier has no coordinate for a host limiting theorem or chosen nearest point, so the exported lower-semicontinuity surface is exactly the displayed BEDC handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDistanceFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDistanceFunction}^{\uparrow}$ packet is generated from metric source, located-set source, DistanceToSet row, function graph, Real seal, lower-semicontinuity and located-real comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedDistanceFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6402.1, Definition 6402.2, and Definition 6402.3 seed the finite real-valued located-distance-function surface over displayed point-to-set distance rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedDistanceFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host function-space construction, host infimum, selected nearest points, quotient real equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, point-request routing, distance-to-set handoff, Real and located-real sealing, lower-semicontinuity exposure, transport, replay, provenance, and local naming for BEDC.Derived.LocatedDistanceFunctionUp.

Chapter 6403

A Concrete Naming Certificate for $\mathsf{HermitianMatrix}^{\uparrow}$

Following Horn and Johnson on matrix analysis, the $\mathsf{HermitianMatrix}^{\uparrow}$ packet records the finite BEDC surface for a square complex matrix displayed together with its conjugate-transpose and self-adjointness rows. It sits after the matrix carrier of chapter 49, the complex scalar rows of chapter 39, the vector-space source of chapter 47, the field source of chapter 45, and the local naming discipline exemplified by chapter 481. The packet names finite Hermitian-matrix evidence; it does not assert a spectral theorem, diagonalization, eigenbasis selection, positive semidefiniteness, quotient matrix equality, or host matrix equality.

Definition 6403.1 (Hermitian matrix carrier)**.** *A* $\mathsf{HermitianMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (D, F, V, M, K, T, S, E, C, P, L)$$

with the following displayed rows:

1. *D is the finite dimension row naming the shared square index window for matrix entries.*
2. *F is the consumed* $\mathsf{Field}^{\uparrow}$ *scalar-source row through which addition, multiplication, zero, and one are read.*
3. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *coordinate source over the same scalar rows.*
4. *M is the square* $\mathsf{Mat}^{\uparrow}$ *entry ledger, indexed by $D \times D$ and carrying complex-valued entry histories.*
5. *K is the* $\mathsf{Complex}^{\uparrow}$ *conjugation row used for each displayed entry of M.*
6. *T is the conjugate-transpose row, recording for every displayed index pair (i, j) the row that reads $\overline{M_{j,i}}$ from K and the transposed entry of M.*
7. *S is the self-adjoint equality row, identifying each displayed entry $M_{i,j}$ with the corresponding entry of T through componentwise* hsame *transport.*
8. *E records componentwise transport for the dimension, field, vector-space, matrix-entry, conjugation, transpose, self-adjointness, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from finite matrix-entry inspection through conjugation, transpose readback, and self-adjointness checking.*
10. *P is the* Pkg *provenance over* $\mathsf{HermitianMatrix}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. L is the local $\mathsf{NameCert}_{\mathsf{HermitianMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, F, V, M, K, T, S, E, C, P, L$. The carrier has no coordinate for spectral decomposition, eigenvalue ordering, positive-semidefinite witness, quotient matrix equality, selected basis, or ambient host equality.

Theorem 6403.2 (Hermitian matrix NameCert obligations)**.** *For every accepted* $\mathsf{HermitianMatrix}^{\uparrow}$ *carrier*

$$H = (D, F, V, M, K, T, S, E, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{HermitianMatrix}^{\uparrow}}$ *surface consists exactly of carrier admission, finite square dimension exposure, scalar-field source readback, vector-space coordinate exposure, matrix-entry ledger admission, complex conjugation readback, conjugate-transpose display, self-adjoint entry comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 6403.1. The accepted packet exposes exactly the dimension, field, vector-space, matrix, conjugation, transpose, self-adjointness, transport, replay, provenance, and naming rows.

The conjugate-transpose obligation is finite. The row T is read entry by entry from D, the transposed matrix-entry row of M, and the complex conjugation row K.

The self-adjointness obligation is also componentwise. The row S compares each displayed $M_{i,j}$ with the displayed conjugate-transpose entry through hsame, and E transports only those rows.

Finally C, P, L keep every replay and downstream consumer behind the same finite packet. Since no carrier row stores eigenvalues, selected eigenvectors, positive-semidefinite data, quotient matrix equality, a basis selector, or host matrix equality, the listed rows exhaust the local NameCert obligations. □

Theorem 6403.3 (Hermitian matrix self-adjointness boundary)**.** *Every consumer that reads an accepted* $\mathsf{HermitianMatrix}^{\uparrow}$ *packet as self-adjoint matrix data must pass through the displayed* $\mathsf{Mat}^{\uparrow}$ *ledger M, the* $\mathsf{Complex}^{\uparrow}$ *conjugation row K, the conjugate-transpose row T, and the componentwise self-adjointness row S over the same finite dimension, field, and vector-space rows D, F, V. The packet alone cannot export spectral theorem data, diagonalization, eigenvalue selection, positive-semidefinite evidence, quotient matrix equality, selected basis data, or host matrix equality.*

Proof. Start with the NameCert obligations of Definition 6403.2. They expose the matrix ledger, complex conjugation, conjugate-transpose readback, self-adjointness comparison, transport, replay, provenance, and local naming rows.

Use the carrier definition to keep those rows over one square index window. The dimension row D fixes the entry domain, while F, V fix the scalar and coordinate sources through which matrix reads are typed.

The self-adjointness read cannot bypass T or S. The transpose row T computes the conjugate-transpose entry from displayed rows, and S is the only row comparing that entry with the original matrix entry.

Thus any self-adjoint consumer receives only the finite Hermitian matrix packet. Spectral theorem data, diagonalization, selected eigenvectors, positive-semidefinite evidence, quotient matrix equality, selected bases, and host equality are absent from the carrier and cannot be recovered by replay. □

Closure status for $\mathsf{NameCert}_{\mathsf{HermitianMatrix}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HermitianMatrix}^{\uparrow}$ packet is generated from a finite square index row, scalar-field and vector-space sources, a complex matrix-entry ledger, a conjugation row, a conjugate-transpose row, componentwise self-adjointness evidence, hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{HermitianMatrix}^{\uparrow}}$, seed)

Scope closed: Definition 6403.1, Definition 6403.2, and Definition 6403.3 seed the finite Hermitian matrix packet over displayed Mat$^{\uparrow}$, Complex$^{\uparrow}$, VecSpace$^{\uparrow}$, Field$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{HermitianMatrix}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close spectral theorem data, diagonalization, eigenbasis selection, positive-semidefinite evidence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, conjugation readback, conjugate-transpose exactness, self-adjoint component comparison, transport, replay, provenance, and local naming for the same finite packet.

Chapter 6404

A Concrete Naming Certificate for $\mathsf{DiniModulusContinuity}^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the $\mathsf{DiniModulusContinuity}^{\uparrow}$ packet records a finite route from displayed Dini-style local modulus requests to Real-facing continuity reads. It sits between the ordinary modulus-control surface of chapter 1631, the derivative-side Dini packet of chapter 2041, the finite StreamName windows of chapter 126, the regular rational readback rows of chapter 301, the dyadic tolerance budget of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the finite continuity-modulus handoff only; it does not assert ambient Real completeness, selected limits, quotient streams, or a host-level continuity principle.

Definition 6404.1 (Dini modulus continuity carrier)**.** *A* $\mathsf{DiniModulusContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, R, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the source* $\mathsf{StreamName}^{\uparrow}$ *window ledger. It stores the finite source windows on which the continuity request is allowed to read names.*
2. *R is the Dini modulus request row. It records the displayed neighbourhood request, the local oscillation bound, and the monotone precision schedule used by the packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget. It displays the input tolerance, the output tolerance, the local split cells, and the finite descent route binding them to R.*
4. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the rational observations returned from the accepted StreamName windows under the dyadic tolerance budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It is reachable only after the StreamName windows, Dini request row, dyadic budget, and rational readback row have been displayed.*
6. *H records componentwise* hsame *transport for W, R, D, T, E, C, P, N.*
7. *C records displayed* Cont *replay from an outer continuity-modulus request through W, R, D, T, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{DiniModulusContinuity}^{\uparrow}$, $\mathsf{ModulusContinuity}^{\uparrow}$, $\mathsf{DiniDerivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniModulusContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $W, R, D, T, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, host limits, ambient Real completeness, selected representatives, countable choice, Lean verification, or bridge checking.

Theorem 6404.2 (Dini modulus continuity NameCert obligations)**.** *For every accepted* $\mathsf{DiniModulusContinuity}^{\uparrow}$ *carrier*

$$M = (W, R, D, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniModulusContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName window ledger, Dini modulus request, dyadic tolerance budget, RegSeqRat readback row, Real seal, transport row, replay row, provenance row, and local naming row;*
2. *source-window exactness, requiring every observation used by the modulus request to appear in W;*
3. *Dini-request exactness, requiring the neighbourhood request, oscillation bound, and monotone precision schedule to be the displayed cells of R;*
4. *dyadic budget compatibility, requiring D to bind the input and output tolerances to the finite local split cells consumed by R and T;*
5. *rational readback exactness, requiring every exported rational observation to come from T after W, R, D have been displayed;*
6. *Real-seal non-escape, requiring E to remain downstream of W, R, D, T and the structural rows;*
7. *componentwise structural preservation, requiring H and C to transport and replay the displayed packet without changing the modulus route;*
8. *provenance exhaustion, requiring P and N to source and name exactly the displayed packet and no quotient stream, host limit, ambient Real completeness, selected representative, countable-choice row, Lean verification, or bridge checker.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6404.1. The projection exposes one source-window ledger, one Dini modulus request row, one dyadic tolerance budget, one regular rational readback row, one terminal Real seal, and the structural rows.

The window and request obligations are read from W and R. A continuity read can inspect only the displayed StreamName windows, and the neighbourhood request, oscillation bound, and monotone precision schedule must be the cells named in R.

The tolerance and readback obligations are then read from D and T. The dyadic budget displays the local split cells used by the Dini request, while T lists the regular rational observations returned from those windows.

Finally, E, H, C, P, N only seal, transport, replay, source, and name the displayed route. Since the carrier has no further analytic coordinate, the local NameCert exports exactly the listed finite obligations and no ambient completion principle. □

Theorem 6404.3 (Dini modulus continuity Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read out of an accepted* $\mathsf{DiniModulusContinuity}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DiniModulusContinuity}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by $W, R, D, T, E, H, C, P, N$. Thus a Real and Completion consumer can use the packet only as a displayed modulus-control handoff, not as a claim of quotient-stream equality, selected limits, host continuity, or ambient Real completeness.

Proof. Take a Real-facing read admitted by the packet. Projection of M gives no coordinate from an outer request directly to the terminal seal E.

The read first opens the StreamName windows and the Dini modulus request. The row W displays the finite windows, and R displays the local neighbourhood request and oscillation bound that governs those windows.

The dyadic tolerance budget and regular rational readback determine the numeric data. The row D records the local split cells, while T records the rational observations consumed under those tolerances.

Only after those rows are visible can E be consumed. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same route, so no quotient stream, selected limit, host continuity service, or ambient Real completeness claim can be inserted. □

Falsifiable prediction: An accepted $\mathsf{DiniModulusContinuity}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without first displaying the $\mathsf{StreamName}^{\uparrow}$ windows, Dini modulus request, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget, and $\mathsf{RegSeqRat}^{\uparrow}$ readback row refutes the carrier surface.

Independence witness: moduluscontinuity, dini-derivative, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole packet $M = (W, R, D, T, E, H, C, P, N)$, because each sibling contributes only ordinary modulus control, derivative-side Dini data, window data, rational readback, tolerance budgeting, or terminal seal data while this chapter binds them into one finite continuity-modulus NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniModulusContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{DiniModulusContinuity}^{\uparrow}$ packet is generated from StreamName source windows, a Dini modulus request, a DyadicRatCore tolerance budget, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniModulusContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6404.1, Definition 6404.2, and Definition 6404.3 seed the finite Dini modulus continuity route over StreamName, DyadicRatCore, RegSeqRat, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniModulusContinuity}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host limits, ambient Real completeness, selected representatives, countable choice, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Dini-request exactness, dyadic-budget compatibility, RegSeqRat readback exactness, Real-seal non-escape, classifier transport, and ledger non-escape proofs for BEDC.Derived.DiniModulusContinuityUp.

Chapter 6405

A Concrete Naming Certificate for FiniteDiagonalModulusScheduler$^{\uparrow}$

Following Bishop–Bridges constructive completion practice, the FiniteDiagonalModulusScheduler$^{\uparrow}$ packet records the finite diagonal-window scheduler used before a Real-facing regular Cauchy read is sealed. It sits over the StreamName window route of chapter 126, the rational regularity rows of chapter 301, the dyadic tolerance budget of chapter 291, the tolerance-comparison discipline of chapter 1211, and the terminal real-name seal of chapter 38. The packet exposes displayed diagonal scheduling and tolerance data only; it does not choose a limit, quotient streams, selected representatives, or ambient Real completeness.

Definition 6405.1 (Finite diagonal modulus scheduler carrier)**.** *A* FiniteDiagonalModulusScheduler$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (J, W, D, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the finite diagonal-window ledger. It lists the outer precision requests, the selected finite diagonal windows, and the inclusion order among those windows.*
2. *W is the* StreamName$^{\uparrow}$ *schedule row. It records the StreamName reads licensed by each diagonal window of J.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance split ledger. It displays the outer tolerance, the window tolerance, the endpoint tolerance, and the finite dyadic descent cells.*
4. *R is the* RegSeqRat$^{\uparrow}$ *endpoint readback row. It records the regular rational observations returned at the scheduled endpoints.*
5. *L is the* DyadicToleranceTriangleLedger$^{\uparrow}$ *handoff row. It records the displayed comparison triangle binding the split tolerances of D to the endpoint reads of R.*
6. *E is the terminal* Real$^{\uparrow}$ *seal. It is reachable only after the diagonal windows, StreamName schedule, dyadic tolerance split, endpoint readbacks, and triangle handoff have been displayed.*
7. *H records componentwise* hsame *transport for $J, W, D, R, L, E, C, P, N$.*
8. *C records displayed* Cont *replay from an outer diagonal regularity request through $J, W, D, R, L, E, H, P, N$.*
9. *P is the* Pkg *provenance over* FiniteDiagonalModulusScheduler$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicToleranceTriangleLedger$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $J, W, D, R, L, E, H, C, P, N$. The carrier has no coordinate for selected limits, quotient stream equality, ambient Real completeness, countable choice, Lean verification, or bridge checking.

Theorem 6405.2 (Finite diagonal modulus scheduler NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}$ *carrier*

$$S = (J, W, D, R, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite diagonal-window ledger, StreamName schedule, dyadic tolerance split ledger, RegSeqRat endpoint readback row, tolerance-triangle handoff, Real seal, transport row, replay row, provenance row, and local naming row;*
2. *diagonal-window exactness, requiring every scheduled read to be listed in J with its finite inclusion relation;*
3. *StreamName schedule exactness, requiring each read in W to be licensed by a displayed diagonal window;*
4. *dyadic split compatibility, requiring D to display the outer, window, and endpoint tolerances consumed by the schedule;*
5. *endpoint readback exactness, requiring R to display the regular rational observations returned at the scheduled endpoints;*
6. *triangle-handoff exactness, requiring L to bind the split tolerances to the endpoint rows through the displayed dyadic tolerance triangle;*
7. *Real-seal non-escape, requiring E to remain downstream of J, W, D, R, L and the structural rows;*
8. *provenance exhaustion, requiring P and N to source and name exactly the displayed packet and no selected limit, quotient stream, ambient Real completeness, countable-choice row, Lean verification, or bridge checker.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6405.1. The projection exposes the diagonal-window ledger, StreamName schedule, dyadic tolerance split ledger, endpoint readback row, tolerance-triangle handoff, terminal seal, and structural rows.

The scheduling obligations are read from J and W. Every StreamName read is attached to a displayed finite diagonal window, and the inclusion relation among the windows is part of the same finite ledger.

The numeric obligations are read from D, R, L. The tolerance split ledger displays the outer, window, and endpoint tolerances; the endpoint readback row lists the regular rational observations; the triangle handoff binds these cells through the same dyadic comparison route.

Finally, E, H, C, P, N only seal, transport, replay, source, and name the displayed packet. Because no further coordinate is present, the NameCert surface exports exactly the listed finite obligations and no selected limit or ambient completeness principle. □

Theorem 6405.3 (Finite diagonal modulus scheduler Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read out of an accepted* $\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicToleranceTriangleLedger}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by $J, W, D, R, L, E, H, C, P, N$*. Thus a Real and Completion consumer receives displayed diagonal windows and tolerance rows, not a selected limit, quotient-stream representative, or ambient Real completeness claim.*

Proof. Take a Real-facing read admitted by the carrier. Projection of S gives no direct coordinate from an outer diagonal request to the terminal seal E.

The read first passes through the finite diagonal windows and StreamName schedule. The row J displays the diagonal windows, while W records the StreamName reads licensed by those windows.

The dyadic and rational rows then supply the endpoint data. The row D displays the tolerance split, R displays the endpoint readbacks, and L records the tolerance triangle that binds the split cells to those readbacks.

Only after those rows are displayed can the terminal seal E be consumed. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same route, so the packet cannot introduce a selected limit, quotient stream, countable-choice schedule, or ambient Real completeness assertion. □

Falsifiable prediction: An accepted $\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without first displaying the finite diagonal windows, $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance split, $\mathsf{RegSeqRat}^{\uparrow}$ endpoint readbacks, and $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, dyadic-tolerance-triangle-ledger, real: no listed sibling supplies the whole packet $S = (J, W, D, R, L, E, H, C, P, N)$, because each sibling contributes only windows, endpoint readbacks, tolerance cells, triangle comparison, or terminal seal data while this chapter binds them into one finite diagonal scheduler NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}$ packet is generated from finite diagonal windows, StreamName schedules, DyadicRatCore tolerance splits, RegSeqRat endpoint readbacks, a DyadicToleranceTriangleLedger handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}}$, seed)

Scope closed: Definition 6405.1, Definition 6405.2, and Definition 6405.3 seed the finite diagonal-window scheduler route over StreamName, DyadicRatCore, RegSeqRat, DyadicToleranceTriangleLedger, and Real-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteDiagonalModulusScheduler}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, ambient Real completeness, countable choice, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, diagonal-window exactness, StreamName schedule exactness, dyadic-split compatibility, endpoint readback exactness, triangle-handoff exactness, Real-seal non-escape, and ledger non-escape proofs for BEDC.Derived.FiniteDiagonalModulusSchedulerUp.

Chapter 6406

A Concrete Naming Certificate for $\mathsf{FiniteVariationPath}^{\uparrow}$

Following Jordan and Bishop–Bridges constructive analysis, the $\mathsf{FiniteVariationPath}^{\uparrow}$ packet records finite-variation data for a displayed metric-valued path by finite partition windows and regular rational variation ledgers. It sits beside the bounded-variation surface of chapter 398, the path-length boundary of chapter 3443, the dyadic tolerance core of chapter 291, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a path-level finite-variation certificate for L10 Real and Completion consumers; it does not import a host path space, a supremum over all partitions, quotient equality of paths, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6406.1 (Finite variation path carrier)**.** *A* $\mathsf{FiniteVariationPath}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (M, \gamma, I, \Pi, D, B, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric and continuous-path source row, exposing the accepted metric carrier, the displayed distance read, and the* $\mathsf{ContinuousMap}^{\uparrow}$ *path graph through the same source and target windows.*
2. *γ is the path-evaluation schedule, recording the finite endpoint probes of the path on the inspected interval row.*
3. *I is the finite interval-domain row supplying the ordered endpoints and the admissible subdivision boundary.*
4. *Π is the finite partition row over I, including adjacency, endpoint membership, and finite common-refinement witnesses for pairs of displayed partitions.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge-distance ledger, recording the adjacent distance terms and partial variation sums for the partition window Π.*
6. *B is the variation-sum bound row, comparing the dyadic edge-distance sum in D with the displayed finite bound attached to the accepted path packet.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row by which a downstream regular-rational consumer reads the same edge-distance ledger and bound through finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after $M, \gamma, I, \Pi, D, B, Q$ have all been displayed.*

9. *H records componentwise* hsame *transport for the metric source, path schedule, interval, partition, edge-distance ledger, bound row, regular-rational readback, real seal, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a finite-variation request through path evaluation, partition exposure, dyadic edge-distance summation, common-refinement comparison, regular-rational readback, and the real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteVariationPath}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RectifiableCurve}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteVariationPath}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, \gamma, I, \Pi, D, B, Q, E, H, C, P, N$. It has no coordinate for a host path space, a total variation supremum over all partitions, quotient equality of paths, selected representatives, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6406.2 (Finite variation path NameCert obligations)**.** *For every accepted* $\mathsf{FiniteVariationPath}^{\uparrow}$ *carrier $V = (M, \gamma, I, \Pi, D, B, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteVariationPath}^{\uparrow}}$ *surface consists exactly of carrier admission, metric and continuous-path source exposure, finite interval and partition exposure, dyadic edge-distance ledger readback, variation-sum bound comparison, common-refinement comparison, RegSeqRat readback, RealUp seal routing, componentwise transport, continuation replay, provenance, and local naming.*

Every path-variation consumer in this scope must therefore read the finite route

$$M, \gamma, I, \Pi \longmapsto D, B \longmapsto Q, E$$

together with H, C, P, N, and receives no host path-space object, all-partitions supremum, quotient path equality, hidden selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 6406.1. The visible analytic rows are the metric and path source M, γ, the interval and partition rows I, Π, the dyadic edge-distance ledger D, the bound row B, the regular-rational readback Q, and the real seal E.

The variation request is finite at the displayed partition. The interval row supplies the ordered domain, the path schedule supplies endpoint probes, and the partition row lists the adjacent pairs whose metric distance terms are consumed by D.

The bound comparison is read through B. Common-refinement witnesses live in Π and compare only displayed finite partition ledgers and their dyadic sums, so the classifier does not range over all partitions.

The L10 readback is downstream of the ledger. The row Q returns the inspected variation sum and bound as regular rational data, while E seals that same displayed route as $\mathsf{Real}^{\uparrow}$ data.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no remaining coordinate names a host path space, quotient path equality, hidden selector, or completeness principle, the listed rows exhaust the local NameCert obligations. □

Theorem 6406.3 (Finite variation path RegSeqRat–Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteVariationPath}^{\uparrow}$ *carrier factors through the displayed metric-path source row, finite partition row, dyadic edge-distance ledger, variation-sum bound, and common-refinement comparison before it may read the regular-rational row Q or the terminal real-name seal E.*

The handoff is compatible with the bounded-variation and rectifiable-curve neighbors: bounded-variation consumers read only the finite partition-variation ledger, and rectifiable-curve consumers

read only the displayed partition-length route. Neither consumer receives a host path space, an all-partitions supremum, quotient equality of paths, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a RegSeqRat or Real-facing read. The continuation row C first replays the displayed source rows M, γ and the interval-partition rows I, Π, so the downstream consumer is attached to a finite path window before any variation value is exposed.

Next the dyadic ledger D supplies the adjacent distance terms and the partial sum for the displayed partition. The bound row B compares that finite sum with the accepted variation budget, and the common-refinement data in Π compare only finite ledgers over displayed subdivisions.

Only after those rows are present can the read reach Q and E. The regular-rational row Q returns the inspected ledger and bound through finite readback windows, and the real seal E packages the same route for $\mathsf{Real}^{\uparrow}$ consumers.

The neighboring bounded-variation and rectifiable-curve reads are projections of the same displayed packet. They use the partition-variation and partition-length coordinates already named above, without adding a path quotient, a selected representative, a supremum over all partitions, or a completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteVariationPath}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteVariationPath}^{\uparrow}$ packet is generated from a metric and continuous-path source row, a finite interval row, a displayed partition ledger, DyadicRatCore edge-distance rows, a variation-sum bound, common-refinement comparison, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteVariationPath}^{\uparrow}}$, seed)

Scope closed: Definition 6406.1, Definition 6406.2, and Definition 6406.3 seed the finite path-variation packet over displayed metric-path source rows, finite partition ledgers, dyadic edge-distance sums, regular rational readback, and a real-name seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteVariationPath}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host path space, total variation as an all-partitions supremum, quotient equality of paths, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-path source exposure, finite partition exposure, dyadic edge-distance exactness, variation-bound comparison, common-refinement comparison, RegSeqRat readback, RealUp seal routing, componentwise transport, replay, provenance, and local naming for BEDC.Derived.FiniteVariationPathUp.

Chapter 6407

A Concrete Naming Certificate for $\mathsf{BrzozowskiDerivative}^{\uparrow}$

Following Brzozowski's regular-expression derivatives and the finite-automaton presentation of Hopcroft–Ullman, the $\mathsf{BrzozowskiDerivative}^{\uparrow}$ packet records the finite derivative closure of a regular language as BEDC NameCert data. It consumes the accepted-word surface of chapter 351, the deterministic presentation rows of chapter 2364, the finite word-spine rows of chapter 36, the right-congruence classifier of chapter 5729, and the minimal deterministic consumer of chapter 6188. The packet names the derivative table and nullability replay before any consumer may import a host language quotient, regular-expression completeness theorem, nondeterministic branch selector, or minimization canonicality claim.

Definition 6407.1 (Brzozowski derivative carrier)**.** *A* $\mathsf{BrzozowskiDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\Sigma, W, L, R, \partial, \nu, C, Q, \delta, q_0, F, \mu, H, K, P, N)$$

with the following displayed rows:

1. Σ *is the finite alphabet row.*
2. W *is the finite word-spine row read through* $\mathsf{List}^{\uparrow}$ *over* Σ*.*
3. L *is the accepted-word observation row supplied by a* $\mathsf{RegularLanguage}^{\uparrow}$ *packet.*
4. R *is the displayed regular-expression or regular-description row whose derivative reads are exposed only through finite syntax names.*
5. ∂ *is the derivative table, assigning to each displayed derivative state and alphabet symbol the next displayed derivative state.*
6. ν *is the nullability row, recording whether each displayed derivative accepts the empty word.*
7. C *is the closure ledger showing that repeated derivatives of* R *by displayed words land back in the finite derivative table.*
8. Q *is the finite derivative-state carrier admitted by the closure ledger.*
9. δ *is the deterministic transition row induced by* ∂*.*
10. q_0 *is the starting derivative state named by the original description* R*.*
11. F *is the accepting-state row determined by* ν*.*

12. *μ is the handoff row to the* $\mathsf{MyhillNerode}^{\uparrow}$ *and* $\mathsf{MinimalDfa}^{\uparrow}$ *consumers through the displayed derivative classes.*
13. *H records componentwise* hsame *transport for alphabet, word-spine, accepted-language observation, syntax, derivative table, nullability, closure, state, transition, start, accepting, handoff, replay, provenance, and local naming rows.*
14. *K records displayed* Cont *replay from finite word reads through derivative iteration and nullability lookup.*
15. *P is the* Pkg *provenance over* $\mathsf{BrzozowskiDerivative}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{MyhillNerode}^{\uparrow}$, $\mathsf{MinimalDfa}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
16. *N is the local* $\mathsf{NameCert}_{\mathsf{BrzozowskiDerivative}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Sigma, W, L, R, \partial, \nu, C, Q, \delta, q_0, F, \mu, H, K, P, N$. It has no coordinate for a host quotient of all languages, a proof that every regular language has a displayed expression, a nondeterministic branch choice, a canonical minimal automaton proof, or an external regular-expression equivalence oracle.

Theorem 6407.2 (Brzozowski derivative NameCert obligations)**.** *For every accepted* $\mathsf{BrzozowskiDerivative}^{\uparrow}$ *carrier*

$$D = (\Sigma, W, L, R, \partial, \nu, C, Q, \delta, q_0, F, \mu, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrzozowskiDerivative}^{\uparrow}}$ *surface consists exactly of finite alphabet exposure, word-spine exposure, accepted-language observation, displayed syntax naming, derivative-table replay, nullability lookup, finite closure coverage, derivative-state exposure, deterministic transition replay, start-state naming, accepting-state naming, Myhill–Nerode and minimal-DFA handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6407.1. The rows Σ, W, L, R expose the finite alphabet, finite word spine, accepted-word observation, and displayed syntax source before any derivative table can be consumed.

Read $\partial, \nu, C, Q, \delta, q_0, F$ next. The derivative table ∂ gives one-step symbolic evolution, ν decides empty-word acceptance at a displayed derivative, and C certifies that iterating derivatives along displayed words remains inside the finite state carrier Q. The transition row δ, start row q_0, and accepting row F are therefore the deterministic automaton presentation obtained from those rows.

The handoff row μ is bounded by this finite derivative table. It may be read by the Myhill–Nerode and minimal-DFA siblings, but it does not add a host quotient, regular-expression completeness theorem, nondeterministic branch selector, or canonical minimization proof.

The rows H, K, P, N transport, replay, source, and name the same packet. Since no further coordinate exists, the listed rows exhaust the local NameCert obligations. □

Theorem 6407.3 (Brzozowski derivative regular-language handoff)**.** *Every* $\mathsf{RegularLanguage}^{\uparrow}$ *or* $\mathsf{FiniteAutomaton}^{\uparrow}$ *consumer of an accepted* $\mathsf{BrzozowskiDerivative}^{\uparrow}$ *packet first reads the displayed alphabet row, finite word-spine row, accepted-language observation, derivative table, nullability row, closure ledger, derivative-state carrier, deterministic transition row, start row, accepting row, and componentwise replay rows. The handoff through chapter 351, chapter 2364, chapter 5729, and chapter 6188 therefore exports only the finite derivative automaton route.*

Proof. Begin with an accepted carrier $D = (\Sigma, W, L, R, \partial, \nu, C, Q, \delta, q_0, F, \mu, H, K, P, N)$. The regular-language sibling reads the accepted-word observation L only after the displayed alphabet, word spine, syntax row, derivative table, nullability row, and closure ledger have been exposed.

The finite-automaton sibling then consumes Q, δ, q_0, F as a deterministic presentation. These rows are determined by derivative iteration and nullability lookup, so the consumer obtains a finite derivative automaton rather than an arbitrary presentation.

Finally, the Myhill–Nerode and minimal-DFA siblings may read μ as a bounded classifier handoff. The route does not assert that every regular language has a chosen expression, identify external language quotients, choose nondeterministic branches, or prove minimization canonicality. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrzozowskiDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{BrzozowskiDerivative}^{\uparrow}$ packet is generated from finite alphabet, word-spine, accepted-language observation, displayed syntax, derivative table, nullability, closure, derivative-state, deterministic transition, start, accepting, handoff, componentwise hsame transport, displayed continuation replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrzozowskiDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6407.1, Definition 6407.2, and Definition 6407.3 seed the finite derivative-automaton route over RegularLanguageUp, FiniteAutomatonUp, ListUp, MyhillNerodeUp, and MinimalDfaUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrzozowskiDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host language quotients, regular-expression completeness, nondeterministic branch choice, minimization canonicality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-table replay, nullability exactness, closure coverage, deterministic automaton handoff, Myhill–Nerode handoff, minimal-DFA handoff, transport, replay, provenance, and local naming for BEDC.Derived.BrzozowskiDerivativeUp.

Chapter 6408

A Concrete Naming Certificate for $\mathsf{FreedmanInequality}^{\uparrow}$

Following Freedman's martingale inequality, the $\mathsf{FreedmanInequality}^{\uparrow}$ packet names the finite bounded-window concentration surface where martingale differences, bounded stopping decisions, and predictable variance budgets are read as BEDC rows before any tail estimate is exposed. It sits after the probability, random-variable, martingale, stopping-time, optional-stopping, and upcrossing packets of chapter 184, chapter 185, chapter 190, chapter 344, chapter 383, and chapter 1629. The chapter records the finite ledger boundary consumed by concentration estimates; it does not import completed filtrations, almost-sure quotient equality, exponential supermartingale limits, unbounded stopping choices, or ambient measure completion.

Definition 6408.1 (Freedman inequality carrier)**.** *A* $\mathsf{FreedmanInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (\Omega, X, M, T, O, U, B, V, H, C, P, N)$$

with the following rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row exposing the finite probability ledger.*
2. X *is the* $\mathsf{RandomVar}^{\uparrow}$ *martingale-difference family row, with every endpoint read routed through the random-variable preimage and total-readback surface.*
3. M *is the* $\mathsf{Martingale}^{\uparrow}$ *finite-window row carrying adaptedness and zero-conditional-mean reads.*
4. T *is the* $\mathsf{StoppingTime}^{\uparrow}$ *bounded decision row used to stop the inspected martingale window.*
5. O *is the* $\mathsf{OptionalStopping}^{\uparrow}$ *stopped-read row, exposing stopped values only through bounded windows.*
6. U *is the* $\mathsf{Upcrossing}^{\uparrow}$ *crossing-control row used to keep the same finite martingale window visible to pathwise consumers.*
7. B *is the bounded-step row recording the displayed bound on each martingale difference.*
8. V *is the variance-budget row recording the predictable quadratic-variation budget inspected before a tail row is exposed.*
9. H *records componentwise* hsame *transport for the probability, random-variable, martingale, stopping, stopped-read, upcrossing, bounded-step, variance-budget, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a probability read through martingale differences, finite windows, bounded stopping, stopped reads, crossing control, bounded-step rows, variance budgets, and the local certificate.*
11. *P is the* Pkg *provenance over* $\mathsf{FreedmanInequality}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FreedmanInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $\Omega, X, M, T, O, U, B, V, H, C, P, N$. It has no coordinate for a completed sigma-algebra, host measurable functions, almost-sure quotient equality, selected exponential limits, unbounded stopping choices, countable choice, or ambient measure completion.

Theorem 6408.2 (Freedman inequality NameCert obligations)**.** *For every accepted* $\mathsf{FreedmanInequality}^{\uparrow}$ *carrier $F = (\Omega, X, M, T, O, U, B, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FreedmanInequality}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the displayed probability, random-variable, martingale, stopping-time, optional-stopping, upcrossing, bounded-step, variance-budget, transport, replay, provenance, and local naming rows; martingale-difference exposure through X, M; bounded stopped-window exposure through T, O; crossing-control compatibility through U; variance-budget accountability through V; and ledger non-escape through H, C, P, N.*

Proof. Carrier admission is projection from Definition 6408.1. The accepted packet displays exactly the rows $\Omega, X, M, T, O, U, B, V, H, C, P, N$, so every local obligation is attached to one of those coordinates.

The martingale-difference obligations are the rows X, M. The $\mathsf{RandomVar}^{\uparrow}$ endpoint family supplies finite random-variable reads, while the $\mathsf{Martingale}^{\uparrow}$ row supplies adaptedness and conditional-expectation faces inside the inspected window.

The bounded stopped-window obligations are T, O, U. The bounded stopping row determines which finite indices may be read, the optional-stopping row exposes stopped values only through those indices, and the upcrossing row keeps the same martingale window visible to crossing-control consumers.

The concentration-specific obligations are B, V. The bounded-step row records the displayed step bound, and the variance-budget row records the predictable quadratic-variation budget before a tail estimate can be named.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed sigma-algebras, host measurable functions, almost-sure quotient equality, selected exponential limits, unbounded stopping choices, countable choice, or ambient measure completion, no NameCert obligation can export them. □

Theorem 6408.3 (Freedman inequality martingale handoff)**.** *Every downstream concentration consumer of an accepted* $\mathsf{FreedmanInequality}^{\uparrow}$ *packet receives its martingale data only after the route*

$$\mathsf{ProbSpace}^{\uparrow}, \mathsf{RandomVar}^{\uparrow}, \mathsf{Martingale}^{\uparrow}, \mathsf{StoppingTime}^{\uparrow}, \mathsf{OptionalStopping}^{\uparrow}, \mathsf{Upcrossing}^{\uparrow} \longmapsto \textit{bounded-step and varianc}$$

has been displayed. Thus the packet hands off a finite bounded-window concentration ledger, not an ambient exponential-supermartingale theorem, completed filtration, almost-sure quotient, selected stopping time, or unbounded convergence principle.

Proof. Begin with a concentration consumer. Projection from the carrier forces the consumer to read the probability source Ω, the random-variable endpoint row X, and the finite martingale window M before any tail-bound row is available.

Bounded stopping is the next gate. The $\mathsf{StoppingTime}^{\uparrow}$ row T names the displayed finite stopping decisions, and chapter 383 supplies the stopped-read surface O only over those bounded windows.

Crossing control remains on the same finite path. The $\mathsf{Upcrossing}^{\uparrow}$ row U records the crossing ledger consumed by martingale-window arguments, so the route cannot switch to an ambient almost-sure event or an unbounded stopping theorem.

The Freedman-specific read is then B, V. The bounded-step row and predictable variance-budget row are inspected before the concentration row is exposed, and the structural rows H, C, P, N replay and name that same finite ledger. Therefore the handoff contains no completed filtration, quotient equality, selected stopping choice, exponential-limit selector, or ambient convergence principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{FreedmanInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{FreedmanInequality}^{\uparrow}$ packet is generated from probability, random-variable martingale-difference, finite martingale, bounded stopping-time, optional-stopping, upcrossing, bounded-step, predictable variance-budget, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FreedmanInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6408.1, Definition 6408.2, and Definition 6408.3 seed the finite bounded-window martingale concentration packet for Freedman-style tail consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FreedmanInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed filtrations, almost-sure quotient equality, exponential supermartingale limit selection, unbounded stopping choices, measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, martingale-difference exposure, bounded stopped-window exposure, upcrossing compatibility, predictable variance-budget accountability, and non-escape for BEDC.Derived.FreedmanIne

Chapter 6409

A Concrete Naming Certificate for $\mathsf{CompactUniformCoverRead}^{\uparrow}$

Following Bishop-style compact uniform continuity, the $\mathsf{CompactUniformCoverRead}^{\uparrow}$ packet names the finite cover-read route that turns pointwise modulus rows on a compact metric source into a tolerance-only uniform-modulus handoff. It consumes compact, metric, continuous, rational, ProbeBundle, and uniform-modulus surfaces from chapter 60, chapter 57, chapter 59, chapter 37, and chapter 369. The chapter records finite cover data and rational lower-bound readback; it does not choose an external finite subcover, invoke open-cover compactness, select a global modulus by choice, or import ambient metric completion.

Definition 6409.1 (Compact-uniform cover-read carrier)**.** *A* $\mathsf{CompactUniformCoverRead}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Cpt, M, F, Q, B, U, H, R, P, N)$$

with the following rows:

1. *Cpt is the* $\mathsf{Compact}^{\uparrow}$ *finite-cover row exposing a located finite net.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to read source and target triangle estimates.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row attached to the displayed map or graph.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *positive-radius and lower-bound readback row.*
5. *B is the* ProbeBundle *finite cover row whose probes index the compact net centers and local modulus radii.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row receiving the tolerance-only precision ledger after the finite fold.*
7. *H records componentwise* hsame *transport for the compact, metric, continuous, rational, ProbeBundle, uniform-modulus, replay, provenance, and naming rows.*
8. *R records displayed* Cont *replay from a compact finite cover through pointwise moduli, rational lower-bound fold, metric triangle reads, and the uniform-modulus consumer row.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformCoverRead}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCoverRead}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Cpt, M, F, Q, B, U, H, R, P, N$. It has no coordinate for an external subcover selector, open-cover compactness, quotient point equality, countable choice, or ambient metric completion.

Theorem 6409.2 (Compact-uniform cover-read NameCert obligations)**.** *For every accepted* CompactUniformCover *carrier $K = (Cpt, M, F, Q, B, U, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCoverRead}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact finite-cover row, metric distance row, continuous pointwise-modulus row, rational radius and lower-bound row, ProbeBundle finite-cover row, UniformModulus consumer row, transport, replay, provenance, and local naming row; cover-read compatibility through Cpt, B; pointwise-modulus exposure through F; rational-fold accountability through Q; metric-triangle compatibility through M; and non-escape through H, R, P, N.*

Proof. Carrier admission is projection from Definition 6409.1. The accepted packet displays exactly $Cpt, M, F, Q, B, U, H, R, P, N$, so the local NameCert cannot refer to data outside those rows.

The cover-read obligations are Cpt, B. The compact row supplies the located finite net, while the ProbeBundle row indexes the centers and local radius rows that are actually folded.

The modulus obligations are F, Q, U. The continuous row exposes pointwise moduli at bundled centers, the rational row supplies positive-radius comparisons and the finite lower-bound fold, and the UniformModulus row receives only the resulting tolerance-only precision ledger.

Metric compatibility is read through M. Source and target triangle estimates are finite metric rows attached to the same cover-read route, not ambient metric-space theorems.

Finally H, R, P, N preserve, replay, source, and name the same finite packet. Since the carrier lacks an external subcover selector, open-cover compactness, quotient point equality, countable choice, and ambient metric completion, none of those objects is exported. □

Theorem 6409.3 (Compact finite cover to uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformCoverRead}^{\uparrow}$ *packet receives data only after the compact finite-net row, pointwise-modulus rows, rational lower-bound fold, ProbeBundle cover index, metric triangle rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row have all been displayed. The handoff is a finite ProbeBundle read, not a selected open-cover subcover, external modulus function, quotient point equality, countable choice principle, or ambient compactness theorem.*

Proof. Start with the compact finite-cover row of Definition 6409.1. The row Cpt exposes located finite-net data, and B records the ProbeBundle index through which bundled centers and radius rows are read.

At each bundled center, the continuous row F supplies a pointwise-modulus read. The rational row Q then folds the finite family of positive radii into a displayed lower-bound ledger, so the precision handed to the consumer is a BEDC history rather than an external selector.

Use the metric row M for the source and target triangle estimates. These estimates are finite distance reads attached to the bundled center and lower-bound ledger, and they are the only route by which the pointwise data become a uniform estimate.

Finally the structural rows H, R, P, N transport, replay, source, and name the same finite cover-read. Thus the $\mathsf{UniformModulus}^{\uparrow}$ row U receives only the compact finite-net, pointwise-modulus, rational-fold, ProbeBundle, metric, and structural data already displayed, with no open-cover selector, quotient point equality, countable choice, or ambient compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCoverRead}^{\uparrow}}$.

Constructive story: A CompactUniformCoverRead$^{\uparrow}$ packet is generated from compact finite-cover rows, metric distance rows, continuous pointwise-modulus rows, rational radius and lower-bound rows, ProbeBundle finite indices, UniformModulus consumer rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformCoverRead}^{\uparrow}}$, seed)

Scope closed: Definition 6409.1, Definition 6409.2, and Definition 6409.3 seed the finite cover-read route from compact pointwise moduli to UniformModulus consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformCoverRead}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected subcovers, open-cover compactness, quotient point equality, countable choice, ambient metric completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover-read compatibility, pointwise-modulus exposure, rational-fold accountability, metric-triangle compatibility, and non-escape for BEDC.Derived.CompactUniformCoverReadUp.

Chapter 6410

A Concrete Naming Certificate for $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$ packet records the finite bisection surface by which a continuous real-valued map on a located interval exposes an intermediate-value bracket without invoking a host intermediate-value theorem. It sits after the terminal real-name seal of chapter 38, the located-real comparison surface of **??**, the continuous-map route of chapter 130, and the bisection method packet of chapter 2108. The packet gives L10 Real and Completion readers a finite sign-window route, not a selected root, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6410.1 (Constructive intermediate-value carrier)**.** *A* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, F, S, B, H, C, P, N)$$

with the following rows:

1. *I is the located interval row, recording displayed endpoint names, endpoint apartness, rational or dyadic enclosure windows, and the source interval orientation;*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, recording the finite modulus, graph, and value-readback data for the displayed map on the interval row I;*
3. *S is the sign-apartness window, recording endpoint sign evidence and the retained crossing condition available at the current finite bisection depth;*
4. *B is the bisection schedule row, recording the requested depth, midpoint reads, retained subintervals, and branch evidence consumed through the* $\mathsf{BisectionMethod}^{\uparrow}$ *route;*
5. *H records componentwise* hsame *transport for the interval, map, sign window, bisection schedule, replay, provenance, and local naming rows;*
6. *C records displayed* Cont *replay from a finite intermediate-value request through continuous-map readback, sign-apartness inspection, bisection refinement, and terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure;*
7. *P is the* Pkg *provenance over* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BisectionMethod}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveIntermediateValue}^{\uparrow}}$ *row binding the paper-visible name to the finite packet.*

The carrier has no coordinate for a host intermediate-value theorem, a choice-selected root, trichotomy on arbitrary reals, quotient real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6410.2 (Constructive intermediate-value NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$ *carrier*

$$V = (I, F, S, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveIntermediateValue}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row* I*, continuous-map row* F*, sign-apartness window* S*, bisection schedule* B*, componentwise transport* H*, replay route* C*, provenance row* P*, and local naming row* N*.*

Proof. Carrier admission is projection from Definition 6410.1. The accepted packet exposes only the displayed interval, map, sign, bisection, transport, replay, provenance, and naming rows.

The analytic rows are I, F, S, B. The located interval supplies the endpoint windows, the continuous-map row supplies finite value readbacks, the sign row records the crossing evidence, and the bisection row records retained branches at finite depth.

The structural rows are H, C, P, N. They transport the same packet, replay the finite request, record provenance, and bind the local name. Since no other coordinate exists, every NameCert obligation is one of these rows. □

Theorem 6410.3 (Constructive intermediate-value bisection route)**.** *Every accepted* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$ *consumer that reads an intermediate-value bracket must factor through the finite route*

$$I \longrightarrow F \longrightarrow S \longrightarrow B \longrightarrow P \longrightarrow N$$

before any $\mathsf{Real}^{\uparrow}$*-facing seal is inspected. The route may expose retained intervals, midpoint values, sign windows, and regular real-name readbacks, but it cannot supply a selected root, a host existence theorem, trichotomy, quotient real equality, countable choice, or ambient completeness.*

Proof. First read the located interval row I. It fixes the endpoint windows and the interval orientation before the map can be evaluated.

Next read the continuous-map row F and sign-apartness row S. The map values are available only through the displayed finite graph and modulus data, and the crossing evidence is recorded as endpoint and retained-window sign data rather than as a host order case split.

Now apply the bisection schedule row B. Each retained branch is a finite refinement of the displayed interval and sign rows, so the consumer receives a bracketed route, not a choice-selected root.

Finally pass through P and N. Provenance and local naming attach the route to the packet boundary, while the excluded root-selection, trichotomy, quotient, choice, and completeness principles have no row to occupy. □

Theorem 6410.4 (Constructive intermediate-value L10 scope)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$ *packet may use it only as a finite-window bisection certificate over* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and* $\mathsf{BisectionMethod}^{\uparrow}$ *rows. The scope closes the local route from displayed interval endpoints and continuous-map readbacks to retained bisection windows; it does not close the host intermediate-value theorem, trichotomy, selected roots, countable choice, quotient real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 6410.2. They require the interval, map, sign, bisection, transport, replay, provenance, and local naming rows to be visible before a consumer can read the packet.

Apply the bisection route of Definition 6410.3. It orders every intermediate-value read through I, F, S, B, P, N and keeps the Real-facing seal downstream of finite retained-window evidence.

Thus the L10 consumer receives exactly the displayed finite-window certificate. Any claim requiring host IVT, trichotomy, a selected root, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness lies outside the packet scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveIntermediateValue}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$ packet is generated from located interval endpoints, a continuous-map row, finite sign-apartness windows, a bisection schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveIntermediateValue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6410.1, Definition 6410.2, Definition 6410.3, and Definition 6410.4 seed the finite-window intermediate-value certificate over located interval endpoints, continuous-map readbacks, sign-apartness windows, retained bisection branches, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveIntermediateValue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close the host intermediate-value theorem, trichotomy, selected roots, countable choice, quotient real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, sign-window stability, bisection-route exactness, continuous-map replay, provenance, and Real-seal nonescape for BEDC.Derived.ConstructiveIntermediateValueUp.

Chapter 6411

A Concrete Naming Certificate for $\mathsf{AsymptoticDensity}^{\uparrow}$

Following Hardy and Wright on asymptotic enumeration in elementary number theory, the $\mathsf{AsymptoticDensity}^{\uparrow}$ packet records natural density as a finite BEDC NameCert surface. It sits after the unary counting discipline of chapter 28, the cofinal-tail filter route of chapter 1119, the finite averaging surface of chapter 1765, and the convergence-window sibling of chapter 1827. The packet names finite initial-segment counts, denominator rows, dyadic quotient budgets, tail-window comparison, regular rational readback, and terminal Real sealing; it does not import a host subset of natural numbers, quotient equality of predicates, a selected limiting subsequence, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6411.1 (Asymptotic density carrier)**.** *An* $\mathsf{AsymptoticDensity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (U, I, C, D, Q, T, R, E, H, K, P, N)$$

with the following displayed rows:

1. *U is the unary membership-observation row over $\mathsf{Nat}^{\uparrow}$, recording only the finite yes/no cells opened by the current density request.*
2. *I is the finite initial-segment row naming the inspected prefix lengths and their successor-denominator rows.*
3. *C is the counting ledger, storing for each displayed prefix the unary count of accepted membership cells inside that prefix.*
4. *D is the denominator ledger, storing the positive prefix lengths used by the displayed quotient reads.*
5. *Q is the $\mathsf{DyadicRatCore}^{\uparrow}$ quotient-budget row for the displayed ratios C/D, including division tolerances, slack cells, and readback budgets.*
6. *T is the $\mathsf{FiniteTailFilter}^{\uparrow}$ tail-window row that records which later prefixes are compared for density stability.*
7. *R is the $\mathsf{RegSeqRat}^{\uparrow}$ readback row for the displayed prefix-density sequence.*
8. *E is the $\mathsf{Real}^{\uparrow}$ seal row reached only after U, I, C, D, Q, T, R have been displayed.*

9. *H records componentwise* hsame *transport for membership observations, prefix rows, counts, denominators, quotient budgets, tail windows, readback, seal, replay, provenance, and local naming rows.*
10. *K records displayed* Cont *replay from membership-window reads through counting, quotient formation, tail comparison, regular readback, and Real sealing.*
11. *P is the* Pkg *provenance over* $\mathsf{AsymptoticDensity}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{CesaroConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{AsymptoticDensity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, I, C, D, Q, T, R, E, H, K, P, N$. It has no coordinate for a host set of naturals, quotient predicate equality, a completed limit object, selected subsequence, trichotomy, countable choice, or ambient completeness theorem.

Theorem 6411.2 (Asymptotic density NameCert obligations)**.** *For every accepted* $\mathsf{AsymptoticDensity}^{\uparrow}$ *carrier*

$$A = (U, I, C, D, Q, T, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AsymptoticDensity}^{\uparrow}}$ *surface consists exactly of finite membership-window admission, prefix-row admission, counting-ledger exposure, positive-denominator exposure, dyadic quotient-budget exactness, finite-tail density comparison, regular rational readback, Real seal factorization, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the same displayed rows.*

Proof. Project the carrier of Definition 6411.1. The rows $U, I, C, D, Q, T, R, E, H, K, P, N$ are the whole public surface, so carrier admission is exactly admission of those rows as one finite packet.

The counting part is forced by the prefix rows. The membership observations in U are read only for the prefixes named in I, and the ledger C stores exactly the corresponding finite counts. The denominator row D names the same prefix lengths, so the quotient row Q can form only the displayed prefix-density ratios.

The tail comparison is then read through T. This row imports the finite-tail discipline of chapter 1119 without adding a second selector for later prefixes or a completed limit coordinate.

Finally R and E are downstream of the displayed quotient and tail rows. The structural rows H, K, P, N transport, replay, source, and name the same route, so none of the excluded host objects can appear as an additional NameCert obligation. □

Theorem 6411.3 (Asymptotic density finite-prefix stability)**.** *Let*

$$A = (U, I, C, D, Q, T, R, E, H, K, P, N)$$

be an accepted $\mathsf{AsymptoticDensity}^{\uparrow}$ *carrier. Replacing finitely many initial membership observations in U preserves the same density-facing classifier whenever the displayed tail row T, quotient-budget row Q, regular readback row R, and Real seal row E are unchanged. The stability is a finite-tail comparison inside the packet, not an appeal to host set equality modulo finite difference or to an ambient limit theorem.*

Proof. Read the affected prefix rows first. A finite change in U can alter only the counting ledger entries C attached to the finitely many prefixes of I that inspect those cells.

Move to the tail row T. Once the displayed finite-tail filter has passed beyond those prefixes, later density comparisons use the same membership windows, quotient budgets, and prefix denominators as before.

The regular readback R is downstream of Q and T, and the Real seal E is downstream of R. If those rows are unchanged, every density-facing consumer receives the same displayed route after the finite initial segment has been skipped.

The conclusion is therefore internal to the finite carrier. No host equality modulo finite sets, selected limiting subsequence, quotient predicate equality, trichotomy, countable-choice row, or ambient completeness theorem is introduced. □

Falsifiable prediction: Every $\mathsf{AsymptoticDensity}^{\uparrow}$ density-facing read exposes finite Nat membership observations, initial-segment rows, counting ledgers, denominator rows, DyadicRatCore quotient budgets, finite-tail comparison, RegSeqRat readback, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert before it exports a density classifier.

Independence witness: nat, finitailfilter, hardycesaromean, cesaroconvergence, regseqrat, dyadicratcore, real: $\mathsf{AsymptoticDensity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite membership observations, prefix counts, denominator rows, quotient budgets, tail comparison, regular readback, Real sealing, transport, replay, provenance, and local naming as one natural-density certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticDensity}^{\uparrow}}$.

Constructive story: An $\mathsf{AsymptoticDensity}^{\uparrow}$ packet is generated from finite Nat membership observations, prefix rows, counting ledgers, denominator rows, dyadic quotient budgets, finite-tail comparison, RegSeqRat readback, RealUp sealing, componentwise hsame transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AsymptoticDensity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6411.1, Definition 6411.2, and Definition 6411.3 seed the finite natural-density route from Nat prefix observations through quotient budgets, tail comparison, regular readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AsymptoticDensity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subsets of naturals, quotient predicate equality, completed limits, selected subsequences, trichotomy, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked membership-window admission, prefix counting, denominator admission, quotient-budget exactness, tail comparison, finite-prefix stability, readback, Real seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.AsymptoticDensityUp.

Chapter 6412

A Concrete Naming Certificate for $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$

The $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$ packet realizes the MetaCIC decidability audit map as finite local-checker data. It sits after the lambda-calculus syntax carrier of chapter 200, the computability boundary of chapter 199, the first-order coding surface of chapter 197, and the MetaCIC audit routes named in chapter 9379. The packet records accepted checker schedules, rejection ledgers, bounded normal-comparison endpoints, strong-normalisation handoff rows, confluence handoff rows, transport, replay, provenance, and local naming; it does not claim a global closed-term conversion decider, an unrestricted normalisation theorem, a confluence theorem, or a host proof search oracle.

Definition 6412.1 (Candidate decidability trace carrier)**.** *A* $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Gamma, t, A, S, J, B, F, R, N, C, H, K, P, L)$$

with the following displayed rows:

1. Γ *is the finite local context row used by the MetaCIC checker request.*
2. t *is the displayed candidate term row.*
3. A *is the displayed candidate type row.*
4. S *is the finite checker schedule, listing the syntax nodes, local context extensions, same-term reads, and bounded-conversion calls opened by the request.*
5. J *is the accepted-judgement row produced by the local checker when the schedule succeeds.*
6. B *is the bounded normal-comparison row, storing fuel, endpoint names, and equality-readback cells for every conversion subcall.*
7. F *is the refusal ledger for schedule branches that fail before a decidability read is exported.*
8. R *is the strong-normalisation handoff row, naming the endpoint obligations that a later SN packet must close.*
9. N *is the confluence handoff row, naming the join obligations that a later confluence packet must close.*
10. C *is the critical-path row binding the local checker schedule, rejection ledger, SN handoff, and confluence handoff into one audit trace.*

11. *H records componentwise* hsame *transport for context, term, type, schedule, judgement, bounded comparison, refusal, handoff, critical-path, replay, provenance, and local naming rows.*
12. *K records displayed* Cont *replay from local syntax reads through the checker schedule, rejection ledger, bounded comparison, and handoff rows.*
13. *P is the* Pkg *provenance over* $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{Computable}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
14. *L is the local* $\mathsf{NameCert}_{\mathsf{CandidateDecidabilityTrace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $\Gamma, t, A, S, J, B, F, R, N, C, H, K, P, L$. It has no coordinate for unrestricted decidability, global closed beta-conversion, an unbounded normalizer, an external confluence proof, a proof-search oracle, Lean verification, or a standard bridge.

Theorem 6412.2 (Candidate decidability trace NameCert obligations)**.** *For every accepted* CandidateDecidabilityTr *carrier*

$$T = (\Gamma, t, A, S, J, B, F, R, N, C, H, K, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CandidateDecidabilityTrace}^{\uparrow}}$ *surface consists exactly of context admission, candidate term admission, candidate type admission, finite checker-schedule exposure, accepted-judgement exposure, bounded normal-comparison exposure, rejection-ledger exposure, strong-normalisation handoff, confluence handoff, critical-path binding, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the same displayed rows.*

Proof. Project the carrier of Definition 6412.1. The local context, term, type, schedule, judgement, bounded comparison, rejection, handoff, critical-path, transport, replay, provenance, and naming rows are the only coordinates of the packet.

The checker schedule S is read before any decidability-facing result. It lists the local syntax inspections, context extensions, same-term reads, and bounded-conversion calls that the accepted trace exposes.

The bounded comparison and rejection rows are then read together. The row B records the finite fuel and endpoint data for successful bounded normal comparisons, while F records the finite reasons why failed branches do not export a decidability read.

The rows R, N, C make the open boundary explicit. They point to the strong-normalisation and confluence obligations needed by later packets, but they do not close those obligations inside this carrier.

Finally, H, K, P, L transport, replay, source, and name the same finite trace. Since no further coordinate exists, the listed rows exhaust the local NameCert obligations. □

Theorem 6412.3 (Candidate decidability trace checker-schedule precedence)**.** *Every accepted* $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$ *read exposes the finite checker schedule S before it exposes any accepted judgement J, bounded comparison row B, rejection ledger F, strong-normalisation handoff R, confluence handoff N, or critical-path row C. A consumer may therefore inspect a decidability candidate only through the displayed local-checker schedule and its finite ledger rows.*

Proof. Begin with the carrier projection. The rows Γ, t, A name the local request, and S is the first row that records how the request is checked.

The judgement row J and bounded comparison row B depend on that schedule. Without the syntax-node order, context extensions, same-term reads, and conversion subcalls listed in S, neither row has a displayed local-checker route.

The refusal ledger F is also downstream of S. It records which schedule branches fail before any decidability read is exported, so it cannot be detached from the schedule that produced those branches.

The handoff rows R, N, C bind the same finite trace to later strong-normalisation and confluence work. Thus every accepted consumer first reads S, and no unrestricted decidability theorem or proof-search oracle is introduced. □

Falsifiable prediction: Every accepted $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$ trace exposes a finite checker schedule before any decidability read, bounded normal-comparison export, rejection-ledger export, strong-normalisation handoff, confluence handoff, or critical-path row is consumed.

Independence witness: metaciccriticalpath, lambdacalc, computable, firstorder: $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries local context, candidate term, candidate type, checker schedule, accepted judgement, bounded normal-comparison, rejection ledger, strong-normalisation handoff, confluence handoff, critical-path binding, transport, replay, provenance, and local naming as one finite decidability-audit trace.

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateDecidabilityTrace}^{\uparrow}}$.

Constructive story: A $\mathsf{CandidateDecidabilityTrace}^{\uparrow}$ packet is generated from local context rows, candidate term rows, candidate type rows, finite checker schedules, accepted judgement rows, bounded normal-comparison rows, rejection ledgers, strong-normalisation handoff rows, confluence handoff rows, critical-path rows, componentwise hsame transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CandidateDecidabilityTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6412.1, Definition 6412.2, and Definition 6412.3 seed the finite MetaCIC decidability-audit trace over local checker schedules, rejection ledgers, bounded comparison, SN handoff, and confluence handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CandidateDecidabilityTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted decidability, global closed beta-conversion, strong normalisation, confluence, host proof search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, checker-schedule precedence, bounded-comparison exposure, rejection-ledger exposure, SN handoff, confluence handoff, critical-path binding, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.CandidateDecidabilityTraceUp.

Chapter 6413

A Concrete Naming Certificate for $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$ packet records the finite modulus data by which an equicontinuous family over a compact metric source is read as a uniform finite-window handoff. It sits beside the shared-radius surface of chapter 4076, the finite-net handoff of chapter 2362, the compact-uniform-continuity route of chapter 388, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the constructive compact-metric neighbour of the L10 real and completion route; it does not import open-cover compactness, selected subsequences, host function-space compactness, quotient equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6413.1 (Bishop equicontinuity modulus carrier)**.** *A* $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (E, N, U, W, R, S, H, C, P, L)$$

with the following displayed rows:

1. *E is the* $\mathsf{Equicontinuity}^{\uparrow}$ *shared-radius row, read over the same compact metric source and finite family ledger.*
2. *N is the* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *handoff row, recording the compact finite-net centers and the family-radius comparisons available at the inspected scale.*
3. *U is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *row consumed after the finite-net and shared-radius data are displayed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for source and target observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows and tolerance histories.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after E, N, U, W, R have fixed the finite modulus route.*
7. *H records componentwise* hsame *transport for the shared-radius, finite-net, compact-uniform, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through the finite route*

$$E, N, U \longmapsto W, R, S, H, P, L.$$

9. *P is the* Pkg *provenance over* $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{BishopEquicontinuityModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, N, U, W, R, S, H, C, P, L$. It has no coordinate for open-cover compactness, selected subsequences, host function-space compactness, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6413.2 (Bishop equicontinuity modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$ *carrier*

$$M = (E, N, U, W, R, S, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{BishopEquicontinuityModulus}^{\uparrow}}$ *surface consists exactly of shared-radius admission through E, finite-net equicontinuity admission through N, compact-uniform-continuity admission through U, finite-window exposure through W, regular rational readback through R, terminal Real sealing through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 6413.1. The analytic rows are E, N, U, W, R, S, and the structural rows are H, C, P, L.

The equicontinuity and finite-net clauses are finite. The row E supplies the shared family-radius data, while N supplies the compact finite-net handoff on the same source route.

The compact-uniform and L10 clauses are then read through U, W, R, S. The finite windows and regular rational readback determine the Real-facing seal without adding a quotient real, a selected limit, or an ambient completeness principle.

Finally H, C, P, L transport, replay, source, and name exactly the displayed rows. Since none of the excluded host objects is a carrier coordinate, the listed rows exhaust the local certificate surface. □

Theorem 6413.3 (Bishop equicontinuity modulus finite-net handoff)**.** *Every* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *or L10 real-facing consumer of an accepted* $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$ *carrier must first read the shared route*

$$\mathsf{Equicontinuity}^{\uparrow}, \mathsf{FiniteNetEquicontinuity}^{\uparrow}, \mathsf{CompactUniformContinuity}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The handoff consists of the shared-radius row E, finite-net row N, compact-uniform row U, window row W, readback row R, seal row S, and the structural rows H, C, P, L.

Proof. Start with the obligation theorem. It identifies $E, N, U, W, R, S, H, C, P, L$ as the complete public surface of the carrier.

The finite-net stage is downstream of the shared-radius row. A consumer reads E and then N before the compact-uniform row U is public, so the route cannot be replaced by a selected finite net outside the packet.

The L10-facing stage is downstream of that compact-uniform handoff. Rows W and R expose finite windows and regular rational readback before S seals the Real-facing output.

The rows H, C, P, L preserve this order by componentwise transport, replay, provenance, and local naming. Therefore every compact-uniform or real-facing consumer receives the displayed finite-net handoff rather than open-cover compactness, host function-space compactness, selected subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 6413.4 (Bishop equicontinuity modulus nonescape)**.** *No accepted* $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$ *packet exports open-cover compactness, selected subsequences, host function-space compactness, quotient equality of real names, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Its public modulus content is exactly the finite row package*

$$E, N, U, W, R, S, H, C, P, L.$$

Proof. Apply Definition 6413.2. Every public read factors through the displayed tuple $E, N, U, W, R, S, H, C, P, L$.

The shared-radius input is confined to E, the finite-net input to N, the compact-uniform handoff to U, and the real-facing route to W, R, S. The structural rows only transport, replay, package, and name these displayed rows.

None of the excluded principles is present as a carrier coordinate or as a structural row. Exporting any of them would leave the local $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$ NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopEquicontinuityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopEquicontinuityModulus}^{\uparrow}$ packet is generated from an EquicontinuityUp shared-radius row, a FiniteNetEquicontinuityUp finite-net handoff, a CompactUniformContinuityUp consumer row, StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopEquicontinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6413.1, Definition 6413.2, Definition 6413.3, and Definition 6413.4 seed the finite modulus route over equicontinuity, finite-net, compact-uniform, window, readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopEquicontinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.BishopEquicontinuityModulusUp`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subsequences, host function-space compactness, quotient equality of real names, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-radius admission, finite-net handoff, compact-uniform handoff, finite-window replay, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopEquicontinuityModulusUp.

Chapter 6414

A Concrete Naming Certificate for $\mathsf{FaberSchauderSystem}^{\uparrow}$

Following Schauder's basis construction and constructive approximation analysis, the $\mathsf{FaberSchauderSystem}^{\uparrow}$ packet records the dyadic hat functions that generate finite piecewise-linear approximation rows. It sits over the dyadic rational core of chapter 291, the real-name seal of chapter 38, the uniform-modulus route of chapter 369, and the sequence-level basis surface of chapter 3669. The packet stores dyadic levels, midpoint hats, finite support intervals, coefficient readbacks, uniform-error budgets, transport, replay, provenance, and naming, but it does not claim convergence of an arbitrary infinite series or a host Banach-space basis theorem.

Definition 6414.1 (Faber–Schauder system carrier)**.** *A* $\mathsf{FaberSchauderSystem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, H, S, C, U, R, T, P, N)$$

with the following rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *level row, recording the displayed dyadic grid, parent interval endpoints, and midpoint name used by a hat function;*
2. *H is the hat-profile row, recording the piecewise-linear rise and fall from the two endpoints through the midpoint;*
3. *S is the finite support row, recording the closed dyadic interval on which the hat can be nonzero and the exterior zero reads;*
4. *C is the coefficient row, recording the displayed scalar readback assigned to the hat;*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row, recording the finite tolerance budget for a partial approximation request;*
6. *R records componentwise* hsame *transport for the dyadic level, hat profile, support, coefficient, modulus, replay, provenance, and naming rows;*
7. *T records displayed* Cont *replay from a finite approximation request through dyadic-grid inspection, hat-support readback, coefficient multiplication, and uniform-modulus budget inspection;*
8. *P is the* Pkg *provenance over* $\mathsf{FaberSchauderSystem}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{SchauderBasis}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FaberSchauderSystem}^{\uparrow}}$ *row binding the paper-visible name to the finite packet.*

The carrier has no coordinate for quotient real equality, selected infinite coefficients, trichotomy, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or convergence of an infinite expansion.*

Lean4 (statement) `BEDC.Derived.FaberSchauderSystemUp`

Theorem 6414.2 (Faber–Schauder system NameCert obligations)**.** *For every accepted* $\mathsf{FaberSchauderSystem}^{\uparrow}$ *carrier*

$$F = (D, H, S, C, U, R, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FaberSchauderSystem}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the dyadic level, hat profile, support, coefficient, modulus, transport, replay, provenance, and local naming rows;*
2. *dyadic-grid exactness, requiring* D *to expose the parent endpoints and midpoint through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before the hat row is read;*
3. *hat-support locality, requiring* S *to name the finite dyadic support and exterior zero reads before any coefficient or real-facing approximation row is consumed;*
4. *uniform-budget compatibility, requiring* U *to provide the finite tolerance row used by partial sums before the packet reaches* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{SchauderBasis}^{\uparrow}$ *consumers;*
5. *non-escape, requiring* R, T, P, N *to preserve the same displayed rows under transport, replay, provenance, and naming, with no quotient real equality, selected infinite coefficient stream, trichotomy, choice, or ambient completeness coordinate.*

Proof. Carrier admission is projection from Definition 6414.1. The accepted packet exposes only the dyadic level, hat profile, support, coefficient, uniform budget, transport, replay, provenance, and naming rows.

The analytic rows are D, H, S, C, U. The dyadic row fixes the grid and midpoint, the hat row records the piecewise-linear profile, the support row confines the nonzero region, the coefficient row records the displayed scalar, and the modulus row supplies the finite approximation budget.

The structural rows are R, T, P, N. They transport the same packet, replay the finite request, record provenance, and bind the local name. Since no other coordinate exists, the excluded quotient, selection, trichotomy, choice, completeness, and infinite-expansion objects cannot enter the NameCert surface. □

Theorem 6414.3 (Faber–Schauder dyadic hat support)**.** *Every accepted* $\mathsf{FaberSchauderSystem}^{\uparrow}$ *carrier* $F = (D, H, S, C, U, R, T, P, N)$ *determines a finite dyadic hat-support route*

$$D \longrightarrow H \longrightarrow S \longrightarrow C \longrightarrow U$$

before any $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{SchauderBasis}^{\uparrow}$ *consumer reads the packet. The support row* S *confines the hat to the displayed dyadic parent interval, records exterior zero reads, and keeps the coefficient and uniform-modulus rows inside the same finite* BHist *route.*

Proof. Start with the dyadic row D. It names the parent endpoints and midpoint through $\mathsf{DyadicRatCore}^{\uparrow}$, so the hat row has a finite grid before any real-facing read occurs.

Next read H and S. The hat profile rises and falls only across the displayed dyadic interval, and the support row records the exterior zero reads that prevent the packet from exporting a host support predicate.

Finally pass through C and U. The coefficient and uniform budget are attached to the same displayed support, while R, T, P, N preserve that route under transport, replay, provenance, and

naming. Thus a Real or Schauder-basis consumer receives a finite hat-support certificate and no selected infinite coefficient stream, quotient equality, trichotomy, choice, or ambient completeness principle. □

Theorem 6414.4 (Faber–Schauder Haar-step route)**.** *Every accepted* $\mathsf{FaberSchauderSystem}^{\uparrow}$ *consumer reading a finite dyadic hat coefficient must pass through the sibling route*

$$\mathsf{DyadicTentFunction}^{\uparrow} \longrightarrow \mathsf{StepFunction}^{\uparrow} \longrightarrow \mathsf{HaarWavelet}^{\uparrow} \longrightarrow \mathsf{SchauderBasis}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The $\mathsf{DyadicTentFunction}^{\uparrow}$ *primitive is the one-hat support row supplied by chapter 8351; finite sampled values are read through the step-function and Haar-wavelet surfaces of chapter 3780 and chapter 3881; and the coordinate handoff reaches the Schauder-basis surface of chapter 3669 before any regular-rational or real seal is consumed.*

Proof. Project an accepted carrier as $F = (D, H, S, C, U, R, T, P, N)$. The rows D, H, S determine the displayed dyadic parent interval, midpoint hat profile, and exterior zero reads, while C records the finite coefficient and U records the finite uniform budget.

The tent primitive is therefore not an ambient function object. It is the one-hat support row obtained by reading D, H, S as a $\mathsf{DyadicTentFunction}^{\uparrow}$ packet, with the coefficient row C still attached to the same finite BHist route.

Finite sampled values next enter $\mathsf{StepFunction}^{\uparrow}$ as displayed intervalwise reads. The Haar surface consumes only those finite step reads, so the route reaches $\mathsf{HaarWavelet}^{\uparrow}$ without asserting Haar measure, quotient function equality, or a completed function space.

Finally the structural rows R, T, P, N preserve the same displayed packet through transport, replay, provenance, and naming. The $\mathsf{SchauderBasis}^{\uparrow}$ consumer receives a coordinate handoff, and the subsequent $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ reads are terminal seals for finite approximation data, not claims of infinite expansion convergence, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FaberSchauderSystem}^{\uparrow}}$.

Constructive story: A $\mathsf{FaberSchauderSystem}^{\uparrow}$ packet is generated from dyadic grid rows, finite hat profiles, support intervals, coefficient readbacks, uniform-modulus budgets, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FaberSchauderSystem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6414.1, Definition 6414.2, and Definition 6414.3 seed the finite dyadic hat system certificate over dyadic levels, support intervals, coefficient rows, uniform budgets, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FaberSchauderSystem}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: The chapter does not close convergence of arbitrary infinite Faber–Schauder expansions, uniqueness of coefficients, quotient real equality, trichotomy, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-grid exactness, hat-support locality, uniform-budget compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FaberSchauderSystemUp.

Chapter 6415

A Concrete Naming Certificate for DyadicBisectionTree$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the DyadicBisectionTree$^{\uparrow}$ packet records the finite tree surface behind repeated dyadic bisection of a located interval. It sits over the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the endpoint refinement route of chapter 6199. The packet is a finite carrier for L10 Real and Completion work: every displayed node is a bounded dyadic interval row with a parent link, a tolerance budget, and a retained-child certificate, while no infinite branch or completeness principle is selected.

Definition 6415.1 (Dyadic bisection tree carrier)**.** *A* DyadicBisectionTree$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, I, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *ledger of endpoints, midpoints, radii, and common dyadic refinements.*
2. *I is the* LocatedIntervalRefinement$^{\uparrow}$ *source row, giving the initial located interval and the finite refinement witnesses used by each retained node.*
3. *T is the finite bisection-tree row: its nodes are addressed by finite binary words, every non-root node records its parent, and every retained child carries the half-interval selected by the displayed midpoint comparison.*
4. *W is the* StreamName$^{\uparrow}$ *finite-window row read by a consumer that asks for a node at a requested depth or tolerance.*
5. *R is the* RegSeqRat$^{\uparrow}$ *regular-Cauchy readback row obtained from nested retained intervals whose dyadic diameters are bounded by the displayed depth budget.*
6. *E is the* Real$^{\uparrow}$ *seal boundary, reachable only after D, I, T, W, R have been projected.*
7. *H records componentwise* hsame *transport for the dyadic, located-interval, tree, window, regular-readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for endpoint admission, midpoint bisection, retained-child transport, finite-window inspection, regular readback, and terminal sealing.*
9. *P is the* Pkg *provenance over* DyadicBisectionTree$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, LocatedIntervalRefinement$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicBisectionTree}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, I, T, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, a selected infinite branch, quotient equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6415.2 (Nested regular-Cauchy readback from a dyadic bisection tree)**.** *For every accepted* $\mathsf{DyadicBisectionTree}^{\uparrow}$ *carrier $K = (D, I, T, W, R, E, H, C, P, N)$ and every displayed retained branch prefix in T, each unary depth request factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{LocatedIntervalRefinement}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The resulting $\mathsf{RegSeqRat}^{\uparrow}$ *row is read from nested retained dyadic intervals with diameter bounded by the depth budget. The route does not assert real completeness, open-cover compactness, countable choice, a selected infinite branch, quotient equality, or any ambient equality of* $\mathsf{Real}^{\uparrow}$ *seals.*

Proof. Start with the accepted carrier and project its dyadic and interval rows. The row D supplies the endpoint arithmetic, midpoint, radius, and common-refinement data, while I supplies the located refinement witness for the current retained interval.

Read the branch prefix inside T. Because node addresses are finite binary words, the requested prefix exposes only finitely many parent links and child selections. Each retained child is justified by the displayed midpoint comparison and by the corresponding row of D and I.

The finite observation row W records the window requested at the chosen depth. The diameter bound is computed from the bisection depth in T and the dyadic radius ledger in D, so the handoff to R is a regular-Cauchy readback over inspected finite intervals rather than a selected limit.

Finally the seal row E is downstream of R, and the structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no row contains an infinite-branch selector, open-cover compactness proof, countable-choice schedule, quotient-equality coordinate, or ambient completeness witness, the listed route is the full exported regular-Cauchy boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBisectionTree}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicBisectionTree}^{\uparrow}$ packet is generated from a DyadicRatCore endpoint and tolerance ledger, a LocatedIntervalRefinement source row, a finite binary bisection-tree row, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicBisectionTree}^{\uparrow}}$, seed)

Scope closed: Definition 6415.1 and Definition 6415.2 seed the finite dyadic bisection-tree carrier over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedIntervalRefinement}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicBisectionTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, open-cover compactness, countable choice, a selected infinite branch, quotient equality, theorem verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint arithmetic, located interval refinement, retained-child bisection, finite-window inspection, regular-Cauchy readback, terminal sealing, transport, replay, provenance, and local naming for BEDC.Derived.DyadicBisectionTreeUp.

Chapter 6416

A Concrete Naming Certificate for $\mathsf{KalmanDecomposition}^{\uparrow}$

Following Kalman, the $\mathsf{KalmanDecomposition}^{\uparrow}$ packet records the finite block-splitting rows that separate a linear control system into controllable/observable, controllable/unobservable, uncontrollable/observable, and residual components. It sits after the finite reachability surface of chapter 297, the observation surface of chapter 294, the matrix-ledger rows of chapter 49, the vector-space carrier rows of chapter 47, and the regulator-facing rows of chapter 296. The packet names only finite plant, basis, block, transition, transport, replay, provenance, and local naming data; it does not claim a canonical host quotient, analytic minimal realization, transfer-function equality, or stochastic filtering law.

Definition 6416.1 (KalmanDecomposition carrier)**.** *A* $\mathsf{KalmanDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, U, Y, A, B, C, S, Q, O, Z_{co}, Z_{cu}, Z_{uo}, Z_{ur}, M, H, T, P, N)$$

with the following displayed rows:

1. *X is the finite state-space row, U is the input row, and Y is the output row, each read through displayed* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *coordinates.*
2. *$A : X \to X$, $B : U \to X$, and $C : X \to Y$ are the finite transition, input, and output rows of the plant.*
3. *S is the displayed change-of-basis ledger whose columns are finite state rows and whose inverse-readback is recorded through* $\mathsf{Mat}^{\uparrow}$*.*
4. *Q is the controllability row consumed from* $\mathsf{ControlControllability}^{\uparrow}$*, and O is the observability row consumed from* $\mathsf{ControlObservability}^{\uparrow}$*.*
5. *Z_{co} is the controllable/observable block, Z_{cu} is the controllable/unobservable block, Z_{uo} is the uncontrollable/observable block, and Z_{ur} is the residual block.*
6. *M is the matrix transition ledger recording the displayed block reads of $S^{-1}AS$, $S^{-1}B$, and CS together with the zero-pattern entries that witness the decomposition route.*
7. *H records componentwise* hsame *transport for state, input, output, plant, basis, controllability, observability, block, matrix-transition, replay, provenance, and naming rows.*
8. *T records displayed* Cont *replay for the finite route*

$$X, U, Y, A, B, C, S, Q, O \longmapsto Z_{co}, Z_{cu}, Z_{uo}, Z_{ur}, M, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{KalmanDecomposition}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KalmanDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, U, Y, A, B, C, S, Q, O, Z_{co}, Z_{cu}, Z_{uo}, Z_{ur}, M, H, T, P, N$. It has no coordinate for a host quotient state space, a canonical ambient basis, analytic transfer-function equality, stochastic covariance data, or an infinite-dimensional realization theorem.

Theorem 6416.2 (KalmanDecomposition NameCert obligations)**.** *For every accepted* $\mathsf{KalmanDecomposition}^{\uparrow}$ *carrier*

$$K = (X, U, Y, A, B, C, S, Q, O, Z_{co}, Z_{cu}, Z_{uo}, Z_{ur}, M, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KalmanDecomposition}^{\uparrow}}$ *surface consists exactly of finite state, input, and output admission through X, U, Y, plant admission through A, B, C, basis-ledger admission through S, controllability admission through Q, observability admission through O, block admission through $Z_{co}, Z_{cu}, Z_{uo}, Z_{ur}$, matrix transition readback through M, componentwise* hsame *transport through H, displayed* Cont *replay through T, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6416.1. The rows X, U, Y, A, B, C, S supply the finite plant and basis data, and the rows Q, O attach the displayed controllability and observability certificates.

The four block rows $Z_{co}, Z_{cu}, Z_{uo}, Z_{ur}$ are read only after Q, O and S have exposed the finite splitting ledger. The row M then records the block transition, input, and output matrices over that same basis route rather than over an ambient quotient or selected canonical form.

Finally H, T, P, N transport, replay, source, and name exactly the displayed rows. Since the carrier has no coordinate for host quotient semantics, analytic transfer equality, stochastic covariance, or an infinite-dimensional realization theorem, the listed rows exhaust the local certificate surface. □

Theorem 6416.3 (KalmanDecomposition controllable-observable split)**.** *Every downstream control consumer that reads an accepted* $\mathsf{KalmanDecomposition}^{\uparrow}$ *packet as a controllable/observable splitting must pass first through the displayed finite route*

$$\mathsf{VecSpace}^{\uparrow}, \mathsf{Mat}^{\uparrow}, \mathsf{ControlControllability}^{\uparrow}, \mathsf{ControlObservability}^{\uparrow} \longmapsto Z_{co}, Z_{cu}, Z_{uo}, Z_{ur}, M.$$

The exported splitting consists only of the finite state, input, output, plant, basis, controllability, observability, block, transition-ledger, transport, replay, provenance, and local NameCert *rows of Definition 6416.1.*

Proof. Start with Definition 6416.2. It exposes the plant rows and the basis ledger before either the controllability or observability rows can be used.

The controllable side is read through Q and chapter 297, while the observable side is read through O and chapter 294. Both rows are finite control certificates over the same $\mathsf{Mat}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ surface, so the consumer cannot replace them by an unlogged reachable quotient or unobservable quotient.

The four block rows and the matrix transition ledger then provide the only public splitting data. The structural rows H, T, P, N preserve that finite route under transport, replay, provenance, and local naming, so the consumer receives the displayed Kalman decomposition packet rather than a host canonical-form theorem. □

Falsifiable prediction: An accepted $\mathsf{KalmanDecomposition}^{\uparrow}$ packet is refuted by any control consumer that reads a controllable/observable block, residual block, or block transition ledger

while bypassing the displayed basis row S, the controllability row Q, the observability row O, or the matrix transition ledger M.

Independence witness: controlcontrollability, controlobservability, matrix, vecspace, lqr: none is bijective to $\mathsf{KalmanDecomposition}^{\uparrow}$ because the decomposition packet jointly carries plant, basis, controllability, observability, four block rows, matrix transition ledger, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{KalmanDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{KalmanDecomposition}^{\uparrow}$ packet is generated from finite state, input, output, plant, basis, controllability, observability, four block, matrix-transition, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KalmanDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6416.1, Definition 6416.2, Definition 6416.3, the displayed falsifiable prediction, and the displayed independence witness seed the finite control decomposition NameCert surface over controllability, observability, matrix, vector-space, and regulator-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KalmanDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, canonical host quotient semantics, analytic minimal realization, transfer-function equality, stochastic covariance laws, or infinite-dimensional realization theory.

Upgrade path: Obligation closure requires checked carrier admission, basis-ledger admission, controllability and observability admission, block admission, matrix-transition exactness, transport, replay, provenance, and local naming for BEDC.Derived.KalmanDecompositionUp.

Chapter 6417

A Concrete Naming Certificate for $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$ packet records a finite nested-interval locator route from dyadic refinement data to stream, regular-rational, and real-seal consumers. It reads the retained-window discipline of chapter 320, the dyadic arithmetic surface of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a local L10 locator object for nested dyadic intervals; it is not a host interval-intersection theorem, a selected point, quotient stream equality, countable choice, or ambient real completeness.

Definition 6417.1 (BishopIntervalNestedLocator carrier)**.** *A* $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, J, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the retained* $\mathsf{NestedInterval}^{\uparrow}$ *row naming the inspected interval chain;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger, including dyadic endpoints, dyadic radii, and the finite containment budget used by the locator;*
3. *J is the nested-refinement row asserting that each inspected interval window is retained inside the previous displayed window;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row obtained from the dyadic endpoint windows and retained containment data;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row determined by the same dyadic windows and not by an independent rational sequence;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S and R have been projected;*
7. *H records componentwise* hsame *transport for I, D, J, S, R, E and the support rows;*
8. *C records displayed* Cont *replay from a locator request through the nested interval, dyadic refinement, stream-window, regular readback, and real-seal rows;*
9. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNestedLocator}^{\uparrow}}$ *row.*

The classifier compares two carriers only through these rows and contains no coordinate for a selected limit point, quotient stream equality, host real equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6417.2 (BishopIntervalNestedLocator NameCert obligations)**.** *For an accepted* BishopIntervalNestedLoca *carrier* $L = (I, D, J, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNestedLocator}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed nested interval, dyadic refinement ledger, containment row, stream row, regular rational readback, real seal, transports, replay routes, provenance, and local naming row; dyadic endpoint and radius exactness through* D*; retained-window nesting through* J*;* $\mathsf{StreamName}^{\uparrow}$ *readback through* S*;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*;* $\mathsf{Real}^{\uparrow}$ *seal delivery through* E*; componentwise transport through* H*; displayed continuation through* C*; package provenance through* P*; and local naming through* N*. No obligation exports host interval intersection, selected limits, quotient stream equality, host real equality, countable choice, open-cover compactness, or real completeness.*

Proof. Project the carrier of Definition 6417.1. The packet displays exactly the nested interval row, dyadic refinement ledger, containment row, stream row, regular rational row, real seal, and structural rows.

The dyadic and containment obligations are row projections. The row D gives the endpoint and radius budget, and J states the retained-window relation between adjacent displayed intervals. Thus a locator-facing read must inspect the finite dyadic refinement data before any stream or real-facing row is available.

The stream, regular, and seal obligations are then forced by the carrier order. The rows S and R are read from the same dyadic windows, and E is downstream of both. Transport, replay, provenance, and local naming preserve that order, leaving no coordinate for the excluded host-level principles. □

Theorem 6417.3 (BishopIntervalNestedLocator dyadic refinement)**.** *Every accepted* $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$ *packet factors each locator precision request through the dyadic refinement route*

$$I, \quad D, \quad J, \quad S, \quad R.$$

The row D *supplies the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius data,* J *supplies retained nested containment,* S *supplies the* $\mathsf{StreamName}^{\uparrow}$ *windows, and* R *supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback. The route cannot be replaced by a selected branch, quotient stream equality, host real equality, or countable choice.*

Proof. Start with carrier admission. A precision request reaches the packet only through the displayed rows $I, D, J, S, R, E, H, C, P, N$.

Apply the obligation surface of Definition 6417.2. Dyadic endpoint and radius exactness in D precede retained-window nesting in J, and both precede stream and regular-rational readback.

Finally use the absence clauses in Definition 6417.1. Since the carrier has no selected branch, quotient stream equality, host real equality, or countable-choice coordinate, every accepted precision request is exhausted by the displayed dyadic refinement route. □

Theorem 6417.4 (BishopIntervalNestedLocator Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$ *carrier must pass through the retained* $\mathsf{NestedInterval}^{\uparrow}$ *row* I*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger* D*, the containment row* J*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the seal row* E *is visible. The seal is therefore a terminal row of the displayed locator packet, not a proof of real completeness or host equality of real numbers.*

Proof. Use Definition 6417.3 to identify the only route into a locator precision request. It places I, D, J, S, R before any real-facing consumer can read the packet.

Now project the seal row in Definition 6417.1. The row E occurs after the stream and regular-rational rows, and the support rows H, C, P, N only transport, replay, package, and name the same route.

Thus the seal consumer receives a finite terminal row rather than an ambient completeness theorem, host real equality, selected point, or quotient stream equality. □

Theorem 6417.5 (BishopIntervalNestedLocator non-escape)**.** *Every consumer of an accepted* $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$ *packet is exhausted by the finite rows* $I, D, J, S, R, E, H, C, P, N$*. In particular, the locator route can feed* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *sibling consumers, but it cannot escape as a selected nested-interval intersection point, a quotient stream representative, a host real equality proof, a countable-choice functional, an open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the packet inventory from Definition 6417.1. The only data rows are I, D, J, S, R, E, and the only structural rows are H, C, P, N.

Use the NameCert obligations of Definition 6417.2. They force every accepted read through the displayed dyadic refinement, nested containment, stream-window, regular-rational, seal, transport, replay, provenance, and naming route.

Apply the Real-seal route of Definition 6417.4 for completion-facing consumers. Since the seal itself remains downstream of I, D, J, S, R and no excluded coordinate is present in the carrier, the locator cannot export any of the host-level objects listed in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalNestedLocator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalNestedLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6417.1, Definition 6417.2, Definition 6417.3, and Definition 6417.4 seed the finite nested-interval locator route from dyadic refinement data to StreamName, RegSeqRat, and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalNestedLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim interval-intersection existence, selected limits, quotient stream equality, host real equality, countable choice, open-cover compactness, real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove carrier admission, dyadic endpoint and radius exactness, retained-window nesting, stream readback, regular rational readback, real-seal delivery, transport, replay, provenance, and local naming for the same displayed packet.

Constructive story: A $\mathsf{BishopIntervalNestedLocator}^{\uparrow}$ packet is generated from a retained nested-interval row, a DyadicRatCore refinement ledger, a containment row, a StreamName row, a RegSeqRat readback row, a RealUp seal, componentwise transports, replay routes, provenance, and a local NameCert row.

Chapter 6418

A Concrete Naming Certificate for $\mathsf{MorseLemma}^{\uparrow}$

Following Milnor's Morse theory treatment and the Bishop–Bridges constructive analysis of finite coordinate data, the $\mathsf{MorseLemma}^{\uparrow}$ packet records the local quadratic normal-form route for a nondegenerate critical point as finite BEDC certificate data. It sits between the Morse-theory surface of chapter 3533, the boundary packet of chapter 6040, the manifold chart rows of chapter 96, the derivative ledger of chapter 122, the implicit-function graph route of chapter 1834, the terminal real-name seal of chapter 38, and the vector-space coordinate carrier of chapter 47. The packet names only displayed chart, critical-point, Hessian-signature, local-coordinate, quadratic normal-form, transport, replay, provenance, and local naming rows; it does not import a host smooth-manifold theorem, a selected chart atlas, quotient germs, or analytic compactness.

Definition 6418.1 (Morse lemma NameCert carrier)**.** *A* $\mathsf{MorseLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, C, Q, S, L, NF, H, R, P, A)$$

with the following displayed rows:

1. *X is the* $\mathsf{Manifold}^{\uparrow}$ *chart-source row, naming the displayed neighbourhood, chart window, coordinate dimension, and local domain in which the critical point is inspected.*
2. *C is the critical-point row, recording the point, the value row, and the derivative-vanishing witness exposed through the* $\mathsf{Derivative}^{\uparrow}$ *ledger.*
3. *Q is the Hessian-signature row, storing the finite symmetric bilinear form, its nondegeneracy witness, and the positive and negative coordinate counts read through* $\mathsf{VecSpace}^{\uparrow}$*.*
4. *S is the local-coordinate row, recording the coordinate transformation routed through the implicit-function packet and the finite neighbourhood on which it is admitted.*
5. *L is the quadratic normal-form row, displaying the equation that reads the function as the critical value plus the signed square sum determined by Q after S has been admitted.*
6. *NF is the normal-form transport row, recording how the chart, critical-point, Hessian, coordinate, and quadratic rows are transported componentwise under* hsame*.*
7. *H records displayed* Cont *replay from a normal-form query through X, C, Q, S, L, NF, P, A.*
8. *R is the Real readback row, exposing the scalar values only after the chart, derivative, Hessian, coordinate, and quadratic rows have been displayed.*

9. *P is the* Pkg *provenance over* $\mathsf{MorseLemma}^{\uparrow}$, $\mathsf{MorseTheory}^{\uparrow}$, $\mathsf{MorseBoundary}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{ImplicitFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *A is the local* $\mathsf{NameCert}_{\mathsf{MorseLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, C, Q, S, L, NF, H, R, P, A$. It has no coordinate for a host smooth atlas, quotient germ equality, selected coordinate theorem, compactness principle, or ambient real manifold semantics.

Theorem 6418.2 (Morse lemma critical-chart ledger)**.** *For every accepted* $\mathsf{MorseLemma}^{\uparrow}$ *carrier $M = (X, C, Q, S, L, NF, H, R, P, A)$, the critical-chart ledger exposes the chart-source row X, the derivative-vanishing critical-point row C, and the Hessian-signature row Q before any local-coordinate row S or quadratic normal-form row L may be read. A consumer that omits one of X, C, Q receives no accepted Morse-lemma packet.*

Proof. Project the carrier of Definition 6418.1. The chart-source, critical-point, and Hessian-signature data are separate rows, and no later coordinate stores a replacement for them.

The coordinate row S is downstream of these rows. It records a local transformation only after the chart window, derivative-vanishing witness, and nondegenerate Hessian signature have been displayed.

The quadratic row L is downstream again. Since L reads the signed square decomposition determined by Q inside the chart named by X at the critical point named by C, the packet cannot admit a normal-form read with any of those rows missing. □

Theorem 6418.3 (Morse lemma Hessian normal-form obligation)**.** *For an accepted* $\mathsf{MorseLemma}^{\uparrow}$ *carrier, every quadratic normal-form read factors through*

$$\mathsf{Manifold}^{\uparrow},\ \mathsf{Derivative}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow} \longmapsto X, C, Q \longmapsto S, L \longmapsto NF, H, R, P, A.$$

The Hessian-signature row determines the positive and negative square counts in L, while NF, H, R, P, A transport, replay, source, read back, and name the same finite route without adding a host Morse-lemma theorem.

Proof. Begin with the displayed analytic rows. The manifold row supplies the local chart window, the derivative row supplies the critical-point witness, and the vector-space row supplies the finite coordinate carrier for the Hessian signature.

Next read S and L. The coordinate transformation S is admitted only inside the displayed neighbourhood, and the normal-form row L records the signed quadratic expression using the signature data in Q.

Finally route the read through NF, H, R, P, A. These rows preserve and replay the same finite packet, expose scalar values only through the Real readback row, and bind the local NameCert. Because the carrier has no host-atlas, quotient-germ, or selected-theorem coordinate, the result is a BEDC normal-form obligation rather than an imported smooth-manifold theorem. □

Falsifiable prediction: Every accepted $\mathsf{MorseLemma}^{\uparrow}$ normal-form read exposes chart, critical-point, Hessian-signature, local-coordinate, quadratic normal-form, componentwise transport, displayed replay, Real readback, provenance, and local NameCert rows before any Morse-theory consumer reads the local quadratic model.

Independence witness: morse-theory, morse-boundary, manifold, derivative, implicitfunction, real, vecspace: $\mathsf{MorseLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a

nondegenerate critical-point chart, Hessian signature, local coordinate transformation, quadratic normal-form row, transport, replay, Real readback, provenance, and local naming as one finite packet.

The Lean follow-up namespace is expected at `BEDC.Derived.MorseLemmaUp`. It must preserve the chart, critical-point, Hessian-signature, local-coordinate, quadratic normal-form, transport, replay, Real readback, provenance, and local NameCert rows before any checked marker may cite the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MorseLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{MorseLemma}^{\uparrow}$ packet is generated from manifold chart rows, critical-point derivative rows, Hessian-signature rows, local coordinate rows, quadratic normal-form rows, componentwise transport, displayed replay, Real readback, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MorseLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6418.1, Definition 6418.2, and Definition 6418.3 seed the finite local quadratic normal-form route consumed by Morse-theory packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MorseLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host smooth-manifold Morse theory, selected coordinate atlases, quotient germs, analytic compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, critical-chart ledger exactness, Hessian-signature normal-form coverage, transport stability, replay stability, Real readback, provenance exhaustion, and local naming for BEDC.Derived.MorseLemmaUp.

Chapter 6419

A Concrete Naming Certificate for $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$

The $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$ packet realizes the residual-substitution and confluence frontier of section 9386.3 as finite NameCert data. It sits beside the critical-path packet of chapter 765, the confluence audit packet of chapter 735, the decidability boundary of chapter 749, the normalization-confluence bridge of chapter 1190, and the closed-term substitution boundary of chapter 527. The packet names a typed window, substitution route, residual frontier, bounded local-diamond checker, obstruction retention, transport, replay, provenance, and local naming surface before any confluence read is admitted.

Falsifiable prediction: Every accepted $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$ packet exposes typed-window, substitution-route, residual-frontier, bounded local-diamond checker, obstruction-retention, transport, replay, provenance, and local NameCert rows before any confluence read.

Independence witness: metaciccriticalpath, metacicconfluenceauditpacket, metacicdecidable-boundary, metacicnormalizationconfluencebridge, closedtermsubstitutioncompiler: no listed sibling is bijective to $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$ because the substitution-diamond packet jointly carries typed-window data, substitution routing, residual-frontier rows, a bounded local-diamond checker, obstruction retention, transport, replay, provenance, and local naming as one finite confluence boundary.

Definition 6419.1 (MetaCIC substitution diamond carrier)**.** *A* $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, S, R, B, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, recording the source term, typing context, two substitution-sensitive reduct branches, binder depth, and candidate common endpoint under inspection.*
2. *S is the substitution-route row, exposing the closed substitution or compiler-facing substitution boundary used by each branch before residual comparison begins.*
3. *R is the residual-frontier row, listing the beta positions, residual descendants, variable-escape checks, and branch-local substitution dependencies that remain visible.*
4. *B is the bounded local-diamond checker row, recording the finite checks that either produce a local common endpoint or stop at a named obstruction.*

5. *O is the obstruction-retention row, naming unrestricted substitution compatibility, premise-free closed parallel diamond, arbitrary closed Church–Rosser, subject-reduction discharge, evaluator equality, and kernel consistency as nonexported endpoints.*
6. *H records componentwise* hsame *transport for typed windows, substitution routes, residual frontiers, bounded checker rows, obstruction rows, replay routes, provenance, and local naming.*
7. *C records displayed* Cont *replay from a confluence query through T, S, R, B, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, MetaCICConfluenceAuditPac MetaCICDecidableBoundary$^{\uparrow}$, $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$, $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, R, B, O, H, C, P, N$. It has no coordinate for global confluence, unrestricted substitution composition, subject reduction, evaluator soundness, quotient syntax equality, or kernel consistency.

Theorem 6419.2 (MetaCIC substitution diamond confluence obligation)**.** *For every accepted* $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$ *carrier $D = (T, S, R, B, O, H, C, P, N)$, a confluence consumer may read a local diamond only through the route*

$$T, S, R \longmapsto B \longmapsto O, H, C, P, N.$$

The checker row B may expose a bounded common endpoint for the displayed typed window, but the obstruction row O remains part of the packet and prevents the read from becoming unrestricted substitution compatibility or global closed-term confluence.

Proof. Read the typed-window and substitution rows first. The source term, branch data, binder depth, and substitution route are visible in T and S before any residual comparison is made.

Next inspect the residual-frontier row R. It names the beta positions, residual descendants, and branch-local dependencies, so the bounded checker receives a finite frontier rather than an unbounded substitution algebra.

Finally apply the checker and obstruction rows. If B exposes a local common endpoint, O still records the endpoints not supplied by the packet. Transport, replay, provenance, and naming preserve this same finite route, so a consumer cannot cite the accepted packet as a premise-free confluence theorem. □

Lean follow-up must provide Nontrivial $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$ and FieldFaithful MetaCICSubstitutionDian TasteGate instances in `BEDC.Derived.MetaCICSubstitutionDiamondUp`. Those instances must preserve $T, S, R, B, O, H, C, P, N$ as distinct displayed rows before any checked marker may cite the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}$ packet is generated from typed-window rows, substitution-route rows, residual-frontier rows, bounded local-diamond checker rows, obstruction-retention rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}}$, seed)

Scope closed: Definition 6419.1, Definition 6419.2, the falsifiable prediction, and the independence witness seed the finite substitution-sensitive local-diamond boundary for MetaCIC confluence consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamond}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted substitution compatibility, premise-free closed parallel diamond, arbitrary closed Church–Rosser, subject-reduction discharge, evaluator equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, substitution-route exactness, residual-frontier coverage, bounded-checker determinacy, obstruction retention, transport stability, replay stability, provenance exhaustion, local naming, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.MetaCICSubstitutionDiamondUp

Chapter 6420

A Concrete Naming Certificate for $\mathsf{AbelSummability}^{\uparrow}$

Following Abel and Hardy, the $\mathsf{AbelSummability}^{\uparrow}$ packet records the finite radial-window surface by which a displayed power-series family is read as summability data before the L10 Real and Completion route may consume an endpoint seal. It sits after the Abel summation row of chapter 1763, the radial-limit route of chapter 6058, the Cesaro-facing mean surface of chapter 1765, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ boundary of chapter 38. The packet is a traditional summability carrier expressed as finite BEDC rows; it is not a quotient of power series, a selected host sum, countable choice, trichotomy on arbitrary coefficients, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6420.1 (Abel summability carrier)**.** *An* $\mathsf{AbelSummability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, T, M, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{AbelSummation}^{\uparrow}$ *source row carrying the finite polynomial-window and summation-by-parts reads.*
2. *T is the* $\mathsf{AbelTheorem}^{\uparrow}$ *radial-boundary row that binds the same Abel data to a displayed endpoint route.*
3. *M is the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *or Cesaro-facing mean row used as the traditional summability comparison surface.*
4. *D is the dyadic radial-parameter and tolerance ledger for the inspected radius window.*
5. *W records the finite coefficient, partial-sum, and radial windows inspected by S, T, M, D.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same radial windows and tolerance data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after S, T, M, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the Abel, theorem, mean, tolerance, window, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from each radial precision request through S, T, M, D, W to R and E.*

10. *P is the* Pkg *provenance over* $\mathsf{AbelSummability}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTheorem}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelSummability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, M, D, W, R, E, H, C, P, N$. It has no coordinate for host power-series semantics, a selected infinite sum, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AbelSummabilityUp.AbelSummabilityTasteGate single carrier alignment`

Theorem 6420.2 (Abel summability NameCert obligations)**.** *For every accepted* $\mathsf{AbelSummability}^{\uparrow}$ *carrier $A = (S, T, M, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbelSummability}^{\uparrow}}$ *surface consists exactly of Abel summation admission through S; radial-boundary admission through T; Cesaro-facing mean exposure through M; dyadic radial tolerance accounting through D; finite coefficient, partial-sum, and radius-window exhaustion through W;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R;* $\mathsf{Real}^{\uparrow}$ *seal ordering through E; and componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 6420.1. The tuple displays exactly the Abel summation row, radial-boundary row, Cesaro-facing mean row, dyadic tolerance ledger, finite windows, regular readback, Real seal, and structural rows.

The analytic data are finite. Rows S, T, M, D, W name the polynomial windows, radial parameters, and comparison means that the summability read may inspect, while R repacks those same rows as regular rational data.

The seal row E is downstream from R. Transport through H and replay through C preserve the same displayed route, and P, N only source and name it. Since no further coordinate exists in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 6420.3 (Abel summability power-series handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{AbelSummability}^{\uparrow}$ *carrier must read the finite radial route*

$$\mathsf{AbelSummation}^{\uparrow}, \quad \mathsf{AbelTheorem}^{\uparrow}, \quad \mathsf{HardyCesaroMean}^{\uparrow}, \quad D, W, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the same packet rows $S, T, M, D, W, R, E, H, C, P, N$. Thus the power-series summability handoff is a displayed radial-window readback and not a host power-series limit, selected sum, quotient stream equality, countable-choice selector, or ambient Real-completeness principle.

Proof. Begin with an accepted carrier and project the route rows S, T, M, D, W, R, E. The rows S and T provide the Abel summation and Abel theorem faces, while M supplies the Hardy-Cesaro comparison surface over the same displayed request.

Read the finite radial window through D and W. These rows fix the tolerances, radius parameters, coefficient windows, and partial-sum windows that determine the regular rational readback R.

Finally pass through E, H, C, P, N. The seal row receives its analytic input from R, and the structural rows transport, replay, source, and name that same path. Therefore a downstream Real or Completion consumer obtains only the displayed finite handoff. □

Falsifiable prediction: An accepted $\mathsf{AbelSummability}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the Abel summation row, Abel theorem row, Hardy-Cesaro mean row, dyadic radial ledger, finite radial windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: abel-summation, abel-theorem, hardy-cesaro-mean, regseqrat, real: $\mathsf{AbelSummability}^{\uparrow}$ is not bijective to any listed sibling because it binds radial-window summability data, Cesaro-facing comparison, regular readback, and Real sealing into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelSummability}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelSummability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6420.1, Definition 6420.2, and Definition 6420.3 seed the finite Abel summability route over Abel summation rows, Abel theorem radial windows, Hardy-Cesaro mean data, regular rational readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelSummability}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.AbelSummabilityUp.AbelSummabilityTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host power-series semantics, selected sums, quotient stream equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Abel summation admission, Abel theorem radial-boundary admission, Hardy-Cesaro mean exposure, dyadic radial tolerance accounting, finite-window exhaustion, regular readback, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.AbelSummabilityUp.

Constructive story: An $\mathsf{AbelSummability}^{\uparrow}$ packet is generated from Abel summation data, Abel theorem radial-boundary data, Hardy-Cesaro mean data, dyadic radial tolerances, finite coefficient and radius windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6421

A Concrete Naming Certificate for $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$

Following Brouwer, Bishop, and Bridges, the $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$ packet names the finite prefix-cylinder basis used before $\mathsf{BaireMetric}^{\uparrow}$ consumers read compact-window or fan-style coverage data. It sits after the Baire metric of chapter 1602, the prefix carrier of chapter 334, the finite observation schedules of chapter 126, the dyadic radius rows of chapter 291, and the finite bar surface of chapter 400. The packet records cylinders as displayed finite prefixes with dyadic radius witnesses; it is not a completed-stream topology, quotient equality of names, countable choice, or an open-cover compactness principle.

Definition 6421.1 (Located Baire metric compactness carrier)**.** *A* $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (B, S, W, D, C, F, H, T, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet whose finite word names the cylinder stem.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that authorizes every inspected prefix window.*
3. *W is the* $\mathsf{Nat}^{\uparrow}$ *window row recording the displayed stem length and the first-disagreement boundary available to metric reads.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row attached to W, recording the dyadic cylinder radius read by* $\mathsf{BaireMetric}^{\uparrow}$*.*
5. *C is the* $\mathsf{BaireMetric}^{\uparrow}$ *cylinder-consumer row, requiring every metric read to pass through B, S, W, D before any parent metric or ultrametric handoff.*
6. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-window handoff row, available only as finite bar or compact-window evidence over displayed prefix cylinders.*
7. *H records componentwise* hsame *transport for the prefix packet, schedule, window, radius, metric consumer, fan handoff, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay from cylinder requests through $B, S, W, D, C, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$, $\mathsf{BaireMetric}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BaireMetricCylinderBasis}^{\uparrow}}$ *row.*
The carrier predicate is exactly the assertion that these rows form one finite prefix-cylinder basis packet. It has no coordinate for completed Baire streams, quotient equality of names, an arbitrary topology, countable choice, or open-cover compactness.

Theorem 6421.2 (BaireMetricCylinderBasis NameCert obligations)**.** *For every accepted* $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$ *carrier $Z = (B, S, W, D, C, F, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireMetricCylinderBasis}^{\uparrow}}$ *surface consists exactly of carrier admission for Z, prefix-packet admission through B, finite schedule admission through S, window exactness through W, dyadic radius exactness through D, BaireMetric cylinder handoff through C, FanTheorem compact-window handoff through F, componentwise* hsame *stability through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N. No obligation is stored outside these finite rows.*

Proof. Project the carrier of Definition 6421.1. The analytic rows are B, S, W, D, C, F, and the structural rows are H, T, P, N.

The prefix row B and schedule row S are inspected before any radius data is available. The window row W then fixes the finite stem length and first-disagreement boundary, and the dyadic row D records the corresponding radius.

The metric row C and fan row F consume the same displayed prefix-cylinder data. Since H, T, P, N only transport, replay, source, and name the listed rows, the NameCert surface has no remaining coordinate for completed streams, quotient equality, countable choice, or open-cover compactness. □

Theorem 6421.3 (BaireMetricCylinderBasis prefix cover)**.** *Let $Z = (B, S, W, D, C, F, H, T, P, N)$ be an accepted* $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$ *carrier. Every cylinder cover read exported by Z is covered by the finite prefix route*

$$B, S, W, D \longmapsto C \longmapsto F \longmapsto H, T, P, N.$$

Thus a BaireMetric consumer sees a located prefix stem, a finite StreamName schedule, a Nat first-disagreement window, and a DyadicRatCore radius row before any compact-window handoff is public.

Proof. Start with the prefix and schedule rows B, S. They are the only rows that authorize a cylinder stem and its inspected finite windows.

Read the window and radius rows W, D. These rows locate the cylinder by finite length and dyadic radius, so the metric consumer row C cannot begin from a completed stream or a quotient name.

Finally pass through F, H, T, P, N. The FanTheorem row receives the displayed finite cylinder route, while transport, replay, provenance, and local naming preserve that route without adding an arbitrary topology or compactness oracle. □

Theorem 6421.4 (BaireMetricCylinderBasis compact-window handoff)**.** *For an accepted* $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$ *carrier $Z = (B, S, W, D, C, F, H, T, P, N)$, every compact-window consumer that reads the* $\mathsf{FanTheorem}^{\uparrow}$ *row F must first display the same* $\mathsf{BaireSpace}^{\uparrow}$ *prefix packet,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{Nat}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius, and* $\mathsf{BaireMetric}^{\uparrow}$ *cylinder row used by the prefix cover theorem. The handoff is therefore a finite cylinder-basis surface for compact-window consumers, not a completed-stream topology, quotient equality principle, selected infinite branch, or open-cover compactness theorem.*

Proof. Use Definition 6421.3. It identifies every exported cover read with the displayed route $B, S, W, D, C, H, T, P, N$.

The fan row F is downstream of that route. It may read finite bar or compact-window evidence over the displayed cylinders, but it receives no separate branch selector or open-cover compactness coordinate.

The structural rows H, T, P, N preserve the same finite data under componentwise transport, continuation replay, provenance, and local naming. Hence compact-window consumers receive exactly the prefix-cylinder basis surface named in the statement. □

Falsifiable prediction: A $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$ consumer that exports a compact-window or BaireMetric cylinder cover without reading the prefix packet B, StreamName schedule S, Nat window W, DyadicRatCore radius D, and cylinder row C refutes the carrier surface.

Independence witness: bairemetric, bairespace, streamname, dyadicratcore, fantheorem: BaireMetricCylinderBas is not bijective to any listed sibling because it binds prefix stems, finite schedules, first-disagreement windows, dyadic radii, metric cylinder reads, fan compact-window handoff, transport, replay, provenance, and local naming as one finite basis packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireMetricCylinderBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireMetricCylinderBasis}^{\uparrow}$ packet is generated from a BaireSpace prefix packet, StreamName schedule, Nat window, DyadicRatCore radius row, BaireMetric cylinder-consumer row, FanTheorem compact-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireMetricCylinderBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6421.1, Definition 6421.2, Definition 6421.3, and Definition 6421.4 seed the finite prefix-cylinder basis surface for BaireMetric and compact-window consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireMetricCylinderBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed-stream topology, quotient equality of Baire names, selected infinite branches, countable choice, open-cover compactness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, schedule exactness, dyadic radius exactness, metric cylinder handoff, compact-window handoff, transport, replay, provenance, and local naming for BEDC.Derived.BaireMetricCylinderBasis

Chapter 6422

A Concrete Naming Certificate for BishopCompletionApproximationTheorem$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the BishopCompletionApproximationTheorem$^{\uparrow}$ packet records the finite theorem-facing surface by which a displayed Bishop approximation route is allowed to serve completion-facing Real reads. It sits after the approximation source of chapter 3510, the criterion row of chapter 3404, the completion theorem packet of chapter 3484, the regular rational source of chapter 301, and the terminal seal of chapter 38. The packet is a finite NameCert theorem certificate; it is not a quotient completion, not a selected limit, not countable choice, not trichotomy, and not ambient Real$^{\uparrow}$ completeness.

Definition 6422.1 (Bishop completion approximation theorem carrier)**.** *A* BishopCompletionApproximationTheorem *carrier is a finite* BHist *packet*

$$T = (A, B, M, W, R, K, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* BishopCauchyApproximation$^{\uparrow}$ *approximation-service row.*
2. *B is the* BishopCompletionCriterion$^{\uparrow}$ *admissibility row that permits the displayed approximation route to enter a completion boundary.*
3. *M is the* CauchyConvergenceModulus$^{\uparrow}$ *schedule read by the criterion and approximation service.*
4. *W is the finite* StreamName$^{\uparrow}$ *window opened at the displayed precision request.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback extracted from the same window and tolerance schedule.*
6. *K is the* BishopCompletionTheorem$^{\uparrow}$ *handoff row reached only after A, B, M, W, R have been displayed.*
7. *E is the terminal* Real$^{\uparrow}$ *seal for Real-facing completion reads.*
8. *H records componentwise* hsame *transport for the approximation, criterion, modulus, window, readback, completion handoff, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion-facing approximation request through A, B, M, W, R, K, E.*
10. *P is the* Pkg *provenance over* BishopCompletionApproximationTheorem$^{\uparrow}$, BishopCauchyApproximation$^{\uparrow}$, BishopCompletionCriterion$^{\uparrow}$, BishopCompletionTheorem$^{\uparrow}$, CauchyConvergenceModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionApproximationTheorem}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through these rows and their displayed replay route. It has no coordinate for quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6422.2 (Bishop completion approximation carrier certificate)**.** *For every accepted* BishopCompletionAppr *carrier $T = (A, B, M, W, R, K, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionApproximationTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed approximation service, completion criterion, modulus schedule, finite stream window, regular rational readback, completion theorem handoff, Real seal, transport, replay, provenance, and local naming rows.*

Proof. Project the carrier of Definition 6422.1. The displayed rows are precisely $A, B, M, W, R, K, E, H, C, P, N$.

The source side is exhausted by A, M, W, R. The completion side is admitted only through B and reaches K before the terminal Real seal E is visible.

Finally H, C, P, N transport, replay, source, and name the same finite theorem packet. Since no excluded quotient, selected-limit, choice, trichotomy, host-equality, compactness, or ambient-completeness coordinate occurs in the carrier, the local NameCert surface has no other obligation row. □

Theorem 6422.3 (Bishop completion approximation density factorization)**.** *Every completion-facing dense approximation read of $T = (A, B, M, W, R, K, E, H, C, P, N)$ factors through A, then B, then the finite schedule and readback rows M, W, R, before it reaches the* $\mathsf{BishopCompletionTheorem}^{\uparrow}$ *handoff K and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The factorization exports no quotient stream, selected representative, countable-choice selector, trichotomy row, open-cover compactness witness, or ambient completeness proof.*

Proof. Begin with a completion-facing approximation request. The approximation service row A supplies only the finite Bishop Cauchy approximation route, so the request has not yet obtained a completion object or Real value.

Apply the criterion row B. It authorizes the same displayed route to enter the completion boundary only after the modulus schedule M, finite stream window W, and regular rational readback R are present.

The completion theorem handoff K is therefore downstream of A, B, M, W, R. The Real seal E is downstream of K, and H, C, P, N replay and name exactly that route. The missing quotient, selector, choice, trichotomy, compactness, and ambient-completeness rows cannot be recovered from the factorization. □

Theorem 6422.4 (Bishop completion approximation Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by a* $\mathsf{BishopCompletionApproximationTheorem}^{\uparrow}$ *packet is sealed through E after the approximation-service row, completion criterion, modulus schedule, finite stream window, regular rational readback, and completion theorem handoff have all been displayed. A Real-facing consumer receives only that sealed route with H, C, P, N support, not host real equality, quotient completion equality, countable choice, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier rows in the order fixed by Definition 6422.1. The rows A, B, M, W, R, K are all displayed before E can be consumed.

The support rows then keep the Real-facing export on the same route: H transports componentwise, C replays the displayed continuation, P records only the cited sibling packets, and N names the local certificate.

Since the seal row is reached only through those displayed rows, the consumer cannot replace it by host real equality, quotient completion equality, countable choice, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionApproximationTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionApproximationTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6422.1, Definition 6422.2, Definition 6422.3, and Definition 6422.4 seed the finite Bishop completion approximation theorem route from approximation service through criterion, modulus, stream window, regular readback, completion handoff, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionApproximationTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host real equality, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, approximation-service exactness, completion-criterion compatibility, density factorization, Real-seal nonescape, transport replay, provenance, and local NameCert rows for BEDC.Derived.BishopCompletionApproximationTheoremUp.

Constructive story: A $\mathsf{BishopCompletionApproximationTheorem}^{\uparrow}$ packet is generated from a BishopCauchyApproximation service row, BishopCompletionCriterion admissibility row, CauchyConvergenceModulus schedule, finite StreamName window, RegSeqRat readback, BishopCompletionTheorem handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6423

A Concrete Naming Certificate for $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers and Troelstra–van Dalen on located cuts, the $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ packet records the finite comparison surface between located lower/upper Dedekind data and the regular-Cauchy real-name route. It sits beside the dyadic tolerance ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a traditional representation comparison as finite BEDC data; it is not a quotient of cuts, a host-real equality test, countable choice, trichotomy for arbitrary rationals, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6423.1 (Located Dedekind real comparison carrier)**.** *A* $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the located lower/upper Dedekind row, carrying lower membership windows, upper membership windows, inhabited-side evidence, rounded-side evidence, and the finite locatedness comparison requested by the consumer.*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-window ledger used to compare the displayed lower and upper cuts at the requested dyadic precision.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row exposing only the cut observations and dyadic windows inspected by D and Q.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same located cut data, finite observations, and dyadic tolerance windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located cut row, dyadic tolerance ledger, finite observations, and regular readback have been displayed.*
6. *H records componentwise* hsame *transport for the located cut row, dyadic ledger, stream observations, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each located comparison request through D, Q, W to R and then to E.*

8. *P is the* Pkg *provenance over* $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDedekindRealComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, Q, W, R, E, H, C, P, N$. It has no coordinate for quotient cut equality, selected representatives, host real comparison, countable choice, arbitrary-rational trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6423.2 (Located Dedekind real comparison NameCert obligations)**.** *For every accepted* $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ *carrier $L = (D, Q, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedDedekindRealCompar}}$ *surface consists exactly of located lower/upper cut admission through D; dyadic tolerance-window accounting through Q; finite observation exposure through W; regular-Cauchy readback through R; terminal Real sealing through E; and componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 6423.1. The tuple displays the located cut data, dyadic tolerance windows, finite stream observations, regular readback, Real seal, and structural rows.

The located comparison is finite. The row D provides the lower and upper cut windows actually inspected, while Q fixes the dyadic tolerance window and W records the finite observations available to the request.

The row R repacks those same displayed observations as regular rational data, and the seal row E is downstream from that readback. Transport through H and replay through C preserve the same route, while P, N only source and name it. □

Theorem 6423.3 (Located Dedekind real comparison regular-Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ *carrier must read the located cut row D, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger Q, and the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row W before consuming the regular readback row R. Thus the comparison from located Dedekind data to regular-Cauchy data is a displayed finite handoff, not a quotient of cuts, selected representative, host comparison, countable-choice schedule, or ambient completeness principle.*

Proof. Begin with an accepted carrier and project the rows D, Q, W, R. The only regular-Cauchy coordinate is R, and the carrier places it after the located cut data, dyadic tolerance ledger, and finite observation row.

Apply Definition 6423.2. The obligation surface requires the readback through R to use the same rows D, Q, W that admitted the located comparison.

The structural rows H, C, P, N do not introduce a second route. They transport, replay, source, and name the same handoff, so a regular-Cauchy or Completion consumer cannot bypass the displayed finite comparison. □

Theorem 6423.4 (Located Dedekind real comparison Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ *carrier reaches the terminal seal E only through the route*

$$D \longmapsto Q \longmapsto W \longmapsto R \longmapsto E.$$

The exported surface contains no quotient cut equality, selected host real, host comparison procedure, countable-choice search, trichotomy split for arbitrary rationals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Inspect the carrier tuple. The terminal Real row is E, and it appears only after the located cut row, dyadic tolerance ledger, finite observation row, and regular readback row.

Use Definition 6423.3. Any Real-facing consumer first receives the regular-Cauchy handoff from the displayed finite located comparison route.

Finally apply the nonescape part of Definition 6423.2. Since the excluded objects have no carrier coordinate and no replay route in C, the terminal Real seal cannot export them. □

Falsifiable prediction: An accepted $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading located lower/upper Dedekind data, dyadic tolerance windows, finite stream observations, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ is not bijective to any listed sibling because it binds located lower/upper cut observations, dyadic tolerance windows, finite observation exposure, regular-Cauchy readback, and Real sealing into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDedekindRealComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedDedekindRealComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6423.1, Definition 6423.2, Definition 6423.3, and Definition 6423.4 seed the finite comparison route from located lower/upper Dedekind rows to regular-Cauchy readback and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedDedekindRealComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient cut equality, selected host reals, host comparison procedures, countable choice, arbitrary-rational trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located cut admission, dyadic tolerance accounting, finite observation exposure, regular readback, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.LocatedDedekindRealComparisonUp.

Constructive story: A $\mathsf{LocatedDedekindRealComparison}^{\uparrow}$ packet is generated from located lower and upper Dedekind rows, dyadic tolerance windows, finite StreamName observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6424

A Concrete Naming Certificate for $\mathsf{CauchyTailMirror}^{\uparrow}$

Following Bishop and Bridges on tail-equivalent Cauchy sequences, the $\mathsf{CauchyTailMirror}^{\uparrow}$ packet records the finite mirror by which two displayed Cauchy tails are read through the same tolerance ledger before any $\mathsf{Real}^{\uparrow}$ consumer identifies their terminal seals. It sits on the L10 route supplied by the stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance carrier of chapter 291, the terminal real-name seal of chapter 38, and the common-tail completion surface of chapter 1639. The packet names a finite cofinal-tail comparison; it does not assert quotient stream equality, host real equality, selected representatives, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6424.1 (Cauchy tail mirror carrier)**.** *A* $\mathsf{CauchyTailMirror}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W_0, W_1, R_0, R_1, D, E_0, E_1, H, C, P, N)$$

with the following displayed rows:

1. W_0 *and* W_1 *are two* $\mathsf{StreamName}^{\uparrow}$ *tail-window rows, recording the finite observations, tail indices, and point cells opened from the two stream names.*
2. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, containing the dyadic precision request, comparison budget, and cofinal tail bound used by both readbacks.*
4. E_0 *and* E_1 *are the two downstream* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after the shared* D *row and the displayed readbacks have been consumed.*
5. H *records componentwise* hsame *transport for the two windows, the two regular readbacks, the shared tolerance ledger, the two Real seals, replay rows, provenance rows, and local naming rows.*
6. C *records displayed* Cont *replay from a tail comparison request through* $W_0, W_1, R_0, R_1, D, E_0, E_1, H, P, N$.
7. P *is the* Pkg *provenance over* $\mathsf{CauchyTailMirror}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailMirror}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $W_0, W_1, R_0, R_1, D, E_0, E_1, H, C, P, N$. *It has no coordinate for quotient stream equality, host real equality, a selected limit, countable choice, hidden cofinal subsequences, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6424.2 (Cauchy tail mirror NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailMirror}^{\uparrow}$ *carrier*

$$M = (W_0, W_1, R_0, R_1, D, E_0, E_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailMirror}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{StreamName}^{\uparrow}$ *tail windows, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the two* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No mirror obligation is stored outside those finite rows.*

Proof. Project the accepted carrier of Definition 6424.1. The visible analytic rows are $W_0, W_1, R_0, R_1, D, E_0, E_1$, and the structural rows are H, C, P, N.

Read the tail windows first. The two $\mathsf{StreamName}^{\uparrow}$ rows fix the finite windows in which the two Cauchy tails are inspected, and the two $\mathsf{RegSeqRat}^{\uparrow}$ rows attach regular rational readbacks to exactly those windows.

The shared dyadic ledger then binds the mirror. Since both readbacks consume the same D row, the comparison has one displayed tolerance budget rather than two unrelated tail witnesses.

Finally the seal, transport, replay, provenance, and local naming rows package the same route. The carrier has no excluded coordinate, so no quotient, host-equality, selected-limit, choice, hidden-subsequence, or ambient-completeness obligation can appear outside the displayed packet. □

Theorem 6424.3 (Cauchy tail mirror shared tolerance handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{CauchyTailMirror}^{\uparrow}$ *packet must read the finite route*

$$W_0, W_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto E_0, E_1$$

together with H, C, P, N *before comparing the terminal seals. Thus the mirror identifies cofinal Cauchy tails only through two displayed StreamName windows, two regular rational readbacks, and one shared dyadic tolerance ledger.*

Proof. Begin with a Real-facing tail comparison. Carrier admission exposes W_0 and W_1 before any regular readback or seal row can be consumed.

Attach the regular readbacks. The rows R_0 and R_1 are tied to those displayed windows, so the comparison cannot switch to an unrecorded stream representative.

Use the shared tolerance ledger D. It is the only dyadic precision row in the packet, and both readbacks must pass through it before either Real seal E_0 or E_1 is available.

The rows H, C, P, N transport, replay, source, and name the same finite order. Hence the consumer receives a finite mirror route, not quotient stream equality, host real equality, selected limits, countable choice, hidden cofinal subsequences, or ambient Real completeness. □

Theorem 6424.4 (Cauchy tail mirror componentwise determinacy)**.** *Let* M *and* M' *be accepted* $\mathsf{CauchyTailMirror}^{\uparrow}$ *packets whose two* $\mathsf{StreamName}^{\uparrow}$ *tail windows, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and structural rows agree componentwise through the displayed* hsame *transport. Then any comparison of their downstream* $\mathsf{Real}^{\uparrow}$ *seals is forced to use the same mirror route before either packet can expose a terminal Real-facing read.*

Proof. Project both carriers. Componentwise agreement on the two window rows fixes the finite observations available on each side, and agreement on the two readback rows fixes the regular rational data read from those observations.

Compare the shared dyadic ledger next. Since the ledger row is common inside each packet and matched by the displayed transport, both packets present the same precision request, budget, and cofinal tail bound to any downstream consumer.

The Real seals are downstream of those rows. Transport and replay preserve only the displayed route, while provenance and local naming add no independent comparison coordinate. Therefore the terminal reads are forced through the same mirror route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailMirror}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailMirror}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6424.1, Definition 6424.2, Definition 6424.3, and Definition 6424.4 seed the finite cofinal-tail mirror route from two StreamName windows through two RegSeqRat readbacks, one DyadicRatCore tolerance ledger, two RealUp seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailMirror}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected representatives, countable choice, hidden cofinal subsequences, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared tolerance exactness, tail-window readback compatibility, Real-seal handoff, componentwise determinacy, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailMirrorUp.

Constructive story: A $\mathsf{CauchyTailMirror}^{\uparrow}$ packet is generated from two StreamName tail windows, two RegSeqRat readbacks, one shared DyadicRatCore tolerance ledger, two RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6425

A Concrete Naming Certificate for $\mathsf{LocatedCompactImage}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCompactImage}^{\uparrow}$ packet records the finite-net image route for a uniformly continuous map whose source is a located compact metric packet. It sits over the compact metric source of chapter 129, the continuous-map surface of chapter 130, the metric rows of chapter 57, the finite-net coverage row of chapter 127, and the terminal real-name boundary of chapter 38. The packet names the displayed image as a finite BEDC carrier; it does not assert open-cover compactness, countable choice, host image equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6425.1 (Located compact image carrier)**.** *A* $\mathsf{LocatedCompactImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, X, Y, F, U, T, R, H, C, P, N)$$

with the following rows:

1. *K is the source* $\mathsf{CompactMetric}^{\uparrow}$ *row, read only through displayed compact-metric and located finite-net data.*
2. *X is the source* $\mathsf{Met}^{\uparrow}$ *row whose distance classifier supplies the finite-net coverage checks.*
3. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row in which image radii and target distances are inspected.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the displayed map from the source packet into the target packet.*
5. *U is the uniform-continuity or finite-modulus row attached to F on the displayed compact source.*
6. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net image ledger obtained by transporting the displayed source net through F and U.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint-radius row used only for displayed target-distance and radius readback.*
8. *H records componentwise* hsame *transport for the compact source, metric rows, map row, modulus row, finite-net image ledger, Real radius row, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from source-net coverage through the continuous-map row, target metric row, radius ledger, and image finite-net handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactImage}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactImage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, X, Y, F, U, T, R, H, C, P, N$. It has no coordinate for a selected image set in the host category, open-cover compactness, countable-choice enumeration, quotient point equality, host image equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6425.2 (Located compact image NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactImage}^{\uparrow}$ *carrier $I = (K, X, Y, F, U, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactImage}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, source and target metric rows, continuous-map row, modulus row, finite-net image ledger, Real radius row, transport, replay, provenance, and local naming; source-net coverage through K, X; map-value routing through F; modulus-accountable target-radius transport through U, Y, R; finite image-net handoff through T; and non-escape through H, C, P, N.*

Proof. Project the carrier of Definition 6425.1. The compact metric source K and source metric row X supply only displayed finite-net coverage data.

The map row F and modulus row U transport the displayed source net into the target metric row Y. Target radii are read through R, so the image ledger is assembled from finite metric and real-name rows rather than from a host image object.

The finite image-net row T is therefore downstream from K, X, Y, F, U, R. Finally H, C, P, N transport, replay, source, and name the same packet, so the listed obligations exhaust the certificate surface and no external compactness or choice datum is exported. □

Theorem 6425.3 (Located compact image finite-net handoff)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedCompactImage}^{\uparrow}$ *packet receives an image finite-net ledger only through the displayed route*

$$K, X, Y, F, U, T, R, H, C, P, N.$$

The handoff transports the finite source net along the continuous-map and modulus rows, reads target distances and radii through Y and R, and then exposes the finite image-net row T. It does not claim open-cover compactness, countable choice, host image equality, quotient point equality, selected image representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source-net coverage rows K and X. They provide the finite source centers and coverage radii that can be inspected by a BEDC consumer.

Next read the continuous-map row F together with the modulus row U. These rows transport each displayed source center and the associated radius request into the target metric row Y, with endpoint-radius readback through R.

The row T then records exactly the transported target centers and radii as the image finite-net ledger. Structural rows H, C, P, N keep the handoff componentwise, replayable, sourced, and locally named. Since the carrier has no host image coordinate, external subcover selector, quotient equality, countable-choice schedule, or completeness row, the consumer receives only the finite-net handoff stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactImage}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedCompactImage}^{\uparrow}$ packet is generated from a compact metric source, source and target metric rows, a continuous-map row, a uniform-modulus row, a totally bounded image ledger, Real radius readback, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6425.1, Definition 6425.2, and Definition 6425.3 seed the finite-net image route for uniformly continuous maps on located compact metric packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, open-cover compactness, countable choice, host image equality, quotient point equality, selected image representatives, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-net coverage, map-value routing, modulus-accountable target-radius transport, finite image-net handoff, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompactImageUp.

Chapter 6426

A Concrete Naming Certificate for $\mathsf{LocatedImageModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedImageModulus}^{\uparrow}$ packet isolates the finite locator-and-modulus witness used when a continuous image is read as located data in the L10 Real and Completion layer. It sits between the located compact image route of chapter 6425, the continuous-image compactness route of chapter 3604, the continuous-map graph surface of chapter 130, the compact metric source of chapter 129, and the terminal real-name seal of chapter 38. The packet records how a displayed source locator and a displayed uniform modulus feed a finite target interval-cell ledger before any downstream image-location consumer sees a located-image boundary.

Definition 6426.1 (Located image modulus carrier)**.** *A* $\mathsf{LocatedImageModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, F, U, T, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the source locator row, read through the compact metric and located-source surfaces that answer finite distance-to-source requests before an image-location query is admitted.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, exposing the displayed graph reads and pointwise continuity faces used to move a located source window into the target.*
3. *U is the uniform-modulus row for F on the displayed compact metric source, converting each target tolerance request into a source locator radius.*
4. *T is the target interval-cell ledger, recording the finite target cells, target radii, and containment checks produced from the source locator and the modulus row.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records which finite source and target observations are inspected by an image-location consumer.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carrying the rational approximants and tolerance comparisons for the source locator, target cells, and modulus response.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal that compares the target-cell readback with the displayed located-image boundary.*

8. *H records componentwise* hsame *transport for the source locator, continuous-map row, modulus row, target interval-cell ledger, StreamName window, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a located-image request through $L, F, U, T, S, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedImageModulus}^{\uparrow}$, $\mathsf{LocatedCompactImage}^{\uparrow}$, $\mathsf{ContinuousImageCompact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedImageModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $L, F, U, T, S, R, E, H, C, P, N$. It has no coordinate for a host image set, selected preimage, quotient equality of target names, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6426.2 (Located image modulus NameCert obligations)**.** *For every accepted* $\mathsf{LocatedImageModulus}^{\uparrow}$ *carrier $M = (L, F, U, T, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedImageModulus}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the source locator, continuous-map row, uniform modulus, target interval-cell ledger, StreamName window, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows;*
2. *source-locator exposure, requiring every source-side locatedness read used by the image route to pass through L before the map row is inspected;*
3. *modulus-accountable image routing, requiring each target tolerance request to pass through U for the displayed continuous-map row F before any target cell is exposed;*
4. *finite target-cell handoff, requiring the target interval-cell ledger T to be assembled from the source locator, the modulus response, the finite StreamName window, and the RegSeqRat readback before the Real seal E is read;*
5. *non-escape, stating that host image sets, selected preimages, quotient equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness are not carrier coordinates and cannot discharge local obligations.*

Proof. Carrier admission is projection from Definition 6426.1. The rows $L, F, U, T, S, R, E, H, C, P, N$ are the complete visible packet.

The source-locator row is read first. A source-side distance or locatedness request supplies only the finite information displayed by L, so no source representative is selected before the map row is consumed.

Next the continuous-map and modulus rows route the image request. The row F supplies the displayed graph read, while U turns the target tolerance into the source radius that the locator row can answer.

The target-cell handoff is finite. Rows S and R record the inspected windows and rational comparisons, T records the corresponding target interval cells, and E is the only Real-facing seal available to the consumer.

The structural rows H, C, P, N transport, replay, source, and name this same route. Since the carrier contains no host image set, selected preimage, quotient equality, countable-choice schedule, or ambient completeness row, the obligations cannot export those objects. □

Theorem 6426.3 (Located image modulus finite-window handoff)**.** *Every image-location consumer of an accepted* $\mathsf{LocatedImageModulus}^{\uparrow}$ *packet reads through the displayed route*

$$L, F, U, T, S, R, E, H, C, P, N.$$

The consumer first receives the source locator, then the continuous-map row and uniform modulus, then the target interval-cell ledger through the finite $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and finally the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It receives no host image set, selected preimage, quotient equality of target names, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the accepted carrier of Definition 6426.1. Its source-facing data are the locator row L, the continuous-map row F, and the uniform-modulus row U.

Route a target tolerance through those rows. The modulus row converts the target request into a source locator radius, the locator row answers through displayed finite data, and the map row supplies only the target reads attached to that inspected source window.

The target handoff then passes through S, R, T, E. The StreamName row records the finite window, the RegSeqRat row records rational approximants and tolerances, the target interval-cell ledger records the cells produced by the route, and the Real seal compares the displayed readback with the image-location boundary.

Finally replay the transport and provenance rows H, C, P, N. They preserve the same finite route and have no coordinate for host image sets, selected preimages, quotient equality, choice, or ambient completeness. Thus every image-location consumer receives exactly the displayed locator/modulus/window handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedImageModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedImageModulus}^{\uparrow}$ packet is generated from a source locator, ContinuousMap row, uniform modulus, target interval-cell ledger, StreamName finite window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedImageModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6426.1, Definition 6426.2, and Definition 6426.3 seed the finite locator-and-modulus route for continuous-image location consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedImageModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host image sets, selected preimages, quotient equality of target names, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-locator exposure, modulus-accountable image routing, finite target-cell handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.LocatedImageModulusU

Chapter 6427

A Concrete Naming Certificate for $\mathsf{RationalIncompletenessWitness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalIncompletenessWitness}^{\uparrow}$ packet records the constructive finite evidence that $\mathsf{Rat}^{\uparrow}$ is not already completion-closed before the $\mathsf{Real}^{\uparrow}$ completion route is inspected. It sits after the dyadic arithmetic of chapter 291, the regular rational sequence interface of chapter 301, and the terminal real-name seal of chapter 38; it also reuses the irrationality obstruction style of chapter 1983. The nested dyadic contradiction route is a direct consumer of chapter 1983, and its completion-facing refusal later feeds the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ completion boundary through the displayed square-bound and tail-modulus rows. The packet names only a displayed nested-interval contradiction route, not a quotient real, not a selected limit, not countable choice, not host completeness of $\mathsf{Real}^{\uparrow}$, and not a classical theorem imported outside the BEDC carrier rows.

Definition 6427.1 (RationalIncompletenessWitness carrier)**.** *A* $\mathsf{RationalIncompletenessWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (I, M, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is a finite nested dyadic-interval ledger, recording left and right* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints, strict containment rows, and the finite square-bound comparisons attached to each inspected stage.*
2. *M is the Cauchy tail modulus row, exposing the displayed stage bound after which all rational candidates must remain inside the currently inspected dyadic interval.*
3. *S is the square-bound contradiction row, storing the finite parity, square comparison, and interval exclusion data used to reject a rational limit candidate for the nested route.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, naming the regular rational sequence surface whose finite windows are inspected by I, M, S.*
5. *R is the* $\mathsf{StreamName}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff row, carrying the terminal stream-name and real-name seal only after the dyadic nesting and rational-candidate contradiction rows have been displayed.*
6. *H records componentwise* hsame *transport for interval nesting, modulus, contradiction, regular rational readback, stream-name handoff, continuation, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a completion-facing request through M, then through the nested intervals I, the square-bound contradiction row S, the regular rational readback row Q, and finally the terminal handoff row R.*

8. *P is the* Pkg *provenance over* $\mathsf{RationalIncompletenessWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIncompletenessWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their componentwise transports, their displayed replay routes, their provenance, and their local names. It has no coordinate for quotient rational completion, selected irrational limits, host real equality, countable choice, or ambient completeness.

Theorem 6427.2 (RationalIncompletenessWitness NameCert obligations)**.** *For every accepted* $\mathsf{RationalIncompletenessWitness}^{\uparrow}$ *carrier $W = (I, M, S, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalIncompletenessWitness}^{\uparrow}}$ *surface consists exactly of carrier admission, nested dyadic-interval ledger exposure, Cauchy tail modulus exposure, square-bound contradiction visibility, regular rational readback, stream-name and* $\mathsf{Real}^{\uparrow}$ *handoff, transport, replay, provenance, and local naming. No obligation is stored outside those finite rows.*

Proof. Carrier admission is projection from Definition 6427.1. The accepted packet displays the nested dyadic interval ledger I, the tail modulus M, the contradiction row S, the regular rational readback Q, and the terminal handoff R before any structural row is used.

The mathematical obligations are row-local. The interval ledger supplies only dyadic endpoints and containment comparisons, the modulus row supplies only the finite late-tail bound, and the contradiction row supplies only the square-bound exclusion attached to those displayed intervals.

The handoff and structural rows do not add a second source. The rows Q and R are downstream of I, M, S, while H, C, P, N transport, replay, source, and name the same finite route. Hence the listed rows exhaust the local certificate and leave no coordinate for quotient completion, selected limits, host equality, countable choice, or ambient completeness. □

Theorem 6427.3 (RationalIncompletenessWitness dyadic nesting)**.** *Every completion-facing read of an accepted* $\mathsf{RationalIncompletenessWitness}^{\uparrow}$ *packet must first inspect a finite nested dyadic-interval route through I and M. The route displays dyadic endpoints from* $\mathsf{DyadicRatCore}^{\uparrow}$, *strict containment rows, the late-tail modulus budget, and the square-bound comparison windows before any* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *handoff is exposed.*

Proof. Project the packet $W = (I, M, S, Q, R, H, C, P, N)$. The only rows available before the regular rational and real-name handoff are the nested interval ledger I, the tail modulus M, and the square-bound contradiction row S.

The continuation row C fixes their order. A completion request first reads the displayed modulus budget, then the nested dyadic interval cells and their containment comparisons, and then the square-bound window attached to the same cells.

Only after this finite route is displayed can Q and R be inspected. Thus the completion-facing handoff cannot bypass dyadic endpoints, containment, and the late-tail budget by invoking a selected limit or host completeness. □

Theorem 6427.4 (RationalIncompletenessWitness no-rational-limit route)**.** *For every accepted* $\mathsf{RationalIncompletenessWitness}^{\uparrow}$ *carrier $W = (I, M, S, Q, R, H, C, P, N)$, any claim that the displayed nested route has a rational limit is routed back to the finite square-bound contradiction row*

S after the dyadic nesting and Cauchy tail modulus rows have been exposed. The rejection is therefore a BEDC finite-history refusal: it does not assert quotient $\mathsf{Real}^{\uparrow}$ *equality, choose an irrational representative, use countable choice, or assume* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a rational-limit candidate read. The carrier forces the read through M and I, so the candidate is compared only after the finite tail budget and the inspected dyadic interval window are visible.

The contradiction row S then supplies the square-bound exclusion for that same window. Since S is part of the packet rather than an external theorem coordinate, the refusal is tied to the displayed dyadic comparisons and not to host real equality.

Finally use the downstream rows. The regular sequence readback Q, handoff row R, transport H, replay C, provenance P, and local name N preserve the same finite route. None of these rows can introduce quotient completion, a selected limit, countable choice, or ambient completeness, so every rational-limit claim is refused inside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIncompletenessWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalIncompletenessWitness}^{\uparrow}$ packet is generated from nested dyadic interval rows, a Cauchy tail modulus row, square-bound contradiction data, regular rational readback, stream-name and RealUp handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIncompletenessWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6427.1, Definition 6427.2, Definition 6427.3, and Definition 6427.4 seed the finite no-rational-limit route that precedes completion-facing RealUp reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIncompletenessWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, a selected irrational limit, countable choice, host rational incompleteness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic nesting exactness, Cauchy tail modulus exposure, square-bound contradiction routing, regular rational readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.RationalIncompletenessWitnessUp.

Chapter 6428

A Concrete Naming Certificate for $\mathsf{BaireMetricCompactWindow}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BaireMetricCompactWindow}^{\uparrow}$ packet records finite prefix-cylinder windows for compact-uniform-continuity consumers over the Baire metric. It reads the prefix carrier of chapter 334, the metric radius route of chapter 1602, compact inspection rows from chapter 129, stream schedules from chapter 126, and dyadic tolerances from chapter 291. The packet is a finite compact-window basis; it is not completed-stream equality, not quotient Baire-name equality, not open-cover compactness, not countable choice, and not a host real-valued metric.

Definition 6428.1 (BaireMetric compact-window carrier)**.** *A* $\mathsf{BaireMetricCompactWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, M, K_0, S, D, W, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-cylinder row, recording the inspected finite prefix family and cylinder-membership ledger.*
2. *M is the* $\mathsf{BaireMetric}^{\uparrow}$ *metric row, carrying first-disagreement data and dyadic radius exactness for the same prefix window.*
3. *K_0 is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact-window source row, exposing only the finite compact inspection data available to downstream uniform-continuity consumers.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, naming the finite prefix windows read from B and M.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, recording the displayed dyadic tolerance and comparison budget.*
6. *W is the compact-window consumer row, requiring every compact-uniform-continuity read to inspect B, M, K_0, S, D before a modulus row is reached.*
7. *H records componentwise* hsame *transport for prefix cylinders, Baire metric radii, compact-window source data, stream schedules, dyadic tolerances, consumer windows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a compact-window request through K_0, then through S, B, M, D, and finally into the consumer row W.*

9. *P is the* Pkg *provenance over* $\mathsf{BaireMetricCompactWindow}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireMetricCompactWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows, their transports, their displayed replay routes, their provenance, and their local names. It has no coordinate for completed streams, quotient Baire names, open-cover compactness, countable-choice selectors, or host real metrics.

Theorem 6428.2 (BaireMetric compact-window NameCert obligations)**.** *For every accepted* BaireMetricCompactW *carrier $K = (B, M, K_0, S, D, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireMetricCompactWindow}^{\uparrow}}$ *surface consists exactly of prefix-cylinder admission, BaireMetric radius admission, compact-window source exposure, stream schedule exposure, dyadic tolerance exactness, compact-window consumer ordering, transport, replay, provenance, and local naming. No obligation is stored outside those rows.*

Proof. Carrier projection exposes $B, M, K_0, S, D, W, H, C, P, N$. These are the only coordinates available to a compact-window read.

The prefix and metric obligations are tied together. The schedule S selects a finite prefix window, B supplies the corresponding cylinder ledger, M supplies first-disagreement and radius data, and D records the dyadic tolerance used by the same read.

The compact source and consumer rows then fix the downstream route. The row K_0 exposes only finite compact inspection data, and W can consume it only after the prefix and dyadic rows have been displayed.

Transport, replay, provenance, and naming preserve that route. Since the carrier has no completed-stream, quotient, open-cover, countable-choice, or host-metric coordinate, the listed obligations exhaust the local certificate. □

Theorem 6428.3 (BaireMetric compact-window cylinder route)**.** *Every compact-window consumer of an accepted* $\mathsf{BaireMetricCompactWindow}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{BaireSpace}^{\uparrow} \longrightarrow \mathsf{BaireMetric}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{CompactMetric}^{\uparrow}.$$

The consumer reads a scheduled prefix cylinder, the corresponding first-disagreement radius, the displayed dyadic tolerance, and the compact-window source row before any uniform-continuity modulus is inspected.

Proof. Start with the consumer row W. By the carrier definition, W is downstream of the compact source K_0 and the prefix-metric rows S, B, M, D.

Replay the route through C. The schedule S opens the finite prefix window, B records the cylinder ledger, M reads the first-disagreement metric row, and D supplies the dyadic radius budget attached to that same window.

Only after this route is visible can K_0 be consumed as compact-window data. The structural rows H, P, N keep the same route under transport and provenance, so no compact-window consumer can use completed-stream equality, quotient Baire names, open-cover compactness, countable choice, or a host real metric. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireMetricCompactWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireMetricCompactWindow}^{\uparrow}$ packet is generated from finite BaireSpace prefix cylinders, BaireMetric first-disagreement radii, compact-window source rows, StreamName schedules, DyadicRatCore tolerances, compact-window consumer rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BaireMetricCompactWindow}\uparrow}$, seed)

Scope closed: Definition 6428.1, Definition 6428.2, and Definition 6428.3 seed the finite prefix-cylinder basis consumed by compact-window uniform-continuity reads.

Formal verification: FormalStatus(NameCert$_{\text{BaireMetricCompactWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed-stream equality, quotient Baire-name equality, open-cover compactness, countable choice, host real metrics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked prefix-cylinder admission, BaireMetric radius exactness, compact-window source exposure, StreamName schedule exposure, DyadicRatCore tolerance exactness, consumer ordering, transport, replay, provenance, and local naming for BEDC.Derived.BaireMetricCompactWindowUp.

Chapter 6429

A Concrete Naming Certificate for $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$

Brouwer's invariance of domain and its constructive topological descendants treat an injective Euclidean map as carrying local open information, but the $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$ packet records only the finite NameCert rows visible before such a handoff reaches a Real or topology consumer. It sits beside the circle boundary carrier of chapter 58, the deformation rows of chapter 156, and the L10 Real finite-name route through chapter 126, chapter 291, chapter 301, and chapter 38. The packet names finite local chart, boundary, embedding, and Real-seal rows; it does not claim classical full open-cover compactness, host topological equality, selected inverse images, quotient embeddings, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6429.1 (Brouwer invariance-domain carrier)**.** *A* $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (U, E, S, Hm, W, D, R, A, T, C, P, N)$$

with the following displayed rows:

1. *U is the local Euclidean-domain chart row, read as a finite neighborhood and coordinate-window surface rather than as a host open subset.*
2. *E is the displayed embedding row, carrying the injective graph and local-image request consumed by downstream topology readers.*
3. *S is the* $\mathsf{S}^{1\uparrow}$ *boundary row used when the local chart is probed through a finite circle or sphere boundary.*
4. *Hm is the* $\mathsf{Homotopy}^{\uparrow}$ *deformation row connecting boundary probes, local chart windows, and embedding data without passing to a quotient homotopy class.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule attached to the Real-coordinate reads.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for coordinate and radius comparisons.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the Real-coordinate windows.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have been displayed.*
9. *T records componentwise* hsame *transport for the local chart, embedding, boundary, homotopy, window, tolerance, readback, and seal rows.*
10. *C records displayed* Cont *replay from a local embedding request through the same finite route.*

11. *P is the* Pkg *provenance over* $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerInvarianceDomain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve displayed rows. It has no coordinate for host topological equality, global openness, open-cover compactness, selected inverse branches, quotient embeddings, countable choice, or ambient Real completeness.

Theorem 6429.2 (Brouwer invariance-domain NameCert obligations)**.** *For every accepted* BrouwerInvarianceDoma *carrier $I = (U, E, S, Hm, W, D, R, A, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BrouwerInvarianceDomain}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed local chart, embedding graph, circle-boundary row, homotopy row, finite StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat readback, terminal Real seal, componentwise transport, continuation replay, package provenance, and local naming. Every consumer that reads an invariance-domain handoff must first see the finite route*

$$\mathsf{S}^{1\uparrow},\ \mathsf{Homotopy}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

No obligation is stored as a host open set, a selected inverse image, a quotient embedding, a countable-choice schedule, or an ambient completeness theorem.

Proof. Project the carrier of Definition 6429.1. The projection exposes exactly the local chart row, embedding row, boundary row, homotopy row, analytic finite-name rows, and structural rows.

The boundary and deformation rows are read through the existing sibling packets. The row S supplies only the finite $\mathsf{S}^{1\uparrow}$ boundary surface of chapter 58, while Hm supplies only the displayed deformation ledger of chapter 156.

The Real-coordinate part is downstream. The rows W, D, R, A force every coordinate or radius read through the L10 Real finite-name route before a Real-facing conclusion is sealed.

Finally, T, C, P, N transport, replay, source, and name that same route. Since the carrier contains no host topology, selected inverse, quotient embedding, choice schedule, open-cover compactness, or ambient completeness row, the listed obligations exhaust the certificate surface. □

Theorem 6429.3 (Brouwer invariance-domain Euclidean open-embedding handoff)**.** *Every topology, manifold, Real, or Completion consumer of an accepted* $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$ *carrier must read the Euclidean open-embedding request as a finite packet:*

$$U, E, S, Hm, W, D, R, A \longmapsto T, C, P, N.$$

The handoff preserves the displayed local chart and embedding graph, reads boundary control through chapter 58, reads deformation control through chapter 156, and reads coordinate precision through the L10 Real finite-name route. It does not assert classical full open-cover compactness, host topological equality, selected inverse branches, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 6429.2. They require a consumer to inspect the displayed chart, embedding, boundary, homotopy, finite-name, transport, replay, provenance, and naming rows before using the packet.

The Euclidean chart and embedding rows remain finite carrier data. They record the local window and graph request, not a host open subset or a completed topological equality.

Boundary and deformation information is then routed through $\mathsf{S}^{1\uparrow}$ and $\mathsf{Homotopy}^{\uparrow}$. These sibling chapters supply the visible circle and homotopy rows used by local topological arguments while refusing quotient-circle, host path-space, and selected deformation objects.

The coordinate handoff closes through W, D, R, A. Thus the consumer reaches $\mathsf{Real}^{\uparrow}$ only after StreamName windows, DyadicRatCore tolerance rows, and RegSeqRat readback have been displayed, leaving no route by which compactness, choice, quotient equality, or ambient completeness can enter. □

Falsifiable prediction: Every accepted $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$ open-embedding read displays one local chart row, one embedding row, one $\mathsf{S}^{1\uparrow}$ boundary row, one $\mathsf{Homotopy}^{\uparrow}$ deformation row, one $\mathsf{StreamName}^{\uparrow}$ schedule, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback, one terminal $\mathsf{Real}^{\uparrow}$ seal row, and the structural rows T, C, P, N.

Independence witness: s1, homotopy, streamname, dyadicratcore, regseqrat, real: $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries local chart data, embedding graph data, boundary rows, deformation rows, finite Real-coordinate schedules, tolerance ledgers, readback, terminal sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerInvarianceDomain}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerInvarianceDomain}^{\uparrow}$ packet is generated from a displayed local Euclidean chart, an embedding graph row, a circle-boundary row, a homotopy deformation row, finite StreamName coordinate windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerInvarianceDomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6429.1, Definition 6429.2, and Definition 6429.3 seed the finite invariance-domain handoff over local chart, embedding, boundary, homotopy, StreamName, DyadicRatCore, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerInvarianceDomain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical full open-cover compactness, host topological equality, selected inverse branches, quotient embeddings, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, local chart exposure, embedding graph routing, boundary and homotopy handoff, Real finite-name ordering, transport, replay, provenance, and local naming for BEDC.Derived.BrouwerInvarianceDomainUp.

Chapter 6430

A Concrete Naming Certificate for $\mathsf{HadamardGapSeries}^{\uparrow}$

Following Hadamard's lacunary power-series theorem and Bishop–Bridges constructive series practice, the $\mathsf{HadamardGapSeries}^{\uparrow}$ packet records a gap-series coefficient route as finite NameCert data before any analytic-continuation or boundary-singularity theorem is available. It sits beside the regular rational readback of chapter 301, the terminal real seal of chapter 38, the uniform tail route of chapter 1736, and the coefficientwise product neighbour chapter 3811. The packet names lacunary coefficient windows and their tail budget; it is not a host infinite sum, not a complex analytic function, not a natural-boundary theorem, and not an ambient completeness principle.

Definition 6430.1 (Hadamard gap series carrier)**.** *A* $\mathsf{HadamardGapSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, G, C, T, R, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the coefficient-window data: a finite list of inspected nonzero coefficient slots, their displayed rational or real-name coefficients, and the zero-window declarations between inspected slots.*
2. *G is the lacunary gap-growth ledger, recording the displayed increasing exponent schedule and the local growth comparisons used to certify the Hadamard gap condition on the inspected window.*
3. *C is the compact dyadic coefficient-bound row, containing the dyadic radius, coefficient bound, and compact-window estimate read through the available coefficient rows.*
4. *T is the uniform tail budget, naming a finite threshold and tail tolerance for partial sums after the gap and coefficient ledgers have been read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, repacking coefficient windows and partial-sum windows as regular rational readback data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after A, G, C, T, R have been replayed.*
7. *H records componentwise* hsame *transport for coefficient windows, gap-growth ledgers, dyadic bounds, tail budgets, readback rows, Real seals, replay, provenance, and local naming.*
8. *K records displayed* Cont *replay from a coefficient or tail request through $A, G, C, T, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{HadamardGapSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{HadamardGapSeries}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, G, C, T, R, E, H, K, P, N$. It has no coordinate for host analytic continuation, natural-boundary claims, completed power-series functions, quotient stream equality, selected infinite sums, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6430.2 (Hadamard gap series NameCert obligations)**.** *For every accepted* $\mathsf{HadamardGapSeries}^{\uparrow}$ *carrier*

$$S = (A, G, C, T, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HadamardGapSeries}^{\uparrow}}$ *surface consists exactly of carrier admission, lacunary growth exactness, coefficient-window stability, uniform Cauchy tail handoff, Real seal nonescape, componentwise transport, displayed replay, provenance, and local naming through $A, G, C, T, R, E, H, K, P, N$.*

Proof. Project the accepted carrier. The coefficient data A and the gap ledger G are the only rows that can name nonzero slots and lacunary spacing, while the dyadic bound C and tail budget T are the only rows that can bound a partial-sum request.

The readback and seal rows are downstream. Row R repacks the displayed coefficient and partial-sum windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, and row E exposes the terminal $\mathsf{Real}^{\uparrow}$ seal only after A, G, C, T, R have been replayed.

The structural rows H, K, P, N transport, replay, source, and name the same finite route. Since no excluded analytic or choice-like coordinate is present in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 6430.3 (Hadamard gap growth exactness)**.** *For an accepted* $\mathsf{HadamardGapSeries}^{\uparrow}$ *packet $S = (A, G, C, T, R, E, H, K, P, N)$, the lacunary growth condition is read exactly from G against the coefficient-window row A. A consumer may inspect the displayed exponent schedule, adjacent gap comparisons, and zero-window declarations, but it cannot replace them by a host sequence limit or an analytic continuation argument.*

Proof. Read the finite exponent schedule inside G. Each inspected comparison is tied to a coefficient slot or zero-window declaration in A, so the gap condition is a displayed ledger relation rather than a property of an unbounded host sequence.

Transport through H and replay through K preserve only those displayed rows. The provenance and naming rows record the same local packet, hence no analytic-continuation principle or host limit can be exported from the gap ledger. □

Theorem 6430.4 (Hadamard gap coefficient-window stability)**.** *Every transported coefficient-window read of an accepted* $\mathsf{HadamardGapSeries}^{\uparrow}$ *packet remains inside the displayed rows A, G, C, H, K, P, N. The transport preserves inspected coefficient slots, zero-window declarations, gap comparisons, and compact dyadic coefficient bounds, and it exports no quotient coefficient stream or selected representative.*

Proof. Project the coefficient-facing rows. The row A lists the inspected slots and zero-window declarations, G accounts for their lacunary spacing, and C supplies the dyadic coefficient bound used on the same window.

Componentwise transport can only compare these rows through H. The replay, provenance, and naming rows preserve the displayed coefficient window, so no quotient stream equality or selected representative is introduced. □

Theorem 6430.5 (Hadamard gap uniform tail handoff)**.** *Every uniform Cauchy tail read through an accepted* $\mathsf{HadamardGapSeries}^{\uparrow}$ *packet factors through*

$$A, G, C \longmapsto T \longmapsto R \longmapsto E.$$

Thus the handoff to the regular-Cauchy series route is a finite tail-budget and regular-readback route, not a selected infinite sum or an ambient completeness theorem.

Proof. Begin with the coefficient and gap data. The rows A, G, C supply the inspected coefficients, gap ledger, and dyadic coefficient bound before any tail estimate is available.

The uniform tail row T then names the finite threshold and tolerance budget. Row R repacks the resulting partial-sum window as $\mathsf{RegSeqRat}^{\uparrow}$ data, and row E is downstream of that readback.

Because H, K, P, N preserve the same displayed route, a consumer reaches the uniform Cauchy series surface without obtaining a selected infinite sum, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 6430.6 (Hadamard gap Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read through an accepted* $\mathsf{HadamardGapSeries}^{\uparrow}$ *packet is downstream of the coefficient-window data A, lacunary gap ledger G, compact dyadic coefficient-bound row C, uniform tail budget T, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R. The seal cannot export host analytic continuation, natural-boundary information, quotient stream equality, selected sums, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the terminal row E. It appears only after the coefficient, gap, bound, tail, and readback rows have been displayed.

Use the carrier definition to trace every Real-facing read through A, G, C, T, R and then through the structural rows H, K, P, N. None of those rows contains analytic-continuation data, a boundary-singularity theorem, quotient equality, a selector for an infinite sum, choice data, or Real completeness.

Therefore the seal is a finite BEDC endpoint for the gap-series route and cannot escape the displayed NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{HadamardGapSeries}^{\uparrow}$ endpoint read factors through coefficient-window data, lacunary gap-growth ledgers, compact dyadic coefficient bounds, uniform tail budgets, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise transport, displayed replay, provenance, and local NameCert rows.

Independence witness: regseqrat, real, uniform-cauchy-series, hadamard-product-series: RegSeqRatUp supplies regular rational readback without lacunary coefficient windows; RealUp supplies terminal seals without gap-growth ledgers; UniformCauchySeriesUp supplies shared tail budgets without the Hadamard exponent schedule; HadamardProductSeriesUp supplies coefficientwise products without lacunary zero-window declarations. None is bijective to $\mathsf{HadamardGapSeries}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardGapSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{HadamardGapSeries}^{\uparrow}$ packet is generated from coefficient-window data, a lacunary gap-growth ledger, compact dyadic coefficient bounds, a uniform tail budget, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HadamardGapSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6430.1, Definition 6430.2, Definition 6430.3, Definition 6430.4, Definition 6430.5, and Definition 6430.6 seed the finite lacunary coefficient route from gap windows to uniform tail budget, regular readback, and terminal real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HadamardGapSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host analytic continuation, natural-boundary theorems, completed power-series functions, quotient stream equality, selected infinite sums, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lacunary growth exactness, coefficient-window stability, compact dyadic coefficient bounds, uniform Cauchy tail handoff, RegSeqRat readback, RealUp seal routing, transport, replay, provenance, and local naming for BEDC.Derived.HadamardGapSeriesUp.

Chapter 6431

A Concrete Naming Certificate for $\mathsf{ConstructiveIVTModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ConstructiveIVTModulus}^{\uparrow}$ packet records the finite sign-change modulus surface behind a located intermediate-value bisection request. It sits after the located interval source of chapter 1709, the constructive intermediate-value packet of chapter 6410, the dyadic bisection tree of chapter 6415, the finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exports a finite modulus and retained-window handoff, not a selected root, host root-selection theorem, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6431.1 (Constructive IVT modulus carrier)**.** *A* $\mathsf{ConstructiveIVTModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, A, B, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval source row. It records endpoint names, a displayed interval orientation, locator reads, and the finite bracket over which the modulus request is made.*
2. *A is the opposite-sign witness row. It records the two endpoint sign certificates and the retained sign-change condition used by the bisection schedule.*
3. *B is the finite bisection schedule row. It records the requested depth, midpoint inspections, retained child intervals, and branch evidence.*
4. *D is the dyadic tolerance ledger. It records the tolerance request, diameter budget, midpoint denominator data, and finite contraction rows used by B.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the retained endpoint and midpoint reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same windows and tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, A, B, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval source, sign witnesses, bisection schedule, tolerance ledger, StreamName window, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a modulus request through $I, A, B, D, S, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveIVTModulus}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$, $\mathsf{DyadicBisectionTree}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveIVTModulus}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite sign-change modulus history. It has no coordinate for host root selection, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6431.2 (Constructive IVT modulus NameCert obligations)**.** *For every accepted* ConstructiveIVTModulus *carrier*

$$Q = (I, A, B, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveIVTModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval source I, opposite-sign witness row A, finite bisection schedule B, dyadic tolerance ledger D,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, provenance row P, and local naming row N.*

Proof. Project the carrier of Definition 6431.1. The accepted packet exposes the located interval source, sign witnesses, bisection schedule, tolerance ledger, finite windows, regular readback, terminal seal, and structural rows.

The analytic rows are I, A, B, D, S, R, E. The interval row fixes the displayed bracket, the sign row supplies the endpoint and retained sign-change certificates, and the bisection and tolerance rows bind each midpoint inspection to a finite diameter budget. The stream, regular-readback, and Real-seal rows are downstream of those displayed inspections.

The structural rows are H, C, P, N. They transport the same finite data, replay the same route, record provenance, and bind the local name. Since the carrier contains no further coordinate, every local NameCert obligation is one of the listed rows. □

Theorem 6431.3 (Constructive IVT modulus bisection-window handoff)**.** *Every accepted* ConstructiveIVTModulus *request that asks for a sign-change modulus must factor through the finite route*

$$I, A \longmapsto B, D \longmapsto S, R \longmapsto E, H, C, P, N.$$

Thus the retained bisection window is exposed only after the located interval source, opposite-sign witnesses, bisection schedule, and dyadic tolerance ledger have been read; the route cannot provide a host-selected root, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $Q = (I, A, B, D, S, R, E, H, C, P, N)$. The source stage is I, A: the located interval row fixes the bracket and the opposite-sign row records the endpoint and retained sign evidence.

The bisection stage is B, D. Each midpoint inspection and retained child interval is paired with a dyadic tolerance entry, so the request opens only the finite schedule specified by the carrier.

The window and readback stage is S, R. The $\mathsf{StreamName}^{\uparrow}$ windows are opened from the retained endpoint and midpoint reads, and the $\mathsf{RegSeqRat}^{\uparrow}$ row repacks exactly those windows against the same tolerance ledger.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Because no row carries a root selector, quotient equality, trichotomy split, choice schedule, open-cover compactness proof, or completeness principle, the displayed handoff is exhaustive. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveIVTModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveIVTModulus}^{\uparrow}$ packet is generated from a located interval source, opposite-sign witnesses, a finite bisection schedule, a dyadic tolerance ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveIVTModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6431.1, Definition 6431.2, and Definition 6431.3 seed the finite sign-change modulus route from located interval and sign rows through bisection, StreamName, RegSeqRat, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveIVTModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host root selection, quotient real equality, trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, sign-witness stability, bisection schedule exactness, tolerance-ledger discipline, finite-window exposure, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveIVTModulusUp.

Chapter 6432

A Concrete Naming Certificate for $\mathsf{LocatedSupremumModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedSupremumModulus}^{\uparrow}$ packet records the finite data by which a located bounded subset of a constructive real line exposes a supremum-search modulus. It sits beside the dyadic tolerance route of chapter 291, the regular rational readback of chapter 301, the real seal of chapter 38, the bounded-set carrier of chapter 1757, and the bracketing interval route of chapter 1807. The packet extracts located interval brackets and dyadic tolerances; it does not assert classical least-upper-bound completeness, trichotomy, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6432.1 (Located supremum modulus carrier)**.** *A* $\mathsf{LocatedSupremumModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, I, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedSet}^{\uparrow}$ *row, recording the bounded-set membership window, upper-bound ledger, and nonempty witness surface used by the supremum search.*
2. *I is the* $\mathsf{FiniteBracketingInterval}^{\uparrow}$ *row, storing located interval brackets $[l, u]$ and the side evidence that the set is below u while values can be found inside any admitted lower window near l.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing dyadic precision requests, refinement steps, and interval-width certificates.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating dyadic bracket refinements into regular rational observations before the real seal is consumed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after bounded-set, bracket, tolerance, and readback rows have been displayed.*
6. *H records componentwise* hsame *transport for bounded-set data, interval brackets, dyadic tolerances, regular-rational readbacks, the seal row, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a supremum-modulus request through B, I, D, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedSupremumModulus}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{FiniteBracketingInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSupremumModulus}^{\uparrow}}$ *row.*

The carrier exports only the displayed modulus route $B, I, D, R, E, H, C, P, N$. It has no coordinate for a classical supremum theorem, trichotomy, quotient equality of real names, countable choice, a selected maximizing sequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6432.2 (Located supremum modulus NameCert obligations)**.** *For every accepted* LocatedSupremumMod *carrier*

$$M = (B, I, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedSupremumModulus}^{\uparrow}}$ *surface consists exactly of bounded-set admission through B, located interval bracket exposure through I, dyadic tolerance exactness through D, regular rational readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6432.1. The analytic rows are exactly the bounded-set row, located-bracket row, dyadic tolerance row, regular rational readback row, and terminal Real seal row.

The bracket row is read through the bounded-set row. The upper side records displayed upper-bound evidence, while the lower side records the located search window rather than a choice-selected maximizing sequence.

The dyadic tolerance row supplies the modulus data. It refines bracket widths through $\mathsf{DyadicRatCore}^{\uparrow}$ entries and then exposes those refinements as $\mathsf{RegSeqRat}^{\uparrow}$ readbacks before the $\mathsf{Real}^{\uparrow}$ seal may be consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier row stores trichotomy, quotient equality, countable choice, classical least-upper-bound completeness, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Lean4 (statement) `BEDC.Derived.LocatedSupremumModulusUp`

Falsifiable prediction: A $\mathsf{LocatedSupremumModulus}^{\uparrow}$ consumer that exports a supremum-modulus read while omitting the bounded-set row, located interval bracket row, dyadic tolerance row, RegSeqRat readback row, Real seal row, hsame, Cont, Pkg, or NameCert row is not reading the carrier of Definition 6432.1.

Independence witness: boundedset, finite-bracketing-interval, dyadicratcore, regseqrat, real: $\mathsf{LocatedSupremumModulus}^{\uparrow}$ jointly binds bounded-set data, located interval brackets, dyadic tolerance refinement, regular rational readback, and the Real seal into one modulus packet. Each sibling lacks at least one of those rows as a local supremum-modulus coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSupremumModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedSupremumModulus}^{\uparrow}$ packet is generated from bounded-set rows, located finite interval brackets, dyadic tolerance rows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSupremumModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6432.1 and Definition 6432.2 seed the constructive located supremum-modulus packet over bounded-set, interval-bracket, dyadic tolerance, regular-rational readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSupremumModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim classical least-upper-bound completeness, trichotomy, quotient equality, countable choice, selected maximizing sequences, ambient Real completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bracket exactness, dyadic tolerance refinement, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedSupremumModulusUp.

Chapter 6433

A Concrete Naming Certificate for MetaCICTypedParallelDiamondBoundary$^{\uparrow}$

The MetaCICTypedParallelDiamondBoundary$^{\uparrow}$ packet realizes the typed-window boundary of chapter 9378 as finite confluence-facing NameCert data. It sits beside the residual-substitution boundary of chapter 2181, the critical-pair boundary of chapter 2212, the residual checker of chapter 3827, the local-join ledger of chapter 4126, and the existing parallel-diamond frontier of chapter 4238. The packet records typed windows, residual-substitution premises, critical pairs, local joins, checker rows, obstruction rows, transport, replay, provenance, and local naming without claiming subject reduction, full Church–Rosser, premise-free parallel diamond, evaluator equality, quotient term equality, or kernel consistency.

Definition 6433.1 (MetaCIC typed parallel-diamond boundary carrier)**.** *A* MetaCICTypedParallelDiamondBoundar *carrier is a finite* BHist *packet*

$$T = (W, S, K, J, R, C, N, B, O, H, Q, P, M)$$

with the following displayed rows:

1. *W is the typed-window row, recording context, closedness, binder-depth, and type-checker visibility for the local peak.*
2. *S is the residual-substitution premise row, naming the substitution-compatibility input retained by the confluence audit map.*
3. *K is the critical-pair row, exposing the two branch observations and the local peak boundary.*
4. *J is the local-join row, recording the candidate common reduct and the finite branch-local join evidence.*
5. *R is the residual-frontier row, listing residual descendants, residual budget, and branch-local substitution windows.*
6. *C is the closed-checker row, recording bounded checker acceptance before the typed handoff is consumed.*
7. *N is the closed-normal row, recording the already available normal-source and atom-source fragments.*
8. *B is the bounded-check row over typed-window visibility, residual budget, closed checker, and local-join compatibility.*

9. *O is the obstruction row, retaining the endpoints not supplied by the packet: residual-substitution discharge, subject reduction, full Church–Rosser, premise-free parallel diamond, evaluator equality, quotient term equality, and kernel consistency.*
10. *H records componentwise* hsame *transport for typed-window, premise, critical-pair, local-join, residual, checker, normal, bounded-check, obstruction, replay, provenance, and local naming rows.*
11. *Q records displayed* Cont *replay from a typed confluence query through $W, S, K, J, R, C, N, B, O, H, P, M$.*
12. *P is the* Pkg *provenance over* $\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}$*, the MetaCIC residual and critical-pair siblings,* BHist*,* hsame*,* Cont*, and* NameCert*.*
13. *M is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for subject reduction, full closed Church–Rosser, a premise-free parallel diamond, evaluator equality, quotient equality of terms, or kernel consistency.

Theorem 6433.2 (MetaCIC typed parallel-diamond boundary obligations)**.** *For every accepted* $\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}$ *carrier*

$$T = (W, S, K, J, R, C, N, B, O, H, Q, P, M),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}}$ *surface consists exactly of typed-window exposure through W, residual-substitution premise retention through S, critical-pair exposure through K, local-join exposure through J, residual-frontier exposure through R, closed-checker handoff through C, closed-normal fragment exposure through N, bounded-check exactness through B, obstruction retention through O, componentwise transport through H, displayed replay through Q, provenance through P, and local naming through M.*

Proof. Project the carrier of Definition 6433.1. The confluence-facing rows are $W, S, K, J, R, C, N, B, O$, and the structural rows are H, Q, P, M.

The typed window is first-class. It records the finite context and checker visibility under which the local peak is read, while S keeps the residual-substitution premise visible rather than discharged.

Rows K, J, R, C, N, B then expose the critical pair, candidate join, residual frontier, closed checker, closed-normal fragment, and bounded checks. The obstruction row O remains attached to the same packet.

Finally H, Q, P, M transport, replay, source, and name the displayed rows. Since the carrier has no row for subject reduction, full Church–Rosser, premise-free parallel diamond, evaluator equality, quotient term equality, or kernel consistency, the listed rows exhaust the local obligations. □

Lean4 (statement) `BEDC.Derived.MetaCICTypedParallelDiamondBoundaryUp`

Theorem 6433.3 (MetaCIC typed parallel-diamond boundary nonescape)**.** *Every typed confluence consumer of an accepted* $\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}$ *packet must keep $W, S, K, J, R, C, N, B, O, H$ visible before citing the packet as a local parallel-diamond boundary. The consumer may feed the conditional frontier of chapter 4238, but it may not cite the packet as subject reduction, full Church–Rosser, a premise-free parallel diamond, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Apply the obligation theorem Definition 6433.2. It keeps the typed window, residual-substitution premise, critical pair, local join, residual frontier, checker, normal fragment, bounded-check, and obstruction rows visible.

Use the existing frontier boundary of Definition 4238.16. That theorem permits a typed-window consumer to read a conditional handoff only while retaining the premise, residual, checker, bounded-check, and obstruction rows.

The transport, replay, provenance, and local naming rows preserve the same route for downstream audit consumers. They do not add a row that discharges residual substitution or converts the typed boundary into any stronger confluence theorem.

Therefore the packet can only be cited as a typed boundary feeding the conditional parallel-diamond frontier. A consumer that erases S or O, or reads the handoff as one of the refused endpoints, has left the carrier surface. □

Falsifiable prediction: A MetaCIC confluence read that cites $\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}$ while omitting the typed-window row, residual-substitution premise row, critical-pair row, local-join row, residual-frontier row, checker row, obstruction row, hsame, Cont, Pkg, or NameCert rows refutes the carrier of Definition 6433.1.

Independence witness: metacic-residual-substitution-boundary, metacic-confluence-critical-pair-boundary, metacic-confluence-residual-checker, metacic-local-join-ledger, metacic-parallel-diamond-frontier: these siblings respectively expose premise retention, peak data, residual checking, local joins, and a conditional frontier. None is bijective with the packet that jointly binds typed-window visibility, all four confluence rows, checker and normal rows, bounded checks, obstruction retention, transport, replay, provenance, and local naming.

The Lean TasteGate surface must include both Nontrivial and FieldFaithful instances for the finite carrier: nontriviality separates accepted typed-boundary packets from obstruction-only packets, and field faithfulness matches exactly the rows $W, S, K, J, R, C, N, B, O, H, Q, P, M$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}$ packet is generated from typed-window rows, residual-substitution premise rows, critical-pair rows, local-join rows, residual-frontier rows, checker rows, closed-normal rows, bounded-check rows, obstruction rows, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6433.1, Definition 6433.2, and Definition 6433.3 seed the typed parallel-diamond boundary packet for MetaCIC confluence audit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim residual-substitution compatibility, subject reduction, full Church–Rosser, premise-free parallel diamond, evaluator equality, quotient term equality, kernel consistency, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window exposure, residual-substitution premise retention, critical-pair exposure, local-join exactness, residual-frontier coverage, checker and closed-normal routing, bounded-check exactness, obstruction retention, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICTypedParallelDiamondBoundaryUp.

Chapter 6434

A Concrete Naming Certificate for $\mathsf{BishopLocatedFilterBase}^{\uparrow}$

Following Bishop and Bridges and Kelley, a located filter base is read here as finite boundary data for Real and Completion consumers: it exposes a rounded filter-base request, a Cauchy-filter-base tail budget, a located-real bracket, displayed stream windows, dyadic tolerances, regular rational readback, and a terminal real seal before any completed object is named. The $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ packet sits between the filter-base surface of chapter 1601, the Cauchy-filter-base surface of chapter 1915, the located-real filter surface of chapter 5897, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real boundary of chapter 38. It names a traditional finite filter-base route without quotient filters, selected limits, countable choice, host equality of filters, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6434.1 (Bishop located filter-base carrier)**.** *A* $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, L, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *row, carrying the rounded finite basis requests and inclusion evidence inspected by the consumer.*
2. *L is the* $\mathsf{CauchyFilterBase}^{\uparrow}$ *and located-real bracket row. It records the Cauchy tail budget, lower and upper located brackets, and the handoff discipline inherited from* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$*.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger, displaying the finite source windows read by the bracket and tail requests.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the positive dyadic scale, bracket radius, and split budget used by the located filter-base read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from W and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after F, L, W, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the filter base, Cauchy-base bracket, window, dyadic tolerance, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located filter-base request through $F, L, W, D, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedFilterBase}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilterBase}^{\uparrow}$, $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedFilterBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, L, W, D, R, E, H, C, P, N$. It has no coordinate for quotient filters, host powersets, selected subfilters, selected limits, countable-choice schedules, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.BishopLocatedFilterBaseUp.BishopLocatedFilterBaseUp`

Theorem 6434.2 (Bishop located filter-base NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ *carrier*

$$B = (F, L, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedFilterBase}^{\uparrow}}$ *surface consists exactly of FilterBase admission for F, CauchyFilterBase and located-real bracket admission for L, finite StreamName window coverage for W, dyadic tolerance visibility for D, RegSeqRat readback for R, Real seal routing for E, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No Bishop located filter-base obligation is stored outside these rows.

Proof. Project the carrier of Definition 6434.1. The accepted packet is exactly the tuple $F, L, W, D, R, E, H, C, P, N$ so every local naming obligation must be read from one of those rows.

The analytic route starts with the rounded filter-base row F and the Cauchy located-bracket row L. The finite window ledger W and dyadic tolerance ledger D expose the inspected source windows, bracket radius, and split budget before the regular rational readback R is visible.

The Real seal E is downstream of this displayed route. Transport, replay, provenance, and local naming through H, C, P, N preserve the same evidence and add no quotient filter, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate. □

Theorem 6434.3 (Bishop located filter-base Real handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FilterBase}^{\uparrow},\ \mathsf{CauchyFilterBase}^{\uparrow},\ \mathsf{BishopLocatedRealFilter}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Equivalently, the consumer first reads the rounded basis row F, then the Cauchy located-bracket row L, then the finite windows W, dyadic tolerance ledger D, and regular rational readback R, and only then reaches the terminal Real seal E with H, C, P, N preserving the same route.

Proof. Apply the obligation theorem. It orders carrier admission through the filter base and located Cauchy bracket before any finite window, tolerance, readback, or Real-facing seal is available.

The StreamName, DyadicRatCore, and RegSeqRat rows provide the finite observation route. Because the bracket and Cauchy tail budget are displayed in L, a consumer cannot replace this route by a quotient filter, selected subfilter, or selected limit.

Finally the Real seal is read only after F, L, W, D, R have been displayed and transported. The structural rows H, C, P, N replay, source, and name the same packet, so every Real or Completion handoff factors through the stated finite boundary. □

Theorem 6434.4 (Bishop located filter-base nonescape)**.** *An accepted* $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ *packet cannot export quotient filter equality, host powerset membership, a selected subfilter, a selected limit, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness to a Real or Completion consumer. Any such export would require a coordinate outside $F, L, W, D, R, E, H, C, P, N$ and therefore outside the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedFilterBase}^{\uparrow}}$ *surface.*

Proof. Read the carrier definition together with the NameCert obligations. The only public rows are the rounded filter base, located Cauchy bracket, finite windows, dyadic tolerance ledger, regular rational readback, terminal Real seal, transport, replay, provenance, and local name.

Each excluded object would need an additional coordinate: quotient filters require a quotient equality row, selected subfilters and selected limits require choice rows, host powersets and host equality require external host data, and ambient completeness requires a global Real principle. None of those coordinates occurs in $F, L, W, D, R, E, H, C, P, N$.

Thus every accepted packet remains inside the finite located filter-base boundary, and Real or Completion consumers can inspect only the displayed rows. □

Falsifiable prediction: A $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ consumer that reaches a Real or Completion output after deleting F, L, W, D, or R refutes the carrier of Definition 6434.1.

Independence witness: filterbase, cauchy-filter-base, bishop-located-real-filter, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rounded filter-base admission, located Cauchy bracket data, finite windows, dyadic tolerances, regular rational readback, a terminal Real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedFilterBase}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedFilterBase}^{\uparrow}$ packet is generated from a FilterBase row, a CauchyFilterBase located-bracket row, StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedFilterBase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6434.1, Definition 6434.2, Definition 6434.3, and Definition 6434.4 seed the finite located filter-base route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedFilterBase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filter equality, host powersets, selected subfilters, selected limits, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located filter-base exactness, finite-window coverage, dyadic tolerance visibility, RegSeqRat readback, Real seal routing, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.BishopLocatedFilterBaseUp.

Chapter 6435

A Concrete Naming Certificate for $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$ packet records the finite BEDC surface of the standard unit map from a metric source into its Cauchy completion, with distance preservation exposed before any quotient-completion equality or selected limit is available. It sits after the functorial completion route of chapter 423, the dense embedding boundary of chapter 3351, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet exports the unit-isometry witness needed by Real and Completion consumers, not a quotient construction of the completion.

Definition 6435.1 (Cauchy completion unit-isometry carrier)**.** *A* $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, R, D, U, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric row, including the displayed source points, metric-distance requests, and finite point-classifier observations consumed by the unit map.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the constant Cauchy names associated to the displayed source points.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested dyadic radius, the comparison budget, and the finite descent used to compare source distances with completion distances.*
4. *U is the unit-admission row supplied by the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *route, saying that each displayed source point is sent to its constant completion name before any completion consumer can read it.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by the distance comparison after the source metric row, regular rational readback, dyadic tolerance ledger, and unit-admission row have been exposed.*
6. *H records componentwise* hsame *transport for the source row, readback row, dyadic ledger, unit-admission row, Real seal, replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay from source distance requests through S, R, D, U, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, MetricCompletionDen StreamName$^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite unit-isometry history. It has no coordinate for quotient completion equality, selected representatives, host complete spaces, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6435.2 (Cauchy completion unit-isometry NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$ *carrier*

$$J = (S, R, D, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}}$ *surface consists exactly of carrier admission for the source metric row S, regular rational readback row R, dyadic tolerance ledger D, unit-admission row U, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, provenance row P, and local naming row N. The certificate is local to the constant-Cauchy-name unit route.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionUnitIsometryUp.CauchyCompletionUnitIsometryTasteGate`
`single carrier alignment`

Proof. Project the carrier of Definition 6435.1. The accepted packet exposes the source metric row, regular readback, dyadic ledger, unit admission, terminal seal, and structural support rows.

The analytic rows are S, R, D, U, E. The source row names the points and their distance requests, the readback row names the constant regular Cauchy observations, and the dyadic ledger binds the requested comparison tolerance. The unit row admits the constant completion names before the Real seal is read.

The structural rows are H, C, P, N. They transport the same displayed data, replay the same route, record provenance, and bind the local name. Since the carrier contains no additional coordinate, every local NameCert obligation is one of the listed rows. □

Theorem 6435.3 (Cauchy completion unit-isometry distance route)**.** *Every accepted* CauchyCompletionUnitIsometr *carrier routes a displayed source-distance comparison through the finite chain*

$$S \longmapsto U \longmapsto R, D \longmapsto E, H, C, P, N.$$

The completion distance read is therefore the same finite regular-rational and dyadic comparison attached to the source metric row; it is not a quotient equality of completion classes and not a selected limiting representative.

Proof. Begin with an accepted carrier $J = (S, R, D, U, E, H, C, P, N)$. The source stage is S: the displayed metric row fixes the two source points and the distance request being compared.

Use the unit-admission row U next. It sends each displayed source point to its constant Cauchy completion name before any distance readback is available, so the completion-side comparison is attached to the same source observations.

Read R, D as the finite comparison ledger. The regular rational row supplies the constant-name observations, and the dyadic row supplies the tolerance budget for comparing those observations with the source distance request.

Finally E, H, C, P, N seal, transport, replay, source, and name the displayed route. No quotient class, selected representative, host complete space, or choice schedule appears in the packet, so the distance route is exhausted by the listed finite rows. □

Theorem 6435.4 (Cauchy completion unit-isometry Real-seal consumer)**.** *Every Real-facing consumer of an accepted* $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$ *packet must reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal by first reading the source metric row* S*, the unit-admission row* U*, the regular rational readback* R*, and the dyadic tolerance ledger* D*. The consumer receives the unit-isometry witness only as a finite Real-seal route over constant Cauchy names, with support rows* H, C, P, N *preserving the same packet.*

Proof. Project the accepted packet. The terminal row E is not a detached real object; it is displayed only after S, U, R, D have fixed the source distance request, the constant completion names, and the dyadic comparison budget.

Use Definition 6435.3. It orders the completion-facing distance read through the same source, unit, readback, and tolerance rows before the Real seal is available.

The support rows H, C, P, N preserve that route under componentwise transport, displayed replay, provenance, and local naming. A Real-facing consumer therefore obtains the unit-isometry witness through finite NameCert data only, not through quotient completion equality, selected limits, ambient completeness, or choice. □

Falsifiable prediction: Every $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$ Real-facing read factors through one source metric row, one unit-admission row, one regular rational readback row, one dyadic tolerance ledger, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchycompletionfunctor, metric-completion-dense-embedding, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source metric row, unit-admission row, regular readback, dyadic tolerance, Real seal, transport, replay, provenance, and local NameCert rows as one finite unit-isometry packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}$ packet is generated from a source metric row, constant-Cauchy-name unit admission, RegSeqRat readback, DyadicRatCore tolerance comparison, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6435.1, Definition 6435.2, Definition 6435.3, and Definition 6435.4 seed the finite unit-isometry route from source metric data through constant completion names, RegSeqRat readback, DyadicRatCore tolerance comparison, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionUnitIsometry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host complete spaces, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source metric stability, unit-admission exactness, regular readback, dyadic tolerance discipline, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionUnitIsometryUp.

Chapter 6436

A Concrete Naming Certificate for $\mathsf{DarbouxSums}^{\uparrow}$

Following Darboux and Riemann constructive integration, the $\mathsf{DarbouxSums}^{\uparrow}$ packet records the finite partition-indexed lower and upper sum surface before an integration consumer reads a limiting or Cauchy route. It sits after the real interval seal of chapter 38, the regular rational readback of chapter 301, the dyadic arithmetic core of chapter 291, the finite partition surface of chapter 201, the single Darboux comparison row of chapter 1880, and the Riemann integral consumer of chapter 1526. The packet gives Real and Completion routes a finite family of partition sums without treating integration, supremum, or real completeness as primitive.

Definition 6436.1 (DarbouxSums carrier)**.** *A* $\mathsf{DarbouxSums}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, P, L, U, SL, SU, G, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval-source row naming the endpoint seals and the orientation of the finite partition request.*
2. *P is the* $\mathsf{Partition}^{\uparrow}$ *row naming the ordered finite cell list, adjacency data, and partition coverage.*
3. *L and U are lower-value and upper-value ledgers over the cells of P, with every value read through the same displayed partition route.*
4. *SL and SU are the finite lower and upper sum rows computed from the cell widths of P and the displayed L, U value ledgers.*
5. *G is the upper-minus-lower gap comparison row, exposed only after P, L, U, SL, SU have been displayed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational sum observations attached to the same finite partition and value ledgers.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reachable only after R and the finite Darboux rows have been projected.*
8. *H records componentwise* hsame *transport for interval, partition, value, finite-sum, gap, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the route*

$$I, P, L, U \longmapsto SL, SU \longmapsto G, R \longmapsto E.$$

10. *Q is the* Pkg *provenance over* $\mathsf{DarbouxSums}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxSums}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, P, L, U, SL, SU, G, R, E, H, C, Q, N$. It has no coordinate for quotient functions, host suprema, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6436.2 (DarbouxSums NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxSums}^{\uparrow}$ *carrier $D = (I, P, L, U, SL, SU, G, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxSums}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Real}^{\uparrow}$ *interval source, finite* $\mathsf{Partition}^{\uparrow}$ *row, lower and upper value ledgers, lower and upper finite sum rows, upper-minus-lower gap row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every obligation is read through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *cell-width arithmetic and the existing* $\mathsf{DarbouxSum}^{\uparrow}$ *comparison boundary before any* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer is available.*

Proof. Project the carrier of Definition 6436.1. The interval, partition, lower-value, upper-value, finite-sum, gap, readback, and seal rows are the only analytic rows carried by the packet.

The partition and arithmetic obligations are finite. Row P supplies the ordered cell list, and $\mathsf{DyadicRatCore}^{\uparrow}$ support in Q supplies the displayed cell-width arithmetic used by SL and SU.

The Darboux comparison obligation is read through G. It is downstream of P, L, U, SL, SU and agrees with the single $\mathsf{DarbouxSum}^{\uparrow}$ boundary cited by the provenance row.

Finally R, E, H, C, Q, N read back, seal, transport, replay, source, and name the same route. Since no coordinate stores quotient functions, host suprema, selected limits, countable choice, or real completeness, no NameCert obligation can export those objects. □

Theorem 6436.3 (DarbouxSums real partition scope)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *or Real-facing consumer of an accepted* $\mathsf{DarbouxSums}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Real}^{\uparrow}, \quad \mathsf{Partition}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{DarbouxSum}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

as exposed by $I, P, SL, SU, G, R, E, H, C, Q, N$. The route supplies lower and upper finite sums over displayed partition cells, but it refuses quotient functions, host suprema, selected limits, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the partition rows I and P. They expose only a displayed real interval source and a finite partition surface, so a consumer receives cells, adjacency, and endpoint coverage rather than a completed function space.

Use the finite sum rows SL and SU together with the gap row G. These rows compute lower and upper Darboux sums over the same displayed cells and route the comparison through the $\mathsf{DarbouxSum}^{\uparrow}$ boundary.

The readback and seal rows R and E then attach the finite observations to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ only after the partition and Darboux rows are visible. The structural rows H, C, Q, N preserve this order, so no Riemann or Real-facing consumer can bypass the finite partition route or import a refused host principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxSums}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxSums}^{\uparrow}$ packet is generated from a RealUp interval source, a finite PartitionUp cell row, displayed lower and upper value ledgers, lower and upper finite sum rows, a DarbouxSum gap comparison, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DarbouxSums}^{\uparrow}}$, seed)

Scope closed: Definition 6436.1, Definition 6436.2, and Definition 6436.3 seed the finite Darboux partition-sum route over RealUp, RegSeqRatUp, DyadicRatCoreUp, PartitionUp, DarbouxSumUp, and RiemannIntegralUp rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{DarbouxSums}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient functions, host suprema, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite partition coverage, lower and upper value stability, finite-sum exactness, Darboux gap readback, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DarbouxSumsUp.

Chapter 6437

A Concrete Naming Certificate for HyperbolicPhaseCurvatureBudget$^{\uparrow}$

The HyperbolicPhaseCurvatureBudget$^{\uparrow}$ packet realizes the curvature-budget branch of chapter 9463 as finite BEDC NameCert data. It sits after the disk carrier of chapter 377, the Poincare disk metric packet of chapter 6209, the hyperbolic metric rows of chapter 3474, the observer-expansion route of chapter 4167, and the geodesic-flow surface of chapter 3856. The packet names disk, metric, boundary, Real-seal, provenance, and refusal rows without importing host global geometry, a completed boundary, a physical observer law, or an unlogged curvature scalar.

Definition 6437.1 (Hyperbolic phase curvature budget carrier)**.** *A* HyperbolicPhaseCurvatureBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, M, K, O, G, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the displayed disk row, read through* UnitDisk$^{\uparrow}$ *and the Poincare disk coordinate surface.*
2. *M is the* PoincareDiskMetric$^{\uparrow}$ *or* HyperbolicMetric$^{\uparrow}$ *metric-read row over the same disk observations.*
3. *K is the finite curvature-budget row, recording the local comparison budget used by the observer-expansion read.*
4. *O is the* HyperbolicObserverExpansion$^{\uparrow}$ *route consuming D, M, K as a focused expansion ledger.*
5. *G is the* HyperbolicGeodesicFlow$^{\uparrow}$ *or boundary-flow handoff row attached to the same metric budget.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for metric and curvature observations.*
7. *E is the terminal* Real$^{\uparrow}$ *curvature readback seal reached only after D, M, K, O, G, R have been displayed.*
8. *F is the TasteGate-facing row requiring Lean* `Nontrivial` *and* `FieldFaithful` *instances for the same carrier fields.*
9. *H records componentwise* hsame *transport for disk, metric, curvature-budget, observer-expansion, geodesic-flow, readback, Real-seal, TasteGate-facing, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through the route*

$$D, M \longmapsto K \longmapsto O, G \longmapsto R, E.$$

11. *P is the* Pkg *provenance over* HyperbolicPhaseCurvatureBudget$^{\uparrow}$, UnitDisk$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicObserverExpansion$^{\uparrow}$, HyperbolicGeodesicFlow$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{HyperbolicPhaseCurvatureBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, K, O, G, R, E, F, H, C, P, N$. It has no coordinate for a host hyperbolic manifold, quotient boundary equality, unlogged curvature scalar, selected global geodesic, physical observer law, ambient real completeness, Lean verification, or bridge checking.

Theorem 6437.2 (Hyperbolic phase curvature budget obligations)**.** *For every accepted* HyperbolicPhaseCurvatureB *carrier $B = (D, M, K, O, G, R, E, F, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicPhaseCurvatureBudget}^{\uparrow}}$ *surface consists exactly of disk admission, metric-read exposure, curvature-budget admission, observer-expansion routing, geodesic-flow handoff, regular rational readback, Real-seal nonescape, TasteGate-facing nontriviality and field-faithfulness requirements, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A Real-facing curvature readback must expose the* HyperbolicMetric$^{\uparrow}$ *row before it reads E.*

Proof. Project the carrier of Definition 6437.1. The disk row D and metric row M are upstream of every curvature-budget, observer-expansion, geodesic-flow, readback, and Real-seal row.

Use the curvature-budget row K and observer-expansion row O. They bind the focused expansion reading to the displayed metric budget rather than to an ambient global geometry.

The geodesic-flow handoff G and readback row R preserve the same metric-budget route before the Real seal E is visible. The TasteGate-facing row F records that Lean nontriviality and field faithfulness must keep these fields distinct.

Rows H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores host geometry, quotient boundary equality, selected global geodesics, physical observer dynamics, or real completeness, the listed obligation surface is exhaustive. □

Theorem 6437.3 (Hyperbolic phase curvature Real-readback order)**.** *Every accepted* HyperbolicPhaseCurvatureBud *consumer that exports a* Real$^{\uparrow}$ *curvature readback must first display the route*

UnitDisk$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicObserverExpansion$^{\uparrow}$, HyperbolicGeodesicFlow$^{\uparrow}$

In carrier notation, the row E is reachable only after $D, M, K, O, G, R, H, C, P, N$ have been read, and the TasteGate-facing row F keeps the metric and curvature-budget fields noncollapsed.

Proof. Begin with the disk and metric rows. The curvature readback has no source until D and M expose the displayed disk and hyperbolic metric observations.

Read the budget and expansion rows next. The row K records the finite curvature budget, while O and G attach it to observer expansion and geodesic-flow handoff over the same metric route.

Only then can R and E be consumed. The RegSeqRat$^{\uparrow}$ row records the regular rational readback, and the terminal Real$^{\uparrow}$ seal is downstream of that readback. The rows F, H, C, P, N preserve field separation, transport, replay, provenance, and local naming without adding another Real-facing path. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}$ packet exposes a $\mathsf{HyperbolicMetric}^{\uparrow}$ row before any $\mathsf{Real}^{\uparrow}$ curvature readback; omitting that metric row refutes the carrier because the curvature budget can no longer be distinguished from an unlogged Real scalar.

Independence witness: hyperbolic-metric, poincare-disk-metric, hyperbolic-observer-expansion, hyperbolic-geodesic-flow: no listed sibling is bijective to $\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}$ because this packet jointly carries disk observations, metric reads, curvature-budget rows, observer-expansion routing, geodesic-flow handoff, regular readback, Real sealing, TasteGate-facing field separation, transport, replay, provenance, refusal rows, and local naming.

The Lean TasteGate file `lean4/BEDC/Derived/HyperbolicPhaseCurvatureBudgetUp/TasteGate.lean` must provide `Nontrivial` and `FieldFaithful` instances for $\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}$. Those instances must preserve $D, M, K, O, G, R, E, F, H, C, P, N$ as distinct fields before any carrier-alignment theorem can serve as a TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}$ packet is generated from UnitDiskUp disk data, PoincareDiskMetricUp and HyperbolicMetricUp metric rows, a finite curvature-budget row, HyperbolicObserverExpansionUp routing, HyperbolicGeodesicFlowUp handoff, RegSeqRatUp readback, a RealUp seal, TasteGate-facing field-separation requirements, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6437.1, Definition 6437.2, and Definition 6437.3 seed the finite curvature-budget route over disk, metric, boundary, observer-expansion, geodesic-flow, RegSeqRat, Real-seal, provenance, and refusal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host global hyperbolic geometry, quotient boundary equality, selected global geodesics, physical observer dynamics, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, disk exposure, metric-read exposure, curvature-budget exactness, observer-expansion routing, geodesic-flow handoff, Real-seal nonescape, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseCurvatureBudgetUp.

Chapter 6438

A Concrete Naming Certificate for $\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}$

Following Alexandrov–Urysohn metrization, the $\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}$ packet records only the finite BEDC certificate by which countable basis windows and separation witnesses synthesize a metric-radius readback. It sits after the open-row discipline of chapter 88, beside the metric carrier of chapter 57, the finite-window schedule of chapter 126, the regular-rational readback of chapter 301, and the complete separable metric boundary of chapter 1490. The packet names a displayed basis-to-metric route; it does not assert global choice, arbitrary open-cover metrization, quotient topology, selected embeddings, or host-level general metrization.

Definition 6438.1 (Alexandrov–Urysohn metrization carrier)**.** *An* $\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, B, S, R, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, recording the finite open-membership observations available to the packet.*
2. *B is the countable basis-window row, recording a finite* $\mathsf{StreamName}^{\uparrow}$ *schedule of basis names, incidence witnesses, and window bounds.*
3. *S is the separation-witness row, recording the displayed point-open and disjoint-closure tests consumed by the metric synthesis.*
4. *R is the metric-radius synthesis row, assigning dyadic rational radius ledgers to the basis windows and separation witnesses.*
5. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular-rational distance observations produced from R.*
6. *Q is the refusal row, recording that global choice, arbitrary open covers, quotient topology, selected embeddings, and host-level metrization are absent from the packet.*
7. *H records componentwise* hsame *transport for topology, basis-window, separation, radius synthesis, readback, refusal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from* $\mathsf{Topology}^{\uparrow}$ *and basis windows through metric-radius synthesis into* $\mathsf{Met}^{\uparrow}/\mathsf{Met}^{\uparrow}$ *and* $\mathsf{PolishSpace}^{\uparrow}$ *consumers.*

9. *P is the* Pkg *provenance over* AlexandrovUrysohnMetrization$^{\uparrow}$, Topology$^{\uparrow}$, Met$^{\uparrow}$, Met$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, PolishSpace$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{AlexandrovUrysohnMetrization}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice-selected global basis, an arbitrary open-cover refinement theorem, a quotient topology, a host embedding into sequence space, or a classical all-spaces metrization principle.

Theorem 6438.2 (Alexandrov–Urysohn metrization NameCert obligations)**.** *For every accepted* AlexandrovUrysohnMetrization$^{\uparrow}$ *carrier $A = (T, B, S, R, W, Q, H, C, P, N)$, the local* NameCert$_{\text{AlexandrovUrysohnMetrizatio}}$ *surface consists exactly of topology-source admission through T, countable basis-window scheduling through B, separation-witness inspection through S, metric-radius synthesis through R,* RegSeqRat$^{\uparrow}$ *readback through W, refusal of non-displayed classical data through Q, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6438.1. The topology source, basis windows, separation witnesses, radius ledger, readback, refusal, transport, replay, provenance, and naming rows are exactly $T, B, S, R, W, Q, H, C, P, N$.

Read the basis data through B before metric synthesis. The finite StreamName$^{\uparrow}$ schedule exposes only displayed basis windows and incidence witnesses, so no global basis choice or arbitrary open-cover selection is available.

Next read the separation witnesses through S and the radius ledger through R. The metric-facing observation is synthesized from those displayed rows and then exposed as the RegSeqRat$^{\uparrow}$ readback W before any Met$^{\uparrow}$, Met$^{\uparrow}$, or PolishSpace$^{\uparrow}$ consumer can inspect it.

Finally Q, H, C, P, N refuse absent classical data, preserve the displayed rows, replay the route, source the packet, and name it locally. Since the carrier contains no quotient-topology coordinate, selected embedding, or host-level general metrization theorem, the NameCert obligations are exactly the finite basis-to-metric route stated above. □

Theorem 6438.3 (Alexandrov–Urysohn finite basis-to-metric route)**.** *Every* PolishSpace$^{\uparrow}$ *or* Met$^{\uparrow}$ *consumer of an* AlexandrovUrysohnMetrization$^{\uparrow}$ *packet must first read the* Topology$^{\uparrow}$ *row, finite basis-window schedule, separation-witness row, metric-radius synthesis ledger,* StreamName$^{\uparrow}$ *schedule,* RegSeqRat$^{\uparrow}$ *readback,* BHist *carrier, componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The consumer receives a finite certificate for the displayed basis-to-metric handoff, not a quotient topology, arbitrary open-cover theorem, selected global basis, or host-level general metrization result.*

Proof. Start with the NameCert obligations of Definition 6438.2. They force topology admission, basis-window scheduling, separation witnesses, radius synthesis, readback, refusal, transport, replay, provenance, and naming to remain rows of one finite packet.

The metric consumer then reads R and W after T, B, S. Thus the distance observations are regular-rational readbacks from displayed basis and separation data, not host real distances selected from an external metric.

For a PolishSpace consumer, replay the same metric-facing row through C and provenance P. Completeness and separability consumers may inspect the handoff only as a routed finite NameCert surface over the sibling Met$^{\uparrow}$/Met$^{\uparrow}$, StreamName$^{\uparrow}$, and RegSeqRat$^{\uparrow}$ rows.

The refusal row Q records the boundary. No global choice, arbitrary open-cover compactness, quotient topology, selected embedding, or host-level metrization theorem is exported by this packet. □

Falsifiable prediction: An accepted $\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}$ packet cannot export a MetricSpace or PolishSpace handoff without displaying the topology source, basis-window schedule, separation witnesses, radius synthesis, RegSeqRat readback, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: topology, metric, streamname, regseqrat, polishspace: $\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}$ binds countable basis windows, separation witnesses, and metric-radius synthesis in one finite carrier; the cited siblings expose the source, readback, and consumer rows but not the local basis-to-metric certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}}$.

Constructive story: An $\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}$ packet is generated from a TopologyUp source row, finite countable-basis windows, separation witnesses, metric-radius synthesis, RegSeqRat readback, refusal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6438.1, Definition 6438.2, and Definition 6438.3 seed the finite basis-to-metric certificate over topology, stream, regular-rational, metric, and Polish-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlexandrovUrysohnMetrization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, global choice, arbitrary open-cover metrization, quotient topology, selected embeddings, or host-level general metrization.

Upgrade path: Formal closure requires a checked carrier and NameCert obligation theorem for the displayed basis-window, separation, radius-synthesis, readback, transport, replay, provenance, and naming rows.

Chapter 6439

A Concrete Naming Certificate for $\mathsf{CauchySelectionPrinciple}^{\uparrow}$

Following Bishop-style constructive analysis, the $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ packet records the finite selection-window route used by Real-completion consumers before any selected subsequence, quotient real, or countable-choice schedule is available. It sits after the dyadic tolerance ledger of chapter 291, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the equality-facing comparison surface of chapter 1820. The packet names the bounded choice-free handoff needed by Cauchy subsequence arguments, not a global choice principle and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6439.1 (Cauchy selection principle carrier)**.** *A* $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested precision, the finite dyadic comparison window, and the descent budget used by the selection read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only the bounded stream observations inspected by the selection request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to D and W.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic ledger, stream windows, and regular readback have been displayed.*
5. *Q is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison row used to compare two accepted selection reads through the same displayed tail window.*
6. *H records componentwise* hsame *transport for dyadic tolerances, stream windows, regular readback, Real seal, Cauchy-equivalence comparison, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion-facing precision request through D, W, R, E, Q, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchySelectionPrinciple}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySelectionPrinciple}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $D, W, R, E, Q, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, host real equality, countable choice, trichotomy, metric completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySelectionPrincipleUp.CauchySelectionPrincipleTasteGate single carrier alignment`

Theorem 6439.2 (Cauchy selection subsequence window)**.** *Every subsequence-facing read of an accepted* $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ *carrier* $S = (D, W, R, E, Q, H, C, P, N)$ *is confined to the displayed finite window* D, W, R*. The read may inspect a dyadic precision request, a bounded StreamName observation family, and the attached RegSeqRat readback, but it receives no selected infinite subsequence and no countable-choice schedule.*

Proof. Project the accepted carrier. The only value-facing rows before the Real seal are the dyadic ledger D, the stream-window row W, and the regular rational readback R.

The continuation row C fixes the order of inspection. A precision request first reads the dyadic budget, then the bounded stream observations, and then the regular rational readback attached to those observations.

The structural rows H, P, N preserve the same displayed route, and Q is only a comparison row for accepted reads. Since no row stores a selected infinite subsequence or a choice schedule, every subsequence-facing read remains inside the finite window. □

Theorem 6439.3 (Cauchy selection regularity handoff)**.** *For every accepted* $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ *carrier* $S = (D, W, R, E, Q, H, C, P, N)$*, the selection window reaches a completion-facing name only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *after the dyadic tolerance ledger* D *and the StreamName window* W *have been exposed. The handoff is therefore a regular rational readback, not a quotient stream and not a selected representative.*

Proof. Begin with the displayed rows D and W. They bind the finite precision request and the bounded observations from which the selection read is made.

The row R consumes exactly those displayed rows as a $\mathsf{RegSeqRat}^{\uparrow}$ readback. Thus the completion-facing handoff is already regular-rational before the Real seal or comparison row can be used.

Rows E, Q, H, C, P, N do not add another value source. They seal, compare, transport, replay, source, and name the same handoff, so the route cannot introduce quotient streams, selected representatives, or countable choice. □

Theorem 6439.4 (Cauchy selection Real-seal nonescape)**.** *Every Real-facing consumer of an accepted* $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The packet exports no $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient equality of stream names, host real equality, trichotomy, selected limit, selected subsequence, metric completeness, open-cover compactness, or countable-choice row.*

Proof. Project $S = (D, W, R, E, Q, H, C, P, N)$. The Real seal E is present only as the fourth value-facing row after the dyadic tolerance ledger, finite stream windows, and regular rational readback.

Use Definition 6439.3. It shows that any completion-facing name read has already passed through D, W, R, so the terminal Real seal cannot be detached from the finite selection window.

The comparison and structural rows preserve the same path. Because the carrier has no coordinate for completeness, quotient equality, host equality, trichotomy, selected limits, selected subsequences, metric completeness, open-cover compactness, or countable choice, the Real-facing consumer receives only the displayed finite NameCert route. □

Falsifiable prediction: Every $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ Real-completion read factors through one DyadicRatCore tolerance ledger, one StreamName finite-window row, one RegSeqRat readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, one CauchyEquivalenceSetoid comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-equivalence-setoid: $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite selection window, regularity handoff, Real seal, comparison, transport, replay, provenance, and local NameCert rows as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySelectionPrinciple}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{CauchySelectionPrinciple}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, CauchyEquivalenceSetoid comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySelectionPrinciple}^{\uparrow}}$, seed)

Scope closed: Definition 6439.1, Definition 6439.2, Definition 6439.3, and Definition 6439.4 seed the finite selection-window route from dyadic precision through StreamName, RegSeqRat, and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySelectionPrinciple}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected subsequences, selected limits, quotient stream equality, host real equality, trichotomy, countable choice, metric completeness, open-cover compactness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selection-window exactness, regularity handoff, Real-seal nonescape, Cauchy-equivalence comparison, transport, replay, provenance, and local naming for BEDC.Derived.CauchySelectionPrinc

Chapter 6440

A Concrete Naming Certificate for $\mathsf{RealCompletionSelectionGate}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealCompletionSelectionGate}^{\uparrow}$ packet records the finite gate that separates allowed Real-completion reads from off-table completeness claims. It realizes the four-object route of chapter 9238 as displayed rows over chapter 291, chapter 126, chapter 301, and chapter 38, with comparison discipline inherited from chapter 1820. The gate permits finite selection windows and regular rational readback; it does not certify quotient completion, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6440.1 (Real completion selection gate carrier)**.** *A* $\mathsf{RealCompletionSelectionGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, W, R, E, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger for the requested Real-completion precision.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row, storing only the bounded windows read by the gate.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to D and W.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, W, R have been displayed.*
5. *T records componentwise* hsame *transport for the four value-facing rows and for the replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a Real-completion request through D, W, R, E, T, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RealCompletionSelectionGate}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionSelectionGate}^{\uparrow}}$ *row.*

The classifier compares accepted gates only through D, W, R, E, T, C, P, N. It has no coordinate for quotient stream equality, selected representatives, global Cauchy choice, host real equality, trichotomy, metric completeness, open-cover compactness, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6440.2 (Real completion selection gate four-object route)**.** *Every accepted* $\mathsf{RealCompletionSelectionGate}^{\uparrow}$ *carrier routes an allowed Real-completion read through the ordered four-object chain*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The gate exposes no completion-facing value before the dyadic tolerance ledger, finite StreamName window, regular rational readback, and terminal Real seal have all been displayed.

Proof. Project the accepted gate $G = (D, W, R, E, T, C, P, N)$. The value-facing rows are exactly D, W, R, E.

The continuation row C fixes the reading order. A Real-completion request first consumes the dyadic precision ledger, then the bounded stream observations, then the regular rational readback, and only then the terminal Real seal.

Rows T, P, N transport, source, and name the same route. Since no other value-facing row exists in the carrier, every allowed completion read factors through the four-object chain. □

Theorem 6440.3 (Real completion selection gate transport replay)**.** *For every accepted* RealCompletionSelectionGa *carrier* $G = (D, W, R, E, T, C, P, N)$*, componentwise transport and displayed replay preserve the same four-object route. Transport cannot replace the finite StreamName window by a quotient stream, and replay cannot introduce a selected limit or countable-choice schedule.*

Proof. The transport row T is componentwise over D, W, R, E, C, P, N. It can identify two displayed gates only by transporting the same dyadic ledger, finite window, regular readback, Real seal, replay, provenance, and local name.

The replay row C records the route from a Real-completion request through those same displayed rows. Thus replay reuses the already named four-object chain rather than adding a second completion source.

Because neither T nor C has a coordinate for quotient streams, selected representatives, selected limits, or choice schedules, the transported and replayed gate remains inside the finite route of Definition 6440.2. □

Theorem 6440.4 (Real completion selection gate nonescape)**.** *Every consumer of an accepted* $\mathsf{RealCompletionSelectionGate}^{\uparrow}$ *packet receives only dyadic tolerance data, finite StreamName observations, RegSeqRat readback, a terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming. The packet exports no quotient completion, no selected representative, no selected limit, no host real equality, no trichotomy, no countable choice, no metric completeness theorem, no open-cover compactness theorem, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Use Definition 6440.1. The accepted packet is exhausted by D, W, R, E, T, C, P, N.

The value-facing rows give the four-object completion route, and the structural rows preserve that route under transport, replay, provenance, and local naming. None of these rows stores a detached completion object or a global selection principle.

Therefore every consumer remains inside the finite gate. Any claim requiring quotient completion, selected representatives, selected limits, host equality, trichotomy, countable choice, metric completeness, open-cover compactness, or ambient Real completeness asks for a row absent from the carrier. □

Falsifiable prediction: Every $\mathsf{RealCompletionSelectionGate}^{\uparrow}$ Real-completion read factors through one DyadicRatCore tolerance ledger, one StreamName finite-window row, one RegSeqRat readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-selection-principle: $\mathsf{RealCompletionSelectionGate}^{\uparrow}$ is not bijective to any listed sibling because it packages the four-object route as a gate with transport, replay, provenance, and local NameCert rows that reject off-table completion claims.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionSelectionGate}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionSelectionGate}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionSelectionGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6440.1, Definition 6440.2, Definition 6440.3, and Definition 6440.4 seed the four-object Real-completion gate and its nonescape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionSelectionGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, selected limits, host real equality, trichotomy, countable choice, metric completeness, open-cover compactness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four-object route exactness, transport replay, nonescape, provenance, and local naming for BEDC.Derived.RealCompletionSelectionGateUp.

Chapter 6441

A Concrete Naming Certificate for BolzanoDedekindLocatedCluster$^{\uparrow}$

Following Bolzano, Dedekind, and Bishop–Bridges constructive analysis, the BolzanoDedekindLocatedCluster$^{\uparrow}$ packet records a finite located-cluster surface for bounded real sequences. It consumes the bounded sequence source of chapter 1415, the nested and located interval routes of chapter 320 and chapter 394, the finite stream and regular-rational rows of chapter 126 and chapter 301, the terminal real-name seal of chapter 38, and the boundary siblings chapter 1254, chapter 1580, and chapter 2372. The packet is a located finite-window cluster certificate; it is not general sequential compactness, not a choice-selected subsequence theorem, and not an ambient completeness principle for Real$^{\uparrow}$.

Definition 6441.1 (Bolzano–Dedekind located cluster carrier)**.** *A* BolzanoDedekindLocatedCluster$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, I, L, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* BoundedRealSequence$^{\uparrow}$ *source row, including only the inspected finite sequence windows and the displayed bound surface.*
2. *I is the nested interval row, recording the retained finite interval chain used by the Bolzano–Dedekind search.*
3. *L is the located interval row, carrying endpoint-apartness and retained-window location data for the intervals in I.*
4. *S is the* StreamName$^{\uparrow}$ *schedule that names which sequence windows and interval windows are inspected.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the scheduled sequence and interval windows.*
6. *E is the* Real$^{\uparrow}$ *cluster seal reached only after B, I, L, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the bounded source, nested interval, located interval, stream, regular readback, and real-seal rows.*
8. *C records displayed* Cont *replay from a cluster request through the same finite rows.*

9. *P is the* Pkg *provenance over* BolzanoDedekindLocatedCluster$^{\uparrow}$, BoundedRealSequence$^{\uparrow}$, NestedInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BolzanoWeierstrass$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BolzanoDedekindLocatedCluster}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, I, L, S, R, E, H, C, P, N$. It has no coordinate for a globally selected subsequence, open-cover compactness, quotient real equality, real trichotomy, countable choice, general sequential compactness, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6441.2 (Bolzano–Dedekind located cluster NameCert obligations)**.** *For every accepted* BolzanoDedekindLocatedCluster$^{\uparrow}$ *carrier*

$$K = (B, I, L, S, R, E, H, C, P, N),$$

the local NameCert$_{\text{BolzanoDedekindLocatedCluster}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, bounded-sequence source exposure through B, nested-window retention through I, located endpoint and interval comparison through L, finite stream scheduling through S, regular rational readback through R, terminal cluster sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. The obligation surface refuses general sequential compactness, choice-selected subsequences, open-cover compactness, quotient real equality, trichotomy, and ambient Real completeness as certificate rows.*

Proof. Project the carrier of Definition 6441.1. The bounded sequence can be read only through B, and B itself supplies finite windows and a displayed bound surface rather than a global compactness theorem.

Next inspect the interval rows. The nested interval row I records the retained finite chain, while the located interval row L records the endpoint and apartness comparisons needed to keep the cluster window located. These rows are packet data, not consequences of an ambient interval-intersection theorem.

The readback and seal are downstream. The schedule row S names the inspected windows, R supplies the regular rational readback for those windows, and E is visible only after those finite rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded compactness, choice, quotient, trichotomy, or completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6441.3 (Bolzano–Dedekind located cluster Real handoff)**.** *Every* Real$^{\uparrow}$*-facing read of an accepted* BolzanoDedekindLocatedCluster$^{\uparrow}$ *carrier factors through the finite route*

$$B,\ I,\ L,\ S,\ R,\ E,\ H,\ C,\ P,\ N.$$

The handoff supplies a located cluster seal for bounded real sequence consumers and for the Bolzano–Weierstrass boundary siblings, but it does not supply general sequential compactness, a choice-selected subsequence, open-cover compactness, quotient real equality, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Start with the bounded source row. By Definition 6441.1, the sequence source is the displayed BoundedRealSequence$^{\uparrow}$ row B, so any Real-facing consumer first reads finite sequence windows and the boundedness surface already present in B.

Use the NameCert obligations of Definition 6441.2. They place nested-window retention I and located interval comparison L before the stream schedule, regular rational readback, and terminal cluster seal.

Now read the seal row E. It is downstream of S and R, so the cluster handoff reaches $\mathsf{Real}^{\uparrow}$ through finite stream and regular-rational data rather than through quotient real equality, trichotomy, or ambient completeness.

The structural rows H, C, P, N preserve the same displayed route. Thus a Bolzano–Weierstrass or cluster-point consumer receives a located finite-window cluster seal, while the excluded compactness and choice principles remain outside the packet. □

Falsifiable prediction: Every $\mathsf{BolzanoWeierstrass}^{\uparrow}$ boundary read that cites $\mathsf{BolzanoDedekindLocatedCluster}^{\uparrow}$ must display a $\mathsf{BoundedRealSequence}^{\uparrow}$ source row, nested and located interval rows, StreamName windows, RegSeqRat readback, a RealUp seal, transport, replay, provenance, and local naming before any cluster consumer can proceed.

Independence witness: boundedrealsequence, nestedinterval, locatedinterval, streamname, regseqrat, real, bolzanoweierstrass: $\mathsf{BolzanoDedekindLocatedCluster}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded source exposure, nested-window retention, located interval comparison, stream scheduling, regular readback, terminal cluster sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoDedekindLocatedCluster}^{\uparrow}}$.

Constructive story: A $\mathsf{BolzanoDedekindLocatedCluster}^{\uparrow}$ packet is generated from a bounded real sequence row, nested and located interval rows, StreamName windows, RegSeqRat readback, a terminal RealUp cluster seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoDedekindLocatedCluster}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6441.1, Definition 6441.2, and Definition 6441.3 seed the finite located-cluster certificate for bounded real sequence windows through nested and located interval rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BolzanoDedekindLocatedCluster}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general sequential compactness, choice-selected subsequences, open-cover compactness, quotient real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source exposure, nested-window retention, located interval comparison, stream scheduling, regular rational readback, real-seal handoff, transport, replay, provenance, and local naming for the same packet.

Chapter 6442

A Concrete Naming Certificate for $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$ packet records the finite criterion by which tight Cauchy evidence is read as regular Cauchy data before the completion route consumes a real-name seal. It sits between the tightness surface of chapter 1870, the regularizing route of chapter 2227, the modulus schedule of chapter 292, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic arithmetic of chapter 291, and the visible real-name boundary of chapter 38. The packet is a finite NameCert surface for the textbook criterion; it is not a quotient completion, a selected limit, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6442.1 (Bishop tight Cauchy criterion carrier)**.** *A* $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, G, M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyTightness}^{\uparrow}$ *evidence row, recording tight-tail comparisons for the inspected sequence data.*
2. *G is the* $\mathsf{RegularCauchyTightening}^{\uparrow}$ *handoff row that turns tight-tail evidence into regular Cauchy readback data.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule attached to the same tail comparisons.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which every tail and threshold read is inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row assembled from the scheduled windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the tight-tail and regular-readback comparisons.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, G, M, W, R, D have all been displayed.*
8. *H stores componentwise* hsame *transport for tightness evidence, regular tightening, modulus schedules, stream windows, rational readbacks, dyadic ledgers, and the real seal.*
9. *C stores displayed* Cont *replay for the same route.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyTightness}^{\uparrow}$, $\mathsf{RegularCauchyTightening}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopTightCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $T, G, M, W, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limit representatives, countable choice, trichotomy on real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6442.2 (Bishop tight Cauchy criterion NameCert obligations)**.** *For every accepted* $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$ *carrier $B = (T, G, M, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopTightCauchyCriterion}}$ *obligations are exactly carrier admission, tight-tail stability, regular-readback transport,* $\mathsf{Real}^{\uparrow}$*-seal nonescape, and completion-consumer handoff. Each obligation is a finite BEDC row over the displayed tightness, tightening, modulus, stream, regular-rational, dyadic, real-seal, transport, replay, provenance, and naming coordinates.*

Proof. Carrier admission is projection from Definition 6442.1. The packet displays the tightness row T, the regularizing row G, the modulus row M, the window row W, the readback row R, the dyadic row D, the seal row E, and the structural rows H, C, P, N.

Tight-tail stability is read from T together with M, W, D. A tolerance request first enters the dyadic ledger, is matched to a finite stream window, and then receives the tail threshold recorded by the modulus schedule. Transport by H preserves the same displayed rows, and replay by C repeats the same finite route.

Regular-readback transport uses G and R. The tightening row converts the stable tight-tail data into the regular Cauchy surface, and the regular rational row records the finite readback before any real-facing seal is available.

The $\mathsf{Real}^{\uparrow}$ seal is nonescaping because E is downstream of T, G, M, W, R, D. No row in the carrier can supply a host limit, quotient equality, selected representative, or ambient completeness principle before that finite route has been displayed.

Finally, a completion consumer receives only the packet named by P, N. The consumer can hand off the tight Cauchy criterion to the regular Cauchy and Real route, but it cannot bypass the displayed finite rows or import an unlisted completion principle. □

Falsifiable prediction: Every $\mathsf{Completion}^{\uparrow}$ consumer of a $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$ packet factors through tight-tail evidence, regular tightening, Cauchy-modulus thresholds, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, the RealUp seal, transport, replay, provenance, and local naming before completion data is consumed.

Independence witness: cauchytightness, regularcauchytightening, cauchymodulus, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries tight-tail evidence, the regularizing handoff, the threshold schedule, finite windows, regular rational readback, dyadic tolerance rows, a real seal, componentwise transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopTightCauchyCriterion}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{BishopTightCauchyCriterion}^{\uparrow}$ packet is generated from tight Cauchy evidence, a regular Cauchy tightening row, a CauchyModulus threshold schedule, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance rows, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopTightCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6442.1 and Definition 6442.2 seed the finite Bishop tight Cauchy criterion between tight Cauchy evidence and regular Cauchy readback.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopTightCauchyCriterion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, trichotomy on real names, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tight-tail stability, regular-readback transport, RealUp seal nonescape, and completion-consumer handoff for BEDC.Derived.BishopTightCauchyCriterionUp.

Chapter 6443

A Concrete Naming Certificate for BishopFiniteIntervalChain$^{\uparrow}$

Following Bishop and Bridges, the BishopFiniteIntervalChain$^{\uparrow}$ packet records the finite interval-chain carrier used when compact interval arguments reduce a cover request to adjacent endpoint checks and refinement over a displayed list. It sits after the dyadic interval arithmetic of chapter 1645, the real interval enclosure rows of chapter 1625, and the compact-cover Lebesgue ledger of chapter 1302. The packet is a finite NameCert surface for interval-chain reasoning; it is not open-cover compactness, a selected subcover, countable choice, quotient real equality, or ambient completeness of Real$^{\uparrow}$.

Definition 6443.1 (Bishop finite interval chain carrier)**.** *A* BishopFiniteIntervalChain$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (E, A, R, M, I, H, C, P, N)$$

with the following displayed rows:

1. *E is the endpoint-interval row. It records the finite list of located endpoint intervals, their dyadic endpoint readbacks, and the real interval-enclosure seals inspected by the chain.*
2. *A is the adjacency and overlap row. It records, for each consecutive pair, the displayed nonempty overlap or endpoint contact certificate that lets a local cover row pass to the next interval.*
3. *R is the refinement-map row. It records the finite monotone map from a coarse interval chain to a finer chain and the endpoint containment certificates for every refined cell.*
4. *M is the cover-membership row. It records the named cover packet, the interval cell named by each cover row, and the finite witness that every inspected point of the chain lies in one displayed member.*
5. *I is the finite induction row. It records the base cell, the successor transport along adjacency, and the terminal interval claim produced by primitive recursion over the chain.*
6. *H stores componentwise* hsame *transport for endpoint intervals, adjacency and overlap rows, refinement maps, cover membership, finite induction, replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay for the same interval-chain route.*
8. *P is the* Pkg *provenance over* BishopFiniteIntervalChain$^{\uparrow}$, DyadicIntervalArithmetic$^{\uparrow}$, RealIntervalEnclosure$^{\uparrow}$, CompactCoverLebesgueLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopFiniteIntervalChain}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the displayed tuple $E, A, R, M, I, H, C, P, N$. It has no coordinate for an external open-cover compactness theorem, a selected subcover, countable choice, quotient real equality, trichotomy on real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6443.2 (Bishop finite interval chain NameCert obligations)**.** *For every accepted* BishopFiniteIntervalChain *carrier $Q = (E, A, R, M, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopFiniteIntervalChain}^{\uparrow}}$ *obligations are exactly carrier admission, endpoint-interval stability, adjacency and overlap transport, refinement-map exactness, cover-membership locality, finite induction replay, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 6443.1. The accepted packet displays endpoint intervals, adjacency and overlap certificates, refinement maps, cover-membership rows, finite induction data, and the structural rows H, C, P, N.

Endpoint-interval stability is read from E together with the dyadic and real interval enclosure rows named in P. Transport by H preserves the same endpoint readbacks and enclosure seals, so no quotient equality or external real-completeness principle is introduced.

Adjacency and refinement obligations are carried by A and R. Each successor step has a displayed overlap or endpoint-contact certificate, and each refined cell has a displayed containment certificate in its coarse ancestor. These rows make the chain handoff finite.

Cover locality is supplied by M, while finite induction is supplied by I. The base interval opens the first cover row, the successor clause moves across the displayed adjacency certificate, and primitive recursion over the finite chain reaches the terminal interval claim.

Finally C, P, N replay, source, and name the same finite route. Since the carrier has no further coordinate, every local NameCert obligation is one of the listed rows. □

Theorem 6443.3 (Bishop finite interval chain refinement induction)**.** *Every accepted* $\mathsf{BishopFiniteIntervalChain}^{\uparrow}$ *refinement request factors through the finite route*

$$E, A \longmapsto R, M \longmapsto I, H, C, P, N.$$

Thus any interval-chain cover argument that consumes the packet must inspect endpoint intervals and adjacent overlaps before it can replay refinement, cover membership, and induction over the chain.

Proof. Begin with an accepted carrier $Q = (E, A, R, M, I, H, C, P, N)$. The source stage is E, A: the endpoint row fixes the finite interval list, and the adjacency row records the overlap or endpoint-contact certificates for consecutive cells.

The refinement stage is R, M. The refinement map can only split a displayed cell into finitely many contained subcells, and the cover-membership row records which named cover packet accepts each inspected cell.

The induction stage is I. Its base clause opens the first interval row, while its successor clause transports the local cover statement across the displayed adjacency or overlap certificate. Primitive recursion over the finite chain therefore supplies the terminal claim without selecting a subcover outside the packet.

The final rows H, C, P, N transport, replay, source, and name the same data. The route cannot produce open-cover compactness, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness because none of those objects appears in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFiniteIntervalChain}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFiniteIntervalChain}^{\uparrow}$ packet is generated from endpoint interval rows, adjacency and overlap certificates, refinement maps, cover-membership rows, finite induction over the chain, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFiniteIntervalChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6443.1, Definition 6443.2, and Definition 6443.3 seed the finite interval-chain route used by compact interval and finite-cover arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFiniteIntervalChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, quotient real equality, trichotomy on real names, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-interval stability, adjacency and overlap transport, refinement-map exactness, cover-membership locality, finite induction replay, transport, replay, provenance, and local naming for BEDC.Derived.BishopFiniteIntervalChainUp.

Chapter 6444

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusBridge}^{\uparrow}$

Following Bishop and Bridges compact metric analysis, the $\mathsf{CompactUniformModulusBridge}^{\uparrow}$ packet records the bridge from compact finite-net data and pointwise continuity rows to the $\mathsf{UniformModulus}^{\uparrow}$ output surface named in chapter 9237. It consumes the compact source of chapter 60, the continuity rows of chapter 59, the rational fold interface of chapter 619, the uniform-modulus packet of chapter 369, and the existing compact uniform modulus carrier of chapter 2299. The packet names the bridge ledger itself; it is not a selected Lebesgue number, a host modulus function, sequential compactness, countable choice, or ambient completeness of the metric carrier.

Definition 6444.1 (Compact uniform modulus bridge carrier)**.** *A* $\mathsf{CompactUniformModulusBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, K, F, T, P, R, L, U, H, C, G, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row shared by the compact and continuous certificates.*
2. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row, including the displayed finite* $\mathsf{ProbeBundle}$ *of centers and coverage radii.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row over the same metric source.*
4. *T is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance request read by the downstream uniform-modulus consumer.*
5. *P is the finite probe-classifier row that lists the center names, local radii, and pointwise-modulus certificates opened by K and F.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row over the finite radius ledger carried by P.*
7. *L is the bridge ledger joining X, K, F, T, P, R to the terminal* $\mathsf{UniformModulus}^{\uparrow}$ *row.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row exposed only after the bridge ledger has replayed the finite fold and the metric triangle estimates.*
9. *H stores componentwise* hsame *transport for the metric source, compact finite net, continuity row, rational tolerance, probe classifier, rational fold, bridge ledger, uniform-modulus output, replay, provenance, and local naming.*
10. *C stores displayed* Cont *replay for the same bridge route.*

11. *G is the* Pkg *provenance over* $\mathsf{CompactUniformModulusBridge}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, F, T, P, R, L, U, H, C, G, N$. It has no coordinate for selected subcovers, selected Lebesgue numbers, host minima, sequence extraction, countable choice, quotient metric equality, or ambient completeness.

Theorem 6444.2 (Compact uniform modulus bridge NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusBridge}^{\uparrow}$ *carrier $B = (X, K, F, T, P, R, L, U, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformMo}}$ *obligations are exactly carrier admission, metric-source lock, compact finite-net coverage, pointwise-modulus binding, finite probe classifier admission, rational lower-bound fold exactness, bridge-ledger replay, uniform-modulus output admission, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from selected compactness or completeness principles.*

Proof. Carrier admission is projection from Definition 6444.1. The packet displays the metric row X, compact row K, continuity row F, rational tolerance T, probe classifier P, rational fold R, bridge ledger L, output row U, and structural rows H, C, G, N.

The source lock is carried by X, K, F. The compact row and continuity row are read over the same metric source before any probe classifier is opened, so the bridge cannot mix finite nets and pointwise moduli from different carriers.

Finite coverage and pointwise-modulus binding are carried by K, F, P. Each bundled center has a displayed coverage row and a displayed pointwise-modulus row, and the classifier only sees those finite entries.

The lower-bound computation is carried by R and replayed by L. Since R is a finite $\mathsf{Rat}^{\uparrow}$ fold over the displayed probe ledger, the bridge has no host minimum selector or selected Lebesgue-number coordinate.

Finally U, H, C, G, N expose, transport, replay, source, and name the same route. Row exhaustion rules out selected subcovers, sequence extraction, choice, quotient metric equality, and ambient completeness. □

Theorem 6444.3 (Compact uniform modulus finite ProbeBundle bridge)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read exported by an accepted* $\mathsf{CompactUniformModulusBridge}^{\uparrow}$ *carrier factors through the finite route*

$$X, K, F, T \longmapsto P, R, L \longmapsto U, H, C, G, N.$$

Thus the bridge first reads the common metric source, compact finite net, continuous pointwise-modulus rows, and rational tolerance; then folds the displayed ProbeBundle *radius ledger; and only then exposes the tolerance-only uniform-modulus output.*

Proof. Begin with an accepted carrier $B = (X, K, F, T, P, R, L, U, H, C, G, N)$. The input stage is X, K, F, T: the common metric source is fixed before the compact finite net, continuity row, and rational tolerance are read.

The finite classifier stage is P, R, L. The probe row lists only finitely many bundled centers and radius entries, the rational row folds those displayed entries, and the bridge ledger records the replay from the finite fold to the output route.

The terminal stage is U, H, C, G, N. The uniform-modulus row is public only after the finite bridge ledger has been displayed, and the structural rows transport and name that same ledger.

Because the carrier has no row for a selected subcover, selected Lebesgue number, host minimum, sequence extraction, countable choice, quotient metric equality, or ambient completeness theorem, every exported read remains inside the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusBridge}\uparrow}$.

Constructive story: A $\mathsf{CompactUniformModulusBridge}^{\uparrow}$ packet is generated from a MetricUp source, CompactUp finite-net rows, ContinuousUp pointwise-modulus rows, a RatUp tolerance, a finite ProbeBundle classifier, a RatUp lower-bound fold, a bridge ledger, a UniformModulusUp output, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusBridge}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6444.1, Definition 6444.2, and Definition 6444.3 seed the finite bridge from compact finite-net and pointwise-continuity rows to a uniform-modulus output.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusBridge}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected Lebesgue numbers, selected subcovers, sequence extraction, host modulus functions, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source lock, compact finite-net coverage, pointwise-modulus binding, finite probe classifier admission, rational fold exactness, bridge-ledger replay, uniform-modulus output admission, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusBridgeUp.

Chapter 6445

Sobolev trace boundary NameCert construction

Following Adams–Fournier on Sobolev spaces and Evans on PDE boundary traces, the $\mathsf{SobolevTraceBoundary}^{\uparrow}$ packet records finite BEDC boundary trace data rather than a host trace theorem. It sits beside the Sobolev source of chapter 5911, the trace packet of chapter 3647, the embedding packet of chapter 2217, the compact witness of chapter 60, and the complete-metric readback surface of chapter 128.

Definition 6445.1 (Sobolev trace boundary package)**.** *A* $\mathsf{SobolevTraceBoundary}^{\uparrow}$ *package is a finite* BHist *packet*

$$Q = (S, B, T, K, M, X, H, C, P, N)$$

with the following displayed rows:

1. *S is the interior Sobolev carrier row, read from* $\mathsf{SobolevSpace}^{\uparrow}$ *or the Sobolev source row named by chapter 5911.*
2. *B is the boundary carrier row. It records the displayed boundary chart, collar, normal-window, or finite boundary-read ledger on which trace values are inspected.*
3. *T is the trace operator row. It is only the finite trace-read arrow from the interior Sobolev row to the boundary carrier row; it is not an ambient operator on a completed quotient space.*
4. *K is the compact boundary window row, read through chapter 60 and the compact-facing Sobolev neighbour chapter 2217.*
5. *M is the complete-metric readback row, exposing the displayed Cauchy and distance checks supplied by chapter 128.*
6. *X is the classifier row. It distinguishes interior-source reads, boundary-carrier reads, compact-window reads, and complete-metric readbacks, but has no coordinate for a host extension theorem or quotient boundary class.*
7. *H stores componentwise* hsame *transport for S, B, T, K, M, X and the structural rows.*
8. *C stores the displayed* Cont *replay from a boundary-trace request through the interior Sobolev row, the trace row, the compact boundary window, and the complete-metric readback row.*
9. *P is the* Pkg *provenance over* $\mathsf{SobolevTraceBoundary}^{\uparrow}$, $\mathsf{SobolevSpace}^{\uparrow}$, $\mathsf{SobolevTrace}^{\uparrow}$, $\mathsf{SobolevEmbedding}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SobolevTraceBoundary}^{\uparrow}}$ *row.*

The package exports a finite boundary-readback bridge for consumers of Sobolev trace theory. It does not include a selected extension operator, an unrestricted trace theorem, quotient equality of boundary functions, or ambient compactness.

Lean4 ✓ `BEDC.Derived.SobolevTraceBoundaryUp.SobolevTraceBoundaryTasteGate single carrier alignment`

Theorem 6445.2 (Sobolev trace boundary exactness)**.** *For every accepted* $\mathsf{SobolevTraceBoundary}^{\uparrow}$ *package* $Q = (S, B, T, K, M, X, H, C, P, N)$*, each accepted consumer reads the interior Sobolev row* S *before the trace row* T*. Boundary readback is reachable only through the compact boundary window* K *and the complete-metric row* M*, with* H, C, P, N *preserving and naming that same finite route.*

Proof. Project the accepted package. The carrier order exposes S as the only interior Sobolev source row, so every trace request must enter through S before it can read T.

The boundary row B supplies the displayed boundary carrier, but it does not by itself export a boundary value. The trace row T merely routes the request from the already-read interior row to the displayed boundary carrier.

The readback rows are K and M. Thus a consumer reaches a boundary value only after the compact boundary window and complete-metric Cauchy readback have been fixed.

Finally H, C, P, N transport, replay, source, and name the same row order. Since the classifier row has no host extension, quotient boundary class, or ambient compactness coordinate, no accepted consumer can bypass S, T, K, M. □

Theorem 6445.3 (Sobolev trace finite replay)**.** *The* $\mathsf{SobolevTraceBoundary}^{\uparrow}$ *package exports finite replay data for boundary trace reads. It does not export a host trace theorem, unrestricted extension operator, quotient boundary class, selected boundary representative, or ambient compactness theorem.*

Proof. The replay surface is the displayed Cont row C together with the provenance and naming rows P, N. These rows can replay only the finite route through S, B, T, K, M, X, H.

The compact information is confined to K, and the metric information is confined to M. Therefore replay can cite compact-window and complete-metric readback data, but it cannot manufacture a host compactness theorem or a global completion theorem.

The classifier row X excludes extension operators, quotient boundary classes, and selected representatives from the package coordinates. Hence the exported object is exactly finite replay data for the named boundary-readback route. □

Falsifiable prediction: Every $\mathsf{SobolevTraceBoundary}^{\uparrow}$ boundary-readback consumer reads displayed SobolevSpaceUp, SobolevTraceUp, SobolevEmbeddingUp, CompactUp, CompleteMetricUp, BHist, hsame, Cont, Pkg, and NameCert rows before receiving a boundary trace value.

Independence witness: sobolev-space, sobolev-trace, sobolev-embedding, compact, complete-metric: $\mathsf{SobolevTraceBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an interior Sobolev row, boundary carrier, trace-read row, compact boundary window, complete-metric readback, classifier, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevTraceBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SobolevTraceBoundary}^{\uparrow}$ packet is generated from an interior Sobolev carrier row, boundary carrier row, trace-read row, compact boundary window, complete-metric readback row, classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SobolevTraceBoundary}\uparrow}$, seed)

Scope closed: Definition 6445.1, Definition 6445.2, and Definition 6445.3 seed the finite boundary-readback bridge over Sobolev space, Sobolev trace, Sobolev embedding, compact, and complete-metric neighbours.

Formal verification: FormalStatus(NameCert$_{\mathsf{SobolevTraceBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host trace theorem, unrestricted extension operator, quotient boundary class, selected representative, ambient compactness theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trace-row ordering, compact boundary window exactness, complete-metric readback, classifier nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SobolevTraceBoundaryUp.

Chapter 6446

A Concrete Naming Certificate for $\mathsf{LocatedIntervalArithmetic}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedIntervalArithmetic}^{\uparrow}$ packet records finite interval arithmetic over located real endpoints while keeping every endpoint, tolerance, and enclosure read inside displayed BEDC rows. It sits after the dyadic endpoint core of chapter 291, the regular-rational readback route of chapter 301, the terminal real-name seal of chapter 38, the endpoint-plus-radius carrier of chapter 1709, and the real interval arithmetic packet of chapter 1969. The packet gives L10 Real and Completion arguments one finite enclosure service for located endpoint operations; it is not a quotient interval type, a trichotomy service, a selected-limit construction, an ambient completeness theorem, or a host interval algebra.

Definition 6446.1 (Located interval arithmetic carrier)**.** *A* $\mathsf{LocatedIntervalArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, J, D, R, Q, E, +_\ell, \cdot_\ell, W, H, C, P, N)$$

with the following displayed rows:

1. *I and J are input interval rows accepted by* $\mathsf{LocatedRealInterval}^{\uparrow}$*, exposing lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, radius rows, locator reads, and locatedness moduli.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger. It records the dyadic tolerances, endpoint probes, outward comparison rows, and scale refinements consumed by the interval operation.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint windows selected from I, J, D.*
4. *Q is the* $\mathsf{RealIntervalArithmetic}^{\uparrow}$ *enclosure row that packages the corresponding real-interval operation over the same displayed endpoint data.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached by every exported endpoint and every width claim.*
6. *$+_\ell$ is the located addition row, whose output interval enclosure is obtained from the displayed endpoint sums, dyadic tolerance ledger, regular-rational readback, and real enclosure row.*
7. *$\cdot_\ell$ is the located multiplication row, whose output interval enclosure is obtained from displayed endpoint products, outward comparison rows, dyadic tolerance ledger, regular-rational readback, and real enclosure row.*
8. *W is the finite-width witness row. It records the requested enclosure width and the displayed tolerance route that bounds the exported interval.*

9. *H records componentwise* hsame *transport for the input intervals, dyadic ledger, regular-rational readback, real interval enclosure, real seal, operation rows, width witness, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a requested located interval operation through $I, J, D, R, Q, E, +_\ell, \cdot_\ell, W, H, P$*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalArithmetic}^\uparrow$, $\mathsf{LocatedRealInterval}^\uparrow$, $\mathsf{RealIntervalArithmetic}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalArithmetic}^\uparrow}$ *row.*

The carrier predicate asserts exactly that these rows form one finite located interval-operation packet. It has no coordinate for quotient interval equality, endpoint trichotomy, countable choice, selected limits, ambient $\mathsf{Real}^\uparrow$ *completeness, host interval algebra, or detached real representatives.*

Theorem 6446.2 (Located interval arithmetic NameCert obligations)**.** *For every accepted* LocatedIntervalArithmeti *carrier*

$$A = (I, J, D, R, Q, E, +_\ell, \cdot_\ell, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalArithmetic}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two located real interval inputs, dyadic endpoint ledger, regular-rational readback, real interval enclosure row, real seal, located addition row, located multiplication row, width witness, and structural rows H, C, P, N;*
2. *endpoint route exactness, requiring each exported endpoint to originate in the displayed* $\mathsf{LocatedRealInterval}^\uparrow$ *inputs and to pass through D, R, Q, E before any Real or Completion consumer reads it;*
3. *dyadic tolerance stability, requiring D to be the only source of endpoint tolerances, outward comparisons, and scale refinements consumed by the operation rows;*
4. *regular-rational readback stability, requiring R to expose the same finite endpoint windows that D and the input interval rows display;*
5. *operation enclosure soundness, requiring $+_\ell$ and $\cdot_\ell$ to preserve located interval containment through the displayed endpoint arithmetic, tolerance ledger, readback row, and real enclosure row;*
6. *seal non-escape, requiring E to be the only* $\mathsf{Real}^\uparrow$ *handoff for exported endpoints and width claims;*
7. *transport and replay stability, requiring H and C to preserve the input interval rows, dyadic ledger, readback row, real enclosure row, seal, operation rows, width witness, provenance, and local name componentwise;*
8. *exclusion, ruling out quotient interval equality, endpoint trichotomy, countable choice, selected limits, ambient* $\mathsf{Real}^\uparrow$ *completeness, host interval algebra, and detached real representatives as local data.*

No located interval arithmetic obligation is stored outside these rows.

Proof. Project the carrier of Definition 6446.1. The projection exposes exactly the two located real interval inputs, the dyadic endpoint ledger, regular-rational readback, real interval enclosure row, real seal, operation rows, width witness, and structural rows.

Endpoint route exactness is the displayed chain

$$I, J \longmapsto D \longmapsto R \longmapsto Q \longmapsto E.$$

The input intervals supply the located endpoint rows, the dyadic ledger supplies tolerances and outward comparisons, the regular-rational row supplies the finite endpoint readback, the real interval arithmetic row packages the enclosure, and the seal row is the only terminal Real handoff.

Dyadic tolerance stability and regular-rational readback stability are read from D and R. The operation rows can inspect endpoint windows only through those two rows, so they cannot substitute a host endpoint comparison or an unrelated real representative.

Operation enclosure soundness is supplied by $+_\ell$ and $\cdot_\ell$. Addition reads displayed endpoint sums, while multiplication reads displayed endpoint products and outward comparison rows; both operations then pass through Q, E, W before any consumer receives the enclosure.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier inventory contains no quotient interval equality, endpoint trichotomy, countable-choice selector, selected limit, ambient Real completeness theorem, host interval algebra, or detached real representative, none of those objects can be exported. □

Theorem 6446.3 (Located interval arithmetic Real-seal non-escape)**.** *Every exported endpoint, width claim, addition enclosure, or multiplication enclosure of an accepted* $\mathsf{LocatedIntervalArithmetic}^{\uparrow}$ *carrier factors through the displayed route*

$$I, J \longmapsto D \longmapsto R \longmapsto Q \longmapsto E \longmapsto +_\ell, \cdot_\ell, W \longmapsto H, C, P, N.$$

Consequently every downstream $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or Completion consumer receives only the located interval enclosure displayed by the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *inputs,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{RealIntervalArithmetic}^{\uparrow}$ *enclosure row. The consumer cannot replace this route by quotient interval equality, endpoint trichotomy, countable choice, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host interval algebra, or a detached real representative.*

Proof. Start with an accepted carrier $A = (I, J, D, R, Q, E, +_\ell, \cdot_\ell, W, H, C, P, N)$. The only interval inputs are the two $\mathsf{LocatedRealInterval}^{\uparrow}$ rows I and J, so every exported operation begins with displayed located real endpoints and radius data.

The dyadic ledger D records the tolerances, endpoint probes, outward comparisons, and scale refinements. The readback row R exposes the regular-rational endpoint windows that those dyadic rows select.

The real interval arithmetic row Q packages the corresponding enclosure over the same endpoints. The seal row E is then the only route into $\mathsf{Real}^{\uparrow}$, so endpoint and width claims cannot bypass the displayed real-name surface.

For addition, project $+_\ell$ and read the output enclosure from the displayed endpoint sums, tolerance ledger, readback, and real enclosure row. For multiplication, project $\cdot_\ell$ and read the output enclosure from displayed endpoint products, outward comparisons, tolerance ledger, readback, and real enclosure row. The width witness W records the finite tolerance route used by both operations.

Componentwise transport and displayed replay through H and C, together with provenance and local naming in P, N, preserve the same route for downstream consumers. Therefore every exported read is exhausted by the displayed finite packet and no excluded quotient, order, choice, limit, completeness, host-algebra, or detached-representative coordinate is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalArithmetic}^{\uparrow}}$.

Constructive story: A LocatedIntervalArithmetic$^{\uparrow}$ packet is generated from two LocatedRealInterval input rows, a DyadicRatCore endpoint tolerance ledger, a RegSeqRat readback row, a RealIntervalArithmetic enclosure row, a terminal RealUp seal, displayed located addition and multiplication rows, a finite-width witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedIntervalArithmetic}^{\uparrow}}$, seed)

Scope closed: Definition 6446.1, Definition 6446.2, and Definition 6446.3 seed the finite located interval arithmetic enclosure packet over LocatedRealInterval, DyadicRatCore, RegSeqRat, RealIntervalArithmetic, and RealUp consumers.

Formal verification: FormalStatus(NameCert$_{\text{LocatedIntervalArithmetic}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient interval equality, endpoint trichotomy, countable choice, selected limits, ambient Real$^{\uparrow}$ completeness, host interval algebra, detached real representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint route exactness, dyadic tolerance stability, regular-rational readback stability, operation enclosure soundness, Real-seal non-escape, transport/replay/provenance coverage, and exclusion for BEDC.Derived.LocatedIntervalArithmeticUp.

Chapter 6447

A Concrete Naming Certificate for $\mathsf{FittingIdeal}^{\uparrow}$

Following Eisenbud and Bourbaki, the $\mathsf{FittingIdeal}^{\uparrow}$ packet records the finite presentation-matrix route by which a finitely presented module exposes its Fitting ideals through generated minor ledgers. The certificate reads rows for the chosen presentation, displayed matrix entries, finite minors, generated ideal handoff, module transport, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert naming. It is not a host commutative-algebra oracle, a hidden determinant computation, or an equality principle for all presentations.

The coefficient row is read through chapter 43, the finitely presented module row is read through chapter 46, and the generated-minor handoff is read through chapter 81. These are substantive carrier dependencies: the packet exposes the displayed algebraic rows used by the minor ledger, not a host commutative-algebra oracle.

Definition 6447.1 (FittingIdeal carrier)**.** *A* $\mathsf{FittingIdeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, M, P, A, I, G, T, H, C, Q, N)$$

with the following rows:

1. *R is the coefficient-ring row used only as displayed scalar data;*
2. *M is the finitely presented module row;*
3. *P is the finite presentation row $R^m \to R^n \to M$;*
4. *A is the displayed presentation matrix with finite row and column ledgers;*
5. *I is the generated-minor ledger, listing the minors of the required size and their finite determinant expansions;*
6. *G is the ideal handoff row generated by the minor ledger I;*
7. *T is the module-transport row recording how a permitted presentation change is read before the ideal handoff is reused;*
8. *H records componentwise* hsame *transport for ring, module, presentation, matrix, minor, ideal, and transport rows;*
9. *C records displayed* Cont *replay from presentation rows to minors and from minors to the ideal handoff;*

10. *Q is the* Pkg *provenance over the algebraic rows,* BHist, hsame, Cont, *and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FittingIdeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient ideal-equality oracle, a presentation-independent quotient proof outside T, H, C, Q, N, an infinite determinant family, or a host module category.

Theorem 6447.2 (FittingIdeal minor-ledger obligations)**.** *For every accepted* $\mathsf{FittingIdeal}^{\uparrow}$ *carrier $F = (R, M, P, A, I, G, T, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FittingIdeal}^{\uparrow}}$ *surface consists exactly of carrier admission, finite presentation exposure, generated-minor ledger exposure, ideal handoff through G, module transport through T, componentwise* hsame *transport through H, displayed replay through C, provenance through Q, and local naming through N. A public Fitting-ideal read must pass through those rows before it may cite the generated ideal.*

Proof. Project the accepted packet. The ring, module, presentation, matrix, generated-minor ledger, ideal handoff, and module-transport rows are displayed coordinates of the finite carrier.

The generated ideal is read only from G after the minor ledger I has been exposed. The determinant expansions in I are finite rows over the matrix A, so the handoff never invokes an unbounded determinant family.

Presentation transport is confined to T, H, C, Q, N. These rows record how the presentation change is transported, replayed, sourced, and named before the ideal handoff is reused by a consumer.

Since the carrier has no ambient ideal-equality oracle, no hidden presentation-independent quotient proof, and no host module category coordinate, the listed rows exhaust the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{FittingIdeal}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FittingIdeal}^{\uparrow}}$, seed)

Scope closed: Definition 6447.1 and Definition 6447.2 seed the finite presentation-matrix, minor-ledger, ideal-handoff, module-transport, and local naming surface for Fitting ideals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FittingIdeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host ideal equality, all-presentation invariance, external commutative-algebra completeness, or a host module category.

Upgrade path: Obligation closure requires checked carrier admission, minor-ledger exactness, ideal handoff locality, module-transport stability, and consumer non-escape for BEDC.Derived.FittingIdealUp.

Constructive story: A $\mathsf{FittingIdeal}^{\uparrow}$ packet is generated from a coefficient-ring row, finitely presented module row, finite presentation matrix, generated-minor ledger, ideal handoff row, module transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 6448

A Concrete Naming Certificate for AlternativeCodeReassignmentSpectra$^{\uparrow}$

The AlternativeCodeReassignmentSpectra$^{\uparrow}$ packet realizes the comparative reassignment-spectra vision of Definition 9462.1208 as a finite science-facing NameCert target. It refines the comparison-table carrier of chapter 3589, reads Walsh and median-closure spectral rows through chapter 3897, keeps the decoded biological bridge explicit through chapter 5177, and routes support-family evidence through chapter 4079. The packet is a finite support, reassignment, spectral, transport, replay, provenance, and local naming surface; it is not a biological mechanism theorem or an exhaustive genetic-code survey.

Definition 6448.1 (Alternative-code reassignment spectra carrier)**.** *An* AlternativeCodeReassignmentSpectra$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, R, W, E, T, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the sparse support row over the* 13 *displayed reassigned codons and their module ledger;*
2. *R is the alternative-code reassignment row, reading standard-table and curated alternative-table comparison through* AlternativeCodeReassignment$^{\uparrow}$*;*
3. *W is the spectral row, recording Walsh, median-closure, and local module spectrum data from the reassignment-spectral-compression vision;*
4. *E is the support-nerve realization row, tying the reassignment support to a finite boundary-subcomplex read;*
5. *T is the transport row from channel-genetic-code bridge data to codon-window and reassignment rows;*
6. *L is the replay row that orders support exposure, reassignment comparison, spectral readback, support-nerve realization, and local naming;*
7. *H records componentwise* hsame *transport for all displayed support, reassignment, spectral, bridge, realization, replay, provenance, and naming rows;*
8. *C records displayed* Cont *replay for the same route;*
9. *P is the* Pkg *provenance over the source vision, sibling concrete-instance packets,* BHist, hsame, Cont, *and* NameCert*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}}$ *row.*
The carrier has no coordinate for uncurated code-table enumeration, biological causality, probabilistic fitness, quotient codon semantics, or a hidden spectral-analysis oracle.

Theorem 6448.2 (Alternative-code reassignment spectra NameCert obligations)**.** *For every accepted* $\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}$ *packet* $A = (S, R, W, E, T, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}}$ *surface consists exactly of support admission through* S*, reassignment comparison through* R*, spectral readback through* W*, support-nerve realization through* E*, channel-to-codon transport through* T*, ordered replay through* L, C*, componentwise* hsame *transport through* H*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted packet. The support row S and reassignment row R expose the finite comparative table data before any spectrum is read.

The spectral row W is downstream from that displayed support. It records Walsh and median-closure information as finite row data and cannot introduce a host Fourier-analysis oracle or uncurated biological table family.

The rows E, T, L, H, C, P, N bind the support-nerve, bridge, replay, transport, provenance, and local naming route. Since all consumer reads pass through these displayed rows, the NameCert surface is exactly the finite packet surface and not a claim of biological mechanism, exhaustive coverage, or quotient codon semantics. □

The Lean follow-up for this packet must provide `Nontrivial` and `FieldFaithful` instances in `BEDC/Derived/AlternativeCodeReassignmentSpectraUp/TasteGate.lean` before a checked local TasteGate can support the carrier.

Falsifiable prediction: Every accepted $\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}$ read displays support, reassignment, spectral, transport, replay, provenance, and local naming rows; a read that reaches a spectral conclusion without any one of those rows refutes the packet.

Independence witness: alternative-code-reassignment, reassignment-spectral-compression, channel-genetic-code-bridge, support-nerve-realization: none is bijective with $\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}$ because this packet jointly carries sparse support, comparative reassignment, Walsh and median-closure spectral rows, channel-to-codon transport, support-nerve realization, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}$ packet is generated from sparse reassignment support rows, alternative-code comparison rows, spectral readback rows, support-nerve realization rows, channel-to-codon transport, ordered replay, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}}$, seed)

Scope closed: Definition 6448.1 and Definition 6448.2 seed the finite support, reassignment, spectral, transport, replay, provenance, and naming surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AlternativeCodeReassignmentSpectra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological causality, exhaustive genetic-code coverage, probabilistic fitness, quotient codon semantics, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, support exposure, reassignment comparison, spectral readback, support-nerve realization, transport stability, replay provenance, Nontrivial AlternativeCodeReassignmentSpectraUp, and FieldFaithful AlternativeCodeReassignmentSpectraUp for BEDC.Derived.AlternativeCodeReassignmentSpectraUp.

Chapter 6449

A Concrete Naming Certificate for $\mathsf{AsymptoticDimension}^{\uparrow}$

Following Gromov and Roe-style coarse geometry, the $\mathsf{AsymptoticDimension}^{\uparrow}$ packet records asymptotic dimension as finite uniformly bounded cover families indexed by displayed scale rows, rather than as an ambient large-scale invariant over a completed category of metric spaces. It reads metric data from chapter 57, proper closed-ball discipline from **??**, entourage-style scale transport from chapter 339, and quasi-isometry-facing stability from chapter 3883. The carrier names exactly the finite rows that downstream coarse consumers can replay.

Definition 6449.1 (AsymptoticDimension carrier)**.** *An* $\mathsf{AsymptoticDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, S, U, M, T, R, P, N)$$

with the following displayed rows:

1. *X is the metric source row, read through the* $\mathsf{Met}^{\uparrow}$ *surface and its proper-metric closed-ball boundary when boundedness is inspected;*
2. *S is a finite list of scale requests, each a displayed positive radius row over the same metric source;*
3. *U assigns to each scale row a finite uniformly bounded cover family, with every cover member carrying a visible diameter bound and membership readback;*
4. *M assigns to each scale row the finite multiplicity ledger proving that every scale ball meets at most the displayed number of cover rows;*
5. *T records the componentwise* hsame *transport of the metric source, scale rows, cover families, diameter bounds, and multiplicity ledgers;*
6. *R records the displayed* Cont *replay route for reading the cover and multiplicity rows in downstream coarse consumers;*
7. *P is the* Pkg *provenance over* $\mathsf{AsymptoticDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{QuasiIsometry}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{AsymptoticDimension}^{\uparrow}}$ *row.*

The carrier is only this finite packet. It does not select an infinite family of covers, construct a quotient coarse category, import choice-selected Lebesgue numbers, or assert host invariance under all quasi-isometries.

Theorem 6449.2 (AsymptoticDimension NameCert obligations)**.** *For every accepted* $\mathsf{AsymptoticDimension}^{\uparrow}$ *carrier* $A = (X, S, U, M, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AsymptoticDimension}^{\uparrow}}$ *surface consists of carrier admission, scale-row coverage, uniform boundedness for each displayed cover family, finite multiplicity for each displayed scale row, componentwise transport, replay through the displayed continuation rows, provenance over the metric/proper/uniform/quasi-isometry dependency surface, and the local naming row. No obligation exports a selected global cover sequence, quotient metric-space equality, open-cover compactness principle, or ambient coarse category.*

Proof. Carrier admission is projection from Definition 6449.1. The accepted packet exposes the metric source, finite scale schedule, uniformly bounded cover rows, multiplicity rows, transport, replay, provenance, and local name.

For each scale row in S, use finite induction over the displayed cover family in U. The base case reads the empty prefix and its vacuous multiplicity ledger; the successor step adds one bounded cover row, its diameter witness, and the corresponding membership readback.

Multiplicity is checked by a second finite induction over the cover rows meeting a displayed scale ball. The ledger M counts only those visible rows and therefore cannot smuggle in an open-cover compactness theorem or a choice-selected subcover.

Finally transport and replay are row projections. The rows T and R preserve the same metric source, scale request, cover family, and multiplicity ledger, while P and N source and name that finite surface. □

Theorem 6449.3 (AsymptoticDimension quasi-isometry handoff)**.** *Every quasi-isometry-facing consumer of an accepted* $\mathsf{AsymptoticDimension}^{\uparrow}$ *carrier must read the source metric row, finite scale schedule, uniformly bounded cover family, and finite multiplicity ledger before it may hand the packet to* $\mathsf{QuasiIsometry}^{\uparrow}$*. The handoff preserves the displayed cover and multiplicity rows under* hsame *transport and* Cont *replay, but it exports no host proof that asymptotic dimension is invariant under all quasi-isometries, no selected coarse inverse, and no quotient equality of metric spaces.*

Proof. Project $A = (X, S, U, M, T, R, P, N)$. The only coarse data visible to the consumer are the metric source, scale rows, cover families, and multiplicity ledgers.

Read the quasi-isometry dependency through the provenance row P. It points to the existing $\mathsf{QuasiIsometry}^{\uparrow}$ surface only after the metric, properness, and uniform-scale rows have already been displayed.

Transport stability is componentwise. The row T moves scale, cover, and multiplicity data together, and R replays that same route for a downstream quasi-isometry consumer.

Thus the handoff is a finite NameCert route. Any full invariance theorem, selected inverse, quotient metric equality, or external coarse category must be supplied elsewhere and is not contained in this packet. □

Falsifiable prediction: An accepted $\mathsf{AsymptoticDimension}^{\uparrow}$ read is refuted if a consumer obtains a dimension bound without displaying the metric source, finite scale rows, uniformly bounded cover families, finite multiplicity ledgers, transport, replay, provenance, and local naming rows.

Independence witness: metric, propermetric, uniformspace, quasi-isometry: none is bijective to $\mathsf{AsymptoticDimension}^{\uparrow}$ because this packet jointly carries scale-indexed uniformly bounded covers and multiplicity ledgers for a coarse dimension read.

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticDimension}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AsymptoticDimension}^{\uparrow}$ packet is generated from a metric source row, finite scale requests, uniformly bounded cover families, finite multiplicity ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{AsymptoticDimension}\uparrow}$, seed)

Scope closed: Definition 6449.1, Definition 6449.2, and Definition 6449.3 seed the finite coarse-dimension certificate over displayed metric, scale, cover, multiplicity, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{AsymptoticDimension}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close a Lean implementation, quasi-isometry invariance for all metric spaces, quotient coarse categories, selected cover sequences, open-cover compactness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite cover boundedness, finite multiplicity exactness, transport replay, provenance, and quasi-isometry handoff for BEDC.Derived.AsymptoticDimensionUp.

Chapter 6450

A Concrete Naming Certificate for $\mathsf{LocatedRealApartness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedRealApartness}^{\uparrow}$ packet records apartness of real names as a positive finite witness rather than as a trichotomy decision. It sits over the dyadic tolerance surface of chapter 291, the finite stream-window route of chapter 126, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, the apartness-to-order bridge of chapter 1905, and the located-order packet of chapter 3640. The chapter names the constructive apartness witness needed by Real and Completion consumers; it does not assert real trichotomy, quotient real equality, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6450.1 (Located real apartness carrier)**.** *A* $\mathsf{LocatedRealApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Y, S, T, D, R, O, L, B, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{Real}^{\uparrow}$ *name rows whose apartness is being witnessed.*
2. *S and T are finite* $\mathsf{StreamName}^{\uparrow}$ *window rows for X and Y.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the two displayed windows at one positive dyadic scale.*
4. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the rational approximants of X and Y at the scale selected by D.*
5. *O is the located-order comparison row consumed from* $\mathsf{RealLocatedOrder}^{\uparrow}$*.*
6. *L is the positive separation row: it records a dyadic gap $\delta > 0$ and the displayed rational-window comparison that places the two names at distance at least δ on the inspected branch.*
7. *B is the bridge row to* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$*, recording that the positive gap is read as apartness and not as a trichotomy of all comparisons.*
8. *H records componentwise* hsame *transport for the real names, stream windows, dyadic ledger, regular readback, located-order row, separation row, bridge row, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an apartness request through $X, Y, S, T, D, R, O, L, B, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealApartness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealApartnessOrderBridge}^{\uparrow}$, $\mathsf{RealLocatedOrder}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealApartness}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one positive located-apartness certificate. It has no coordinate for total order trichotomy, host real equality, quotient stream equality, selected representatives, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6450.2 (Located real apartness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealApartness}^{\uparrow}$ *carrier*

$$A = (X, Y, S, T, D, R, O, L, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealApartness}^{\uparrow}}$ *surface consists exactly of carrier admission, paired window admission, dyadic tolerance exactness, regular-rational readback stability, positive separation display, apartness-order bridge compatibility, componentwise transport, displayed replay, provenance, and local naming. Each obligation is checked by finite projection through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealApartnessOrderBridge}^{\uparrow}$, $\mathsf{RealLocatedOrder}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows.*

Proof. Project the carrier of Definition 6450.1. The real-name rows X, Y are read only through the finite windows S, T, and the dyadic tolerance ledger D selects the positive scale at which the two windows are compared.

The paired readback row R converts the displayed stream windows into regular rational approximants. The located-order row O and the separation row L then display a positive dyadic gap on the inspected branch.

The bridge row B records that this positive gap is consumed as apartness. It does not turn the packet into a global trichotomy service, because the carrier stores only the displayed separated branch and no exhaustive comparison row.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no excluded equality, choice, selected-limit, trichotomy, or completeness coordinate appears in the packet, the local NameCert obligations are exhausted by the stated rows. □

Theorem 6450.3 (Located real apartness finite-witness route)**.** *Every accepted* $\mathsf{LocatedRealApartness}^{\uparrow}$ *packet exposes apartness through the finite route*

$$\mathsf{Real}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RealLocatedOrder}^{\uparrow} \longmapsto \mathsf{Real}$$

The exported witness is a displayed positive separation row, transported and replayed by H, C, P, N. It cannot be consumed as real trichotomy, host equality negation, quotient-name inequality, countable choice, selected representatives, selected limits, or ambient Real completeness.

Proof. Start with the two $\mathsf{Real}^{\uparrow}$ rows X, Y. A consumer cannot read them directly as a comparison theorem; it must first open the finite StreamName windows S, T and the paired RegSeqRat readback row R.

The dyadic tolerance ledger D then fixes the scale of the comparison. The located-order row O displays the chosen branch, and the separation row L records the positive dyadic gap visible on that branch.

The bridge row B turns the displayed gap into the apartness witness consumed by the local NameCert row. Componentwise transport and continuation replay preserve the same rows, while the provenance row records the sibling surfaces involved in the read.

Thus the route supplies a finite positive witness. Nothing in the carrier supplies an exhaustive comparison of all real names, a quotient-name equality test, a choice schedule, a selected representative, a selected limit, or a completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealApartness}\uparrow}$.

Constructive story: A $\mathsf{LocatedRealApartness}^{\uparrow}$ packet is generated from two RealUp name rows, paired StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a RealLocatedOrder comparison row, a positive separation row, a RealApartnessOrderBridge handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealApartness}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6450.1, Definition 6450.2, and Definition 6450.3 seed the finite positive apartness witness over Real, regular-rational, dyadic, located-order, and apartness-order bridge rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealApartness}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close real trichotomy, host real equality negation, quotient-name inequality, countable choice, selected representatives, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired-window admission, dyadic tolerance exactness, regular-rational readback stability, positive separation display, apartness-order bridge compatibility, transport, replay, provenance, and exclusion coverage for BEDC.Derived.LocatedRealApartnessUp.

Chapter 6451

A Concrete Naming Certificate for FiniteBishopConvergenceCriterion$^{\uparrow}$

Following Bishop and Bridges, the FiniteBishopConvergenceCriterion$^{\uparrow}$ packet records the finite convergence-test surface used in the L10 route before any real-completeness theorem or quotient stream equality is available. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the convergence-modulus ledger of chapter 2074, and the Bishop real-line interface of chapter 2062. The packet names a displayed finite test for convergence evidence; it is not Real completeness, a quotient of streams, a selected limit, trichotomy, countable choice, or bridge checking.

Definition 6451.1 (Finite Bishop convergence criterion carrier)**.** *A* FiniteBishopConvergenceCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, W, Q, R, M, I, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row naming the finite request radius and slack budget.*
2. *W is the* StreamName$^{\uparrow}$ *window row recording the finite entries of the tested sequence that are inspected for that request.*
3. *Q is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed windows.*
4. *R is the terminal* Real$^{\uparrow}$ *seal row that may be read only after D, W, Q have been replayed.*
5. *M is the* RealModulusOfConvergence$^{\uparrow}$ *ledger row recording the finite threshold used by the test.*
6. *I is the* BishopRealLineInterface$^{\uparrow}$ *handoff row through which Bishop-style real-line consumers read the same finite convergence evidence.*
7. *H stores componentwise* hsame *transport for tolerance, window, readback, Real seal, modulus, interface, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay for the same finite criterion route.*
9. *P is the* Pkg *provenance over* FiniteBishopConvergenceCriterion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, RealModulusOfConvergence$^{\uparrow}$, BishopRealLineInterface$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, W, Q, R, M, I, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, host real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6451.2 (Finite Bishop convergence window test)**.** *Every accepted* $\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}$ *carrier $F = (D, W, Q, R, M, I, H, C, P, N)$ exposes a convergence test only through the finite route*

$$D, W \longmapsto Q \longmapsto M, R \longmapsto I, H, C, P, N.$$

Thus a consumer must inspect the dyadic tolerance row and the $\mathsf{StreamName}^{\uparrow}$ *window before it can use regular rational readback, convergence-modulus evidence, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, or the Bishop real-line interface.*

Proof. Project the carrier of Definition 6451.1. The first visible stage is the tolerance and window pair D, W, so the request radius and finite observation schedule are fixed before any rational readback is available.

Replay the read through C. The replay opens Q only after the displayed windows have been inspected, and it opens M and R only after the same readback has been tied to the dyadic budget.

Finally transport through H and source the route through P, N. The Bishop interface row I receives exactly the same finite evidence, so no selected limit, quotient stream equality, host equality, choice principle, completeness theorem, Lean target, or bridge row can be exported. □

Theorem 6451.3 (Finite Bishop convergence L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}$ *packet factors through chapter 291, chapter 126, chapter 301, chapter 38, chapter 2074, and chapter 2062 before it may read convergence-test evidence.*

Proof. Read the carrier rows in order. The dyadic tolerance row D supplies the request budget, the stream row W supplies the inspected finite window, and the regular rational row Q supplies the readback seen by L10.

The convergence-modulus row M and Real seal R are downstream of that route. They may certify that the displayed finite window is sufficient for the named request, but they do not introduce a host real limit or a quotient equality of streams.

The interface row I packages the same data for Bishop real-line consumers, while H, C, P, N transport, replay, source, and name it. The L10 handoff is therefore exactly the finite sibling route listed in the statement. □

Theorem 6451.4 (Finite Bishop convergence nonescape)**.** *An accepted* $\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}$ *carrier cannot export Real completeness, quotient stream equality, selected representatives, selected limits, host real equality, trichotomy, countable choice, Lean verification, or bridge checking. Every public read is exhausted by the rows $D, W, Q, R, M, I, H, C, P, N$.*

Proof. Inspect the carrier coordinates. They are exactly the dyadic tolerance row, finite stream window, regular rational readback, Real seal, convergence-modulus ledger, Bishop interface row, componentwise transport, replay, provenance, and local naming.

Each public read must be a projection from those rows or a replay through C, H, P, N. None of the excluded objects is a row of the carrier, and none can be created by projection, replay, or componentwise transport.

Therefore the accepted packet is exhausted by the finite NameCert route displayed above. The nonescape claim follows from row exhaustion rather than from any external completeness or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName finite windows, RegSeqRat readback, a RealUp seal, a RealModulusOfConvergence ledger, a BishopRealLineInterface handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6451.1, Definition 6451.2, Definition 6451.3, and Definition 6451.4 seed the finite Bishop convergence-test route for L10 consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteBishopConvergenceCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, selected representatives, selected limits, host real equality, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-test exactness, L10 handoff exactness, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteBishopConvergenceCriterionUp.

Chapter 6452

A Concrete Naming Certificate for $\mathsf{CauchyTailCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailCriterion}^{\uparrow}$ packet records the finite tail-test route by which a Cauchy read is accepted before a regular rational or real-seal consumer may use it. It sits over the finite window surface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the inspected modulus discipline of chapter 292, the terminal real-name seal of chapter 38, and the fast subsequence route of chapter 1518. The packet is a local L10 finite tail-test object: it does not select a limit, quotient streams, use countable choice, invoke trichotomy, compare host real values, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6452.1 (Cauchy tail criterion carrier)**.** *A* $\mathsf{CauchyTailCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, D, R, M, E, F, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row listing the inspected source windows and the finite stage pairs used by the test.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested radius, comparison slack, and dyadic budget consumed by each inspected pair.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic budgets.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *inspection row naming the stage threshold that licenses the tail test.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row visible only after the window, dyadic, readback, and modulus rows have been consumed.*
6. *F is the* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *handoff row available only as a downstream finite witness that the same tail-test data can feed a fast regular subsequence route.*
7. *B is the tail-test ledger, recording that every displayed pair of inspected tail windows beyond the threshold in M is contained by the tolerance row D.*
8. *H records componentwise* hsame *transport for S, D, R, M, E, F, B and the structural support rows.*

9. *C records displayed* Cont *replay of the route*

$$S, D, M \longmapsto R \longmapsto E \longmapsto F \longmapsto B.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyTailCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FastCauchySubsequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailCriterion}^{\uparrow}}$ *row.*

Accepted carriers are compared only through these displayed rows. There is no coordinate for a selected limit, quotient Cauchy class, host real equality, countable-choice selector, trichotomy row, or ambient completeness principle.

Theorem 6452.2 (Cauchy tail criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailCriterion}^{\uparrow}$ *carrier $T = (S, D, R, M, E, F, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{StreamName}^{\uparrow}$ *tail-window exposure through S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, inspected* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold exposure through M, terminal* $\mathsf{Real}^{\uparrow}$ *seal delivery through E,* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *handoff through F, tail-test accountability through B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted packet. The carrier displays exactly the tail-window, dyadic tolerance, regular readback, inspected modulus, real seal, fast-subsequence handoff, tail-test ledger, transport, replay, provenance, and local naming rows.

The finite test is read through S, D, M, B. The row S lists only inspected windows, M names the displayed threshold, D records the tolerance budget, and B asserts the pairwise tail containment for those displayed rows.

The consumer-facing rows are downstream of that test. The regular rational row R reads the same windows and dyadic budgets, while the real seal E is exposed only after R and the tail-test route have been projected.

Finally F, H, C, P, N preserve and name the same route. The fast-subsequence row may consume the displayed tail-test data as finite evidence, but the carrier has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, trichotomy, or ambient completeness. The listed rows therefore exhaust the local NameCert surface. □

Theorem 6452.3 (Cauchy tail criterion Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyTailCriterion}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{FastCauchySubsequence}^{\uparrow}$$

through the displayed carrier rows before it may use the tail criterion as real-facing evidence. The handoff supplies only a finite tail-test packet; it does not supply a selected limit, quotient stream equality, host real comparison, countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $T = (S, D, R, M, E, F, B, H, C, P, N)$. Projection exposes the finite window row, dyadic tolerance row, inspected modulus row, regular readback row, real seal row, fast-subsequence handoff row, and tail-test ledger.

The tail criterion is available only after S, D, M, B have been read. These rows bind every inspected pair of tail windows to a displayed modulus threshold and a displayed dyadic tolerance budget.

The regular rational and real-facing rows preserve that order. The row R reads the same window and tolerance data, and the seal row E is downstream of the regular readback rather than a host limit-selection operation.

The fast-subsequence handoff F may consume the same finite evidence after the seal route is visible. Since H, C, P, N only transport, replay, source, and name the carrier, no excluded principle remains available to a Real or completion consumer. □

Lean4 ✓ `BEDC.Derived.CauchyTailCriterionUp.CauchyTailCriterionRealSealHandoff`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6452.1, Definition 6452.2, and Definition 6452.3 seed the finite tail-test route from displayed stream windows, dyadic tolerance budgets, and inspected modulus data to regular rational readback, Real seal delivery, and fast-subsequence handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, selected limits, quotient stream equality, host real comparison, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, public closure, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window exposure, dyadic tolerance accounting, modulus-threshold exposure, regular readback, Real seal delivery, fast-subsequence handoff, tail-test accountability, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailCriterionUp.

Constructive story: A $\mathsf{CauchyTailCriterion}^{\uparrow}$ packet is generated from StreamName tail windows, DyadicRatCore tolerance budgets, RegSeqRat readback, inspected CauchyModulus thresholds, a RealUp seal, a FastCauchySubsequence handoff, a finite tail-test ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6453

A Concrete Naming Certificate for CompactNetModulusStability$^{\uparrow}$

Following Bishop and Bridges compact metric analysis, the CompactNetModulusStability$^{\uparrow}$ packet realizes the compact-net direction of chapter 9237 as finite NameCert data. It reads the compact metric source of chapter 129, continuous-map rows from chapter 130, the uniform-modulus output surface of chapter 369, metric triangle rows from chapter 57, and the stream, regular-rational, and Real seals of chapter 126, chapter 301, and chapter 38. The packet names stability of the finite compact-net modulus route; it is not a selected Lebesgue number, an external modulus function, sequential compactness, countable choice, quotient metric equality, or ambient completeness.

Definition 6453.1 (Compact-net modulus stability carrier)**.** *A* CompactNetModulusStability$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, U, M, W, Q, R, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the* CompactMetric$^{\uparrow}$ *finite-net source row.*
2. *F is the* ContinuousMap$^{\uparrow}$ *pointwise-modulus row over the same source.*
3. *U is the* UniformModulus$^{\uparrow}$ *output row produced by the finite compact-net route.*
4. *M is the* Met$^{\uparrow}$ *triangle and distance-comparison row used to transport estimates across a bundled center.*
5. *W is the* StreamName$^{\uparrow}$ *finite observation row for the source and target names read by the map.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *regular rational readback row obtained from those windows.*
7. *R is the terminal* Real$^{\uparrow}$ *seal row for the displayed distance estimates.*
8. *T is the compact-net stability ledger binding X, F, U, M, W, Q, R to one finite modulus route.*
9. *H stores componentwise* hsame *transport for compact-net, continuous-map, uniform-modulus, metric, stream, readback, Real-seal, stability, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay for the same compact-net modulus route.*
11. *P is the* Pkg *provenance over* CompactNetModulusStability$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, Met$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N is the local $\mathsf{NameCert}_{\mathsf{CompactNetModulusStability}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $X, F, U, M, W, Q, R, T, H, C, P, N$. It has no coordinate for a selected subcover, selected Lebesgue number, host modulus function, sequential compactness, countable choice, quotient metric equality, or ambient completeness.

Theorem 6453.2 (Compact-net modulus finite route stability)**.** *Every accepted* $\mathsf{CompactNetModulusStability}^{\uparrow}$ *carrier $K = (X, F, U, M, W, Q, R, T, H, C, P, N)$ exports a uniform-modulus read only through the finite route*

$$X, F, M \longmapsto W, Q, R \longmapsto U, T, H, C, P, N.$$

Thus compact-net coverage, continuous pointwise-modulus rows, metric triangle estimates, stream windows, regular rational readback, Real seals, and the uniform-modulus output remain bound to one displayed NameCert packet.

Proof. Project the carrier and read the source rows X, F, M. The compact metric net, continuous-map modulus row, and metric triangle row are displayed over the same source before any output modulus is available.

Replay the finite observation layer through C. The stream window W is read first, the regular rational row Q reads back the inspected names, and the Real seal R records the distance estimates used by the metric row.

The output stage U, T, H, C, P, N exposes the uniform-modulus row only after the stability ledger has replayed the same compact-net route. Row exhaustion prevents selected subcovers, selected Lebesgue numbers, host modulus functions, sequence extraction, choice, quotient metric equality, or ambient completeness from entering the read. □

Theorem 6453.3 (Compact-net modulus Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *distance estimate consumed by an accepted* $\mathsf{CompactNetModulusStability}^{\uparrow}$ *packet factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows before it reaches the stability ledger T and the* $\mathsf{UniformModulus}^{\uparrow}$ *output row U. Consequently the packet cannot export a Real-completeness principle, quotient equality of metric points, a selected compact subcover, or a host modulus selector.*

Proof. Begin with a Real-facing distance estimate in the accepted packet. The only Real row is R, and it is displayed as downstream of the finite windows W and regular rational readback Q.

Use the metric row M and the stability ledger T to transport the estimate across the compact-net center selected inside the finite packet. This transport is a replayed NameCert route, not an external triangle theorem detached from the carrier.

Finally expose the uniform-modulus row U through H, C, P, N. Since the packet has no row for completeness, quotient point equality, selected subcovers, or host modulus functions, none of those objects can escape from the Real-seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactNetModulusStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactNetModulusStability}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise-modulus rows, a UniformModulus output, Metric triangle estimates, StreamName windows, RegSeqRat readback, RealUp distance seals, a stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactNetModulusStability}^{\uparrow}}$, seed)

Scope closed: Definition 6453.1, Definition 6453.2, and Definition 6453.3 seed the compact-net modulus stability route realized from chapter 9237.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactNetModulusStability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected Lebesgue numbers, selected subcovers, host modulus functions, sequential compactness, countable choice, quotient metric equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net source lock, pointwise-modulus binding, metric-triangle stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactNetModulus

Chapter 6454

A Concrete Naming Certificate for $\mathsf{HausdorffMomentProblem}^{\uparrow}$

Following Hausdorff on moment sequences over a compact interval, the $\mathsf{HausdorffMomentProblem}^{\uparrow}$ packet records the finite BEDC surface for a truncated interval moment table before any consumer asks for a representing measure. It specializes the finite-window route of chapter 6193 by fixing the compact support row through chapter 6257, reading polynomial tests through chapter 1728, sealing scalar values through chapter 38, and routing nonnegative polynomial checks through chapter 2297. The certificate names only displayed compact-interval handoff data, finite polynomial windows, Hankel and localizing positivity ledgers, transport, replay, provenance, and local naming; it does not export a representing measure, determinacy, uniqueness, selected support, or ambient compactness theorem.

Definition 6454.1 (Hausdorff moment problem carrier)**.** *A* $\mathsf{HausdorffMomentProblem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, I, R, P, V, Q, L, S, T, C, G, N)$$

with the following displayed rows:

1. *M is the inherited* $\mathsf{MomentProblem}^{\uparrow}$ *finite moment-window row, including the rational and real readbacks of the inspected moment entries.*
2. *I is the* $\mathsf{CompactRealInterval}^{\uparrow}$ *support row, displaying the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint seals for the compact interval on which the Hausdorff read is requested.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row used for endpoint values, moment entries, and tolerance budgets.*
4. *P is the* $\mathsf{RealPolynomial}^{\uparrow}$ *finite polynomial-test row, naming only the displayed coefficient lists and evaluation windows consumed by the packet.*
5. *V is the* $\mathsf{PositiveCone}^{\uparrow}$ *nonnegative-read row for the finite polynomial tests and scalar comparison witnesses.*
6. *Q is the finite Hankel positivity row inherited from* $\mathsf{MomentProblem}^{\uparrow}$*, restricted to the displayed compact interval support.*
7. *L is the localizing positivity row for the endpoint constraints, recording the finite windows by which $(x-a)p(x)$ and $(b-x)p(x)$ are inspected through P, V, R, I.*

8. *S records componentwise* hsame *transport for the moment window, compact interval support, real readbacks, polynomial tests, positivity rows, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from a Hausdorff finite-window request through M, I, R, P, V, Q, L, S.*
10. *C is the* Pkg *provenance over* $\mathsf{HausdorffMomentProblem}^{\uparrow}$, $\mathsf{MomentProblem}^{\uparrow}$, $\mathsf{CompactRealInterval}^{\uparrow}$, $\mathsf{RealPolynomial}^{\uparrow}$, $\mathsf{PositiveCone}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *G is the compact-interval handoff ledger recording that every support-facing read uses the displayed I row rather than an ambient compactness principle.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMomentProblem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a representing measure, infinite Hausdorff sequence, determinacy theorem, selected support measure, host Riesz representation theorem, or ambient completeness principle.

Theorem 6454.2 (Hausdorff moment problem NameCert obligations)**.** *For every accepted* HausdorffMomentProble *carrier*

$$H = (M, I, R, P, V, Q, L, S, T, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffMomentProblem}^{\uparrow}}$ *surface consists exactly of MomentProblem finite-window admission, compact real interval support admission, real scalar readback, finite real-polynomial test admission, positive-cone nonnegative readback, finite Hankel positivity, localizing endpoint positivity, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, compact-interval handoff, and local naming for the displayed rows*

$$M, I, R, P, V, Q, L, S, T, C, G, N.$$

No consumer of the certificate receives a representing measure, uniqueness, determinacy, selected support, an infinite positivity theorem, or a host compact-interval existence theorem.

Proof. Project the accepted carrier of Definition 6454.1. The inherited moment data are confined to the finite $\mathsf{MomentProblem}^{\uparrow}$ row M, while the compact support is confined to the endpoint row I and the real readback row R.

Polynomial tests are not host functions. They are read through the finite $\mathsf{RealPolynomial}^{\uparrow}$ row P, and their nonnegative comparisons are read through the $\mathsf{PositiveCone}^{\uparrow}$ row V before the finite Hankel row Q or localizing row L may be consumed.

The structural rows S, T, C, G, N transport, replay, source, hand off, and name exactly the same finite rows. Since the carrier contains no representing measure, infinite moment sequence, selected support measure, determinacy proof, Riesz theorem, or ambient completeness coordinate, those objects cannot be exported by the local certificate. □

Theorem 6454.3 (Hausdorff moment problem Hankel positivity route)**.** *Every Hankel-positivity read exported by an accepted* $\mathsf{HausdorffMomentProblem}^{\uparrow}$ *packet first passes through the* $\mathsf{MomentProblem}^{\uparrow}$ *finite-window row, the* $\mathsf{Real}^{\uparrow}$ *scalar readback row, the* $\mathsf{RealPolynomial}^{\uparrow}$ *finite test row, and the* $\mathsf{PositiveCone}^{\uparrow}$ *nonnegative-read row before the localizing endpoint ledger may be consumed. In carrier terms, the route is*

$$M, R, P, V \longmapsto Q, L \longmapsto S, T, C, G, N.$$

It exports no infinite Hankel operator, representing measure, determinacy theorem, or host compact-support solver.

Proof. Read the carrier of Definition 6454.1. The only Hankel source is the inherited finite-window row M, and its scalar entries are sealed by the real readback row R.

The endpoint and polynomial tests used by a Hausdorff read are finite. They pass through P and V before the packet opens the Hankel row Q and the localizing endpoint row L.

Finally S, T, C, G, N preserve the same route for transport, replay, provenance, compact-interval handoff, and naming. Because no carrier row stores an infinite operator, representing measure, selected support, determinacy theorem, or ambient solver, the displayed finite positivity route is the whole exported surface. □

Theorem 6454.4 (Hausdorff moment problem compact interval handoff)**.** *Every compact-support read of an accepted* $\mathsf{HausdorffMomentProblem}^{\uparrow}$ *packet is handed off through the displayed* $\mathsf{CompactRealInterval}^{\uparrow}$ *row before any moment or polynomial positivity ledger is consumed. The read must expose the support row I, the endpoint* $\mathsf{Real}^{\uparrow}$ *seals in R, the finite* $\mathsf{RealPolynomial}^{\uparrow}$ *test row P, the* $\mathsf{PositiveCone}^{\uparrow}$ *nonnegative row V, the Hankel and localizing ledgers Q, L, and the compact-interval handoff ledger G before a Hausdorff moment consumer may use the packet.*

Proof. Project the carrier. The support row I is the only compact interval coordinate, and R is the only endpoint readback coordinate available to the packet.

Any support-facing polynomial test therefore enters through I, R, P, V before it can reach Q or L. The handoff row G records that the same compact interval row, not an ambient compactness theorem, supplies the support boundary.

Transport, replay, provenance, and local naming through S, T, C, N preserve this displayed handoff. A consumer that skips I, R, or G is not reading the $\mathsf{HausdorffMomentProblem}^{\uparrow}$ carrier, and a consumer that adds a representing measure or determinacy proof leaves the named packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMomentProblem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HausdorffMomentProblem}^{\uparrow}$ packet is generated from a MomentProblemUp finite moment-window row, a CompactRealIntervalUp support row, RealUp endpoint and scalar readbacks, RealPolynomialUp finite polynomial tests, PositiveConeUp nonnegative rows, finite Hankel and localizing positivity ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, compact-interval handoff, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HausdorffMomentProblem}^{\uparrow}}$, seed)

Scope closed: Definition 6454.1, Definition 6454.2, Definition 6454.3, and Definition 6454.4 seed the finite Hausdorff moment route over MomentProblemUp, CompactRealIntervalUp, RealPolynomialUp, PositiveConeUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HausdorffMomentProblem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a representing measure, determinacy, uniqueness, selected support, infinite Hausdorff sequence, ambient compactness theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Hankel positivity routing, localizing endpoint positivity, compact-interval handoff, transport, replay, provenance, and local naming for BEDC.Derived.HausdorffMomentProblemUp.

Chapter 6455

A Concrete Naming Certificate for $\mathsf{UniformDyadicMesh}^{\uparrow}$

Following Bishop and Bridges-style dyadic approximation, the $\mathsf{UniformDyadicMesh}^{\uparrow}$ packet records a finite uniform dyadic mesh certificate for the open Real and Completion route. It sits after the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the visible Real seal of chapter 38, and the downstream dyadic cover surface of chapter 1428. The packet names a uniform finite mesh and its readback route; it is not an arbitrary open cover, a selected completion limit, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6455.1 (Uniform dyadic mesh carrier)**.** *A* $\mathsf{UniformDyadicMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L, R, J, \rho, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the dyadic lower-endpoint row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *R is the dyadic upper-endpoint row, read through the same dyadic arithmetic core and paired with L by the local interval classifier.*
3. *J is the mesh index row. It names the unary depth or finite dyadic scale at which all cells in the packet have the same dyadic length.*
4. *ρ is the radius ledger. It records the positive dyadic tolerance associated with each mesh cell and the finite containment checks visible at scale J.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that schedules endpoint, mesh, radius, and containment reads.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that packages the scheduled dyadic endpoint and radius data as regular rational observations.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the endpoint rows, mesh index, radius ledger, finite window, and regular rational readback have been displayed.*
8. *H stores componentwise* hsame *transport for endpoints, mesh index, radius ledger, StreamName windows, RegSeqRat readback, Real seal, continuation replay, provenance, and local naming.*

9. *C stores* Cont *replay from endpoint reads to the uniform mesh row, from mesh and radius reads to regular rational readback, and from that readback to the Real-facing seal and dyadic interval-cover handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformDyadicMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformDyadicMesh}^{\uparrow}}$ *row.*

The classifier compares accepted mesh packets only through the displayed tuple $L, R, J, \rho, S, Q, E, H, C, P, N$. It has no coordinate for nonuniform cell choice, arbitrary open-cover data, selected completion limits, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6455.2 (Uniform dyadic mesh refinement stability)**.** *Let $U = (L, R, J, \rho, S, Q, E, H, C, P, N)$ and $U' = (L', R', J', \rho', S', Q', E', H', C', P', N')$ be accepted* $\mathsf{UniformDyadicMesh}^{\uparrow}$ *carriers. Any displayed refinement from U to U' is stable exactly when the endpoint rows L, R transport to L', R', the mesh index row J' refines J by a finite dyadic scale comparison, the radius ledger ρ' is obtained by finite subdivision of ρ, and the rows S, Q, E, H, C, P, N replay the same StreamName, RegSeqRat, Real seal, transport, continuation, provenance, and local NameCert route. Refinement therefore changes only displayed dyadic mesh rows and never imports nonuniform cell choice, selected subcovers, quotient real equality, countable choice, or ambient completeness.*

Proof. Project the two carrier tuples from Definition 6455.1. Endpoint compatibility is a finite $\mathsf{DyadicRatCore}^{\uparrow}$ comparison on L, R, L', R', and the refinement of J is a displayed scale comparison rather than a host-level subdivision principle.

The radius ledger is then read rowwise. Each cell of the refined packet is attached to a finite dyadic radius in ρ', and the containment check is the replay of the corresponding coarser row in ρ through the displayed continuation route.

Finally, S, Q, E, H, C, P, N preserve the same public route. The stream row schedules the finite reads, the regular rational row packages them, the Real seal is downstream from those reads, and the structural rows transport, replay, source, and name only the displayed mesh data. Thus refinement stability is a finite row statement over the carrier surface. □

Theorem 6455.3 (Uniform dyadic mesh Real-window handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *consumer reading an accepted* $\mathsf{UniformDyadicMesh}^{\uparrow}$ *carrier must first pass through*

$$L, R \longmapsto J, \rho \longmapsto S \longmapsto Q \longmapsto E$$

and then through H, C, P, N. The exported handoff is the finite tuple $L, R, J, \rho, S, Q, E, H, C, P, N$: dyadic endpoint rows, a uniform mesh index, a radius ledger, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise transport, displayed continuation replay, provenance, and the local NameCert row.

Proof. Start with a consumer asking for a real-facing mesh window. The lower and upper dyadic endpoints are the first visible data, and the carrier gives no real name until those endpoint rows have been admitted through $\mathsf{DyadicRatCore}^{\uparrow}$.

Read the mesh index and radius ledger next. The row J fixes a single dyadic scale for the packet, while ρ records the finite tolerance and containment checks attached to that scale. These rows are the only data a dyadic interval-cover consumer may inspect before the finite readback rows appear.

The rows S and Q schedule and package the reads, and E seals the resulting regular rational observations as Real-facing data. Transport, replay, provenance, and naming through H, C, P, N

keep the handoff inside the same finite certificate surface, so no arbitrary open cover, selected limit, quotient equality, countable choice, or ambient completeness principle is exported. □

Falsifiable prediction: Every $\mathsf{UniformDyadicMesh}^{\uparrow}$ consumer read factors through dyadic endpoint rows, a uniform mesh index, a radius ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before dyadic cover or completion data is visible.

Independence witness: dyadicratcore, streamname, regseqrat, real, dyadicintervalcover: $\mathsf{UniformDyadicMesh}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint rows, a single mesh-scale row, a radius ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformDyadicMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformDyadicMesh}^{\uparrow}$ packet is generated from dyadic endpoint rows, a uniform mesh index, a radius ledger, finite StreamName windows, RegSeqRat readbacks, a Real seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformDyadicMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6455.1, Definition 6455.2, and Definition 6455.3 seed the finite uniform dyadic mesh handoff between dyadic arithmetic, regular rational readback, Real windows, and dyadic interval-cover consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformDyadicMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, selected completion limits, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, endpoint and mesh readback, radius-ledger stability, StreamName and RegSeqRat scheduling, Real seal handoff, dyadic interval-cover compatibility, and ledger non-escape for BEDC.Derived.UniformDyadicMeshUp.

Chapter 6456

A Concrete Naming Certificate for $\mathsf{BishopCompletionOperator}^{\uparrow}$

Following Bishop and Bridges on constructive completion, the $\mathsf{BishopCompletionOperator}^{\uparrow}$ packet names the finite operator route that turns displayed regular rational Cauchy data into a Real-facing completion seal. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name boundary of chapter 38. The packet records only the operator rows needed by the L10 completion route; it does not quotient Cauchy names, select representatives, use countable choice, or assert that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 6456.1 (BishopCompletionOperator carrier)**.** *A* $\mathsf{BishopCompletionOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, R, D, E, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observed Cauchy-name windows.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for every precision request.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D have been exposed.*
5. *U is the Bishop completion extension and universal-boundary row, recording the finite handoff by which a completion consumer reads the operator output.*
6. *H records componentwise* hsame *transport for stream windows, regular readbacks, dyadic tolerances, Real seals, extension rows, replay rows, provenance rows, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through S, R, D, then through E and U.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionOperator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionOperator}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient Cauchy equality, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6456.2 (BishopCompletionOperator NameCert obligations)**.** *For every accepted* BishopCompletionOpera *carrier* $O = (S, R, D, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionOperator}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-window exposure, regular rational readback, dyadic tolerance exposure, ordered* $\mathsf{Real}^{\uparrow}$ *seal access, Bishop extension and universal-boundary exposure through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. A public completion-operator read must pass through those rows before it may cite the Real-facing seal or the universal-boundary row.*

Proof. Project the accepted finite BHist packet. The visible carrier rows are precisely $S, R, D, E, U, H, C, P, N$, so carrier admission exposes stream windows, regular readback, dyadic tolerance data, the ordered Real seal, and the extension boundary as displayed data.

The operator read is ordered. A precision request first reaches the finite $\mathsf{StreamName}^{\uparrow}$ windows, then the $\mathsf{RegSeqRat}^{\uparrow}$ readback, then the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and only afterward the $\mathsf{Real}^{\uparrow}$ seal and the universal-boundary row U.

Transport and replay are structural. The row H moves the listed coordinates componentwise by hsame, while C replays the displayed continuation route and P, N source and name the same packet. Since no quotient Cauchy equality, selected representative, countable-choice schedule, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness coordinate appears in the tuple, the listed rows exhaust the local NameCert obligations. □

Theorem 6456.3 (BishopCompletionOperator Real-seal factorization)**.** *Every* $\mathsf{BishopCompletionOperator}^{\uparrow}$ *consumer that reads the Real-facing output of an accepted carrier* $O = (S, R, D, E, U, H, C, P, N)$ *factors through the finite route*

$$S \longmapsto R \longmapsto D \longmapsto E \longmapsto U \longmapsto H, C, P, N.$$

Thus the operator output reaches $\mathsf{Real}^{\uparrow}$ *only through finite stream windows, regular rational readback, dyadic tolerances, the displayed seal row, and the Bishop completion extension boundary. It does not export quotient Cauchy equality, selected representatives, countable choice, host real equality, or any claim that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Start with a consumer request for the operator output. The carrier definition gives the request access to the finite window row S, so the request begins with displayed Cauchy-name observations rather than an external Cauchy quotient.

Next read the regular and dyadic rows. The readback row R and tolerance row D supply the regular rational and precision data used to reach the Real-facing seal E.

Finally read the extension boundary U and replay the structural rows H, C, P, N. The route is therefore the displayed finite chain from stream windows to the Real seal and universal boundary. Because the packet contains no additional coordinate, the factorization cannot produce quotient Cauchy equality, selected representatives, countable choice, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionOperator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCompletionOperator}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, a Bishop extension and universal-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompletionOperator}^{\uparrow}}$, seed)

Scope closed: Definition 6456.1, Definition 6456.2, and Definition 6456.3 seed the finite non-quotient completion-operator route from stream windows and regular rational readback to the Real-facing seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompletionOperator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected representatives, countable choice, host real equality, Lean verification, bridge checking, or any assertion that $\mathsf{Real}^{\uparrow}$ is complete.

Upgrade path: Obligation closure requires checked carrier admission, ordered Real-seal factorization, universal-boundary exposure, transport stability, and non-escape for BEDC.Derived.BishopCompletionOperatorUp.

Chapter 6457

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealCompleteness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedRealCompleteness}^{\uparrow}$ packet records the constructive completeness surface for located real names as a finite NameCert route. It sits after the located-real comparison of **??**, the regular rational readback of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet records which displayed Cauchy source data may be read before a completion-facing $\mathsf{Real}^{\uparrow}$ seal is exposed; it does not assert ambient Real completeness, quotient real equality, selected limits, trichotomy, or countable choice.

Definition 6457.1 (Bishop located real completeness carrier)**.** *A* $\mathsf{BishopLocatedRealCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, W, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the displayed located Cauchy source row, recording the admitted source sequence or modulus request before any completion-facing seal is read.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row through which source observations are inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the same finite windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for source-window comparison, regular readback, and final seal budgeting.*
5. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row, exposing located interval or apartness comparisons available to the completion request.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, R, D, L have been displayed.*
7. *H is the componentwise* hsame *transport row for the source, window, readback, tolerance, located-comparison, seal, continuation, provenance, and naming data.*
8. *C is the displayed* Cont *replay row from located Cauchy source reads through finite windows, regular readback, dyadic tolerance, located comparison, and the terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealCompleteness}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, R, D, L, E, H, C, P, N$. It has no coordinate for quotient real equality, a selected limit operator, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedRealCompletenessUp.BishopLocatedRealCompletenessTasteGate`
`single carrier alignment`

Theorem 6457.2 (Bishop located real completeness NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedRealCompleteness}^{\uparrow}$ *carrier $K = (S, W, R, D, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealComple}}$ *surface consists exactly of carrier admission for the displayed located Cauchy source S, finite* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row L, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming row N.*

Proof. Project the carrier of Definition 6457.1. The rows $S, W, R, D, L, E, H, C, P, N$ are the whole public packet, so carrier admission and local naming are finite row checks.

The source route is read in order. The displayed located Cauchy source S opens only finite windows W; those windows produce the regular rational row R under the dyadic budget D; the located comparison row L is inspected before the terminal seal E is available.

The structural rows preserve the same route. Componentwise hsame transport and displayed Cont replay keep S, W, R, D, L, E attached to the same packet, while P, N only source and name the data. Since the carrier has no row for quotient equality, selected limits, host equality, trichotomy, countable choice, or ambient completeness, no local obligation can read such data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealCompleteness}^{\uparrow}$ packet is generated from a displayed located Cauchy source, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a LocatedReal comparison row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompleteness}^{\uparrow}}$, seed)

Scope closed: Definition 6457.1 and Definition 6457.2 seed the finite located-real completeness route from displayed Cauchy source data through regular rational readback to a terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedRealCompleteness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, host real equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located Cauchy source routing, finite window coverage, RegSeqRat readback, DyadicRatCore tolerance exactness, LocatedReal comparison, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealCompletenessUp.

Chapter 6458

A Concrete Naming Certificate for PointwiseEquicontinuityCompactTransfer$^{\uparrow}$

Following Bishop and the Arzela–Ascoli compact equicontinuity route, the PointwiseEquicontinuityCompactTransfer$^{\uparrow}$ packet records the finite handoff from pointwise family moduli on a compact metric source to a uniform-modulus consumer. It sits after the compact source of chapter 129, the continuous-map rows consumed by chapter 130, the family-modulus surface of chapter 413, and the uniform-modulus boundary of chapter 369. The packet is a finite compact-net and family-radius transfer; it is not a selected global modulus function, open-cover compactness theorem, function-space compactness assertion, countable-choice schedule, or ambient equality of maps.

Definition 6458.1 (Pointwise equicontinuity compact transfer carrier)**.** *A* PointwiseEquicontinuityCompactTransfer *carrier is a finite* BHist *packet*

$$T = (K, F, E, B, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing only the finite compact-net and metric inspection data used by the transfer.*
2. *F is the finite* ContinuousMap$^{\uparrow}$ *family ledger whose graph rows are inspected by the equicontinuity request.*
3. *E is the* EquicontinuityFamily$^{\uparrow}$ *pointwise family-modulus row over the same compact source and target metric data.*
4. *B is the finite* ProbeBundle *cover row of compact-net centers.*
5. *R is the* Rat$^{\uparrow}$ *radius and tolerance fold ledger that lowers the pointwise family radii over the finite bundle.*
6. *U is the* UniformModulus$^{\uparrow}$ *handoff row receiving the tolerance-only family modulus extracted from K, F, E, B, R.*
7. *H is the componentwise* hsame *transport row for compact source, continuous-map, equicontinuity, bundle, rational fold, uniform-modulus, replay, provenance, and naming data.*
8. *C is the displayed* Cont *replay from compact finite-net reads and pointwise family-modulus rows to the uniform-modulus handoff.*

9. *P is the* Pkg *provenance over* PointwiseEquicontinuityCompactTransfer$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, EquicontinuityFamily$^{\uparrow}$, UniformModulus$^{\uparrow}$, Rat$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{PointwiseEquicontinuityCompactTransfer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, E, B, R, U, H, C, P, N$. It has no coordinate for a selected global modulus, an arbitrary open-cover compactness theorem, function-space compactness, host equality of maps, countable choice, or an external family selector.

Theorem 6458.2 (Pointwise equicontinuity compact transfer NameCert obligations)**.** *For every accepted* PointwiseEquicontinuityCompactTransfer$^{\uparrow}$ *carrier $T = (K, F, E, B, R, U, H, C, P, N)$, the local* NameCert$_{\text{PointwiseEquicontinuityCompactTransfer}^{\uparrow}}$ *surface consists exactly of carrier admission for the* CompactMetric$^{\uparrow}$ *source row K, finite* ContinuousMap$^{\uparrow}$ *family ledger F,* EquicontinuityFamily$^{\uparrow}$ *pointwise modulus row E, finite* ProbeBundle *compact-net row B,* Rat$^{\uparrow}$ *fold ledger R,* UniformModulus$^{\uparrow}$ *handoff row U, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming row N.*

Proof. Project the carrier of Definition 6458.1. The rows $K, F, E, B, R, U, H, C, P, N$ are the whole packet, so carrier admission and local naming are finite row checks.

The transfer route is finite. The compact source row K supplies the finite ProbeBundle cover B; the family ledger F and pointwise equicontinuity row E attach a displayed local radius to each inspected center; the Rat$^{\uparrow}$ fold R lowers those radii over B before the uniform-modulus row U is consumed.

Transport and replay remain componentwise. The rows H, C, P, N keep the compact-net, family-modulus, rational-fold, and uniform-modulus data inside one BHist packet. Since no carrier coordinate stores a selected global modulus, open-cover theorem, function-space compactness object, host map equality, countable-choice schedule, or external family selector, no local NameCert obligation can export such data. □

Closure status for NameCert$_{\text{PointwiseEquicontinuityCompactTransfer}^{\uparrow}}$.

Constructive story: A PointwiseEquicontinuityCompactTransfer$^{\uparrow}$ packet is generated from a CompactMetric finite-net source, ContinuousMap family rows, an EquicontinuityFamily pointwise-modulus ledger, a finite ProbeBundle cover, RatUp radius-fold data, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PointwiseEquicontinuityCompactTransfer}^{\uparrow}}$, seed)

Scope closed: Definition 6458.1 and Definition 6458.2 seed the finite compact-net transfer from pointwise equicontinuity rows to a uniform-modulus handoff.

Formal verification: FormalStatus(NameCert$_{\text{PointwiseEquicontinuityCompactTransfer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected global modulus functions, arbitrary open-cover compactness, function-space compactness, countable choice, host equality of maps, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net coverage, family-modulus readback, RatUp fold exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.PointwiseEquicontinu

Chapter 6459

A Concrete Naming Certificate for $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ packet records the finite criterion by which a regular rational Cauchy presentation may be read as convergence-ready data before any real-name seal is consumed. It sits over the finite window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a Bishop-style convergence criterion for the RegSeqRat-to-Real route; it is not a quotient class of Cauchy streams, a selected limit, countable choice, host real completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6459.1 (Bishop Cauchy convergence criterion carrier)**.** *A* $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, carrying the inspected finite observation windows and precision requests.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, naming the regular rational data read from the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, displaying requested radii, split tolerances, comparison budgets, and endpoint observations.*
4. *R is the convergence-criterion row, recording that the Q readback is controlled by the finite dyadic tolerance surface in D along the windows in S.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after S, Q, D, R have been displayed.*
6. *H records componentwise* hsame *transport for the window, readback, tolerance, criterion, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S \longmapsto Q \longmapsto D \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected real limit, countable choice, host completeness, detached convergence, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BishopCauchyConvergenceCriterionUp.BishopCauchyConvergenceCriterionTasteGate`
`single carrier alignment`

Theorem 6459.2 (Bishop Cauchy convergence criterion NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ *carrier*

$$K = (S, Q, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}}$ *surface consists exactly of five finite obligation families:*

1. *carrier admission for the StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, convergence-criterion row, Real seal, transport, replay, provenance, and local naming row;*
2. *window-readback exactness, requiring Q to read only the finite windows displayed by S;*
3. *dyadic tolerance coverage, requiring D to display the requested radii, split tolerances, comparison budgets, and endpoint observations before R is consumed;*
4. *convergence nonescape, requiring R to bind the same S, Q, D rows rather than a quotient Cauchy class, selected limit, countable-choice functional, or host convergence theorem;*
5. *Real seal discipline, requiring E to be downstream of S, Q, D, R while H, C, P, N transport, replay, source, and name only the displayed route.*

No Bishop Cauchy convergence criterion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6459.1. The accepted packet displays exactly the window row, regular readback, dyadic tolerance ledger, convergence row, Real seal, and structural rows.

Window-readback exactness is read from S and Q. The regular rational row is attached to the finite windows, so no quotient stream representative is introduced.

Dyadic tolerance coverage is the role of D. Its requested radii, split tolerances, comparison budgets, and endpoint observations are displayed before the convergence row can be consumed.

The convergence condition is local to R. Since R binds the same S, Q, D route, a consumer receives finite criterion data rather than a selected limit, external choice function, or host convergence theorem.

Finally, E, H, C, P, N add only the terminal seal, transport, replay, provenance, and local naming. The carrier has no coordinate for quotient stream equality, countable choice, detached convergence, host completeness, or ambient completeness, so the listed obligation families exhaust the local NameCert surface. □

Theorem 6459.3 (Bishop Cauchy convergence criterion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ *packet factors through the finite route*

$$S \longmapsto Q \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

The handoff reads StreamName windows, RegSeqRat regular rational data, DyadicRatCore tolerance coverage, the convergence-criterion row, and the terminal Real seal in that order. It exports no selected limit, quotient equality of Cauchy streams, countable choice, detached convergence theorem, host real completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge.*

Proof. Begin with a real-facing or completion-facing read of an accepted packet. Projection exposes the ordered carrier rows $S, Q, D, R, E, H, C, P, N$.

The readback row Q is downstream of the finite windows S, and the dyadic tolerance row D is downstream of the same readback. Thus the consumer cannot start from an unbounded stream representative or a quotient equality class.

The NameCert obligation theorem places the convergence row R after the displayed windows, regular readback, and dyadic tolerance coverage. Hence the Cauchy-to-real route receives convergence criterion data before it can reach E.

The terminal row E is the only $\mathsf{Real}^{\uparrow}$ seal coordinate in the packet. The structural rows preserve and name the same finite route, and the excluded principles are absent from the carrier. Therefore every real-facing or completion-facing consumer factors through the displayed handoff and receives none of the listed escape objects. □

Theorem 6459.4 (Bishop Cauchy convergence criterion tail stability)**.** *Transporting an accepted* $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ *packet along componentwise* hsame *preserves the finite tail request, StreamName observation schedule, RegSeqRat readback, DyadicRatCore tolerance row, convergence-criterion row, and Real seal handoff. Consequently every* $\mathsf{Real}^{\uparrow}$*-facing consumer still reads the same finite tail-window route before it can consume the terminal Real seal. The transport exports no selected limits, quotient equality of Cauchy streams, countable choice, detached convergence, host Real completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 6459.1. The transport row H is componentwise over the StreamName window row S, RegSeqRat readback row Q, DyadicRatCore tolerance row D, convergence row R, Real seal E, replay, provenance, and local naming rows.

Apply Definition 6459.2. Window-readback exactness, dyadic tolerance coverage, convergence nonescape, and Real seal discipline are obligations on the displayed rows themselves, so componentwise hsame cannot replace them with a selected limit, quotient stream class, countable-choice functional, detached convergence theorem, host Real completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally use Definition 6459.3. The Real-facing handoff is downstream of $S, Q, D, R, E, H, C, P, N$ in that order; after transport, the consumer therefore reads the same finite tail-window route before the terminal Real seal is exposed. □

Theorem 6459.5 (Bishop Cauchy convergence criterion obligation-closure package)**.** *For every accepted* $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ *carrier* $K = (S, Q, D, R, E, H, C, P, N)$*, the carrier definition, NameCert obligation theorem, Real handoff theorem, and tail-stability theorem assemble the* obligation *surface over* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the convergence-criterion row, the* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}}$ *row. The assembled package exports no selected limit, quotient stream equality, countable choice, detached convergence theorem, host real completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start from the carrier admission of Definition 6459.1. It fixes the only readable rows as $S, Q, D, R, E, H, C, P, N$, so every package claim is made over the displayed finite route.

Apply Definition 6459.2. The obligation families expose window-readback exactness, dyadic tolerance coverage, convergence nonescape, Real seal discipline, and the structural transport, replay, provenance, and naming rows.

Use Definition 6459.3 for the consumer-facing direction. It forces every $\mathsf{Real}^{\uparrow}$ or completion-facing read through $S, Q, D, R, E, H, C, P, N$ before the terminal seal can be consumed.

Finally apply Definition 6459.4. Componentwise hsame transport preserves the same tail request, observation schedule, readback, tolerance, convergence, and Real-seal rows, so the package is stable under the local classifier. Since none of the cited rows contains a selected limit, quotient stream equality, countable choice, detached convergence, host real completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, the assembled surface is exactly obligation-closed for this finite packet. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ real-facing read factors through $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance coverage, a convergence-criterion row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite observation windows, regular rational readback, dyadic tolerance coverage, an explicit convergence-criterion row, terminal real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a convergence criterion row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6459.1, Definition 6459.2, Definition 6459.3, and Definition 6459.4 seed the finite convergence route through StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, the convergence row, Real seal, transport, continuation, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy streams, countable choice, detached convergence, host real completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback exactness, dyadic tolerance coverage, convergence nonescape, Real seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyConverg

Chapter 6460

A Concrete Naming Certificate for $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$ packet records the finite uniform-limit route for a sequence of regular Cauchy real-name packets before any completion-facing consumer may read a terminal real seal. It sits over the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the convergence-criterion route of chapter 1509. The packet names a constructive uniform-limit handoff; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, host function equality, selected limits, or countable choice.

Definition 6460.1 (Regular Cauchy uniform-limit carrier)**.** *A* $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence row, listing the accepted regular Cauchy real-name packets whose values are available only through displayed finite histories.*
2. *M is the uniform Cauchy modulus row, giving one finite precision schedule that controls the tail of the whole sequence.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the requested dyadic radii, split budgets, and comparison rows consumed by M.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the sequence indices, value names, modulus requests, and terminal read positions.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in W and to the regular rational observations required by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the rows S, M, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the sequence, modulus, tolerance, window, readback, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a uniform-limit request through sequence lookup, modulus inspection, dyadic tolerance, finite windows, regular rational readback, and real sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformLimit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, M, D, W, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable-choice schedules, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6460.2 (Regular Cauchy uniform-limit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$ *carrier*

$$U = (S, M, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows: carrier admission for the displayed regular Cauchy sequence, uniform modulus, DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local name; uniform-modulus exactness through M and D; finite-window readback through W and R; convergence-criterion compatibility through the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *route named by P; terminal Real-seal discipline through E; and componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *support.*

Proof. Project the carrier of Definition 6460.1. The rows $S, M, D, W, R, E, H, C, P, N$ are the only available coordinates, so carrier admission and local naming are finite row projections.

The uniformity row is M, and its tolerance budget is the dyadic row D. Any precision request must read those rows before a tail comparison can be consumed, so the route is uniform over the displayed sequence rather than selected separately for each index.

The observation rows are W and R. They force all inspected values through StreamName windows and RegSeqRat readbacks before the terminal seal E is available.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no quotient, selector, choice, host-function, or ambient-completeness coordinate, the listed rows exhaust the NameCert surface. □

Theorem 6460.3 (Regular Cauchy uniform-limit Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CauchyConvergenceCriterion}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff reads the sequence row, a displayed uniform Cauchy modulus, dyadic tolerance rows, finite StreamName windows, RegSeqRat readbacks, the convergence-criterion route, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before the terminal real seal is consumed. It exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limit, countable choice, or host function equality.*

Proof. Begin with the obligation theorem Definition 6460.2. It places the uniform modulus and dyadic tolerance rows before any real-facing read.

The sibling route then fixes the finite observation order. StreamName supplies the windows, RegSeqRat supplies the rational readback rows, and DyadicRatCore supplies the tolerance comparisons needed by the uniform modulus.

The convergence-criterion row named in the provenance keeps the handoff on the regular Cauchy route before the terminal $\mathsf{Real}^{\uparrow}$ seal is read. Transport and replay through H and C preserve the same packet, while P, N source and name it.

Because none of the excluded principles is present in the carrier, the consumer receives only the displayed finite route and not an ambient completeness or quotient-function endpoint. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$ real-facing read exposes regular Cauchy sequence data, one uniform modulus row, DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readbacks, a convergence-criterion route, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchyconvergencecriterion: none is bijective to $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$ because this packet alone binds a sequence of regular Cauchy real-name packets to one displayed uniform modulus and a terminal RealUp handoff without quotient streams, selected limits, countable choice, host function equality, or ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$ packet is generated from regular Cauchy real-name sequence rows, one uniform Cauchy modulus row, DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readbacks, a convergence-criterion route, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniformLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6460.1, Definition 6460.2, and Definition 6460.3 seed the finite regular-Cauchy uniform-limit route through uniform modulus, dyadic tolerance, StreamName windows, RegSeqRat readback, convergence criterion, transport, replay, provenance, local naming, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniformLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, quotient stream equality, selected limits, countable choice, host function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-modulus exactness, dyadic tolerance coverage, finite-window readback, convergence-criterion compatibility, Real-seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyUniformLimitUp.

Chapter 6461

A Concrete Naming Certificate for $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$ packet records the finite tail-tolerance criterion by which two regular rational names are compared before a $\mathsf{Real}^{\uparrow}$ consumer reads an equality boundary. It sits after the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet names equality by displayed dyadic radii and cofinal regular-sequence tails, not by quotient classes, selected representatives, trichotomy, or choice.

Definition 6461.1 (Regular Cauchy equality criterion carrier)**.** *A* $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened for the compared regular Cauchy names.*
2. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, binding each opened window to rational observations.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the displayed radii, half-radius splits, and comparison cells used by the test.*
4. T *is the common finite tail row, recording that both regular names are read past the displayed tail stage for the same dyadic tolerance request.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *equality-boundary read, available only after the two windows, the two regular readbacks, the dyadic ledger, and the common tail row have been displayed.*
6. H *records componentwise* hsame *transport for the two windows, two readbacks, dyadic ledger, tail row, equality boundary, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the route*

$$S_0, S_1, R_0, R_1, D \longmapsto T \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, R_0, R_1, D, T, E, H, C, P, N$. It has no coordinate for quotient equality of Cauchy names, a selected representative, real trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.RegularCauchyEqualityCriterionUp`

Theorem 6461.2 (Regular Cauchy equality criterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$ *carrier*

$$Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission, two StreamName window exposures, two RegSeqRat readbacks, one DyadicRatCore tolerance ledger, one common tail row, ordered* $\mathsf{Real}^{\uparrow}$ *equality-boundary access, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. A consumer that reads equality of the two regular Cauchy names must pass through those rows before it may cite the Real-facing equality boundary.*

Proof. Project the accepted finite BHist packet. Carrier admission exposes exactly the two windows, two regular readbacks, dyadic tolerance ledger, common tail row, equality-boundary row, transport row, replay row, provenance row, and local naming row.

The two readback sides are symmetric but not quotient data. The rows S_0, R_0 and S_1, R_1 provide only displayed finite windows and regular rational observations.

The dyadic and tail stages are ordered. The row D supplies the displayed radii and comparison cells, and T records the common tail stage at which both regular names are read for that request.

The equality-boundary row E is downstream of S_0, S_1, R_0, R_1, D, T. Since the remaining rows H, C, P, N only transport, replay, source, and name the same route, the listed rows exhaust the local NameCert surface. □

Theorem 6461.3 (Regular Cauchy equality criterion dyadic tail route)**.** *Let*

$$Q = (S_0, S_1, R_0, R_1, D, T, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that reads the equality criterion for the two regular Cauchy names factors through the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Consequently the criterion routes through displayed dyadic radii and regular-sequence tails: the consumer receives the two StreamName windows, two RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the common tail row, the equality-boundary row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data. It receives no quotient class of Cauchy names, selected representative, trichotomy decision, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier and project the two window rows S_0, S_1. These are the only observation windows available to a consumer of the compared names.

Next read the two regular rational rows R_0, R_1. They bind the observations to regular-sequence data for the same consumer request, so the route has not introduced an external representative or quotient object.

The dyadic tolerance row D is then read before the common tail row T. This makes the radius and the tail stage displayed together, with the tail request determined by the same finite ledger.

Finally read the equality-boundary row E and the structural rows H, C, P, N. The route therefore reaches any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ equality consumer only through the displayed dyadic radii and regular-sequence tails, and the carrier has no coordinate from which the excluded quotient, selection, order, choice, host-equality, or completeness principles could be recovered. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$ packet is generated from two StreamName windows, two RegSeqRat readback rows, one DyadicRatCore tolerance ledger, one common tail row, a RealUp equality-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6461.1, Definition 6461.2, and Definition 6461.3 seed the finite tail-tolerance equality route for regular Cauchy names over displayed dyadic radii.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.RegularCauchyEqualityCriterionUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality of Cauchy names, selected representatives, trichotomy, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired readback exactness, dyadic tolerance exposure, common-tail exactness, ordered equality-boundary access, and structural stability for BEDC.Derived.RegularCauchyEqualityCriterionUp

Chapter 6462

A Concrete Naming Certificate for $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$

Following Bishop and Bridges on compact intervals, finite coverings, and fan-theorem style moduli, the $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$ packet records the bounded binary fan/bar modulus surface needed by L10 interval-cover routes. It sits after the located interval-cover packet of chapter 1885, the dyadic interval-cover packet of chapter 1428, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a finite modulus certificate for located interval rows; it does not assert open-cover compactness, countable choice, bar induction outside the displayed finite tree, or an ambient real completeness principle.

Definition 6462.1 (Located interval fan modulus carrier)**.** *A* $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, F, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *row listing the located interval requests, endpoint comparisons, and cover-membership reads exposed to the L10 route;*
2. *F is the binary fan/bar modulus row, a finite tree of binary prefixes with a displayed bar level and a modulus bound for the accepted interval requests;*
3. *D is the* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *window row, recording the dyadic subintervals and mesh refinements read by the fan row;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, listing the finite source windows opened before a branch prefix or interval endpoint is inspected;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the stream windows, dyadic endpoint comparisons, and located interval decisions;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the rows L, F, D, W, Q have been displayed;*
7. *H records componentwise* hsame *transport for located interval rows, fan/bar rows, dyadic windows, stream schedules, rational readbacks, real seals, replay routes, provenance, and local naming;*
8. *C records displayed* Cont *replay from an L10 interval-cover request through the finite fan/bar row and then through D, W, Q, E;*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalFanModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, F, D, W, Q, E, H, C, P, N$. It has no coordinate for an open-cover compactness oracle, countable choice, a branch selected outside the finite fan, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6462.2 (Located interval fan modulus NameCert obligations)**.** *For every accepted* $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$ *carrier*

$$M = (L, F, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalFanModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, located interval-cover admission through L, binary fan/bar modulus admission through F, dyadic cover-window admission through D, stream-schedule admission through W, regular rational readback through Q, terminal real-seal admission through E, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6462.1. The displayed rows are exactly $L, F, D, W, Q, E, H, C, P, N$, so every local obligation is attached to one of those rows.

The located interval-cover row is read before the fan row, and the fan row is read before the dyadic window, stream schedule, rational readback, and real seal. Thus a modulus claim cannot skip from an interval request directly to a real conclusion.

The structural rows H, C, P, N transport, replay, package, and name the same finite route. Since no excluded coordinate is present in the carrier, the local NameCert surface cannot call on open-cover compactness, countable choice, an off-packet branch selector, quotient real equality, or ambient real completeness. □

Theorem 6462.3 (Located interval fan modulus route)**.** *Every L10 interval-cover consumer of an accepted* $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedIntervalCover}^{\uparrow},\ \mathsf{FanFunctional}^{\uparrow},\ \mathsf{DyadicIntervalCover}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In carrier notation this means that every exported modulus first reads the located interval row L, the binary fan/bar row F, the dyadic cover window D, the stream schedule W, the rational readback Q, the terminal real seal E, and the structural rows H, C, P, N. The route exports no open-cover compactness oracle, countable-choice selector, off-packet infinite branch, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from an L10 interval-cover request. By Definition 6462.1, the request enters the packet through L, where the located interval rows and cover-membership reads are displayed.

The fan/bar modulus row F can be inspected only after that located interval surface is present. Its binary prefixes are then compared against the dyadic window row D and the finite stream schedule W.

The rational readback Q and real seal E are downstream of those finite rows. Finally H, C, P, N preserve the same route under transport, replay, provenance, and naming. Hence every consumer-facing modulus is bounded by the displayed finite packet. □

Falsifiable prediction: A purported L10 interval-cover modulus that reads a $\mathsf{Real}^{\uparrow}$ conclusion without displaying the $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows refutes the $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$ carrier.

Independence witness: locatedintervalcover, dyadicintervalcover, fanfunctional, streamname, regseqrat, real: $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$ binds the located interval row, binary fan/bar modulus row, dyadic cover window, stream schedule, regular rational readback, real seal, and structural transport rows in one finite NameCert packet; each named sibling lacks at least one of these rows as a local carrier obligation.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalFanModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalFanModulus}^{\uparrow}$ packet is generated from located interval-cover rows, a finite binary fan/bar modulus row, dyadic cover windows, stream schedules, regular rational readbacks, a terminal real seal, componentwise hsame transport, displayed Cont replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalFanModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6462.1, Definition 6462.2, and Definition 6462.3 bind the finite fan/bar modulus route for L10 located interval-cover consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalFanModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, bar induction outside the displayed finite tree, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: To reach obligationClosure, the located interval-cover row, binary fan/bar row, dyadic window, stream schedule, rational readback, real seal, and route obligations must be encoded as checked finite carrier obligations.

Chapter 6463

A Concrete Naming Certificate for $\mathsf{TukeyOrder}^{\uparrow}$

Following Tukey's theory of cofinal maps and the Moore–Smith reading of nets, the $\mathsf{TukeyOrder}^{\uparrow}$ packet records finite directed-comparison data for net and filter completion routes. It sits over the directed-system surface of chapter 1607, the Moore–Smith net surface of chapter 3403, the Cauchy-net route of chapter 589, the filter-base route of chapter 1601, and the Cauchy-filter route of chapter 333. The packet compares displayed presentations by cofinal response rows; it is not a quotient of nets, not a quotient of filters, not a selected subnet, not a selected limit, and not a countable-choice principle.

Definition 6463.1 (Tukey-order carrier)**.** *A* $\mathsf{TukeyOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, Q, \rho, \lambda, M, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the source directed-system row, read through* $\mathsf{DirectedSet}^{\uparrow}$ *and the source* $\mathsf{MooreSmithNet}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *presentation.*
2. *Q is the target directed-system row, read through* $\mathsf{DirectedSet}^{\uparrow}$ *and the target* $\mathsf{FilterBase}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *presentation.*
3. *ρ is the cofinal response map. For each displayed target request it names a source request and the finite containment or late-tail witness that answers the target request from the source route.*
4. *λ is the reverse comparison ledger when present. It records displayed return comparisons for two-way route comparison, but a one-way Tukey comparison may leave this row empty.*
5. *M is the net-side handoff row, naming the* $\mathsf{MooreSmithNet}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *windows consumed by the comparison.*
6. *F is the filter-side handoff row, naming the* $\mathsf{FilterBase}^{\uparrow}$ *and* $\mathsf{CauchyFilter}^{\uparrow}$ *packets consumed by the comparison.*
7. *H records componentwise* hsame *transport for the source system, target system, cofinal response map, reverse ledger, net handoff, filter handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from any target request through ρ and, when present, through λ.*

9. *P is the* Pkg *provenance over* $\mathsf{TukeyOrder}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TukeyOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, Q, \rho, \lambda, M, F, H, C, P, N$. It has no coordinate for quotient net equality, quotient filter equality, selected subnets, selected cofinal families, selected limits, countable choice, host real equality, or ambient completeness.

Theorem 6463.2 (Tukey-order NameCert obligations)**.** *For every accepted* $\mathsf{TukeyOrder}^{\uparrow}$ *carrier $T = (S, Q, \rho, \lambda, M, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TukeyOrder}^{\uparrow}}$ *surface consists exactly of source directed-system admission through S, target directed-system admission through Q, cofinal response coverage through ρ, optional reverse comparison coverage through λ, net-side handoff through M, filter-side handoff through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No Tukey-order obligation is stored outside those rows.

Proof. Project the carrier of Definition 6463.1. The accepted packet is exhausted by the two directed-system rows, the cofinal response map, the optional reverse ledger, the net and filter handoff rows, and the structural rows H, C, P, N.

The comparison route starts with a target request in Q. The row ρ answers it by naming a source request in S together with the displayed late-tail or containment witness needed by the source route. When a two-way comparison is required, λ supplies only finite return comparisons between the same displayed rows.

The net-side and filter-side handoffs do not add hidden comparison data. The rows M and F merely record which $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, and $\mathsf{CauchyFilter}^{\uparrow}$ presentations are being compared, while H, C, P, N transport, replay, source, and name the same finite packet. □

Theorem 6463.3 (Tukey-order net-filter handoff)**.** *Every net/filter completion consumer of an accepted* $\mathsf{TukeyOrder}^{\uparrow}$ *carrier factors through the finite directed-comparison route*

$$Q \xrightarrow{\rho} S \longmapsto M, F, H, C, P, N,$$

with λ inserted only when the consumer requests a displayed reverse comparison. Consequently a $\mathsf{MooreSmithNet}^{\uparrow}$ *or* $\mathsf{CauchyNet}^{\uparrow}$ *presentation can be compared with a* $\mathsf{FilterBase}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *presentation without quotienting nets or filters, selecting subnets, selecting cofinal families, selecting limits, invoking countable choice, or importing ambient completeness.*

Proof. Begin with a completion-facing net/filter consumer. The carrier definition exposes the target directed-system row Q and the source directed-system row S before any comparison can be read.

Replay the consumer request through ρ. The cofinal response map turns each displayed target request into a displayed source request and records the required late-tail or containment witness. If the route asks for equivalence rather than one-way comparison, the reverse ledger λ supplies a finite list of return comparisons over the same visible rows.

Finally read the handoff rows M and F. They keep the consumer inside the named $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, and $\mathsf{CauchyFilter}^{\uparrow}$ presentations, while H, C, P, N preserve the same finite comparison packet. Since no excluded coordinate appears in the carrier, the handoff cannot export quotient equality, selected subnets, selected limits, countable choice, host equality, or ambient completeness. □

Falsifiable prediction: A net/filter completion route that compares a Cauchy-net presentation with a Cauchy-filter presentation after deleting S, Q, ρ, M, or F refutes the carrier of Definition 6463.1.

Independence witness: directedset, moore-smith-net, cauchynet, filterbase, cauchyfilter: $\mathsf{TukeyOrder}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source and target directed-system rows, a cofinal response map, an optional reverse comparison ledger, net-side and filter-side handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{TukeyOrder}^{\uparrow}}$.

Constructive story: A $\mathsf{TukeyOrder}^{\uparrow}$ packet is generated from source and target directed-system rows, a cofinal response map, an optional reverse comparison ledger, MooreSmithNet and CauchyNet handoffs, FilterBase and CauchyFilter handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TukeyOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6463.1, Definition 6463.2, and Definition 6463.3 seed the finite Tukey comparison surface for net and filter completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TukeyOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient net equality, quotient filter equality, selected subnets, selected cofinal families, selected limits, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source and target directed-system admission, cofinal response coverage, reverse comparison coverage, net and filter handoff exactness, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.TukeyOrderUp.

Chapter 6464

A Concrete Naming Certificate for $\mathsf{SemidecidableOpen}^{\uparrow}$

Following Bishop and Bridges and the constructive-topology reading of observable opens, the $\mathsf{SemidecidableOpen}^{\uparrow}$ packet records positive open evidence as finite BEDC observation data. It sits over the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Sierpinski observable-open classifier of chapter 1860, and the indexed open-row discipline of chapter 88. The packet names the interface by which a positive open observation may be reported without importing host open sets, quotient topology, excluded middle over membership, selected witnesses, or ambient real completeness.

Definition 6464.1 (Semidecidable open carrier)**.** *A* $\mathsf{SemidecidableOpen}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, T, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *classifier row, exposing the observable truth mark for a positive open report.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, recording the indexed open under inspection as displayed topology data.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite window row, listing the observed request prefixes available to the open report.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational witness data used when the open report is read by a real-name consumer.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, attaching the report to the displayed real-name boundary rather than to a host real.*
6. *H stores componentwise* hsame *transport for classifier, topology, window, rational readback, real seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from the positive observation request through S, T, W, Q, R, H.*
8. *P is the* Pkg *provenance over* $\mathsf{SemidecidableOpen}^{\uparrow}$*,* $\mathsf{SierpinskiSpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SemidecidableOpen}^{\uparrow}}$ *row.*

The carrier has no coordinate for a negative open-membership decision, a host powerset open, quotient equality of opens, selected neighbourhood witnesses, countable choice, or a bridge credential.

Theorem 6464.2 (Semidecidable open NameCert obligations)**.** *For every accepted* $\mathsf{SemidecidableOpen}^{\uparrow}$ *carrier* $O = (S, T, W, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SemidecidableOpen}^{\uparrow}}$ *surface consists exactly of Sierpinski classifier admission, Topology open-row admission, StreamName finite-window readback, RegSeqRat rational witness readback, Real seal attachment, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A positive open consumer must read* S, T, W, Q, R *before it consumes* H, C, P, N*.*

Proof. Project the carrier of Definition 6464.1. The rows S and T supply the observable classifier and indexed open source; neither row is a host proposition about arbitrary subsets.

The rows W, Q, R make the positive evidence finite and real-facing. W records the observed StreamName windows, Q records the regular rational readback used by completion consumers, and R seals that readback at the displayed $\mathsf{Real}^{\uparrow}$ boundary.

Finally H, C, P, N transport, replay, source, and name the same displayed packet. Since the carrier has no negative-decision row, selected-neighbourhood row, host powerset row, quotient-open row, countable-choice row, or bridge credential, the listed rows exhaust the local NameCert obligations. □

Theorem 6464.3 (Semidecidable open real observation route)**.** *Every real-facing positive open read exported by an accepted* $\mathsf{SemidecidableOpen}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{SierpinskiSpace}^{\uparrow} \longrightarrow \mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Thus L10 Real and Completion consumers receive positive open evidence through finite observable windows and regular rational readback, not through host open sets, quotient topology, excluded middle over membership, selected witnesses, or ambient completeness.

Proof. Read $O = (S, T, W, Q, R, H, C, P, N)$. The Sierpinski row S classifies the positive observation before the topology row T supplies the indexed open source.

The StreamName row W then fixes the finite observation window. The RegSeqRat row Q supplies the rational readback attached to that window, and the Real row R seals the result at the displayed real-name boundary.

Transport, replay, provenance, and naming through H, C, P, N preserve this order. A real-facing consumer therefore receives only the finite positive-evidence route and cannot bypass it by importing a host open-set predicate, quotient topology, excluded middle, selected witnesses, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{SemidecidableOpen}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SemidecidableOpen}^{\uparrow}$ packet is generated from a SierpinskiSpace classifier row, a Topology indexed-open row, finite StreamName observation windows, RegSeqRat rational readback, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SemidecidableOpen}^{\uparrow}}$, seed)

Scope closed: Definition 6464.1, Definition 6464.2, and Definition 6464.3 seed the finite positive-open observation interface over SierpinskiSpace, Topology, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SemidecidableOpen}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.SemidecidableOpenUp`

Bridge status: none

Not claimed: This chapter does not close negative open-membership decisions, host open sets, quotient topology, excluded middle, selected witnesses, ambient real completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive classifier exactness, finite-window readback, real observation routing, transport, replay, provenance, and local naming for BEDC.Derived.SemidecidableOpenUp.

Chapter 6465

A Concrete Naming Certificate for CauchyCondensationIntegralBound$^{\uparrow}$

Following Hardy, *Divergent Series*, the CauchyCondensationIntegralBound$^{\uparrow}$ packet records the finite integral-bound ledger that sits between the theorem-level condensation surface of chapter 3727 and the bridge packet of chapter 6071. It also shares the dyadic arithmetic, regular rational readback, and terminal real-name corridor of chapter 291, chapter 301, and chapter 38. The carrier names monotone positive term windows and dyadic integral-window majorants as BEDC rows before any Real or Completion consumer reads a bound.

Definition 6465.1 (CauchyCondensationIntegralBound carrier)**.** *A* CauchyCondensationIntegralBound$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, D, I, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the monotone positive term ledger, recording only inspected source windows, positivity witnesses, and monotonicity comparisons for the displayed tail.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *dyadic scale row, carrying powers-of-two windows, endpoint comparisons, and dyadic slack data.*
3. *I is the integral-window ledger, recording finite lower and upper interval cells attached to the displayed dyadic scale.*
4. *B is the dyadic integral-window majorant row, bounding each displayed condensation block by the corresponding integral-window data.*
5. *W is the finite readback schedule for Real and Completion consumers.*
6. *R is the* RegSeqRat$^{\uparrow}$ *tail readback row obtained from M, D, I, B, W.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after the majorant and regular-readback rows are visible.*
8. *H records componentwise* hsame *transport for monotone terms, dyadic scales, integral windows, majorants, schedules, readback rows, seal rows, replay rows, provenance rows, and local names.*
9. *C records displayed* Cont *replay from M, D, I to B, from B, W to R, and from R to the seal row E.*

10. *P is the* Pkg *provenance over* CauchyCondensationIntegralBound$^{\uparrow}$, CauchyCondensationTheorem$^{\uparrow}$, CauchyCondensationIntegralBridge$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyCondensationIntegralBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, I, B, W, R, E, H, C, P, N$. It has no coordinate for an ambient improper integral, selected infinite sum, quotient series equality, countable choice, trichotomy, host real equality, or completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyCondensationIntegralBoundUp.CauchyCondensationIntegralBoundTasteGate`
`single carrier alignment`

Theorem 6465.2 (CauchyCondensationIntegralBound NameCert obligations)**.** *For every accepted* CauchyCondensationIntegralBound$^{\uparrow}$ *carrier $J = (M, D, I, B, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{CauchyCondensatio}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet; monotone positive term exposure through M; dyadic scale exposure through D; integral-window exposure through I; dyadic majorant exposure through B; finite schedule exposure through W;* RegSeqRat$^{\uparrow}$ *readback through R;* Real$^{\uparrow}$ *sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier rows from Definition 6465.1. The packet exposes only monotone term windows, dyadic scale data, integral windows, majorant rows, finite schedules, regular readbacks, Real seals, and the structural rows.

Read the analytic handoff through the adjacent condensation chapters. The theorem packet supplies the monotone dyadic block route, while the integral bridge supplies the finite comparison corridor between condensation tails and integral windows.

The local NameCert row admits exactly those exposed rows and their structural transports. Since the carrier has no coordinate for an ambient integral, selected sum, quotient equality, countable choice, trichotomy, host equality, or Real completeness, the listed obligations exhaust the certificate surface. □

Theorem 6465.3 (CauchyCondensationIntegralBound dyadic majorant)**.** *Every accepted* CauchyCondensationInteg *carrier sends a monotone positive tail to a dyadic integral-window majorant only through the finite route*

$$M, D, I \longmapsto B \longmapsto W \longmapsto R.$$

The route is anchored by CauchyCondensationTheorem$^{\uparrow}$ *on the condensation side and by* CauchyCondensationIntegral *on the integral-window side, and it exports no selected subseries, host integral object, quotient real equality, or ambient completeness principle.*

Proof. Begin with the source rows M, D, I. The monotone positive term ledger and dyadic scale rows determine which finite integral windows may be inspected.

Use the bridge route of chapter 6071. It matches the condensation-side dyadic tail to the integral-window side before any regular rational readback is consumed.

The majorant row B is then read through the finite schedule W into R. Componentwise transport and continuation replay preserve the same route, so the majorant cannot be replaced by an unlisted selected sum, ambient integral, quotient equality, or completeness row. □

Theorem 6465.4 (CauchyCondensationIntegralBound Real seal)**.** *Every Real-facing read of an accepted* CauchyCondensationIntegralBound$^{\uparrow}$ *carrier reaches E only after the displayed route*

$$M, D, I, B, W, R, E$$

has exposed the monotone positive term ledger, dyadic integral-window majorant, $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and structural rows* H, C, P, N*. Thus the seal records a finite integral-bound certificate, not an ambient summability theorem or a completeness assertion for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Apply Definition 6465.3. It places every bound read behind M, D, I, B, W, R and keeps the dyadic and integral-window rows visible.

The terminal seal row E is downstream of the regular readback row. A Real consumer therefore receives the bound only after the regular rational handoff is present.

Finally inspect the carrier exactness from Definition 6465.1. The structural rows transport, replay, source, and name the same finite route, while no coordinate supplies ambient integration, selected infinite sums, quotient equality, countable choice, trichotomy, host equality, or Real completeness. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationIntegralBound}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the monotone positive term row, dyadic scale row, integral-window row, dyadic majorant row, finite readback schedule, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: cauchy-condensation-theorem, cauchy-condensation-integral-bridge, dyadicratcore, regseqrat, real: no listed sibling supplies the whole integral-bound packet $J = (M, D, I, B, W, R, E, H, C,$ because each sibling contributes only a theorem row, bridge row, dyadic ledger, regular readback, or terminal seal while this chapter binds them into one finite majorant certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralBound}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCondensationIntegralBound}^{\uparrow}$ packet is generated from monotone positive term windows, DyadicRatCore scale rows, finite integral-window rows, dyadic majorant rows, readback schedules, RegSeqRat tail readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6465.1, Definition 6465.2, Definition 6465.3, and Definition 6465.4 seed the finite integral-bound ledger over monotone tails, dyadic windows, RegSeqRat readback, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralBound}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyCondensationIntegralBoundUp.CauchyCondensationIntegralBoundTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close ambient improper integration, selected infinite sums, quotient series equality, countable choice, trichotomy, host real equality, Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone positive term exposure, dyadic integral-window majorant exposure, regular readback exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCondensationIntegralBoundUp.

Chapter 6466

A Concrete Naming Certificate for $\mathsf{CompactUniformTailSelector}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactUniformTailSelector}^{\uparrow}$ packet records the finite selector surface that turns compact finite-net data and pointwise modulus ledgers into a tolerance-only uniform tail ledger. It is grounded in the compact-uniform-continuity route of chapter 9237, the compact-net packets of chapter 4760 and chapter 6453, the continuous-map route of chapter 130, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite ProbeBundle tail-radius handoff, not a global choice function, open-cover compactness theorem, or ambient completeness principle.

Definition 6466.1 (CompactUniformTailSelector carrier)**.** *A* $\mathsf{CompactUniformTailSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, F, Pb, L, D, U, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *K is the compact finite-net row, exposing only the inspected* ProbeBundle *of centers and coverage witnesses.*
2. *F is the continuous-map row whose pointwise modulus entries are being folded.*
3. *Pb is the finite* ProbeBundle *spine used by the selector.*
4. *L is the local tail-radius ledger, one displayed radius and pointwise-modulus certificate for each bundled probe.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the local radii and the requested output tolerance.*
6. *U is the tolerance-only uniform tail threshold selected by finite fold over Pb, L, D.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected threshold and the inspected finite net.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, F, Pb, L, D, U, R have been displayed.*
9. *H records componentwise* hsame *transport for compact nets, pointwise modulus rows, bundle spines, local radii, dyadic tolerances, selected thresholds, readbacks, seals, provenance, and names.*
10. *C records displayed* Cont *replay from compact finite-net rows and pointwise moduli to U, and from U to R, E.*

11. *Q is the* Pkg *provenance over* $\mathsf{CompactUniformTailSelector}^{\uparrow}$, $\mathsf{CompactUniformFiniteNet}^{\uparrow}$, CompactNetModulusStab
ContinuousMap$^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformTailSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a global point selector, arbitrary open cover, selected minimum outside the bundle fold, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6466.2 (CompactUniformTailSelector NameCert obligations)**.** *For every accepted* CompactUniformTailS
carrier $T = (K, F, Pb, L, D, U, R, E, H, C, Q, N)$, the local $\mathsf{NameCert}_{\mathsf{CompactUniformTailSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; compact finite-net exposure through K; continuous-map pointwise-modulus exposure through F;* ProbeBundle *spine exposure through Pb; local tail-radius exposure through L; dyadic tolerance comparison through D; uniform threshold exposure through U;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R;* $\mathsf{Real}^{\uparrow}$ *sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through Q; and local naming through N.*

Proof. Project the carrier rows from Definition 6466.1. The accepted packet exposes compact finite-net rows, pointwise-modulus rows, a finite bundle spine, local tail radii, dyadic tolerances, a selected uniform threshold, regular readback, Real seal, and structural rows.

The finite fold is internal to the displayed ProbeBundle. It reads every bundled local radius and keeps the threshold row U as a certificate over the same finite carrier.

The structural rows preserve this route under transport, replay, provenance, and local naming. Since no row supplies a global choice function, arbitrary open-cover compactness, quotient equality, selected external minimum, countable choice, or Real completeness, the listed obligations exhaust the NameCert surface. □

Theorem 6466.3 (CompactUniformTailSelector finite-net handoff)**.** *Every accepted* $\mathsf{CompactUniformTailSelector}^{\uparrow}$ *packet hands compact finite-net data to the uniform selector only through the finite route*

$$K, F, Pb, L, D \longmapsto U.$$

The handoff reads the ProbeBundle *spine and pointwise modulus rows before producing a tolerance-only tail threshold, and it does not choose points, subcovers, or radii outside the displayed bundle.*

Proof. Begin with the compact finite-net row K and the pointwise modulus row F. These rows determine the inspected centers, local radius certificates, and coverage witnesses available to the selector.

Fold over the finite bundle spine Pb. Each local tail-radius row in L is compared through the dyadic tolerance row D, and the fold exports only the threshold row U.

The transport and continuation rows preserve the same finite handoff. The packet therefore cannot import a global point selector, selected subcover, external minimum, quotient real equality, or completeness row. □

Theorem 6466.4 (CompactUniformTailSelector finite-net route)**.** *Every accepted* $\mathsf{CompactUniformTailSelector}^{\uparrow}$ *packet receives compact finite-net data through* $\mathsf{CompactUniformFiniteNet}^{\uparrow}$ *and* $\mathsf{CompactNetModulusStability}^{\uparrow}$ *before the* ProbeBundle *spine, local radius ledger,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal are visible. For a carrier*

$$T = (K, F, Pb, L, D, U, R, E, H, C, Q, N),$$

the route projects K, F, Pb, L, D, U, R, E in that order and exports no open-cover compactness object, point-choice coordinate, external minimum selector, countable-choice schedule, quotient real equality, or ambient completeness witness.

Proof. Project the carrier rows $K, F, Pb, L, D, U, R, E, H, C, Q, N$ from Definition 6466.1. The rows K and F are the compact finite-net and pointwise-modulus inputs, while Pb, L, D are the finite bundle spine, local radius ledger, and dyadic tolerance ledger inspected by the selector.

Apply Definition 6466.3. It forces the selector threshold U to be produced only after the compact finite-net row, pointwise modulus row, bundle spine, local radius rows, and dyadic comparisons have been displayed.

Now apply Definition 6466.5. The regular readback R and terminal Real seal E are downstream of the selected threshold, so the Real-facing route cannot be read before the finite-net and pointwise-modulus data have passed through the displayed ProbeBundle discipline.

Finally inspect the excluded coordinates in the carrier. Since open-cover compactness, point choice, external minima, countable choice, quotient real equality, and ambient completeness are absent from $K, F, Pb, L, D, U, R, E, H, C, Q, N$, every accepted packet consumes the compact finite-net route directly through $\mathsf{CompactUniformFiniteNet}^{\uparrow}$ and $\mathsf{CompactNetModulusStability}^{\uparrow}$ rather than through any external compactness principle. □

Theorem 6466.5 (CompactUniformTailSelector uniform modulus route)**.** *Every Real-facing or uniform-modulus consumer of an accepted* $\mathsf{CompactUniformTailSelector}^{\uparrow}$ *packet must read*

$$K, F, Pb, L, D, U, R, E$$

in that order before treating the selected threshold as a uniform modulus. The route turns compact finite-net coverage and pointwise moduli into a tolerance-only ledger through $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, not through open-cover compactness, sequential compactness, countable choice, or ambient Real completeness.*

Proof. Apply Definition 6466.3. It places the threshold U behind compact finite-net rows, pointwise modulus rows, the finite bundle spine, local radii, and dyadic comparisons.

The readback row R and seal row E are downstream of U. A uniform-modulus consumer therefore receives the selected threshold only after regular rational readback and the Real-facing seal have preserved the same finite route.

Finally inspect the excluded rows in Definition 6466.1. There is no coordinate for an arbitrary open cover, sequential compactness, a global choice function, quotient real equality, selected external minimum, or Real completeness, so the uniform-modulus route remains the displayed finite handoff. □

Falsifiable prediction: An accepted $\mathsf{CompactUniformTailSelector}^{\uparrow}$ consumer that reads a tolerance-only uniform tail threshold without the compact finite-net row, pointwise modulus row, finite ProbeBundle spine, local tail-radius ledger, DyadicRatCore tolerance row, RegSeqRat readback row, RealUp seal row, and structural rows refutes the carrier surface.

Independence witness: compact-uniform-finite-net, compact-net-modulus-stability, continuous-map, dyadicratcore, regseqrat, real: no listed sibling supplies the whole selector packet $T = (K, F, Pb, L, D, U, R, E, H, C, Q, N)$, because each sibling contributes only a compact-net row, pointwise-modulus row, dyadic ledger, regular readback, or terminal seal while this chapter binds them into one tolerance-only tail selector.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformTailSelector}^{\uparrow}}$.

Constructive story: A CompactUniformTailSelector$^{\uparrow}$ packet is generated from compact finite-net rows, continuous-map pointwise modulus rows, a finite ProbeBundle spine, local tail-radius rows, DyadicRatCore tolerance comparisons, a tolerance-only uniform threshold, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformTailSelector}^{\uparrow}}$, seed)

Scope closed: Definition 6466.1, Definition 6466.2, Definition 6466.3, and Definition 6466.5 seed the finite compact-net tail selector from ProbeBundle radii to a tolerance-only uniform-modulus ledger.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformTailSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, sequential compactness, global point selection, selected external minima, quotient real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, pointwise modulus exposure, finite-bundle fold exactness, tolerance-threshold readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformTailSelectorUp.

Chapter 6467

A Concrete Naming Certificate for FinePartitionGauge$^{\uparrow}$

Following Cousin and Bishop–Bridges gauge integration, the FinePartitionGauge$^{\uparrow}$ packet records a finite tagged partition whose cells are already certified fine for a displayed positive gauge. It sits between the existence route of chapter 1861, the cover-facing surface of chapter 3426, the integral packet of chapter 1999, the tagged-sum route of chapter 4115, and the lower–upper comparison surface of chapter 1880. The packet names only finite interval data, positive gauge bounds, tagged cells, fineness proofs, mesh readback, Cousin handoff, regular rational readback, terminal real sealing, transport, replay, provenance, and a local certificate.

Definition 6467.1 (FinePartitionGauge carrier)**.** *A* FinePartitionGauge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, G, T, L, M, U, R, E, H, C, P, N)$$

whose rows expose:

1. *I, the interval source row read from the displayed compact interval or located interval source;*
2. *G, the positive gauge row assigning a strictly positive local radius to each admitted tag;*
3. *T, the finite tagged-cell ledger listing cells, tags, endpoint order, and cell coverage;*
4. *L, the fine-cell proof row stating that every tagged cell of T lies inside the gauge radius supplied by G at its tag;*
5. *M, the mesh row recording the largest displayed cell width and the finite comparison budget used by later sums;*
6. *U, the Cousin handoff row through chapter 1861 and chapter 3426;*
7. *R, the* RegSeqRat$^{\uparrow}$ *readback row for rational mesh and tagged-sum approximants;*
8. *E, the terminal* Real$^{\uparrow}$ *seal row available only after the regular rational readback;*
9. *H, the componentwise* hsame *transport row for interval, gauge, cell, mesh, handoff, readback, and seal data;*
10. *C, the displayed* Cont *replay row preserving the same finite tagged partition route;*
11. *P, the* Pkg *provenance over* FinePartitionGauge$^{\uparrow}$, CousinLemma$^{\uparrow}$, CousinCover$^{\uparrow}$, GaugeIntegral$^{\uparrow}$, RiemannSumGauge$^{\uparrow}$, DarbouxSum$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

12. N, the local $\mathsf{NameCert}_{\mathsf{FinePartitionGauge}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, G, T, L, M, U, R, E, H, C, P, N$. It has no coordinate for a choice-selected partition, an unbounded open cover, host compactness, quotient equality of real functions, or an ambient integration theorem.

Theorem 6467.2 (FinePartitionGauge NameCert obligations)**.** *For every accepted* $\mathsf{FinePartitionGauge}^{\uparrow}$ *carrier $F = (I, G, T, L, M, U, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FinePartitionGauge}^{\uparrow}}$ *surface is exhausted by interval-source admission, positive-gauge admission, finite tagged-cell coverage, fine-cell proof, mesh readback, Cousin handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{GaugeIntegral}^{\uparrow}$*,* $\mathsf{RiemannSumGauge}^{\uparrow}$*, or* $\mathsf{DarbouxSum}^{\uparrow}$ *consumer must read these rows before using the packet.*

Proof. Project the carrier of Definition 6467.1. The rows $I, G, T, L, M, U, R, E, H, C, P, N$ are the entire displayed packet, so any local certificate obligation must be one of the listed interval, gauge, tagged-cell, fineness, mesh, handoff, readback, seal, transport, replay, provenance, or naming rows.

The fineness obligation is read before any sum or integral row. The tagged-cell ledger T supplies only finite cells and tags, while L checks each cell against the positive radius supplied by G.

The Cousin handoff and readback rows keep downstream consumers on the same finite route. The row U is the only route to the Cousin existence surface, R is the only regular rational readback, and E is visible only after R. Since the carrier has no selected-partition, host-compactness, or ambient integration coordinate, the NameCert surface is exactly the displayed packet. □

Theorem 6467.3 (FinePartitionGauge Cousin route)**.** *Every* $\mathsf{FinePartitionGauge}^{\uparrow}$ *carrier routes through the Cousin existence surface before any* $\mathsf{GaugeIntegral}^{\uparrow}$*,* $\mathsf{RiemannSumGauge}^{\uparrow}$*, or* $\mathsf{DarbouxSum}^{\uparrow}$ *read. In the notation of Definition 6467.1, a downstream integration consumer may inspect*

$$I, \quad G, \quad T, \quad L, \quad M, \quad U$$

and only then read the regular rational route R, the terminal seal E, and the structural rows H, C, P, N. Thus the packet separates finite fine-partition data from the Cousin existence theorem and exposes no independent choice-selected partition.

Proof. Start with the interval, gauge, tagged-cell, and fine-cell rows. They display the finite partition candidate and verify fineness against the positive gauge without reading an integral or sum row.

Next route the packet through the Cousin handoff row U. This row points to the Cousin lemma and Cousin cover sibling surfaces, so existence and cover refinement are consumed before any GaugeIntegral, Riemann-sum, or Darboux-sum consumer can read the partition as integration data.

Finally apply the NameCert obligation theorem above. It places R, E, H, C, P, N downstream of the finite Cousin route, and the carrier has no coordinate for a host choice selector or ambient compactness theorem. The downstream read therefore receives a displayed fine partition surface rather than an unbounded existence principle. □

Falsifiable prediction: Any accepted $\mathsf{FinePartitionGauge}^{\uparrow}$ packet must expose interval source, positive gauge, tagged-cell, fine-cell, mesh, Cousin handoff, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows before an integration consumer reads it.

Independence witness: cousinlemma, cousincover, gaugeintegral, riemannsumgauge, darbouxsum: $\mathsf{FinePartitionGauge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite tagged

cells, pointwise gauge fineness, mesh readback, Cousin handoff, regular rational readback, and terminal real sealing.

Closure status for $\mathsf{NameCert}_{\mathsf{FinePartitionGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{FinePartitionGauge}^{\uparrow}$ packet is generated from an interval source, positive gauge, finite tagged cells, fine-cell proof, mesh row, Cousin handoff, regular rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinePartitionGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6467.1, Definition 6467.2, and Definition 6467.3 seed the finite fine-partition surface between Cousin existence and gauge-integration consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinePartitionGauge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-selected partitions, host compactness, ambient integration theorems, quotient equality of real functions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-gauge admission, tagged-cell coverage, fine-cell proof, mesh readback, Cousin handoff, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Chapter 6468

A Concrete Naming Certificate for $\mathsf{JamesSpace}^{\uparrow}$

Following R. C. James, the $\mathsf{JamesSpace}^{\uparrow}$ packet records the classical block-basis norm route for James' nonreflexive Banach space as finite BEDC ledger data. It sits beside the vector-space carrier of chapter 47, the normed-space handoff of chapter 1950, the Banach completion surface of chapter 90, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names a concrete finite inspection surface for $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers; it does not claim a basis projection theorem, reflexivity failure, weak compactness, dual identification, or a selected infinite block decomposition.

Definition 6468.1 (James-space carrier)**.** *A* $\mathsf{JamesSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (B, L, Q, R, V, M, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the basis-block ledger. Each row names a finite interval of the canonical unit-vector basis, its ordered endpoints, and the finite coefficient support inspected inside that block.*
2. *L is the block-link ledger. It records which displayed blocks are read consecutively and which rows remain disjoint, so a consumer can replay the James block pattern without an ambient infinite choice of blocks.*
3. *Q is the norm-budget ledger. Each row records a finite family of consecutive block sums, a rational or dyadic budget for the squared block-sum magnitudes, and the comparison needed for the James norm inspection.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the coefficients and norm budgets.*
5. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *handoff row, recording finite support addition and scalar multiplication over the displayed coefficient rows.*
6. *M is the* $\mathsf{NormedSpace}^{\uparrow}$ *and* $\mathsf{Banach}^{\uparrow}$ *handoff row. It names the normed carrier, the Cauchy-completion route, and the Banach-facing certificate surface consumed by downstream space arguments.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row for every displayed norm-budget comparison reached from Q through R.*
8. *H records componentwise* hsame *transport for the basis-block ledger, block-link ledger, norm-budget ledger, rational readback, vector-space handoff, normed/Banach handoff, real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the carrier through the same finite block rows and norm-budget rows.*
10. *P is the* Pkg *provenance over* $\mathsf{JamesSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{JamesSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, L, Q, R, V, M, A, H, C, P, N$. It has no coordinate for an external Banach-space parameter, an infinite block selector, a dual-space presentation, reflexivity analysis, compactness, quotient equality, or host completeness beyond the displayed $\mathsf{Banach}^{\uparrow}$ *handoff.*

Theorem 6468.2 (James-space NameCert obligations)**.** *For every accepted* $\mathsf{JamesSpace}^{\uparrow}$ *carrier $J = (B, L, Q, R, V, M, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{JamesSpace}^{\uparrow}}$ *surface consists exactly of basis-block admission through B, consecutive-block coverage through L, norm-budget admission through Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{VecSpace}^{\uparrow}$ *finite-support handoff through V,* $\mathsf{NormedSpace}^{\uparrow}$ *and* $\mathsf{Banach}^{\uparrow}$ *handoff through M,* $\mathsf{Real}^{\uparrow}$ *norm-seal admission through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No James-space obligation is stored outside those rows.

Proof. Project the carrier of Definition 6468.1. The accepted packet is exhausted by the displayed basis-block rows, the consecutive-block ledger, the norm-budget rows, the rational readback, the vector/normed/Banach handoffs, and the structural rows H, C, P, N.

The block side is finite. The rows B and L name only inspected basis intervals and their displayed adjacency data, so a consumer can replay the block pattern without selecting an infinite block family.

The norm side is also finite. The row Q records each inspected family of consecutive block sums together with its rational budget, while R reads those budgets through $\mathsf{RegSeqRat}^{\uparrow}$ and A seals the resulting comparisons through $\mathsf{Real}^{\uparrow}$.

Finally V and M carry the same rows to $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, and $\mathsf{Banach}^{\uparrow}$ consumers. The transport, replay, provenance, and naming rows preserve the displayed packet componentwise and cannot introduce any excluded coordinate. □

Theorem 6468.3 (James-space Banach route)**.** *Every* $\mathsf{Banach}^{\uparrow}$*-facing read of an accepted* $\mathsf{JamesSpace}^{\uparrow}$ *carrier factors through the finite route*

$$B, L, Q \longmapsto R, A \longmapsto V, M, H, C, P, N.$$

Thus the Banach-space construction is presented by finite basis-block rows, norm-budget rows, rational readback, real norm seals, vector/normed/Banach handoffs, componentwise transport, displayed replay, provenance, and local naming, rather than by an opaque ambient Banach parameter.

Proof. Start with a Banach-facing consumer. The carrier first exposes B and L, so the consumer sees the inspected canonical-basis blocks and their displayed consecutive-link data before any normed-space handoff is available.

Read the norm route next. The row Q supplies exactly the finite James norm-budget comparisons under inspection, R translates the coefficient and budget data through $\mathsf{RegSeqRat}^{\uparrow}$, and A seals the resulting real-valued norm comparisons through $\mathsf{Real}^{\uparrow}$.

The vector and Banach handoffs are downstream of those rows. The row V supplies the finite-support $\mathsf{VecSpace}^{\uparrow}$ operations, while M records the $\mathsf{NormedSpace}^{\uparrow}$ and $\mathsf{Banach}^{\uparrow}$ handoff over the

same displayed norm data. Since H, C, P, N only transport, replay, source, and name the already displayed packet, the route cannot replace the finite ledger by an external Banach parameter. □

Falsifiable prediction: A Banach-space construction that reads $\mathsf{JamesSpace}^{\uparrow}$ after deleting the basis-block ledger B, the norm-budget ledger Q, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, the $\mathsf{Real}^{\uparrow}$ seal row A, or the $\mathsf{NormedSpace}^{\uparrow}/\mathsf{Banach}^{\uparrow}$ handoff row M refutes the carrier of Definition 6468.1.

Independence witness: vecspace, normedspace, banach, regseqrat, real: $\mathsf{JamesSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite basis-block rows, consecutive-block links, norm-budget rows, rational readback, real norm seals, VecSpace/NormedSpace/Banach handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{JamesSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{JamesSpace}^{\uparrow}$ packet is generated from finite basis-block rows, consecutive-block links, norm-budget rows, RegSeqRat readback, Real norm seals, VecSpace/NormedSpace/Banach handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JamesSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6468.1, Definition 6468.2, and Definition 6468.3 seed the finite James-space construction surface for Banach-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JamesSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close basis projection theory, reflexivity failure, weak compactness, dual identification, infinite block selection, quotient equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked basis-block admission, consecutive-block coverage, norm-budget admission, RegSeqRat readback, Real seal exactness, VecSpace/NormedSpace/Banach handoff exactness, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.JamesSpaceUp.

Chapter 6469

A Concrete Naming Certificate for $\mathsf{AbsoluteRetract}^{\uparrow}$

Following Borsuk and Dugundji, the $\mathsf{AbsoluteRetract}^{\uparrow}$ packet records a constructive retract-extension neighbour for compact metric and located metric analysis. It sits after the compact-source surfaces of chapter 129 and chapter 60, the closed extension route of chapter 1956, the separating-function route of **??**, the convex target rows of chapter 208, and the finite distance comparison route of chapter 1533. The packet names only displayed extension and retraction rows; it does not assert an ambient absolute retract theorem, selected neighbourhood retractions, quotient compacta, open-cover compactness, or choice of extension operators.

Definition 6469.1 (Absolute retract carrier)**.** *An* $\mathsf{AbsoluteRetract}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, K, L, T, U, V, E, R, S, H, C, P, N)$$

where:

- X *is the displayed source carrier row;*
- K *is the compact or compact-metric source row read through* $\mathsf{Compact}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$*;*
- L *is the* $\mathsf{LocatedMetric}^{\uparrow}$ *distance-comparison row;*
- T *is the* $\mathsf{TietzeExtension}^{\uparrow}$ *extension row for closed real-valued data;*
- U *is the* $\mathsf{UrysohnLemma}^{\uparrow}$ *separation row used by closed-neighbourhood reads;*
- V *is the* $\mathsf{ConvexSet}^{\uparrow}$ *target row recording the convex retract codomain;*
- E *records the finite extension request from a displayed closed subpacket;*
- R *records the candidate retraction row;*
- S *records stability of the retraction after the extension route is displayed;*
- H, C, P, N *are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{AbsoluteRetract}^{\uparrow}}$ *row.*

Theorem 6469.2 (Absolute retract NameCert obligations)**.** *For every accepted* $\mathsf{AbsoluteRetract}^{\uparrow}$ *carrier* $A = (X, K, L, T, U, V, E, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AbsoluteRetract}^{\uparrow}}$ *surface consists exactly of source admission, compact-source readback, located-metric comparison, Tietze extension exposure, Urysohn separation exposure, convex-target routing, finite extension request, retraction row, retraction-stability row, componentwise transport, displayed replay, provenance, and local naming. Any consumer that omits one of* $K, L, T, U, V, E, R, S, H, C, P, N$ *is outside the packet.*

Proof. Project the carrier of Definition 6469.1. Each row is displayed as finite BHist data, and the local naming row N records the accepted packet only over those displayed coordinates.

The compact and metric rows give the source scope through $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, and $\mathsf{LocatedMetric}^{\uparrow}$. The extension and separation rows then enter through $\mathsf{TietzeExtension}^{\uparrow}$ and $\mathsf{UrysohnLemma}^{\uparrow}$, while the target constraint is read through $\mathsf{ConvexSet}^{\uparrow}$.

Finally, E, R, S, H, C, P, N package the extension request, retraction, stability, transport, replay, provenance, and name. Since no row contains an ambient absolute retract principle or selected global operator, the listed surface is the entire local obligation set. □

Theorem 6469.3 (Absolute retract retraction stability)**.** *Every accepted* $\mathsf{AbsoluteRetract}^{\uparrow}$ *packet whose retraction row R is consumed must first expose the compact-source row K, located-metric row L, Tietze extension row T, Urysohn separation row U, convex-target row V, and finite extension request E. The stability row S then transports the retraction through H, C, P, N without replacing the packet by an ambient neighbourhood-retract theorem or a selected extension operator.*

Proof. Begin with the NameCert obligations of Definition 6469.2. They make $K, L, T, U, V, E, R, S, H, C, P, N$ the visible surface for any accepted packet.

The retraction read cannot precede the extension route. The compact and located-metric rows bound the source request, the Tietze and Urysohn rows expose the extension and separation data, and the convex row records the target shape before R is read.

The stability row S is therefore only a transport of the displayed retraction along the same finite route. It does not create a host absolute retract theorem, quotient compactum, chosen operator, or open-cover compactness argument. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbsoluteRetract}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbsoluteRetract}^{\uparrow}$ packet is generated from CompactUp and CompactMetricUp source rows, LocatedMetricUp comparison rows, TietzeExtensionUp extension rows, UrysohnLemmaUp separation rows, ConvexSetUp target rows, finite extension and retraction rows, stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AbsoluteRetract}^{\uparrow}}$, seed)

Scope closed: Definition 6469.1, Definition 6469.2, and Definition 6469.3 seed the finite retract-extension packet over compact, located-metric, extension, separation, and convex-target rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AbsoluteRetract}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close an ambient absolute retract theorem, selected neighbourhood retractions, quotient compacta, open-cover compactness, choice of extension operators, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source readback, located-metric comparison, Tietze extension exposure, Urysohn separation exposure, convex-target routing, retraction stability, transport, replay, provenance, and local naming for BEDC.Derived.AbsoluteRetractUp.

Chapter 6470

A Concrete Naming Certificate for $\mathsf{GromovBoundary}^{\uparrow}$

Following Gromov's hyperbolic-boundary construction, the $\mathsf{GromovBoundary}^{\uparrow}$ packet records finite boundary-equivalence data for hyperbolic rays before a visual or cocycle consumer reads the boundary. It sits after the visual-boundary packet of chapter 4181, the basepointed product packet of chapter 6073, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, and the boundary-shadow expansion route of chapter 5814. The packet names a displayed boundary carrier rather than a completed quotient of rays, selected geodesic representatives, host compactification, or ambient hyperbolic space.

Definition 6470.1 (Gromov boundary carrier)**.** *A* $\mathsf{GromovBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, P, V, M, C, Q, E, S, T, H, R, N)$$

where:

- B *is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *boundary row;*
- P *is the* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ *basepointed product row;*
- V *is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *visual-metric row;*
- M *is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *cocycle row;*
- C *is the* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *boundary-shadow expansion row;*
- Q *records finite ray-equivalence comparisons;*
- E *records endpoint admission for the accepted boundary token;*
- S *records visual-cocycle stability under the displayed equivalence row;*
- T, H, R, N *are displayed* Cont *replay, componentwise* hsame *transport,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{GromovBoundary}^{\uparrow}}$ *row.*

Theorem 6470.2 (Gromov boundary NameCert obligations)**.** *For every accepted* $\mathsf{GromovBoundary}^{\uparrow}$ *carrier* $G = (B, P, V, M, C, Q, E, S, T, H, R, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GromovBoundary}^{\uparrow}}$ *surface consists exactly of visual-boundary admission, Gromov-product readback, visual-metric comparison, Busemann-cocycle comparison, boundary-shadow expansion, finite ray-equivalence exposure, endpoint admission, visual-cocycle stability, displayed replay, componentwise transport, provenance,*

and local naming. A consumer that reads a boundary token without one of those rows is outside the packet.

Proof. Project the carrier of Definition 6470.1. The visual boundary, Gromov product, visual metric, Busemann cocycle, and boundary-shadow expansion rows are all explicit coordinates of the accepted packet.

The ray-equivalence row Q and endpoint row E provide the boundary token only as displayed finite data. The packet therefore exposes equivalence information before any visual metric or cocycle consumer receives the boundary.

Finally, S, T, H, R, N record stability, replay, transport, provenance, and naming. Since no carrier row supplies a host quotient of rays, selected geodesic representative, completed compactification, or ambient hyperbolic model, the listed rows exhaust the NameCert obligation surface. □

Theorem 6470.3 (Gromov boundary visual-cocycle stability)**.** *Every accepted* $\mathsf{GromovBoundary}^{\uparrow}$ *packet whose boundary token is consumed by a visual-metric, Busemann-cocycle, or boundary-shadow-expansion consumer must retain the ray-equivalence row* Q *through the* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ *row* P*,* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row* V*,* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row* M*, and* $\mathsf{BoundaryShadowExpansionCocycle}$ *row* C*. The stability row* S *transports those displayed comparisons without turning the packet into a completed ray quotient or global boundary compactification.*

Proof. Begin with Definition 6470.2. It keeps $B, P, V, M, C, Q, E, S, T, H, R, N$ visible for every accepted boundary read.

The product row P and ray-equivalence row Q determine which boundary token is being transported. The visual metric, Busemann cocycle, and boundary-shadow expansion rows then read that token through their own displayed comparison surfaces.

The stability row S preserves those comparisons through T, H, R, N. Because the carrier has no coordinate for a selected ray representative or host quotient, the handoff remains a finite BEDC boundary-equivalence packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{GromovBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{GromovBoundary}^{\uparrow}$ packet is generated from HyperbolicVisualBoundaryUp rows, HyperbolicGromovProductUp rows, HyperbolicVisualMetricUp rows, HyperbolicBusemannCocycleUp rows, BoundaryShadowExpansionCocycleUp rows, finite ray-equivalence rows, endpoint rows, visual-cocycle stability rows, displayed Cont replay, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GromovBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 6470.1, Definition 6470.2, and Definition 6470.3 seed the finite boundary-equivalence packet over visual-boundary, Gromov-product, visual-metric, Busemann-cocycle, and boundary-shadow expansion rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GromovBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a completed quotient of rays, selected geodesic representatives, host compactification, ambient hyperbolic space, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visual-boundary admission, Gromov-product readback, visual-metric comparison, Busemann-cocycle comparison, boundary-shadow expansion, ray-equivalence exposure, visual-cocycle stability, transport, replay, provenance, and local naming for BEDC.Derived.GromovBoundaryUp.

Chapter 6471

A Concrete Naming Certificate for $\mathsf{HausdorffYoung}^{\uparrow}$

Following Hausdorff and Young on Fourier coefficient bounds, and Riesz–Thorin interpolation, the $\mathsf{HausdorffYoung}^{\uparrow}$ packet records a constructive endpoint-to-interpolation route for finite Fourier coefficient windows. It sits beside the convolution bound of chapter 2358, the interpolation certificate of chapter 5725, the energy identity of chapter 1940, the majorant-tail discipline of chapter 399, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names only finite Fourier observations, exponent rows, interpolation and summability handoffs, rational readback, real sealing, transport, replay, provenance, and local certification.

Definition 6471.1 (HausdorffYoung carrier)**.** *A* $\mathsf{HausdorffYoung}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (F, P, Q, Y, T, S, R, E, K, C, G, N)$$

whose rows expose:

1. *F, the Fourier coefficient window row, including the displayed finite source window and the retained coefficient read schedule;*
2. *P, the L^p exponent row recording the admitted source exponent and its finite comparison witnesses;*
3. *Q, the conjugate L^q exponent row recording the target coefficient exponent and the displayed conjugacy ledger;*
4. *Y, the Young-inequality handoff row through chapter 2358;*
5. *T, the Riesz–Thorin interpolation certificate row through chapter 5725;*
6. *S, the summability-tail row, including the finite majorant and truncation witnesses consumed by chapter 399;*
7. *R, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for coefficient norms, tail budgets, and exponent comparisons;*
8. *E, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the real-valued bound after R has been displayed;*
9. *K, the componentwise* hsame *transport row for Fourier windows, exponent rows, interpolation data, tail rows, readback, and seal data;*
10. *C, the displayed* Cont *replay row preserving the same finite Hausdorff–Young route;*

11. *G, the* Pkg *provenance over* HausdorffYoung$^{\uparrow}$, YoungInequality$^{\uparrow}$, RieszThorinInterpolation$^{\uparrow}$, Parseval$^{\uparrow}$, WeierstrassMTest$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N, the local* NameCert$_{\text{HausdorffYoung}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, P, Q, Y, T, S, R, E, K, C, G, N$. It has no coordinate for a host Fourier transform, a completed L^p quotient space, a selected representative, countable choice, or an ambient measure-theoretic interpolation theorem.

Theorem 6471.2 (HausdorffYoung NameCert obligations)**.** *For every accepted* HausdorffYoung$^{\uparrow}$ *carrier $H = (F, P, Q, Y, T, S, R, E, K, C, G, N)$, the local* NameCert$_{\text{HausdorffYoung}^{\uparrow}}$ *surface is exhausted by Fourier coefficient windows, L^p and L^q exponent rows, the* YoungInequality$^{\uparrow}$ *handoff, the* RieszThorinInterpolation$^{\uparrow}$ *interpolation certificate, summability-tail witnesses,* RegSeqRat$^{\uparrow}$ *readback, terminal* Real$^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every coefficient-norm or interpolation consumer must read these rows before using the packet.*

Proof. Project the carrier of Definition 6471.1. The displayed rows $F, P, Q, Y, T, S, R, E, K, C, G, N$ are the full accepted packet, so any local NameCert obligation is one of the listed Fourier-window, exponent, handoff, interpolation, summability, readback, seal, transport, replay, provenance, or naming rows.

The source and target exponent obligations are read before interpolation. The rows P and Q carry only finite exponent comparisons and conjugacy witnesses, while F fixes the coefficient window on which the bound is observed.

The analytic handoff is then forced through the named siblings. The row Y supplies the Young-inequality bound surface, T supplies the Riesz–Thorin interpolation certificate, and S supplies the finite tail witnesses before R and E expose any real-valued read. Since the carrier has no host transform, quotient-space, or choice coordinate, the NameCert surface is exactly the displayed finite packet. □

Theorem 6471.3 (HausdorffYoung Riesz–Thorin route)**.** *Every* HausdorffYoung$^{\uparrow}$ *carrier routes a Fourier coefficient bound through the displayed Riesz–Thorin interpolation row before exposing a real coefficient-norm seal. In the notation of Definition 6471.1, a downstream consumer may inspect*

$$F, \quad P, \quad Q, \quad Y, \quad T, \quad S$$

and only then read the regular rational route R, the terminal seal E, and the structural rows K, C, G, N. Thus the packet separates finite Fourier coefficient observations from the interpolation theorem and exports no independent host L^p Fourier transform.

Proof. Start with the finite coefficient and exponent rows. The row F displays the observed Fourier window, while P and Q display the source and target exponent comparison data without appealing to a completed function space.

Next route the bound through the analytic siblings. The Young row Y provides the endpoint convolution-bound handoff, and the interpolation row T records the Riesz–Thorin certificate that transports the endpoint data to the requested exponent pair.

Finally read the finite tail and endpoint seal. The summability row S supplies the visible truncation witnesses, R repackages the coefficient-norm comparisons as regular rational data, and E seals the resulting real bound. Componentwise transport, replay, provenance, and local naming preserve the same route, so no host transform or selected representative can enter the certificate. □

Falsifiable prediction: Any accepted $\mathsf{HausdorffYoung}^{\uparrow}$ packet must expose Fourier coefficient windows, L^p/L^q exponent rows, Young handoff, Riesz–Thorin interpolation, summability tail, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows before a coefficient-norm consumer reads it.

Independence witness: younginequality, rieszthorin, parseval, weierstrassmtest, regseqrat, real: $\mathsf{HausdorffYoung}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Fourier coefficient windows, paired exponent rows, convolution-bound handoff, interpolation certificate, summability tail, rational readback, terminal real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffYoung}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffYoung}^{\uparrow}$ packet is generated from finite Fourier coefficient windows, source and target exponent rows, a Young handoff, a Riesz–Thorin interpolation certificate, summability-tail witnesses, regular rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffYoung}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6471.1, Definition 6471.2, and Definition 6471.3 seed the finite Fourier interpolation certificate consumed by coefficient-norm work.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffYoung}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Fourier transforms, completed L^p quotient spaces, selected representatives, measure-theoretic interpolation theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exponent rows, Young handoff, Riesz–Thorin interpolation, summability-tail witnesses, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Chapter 6472

A Concrete Naming Certificate for $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$ packet records the finite paired-modulus common-tail certificate used when two Bishop Cauchy schedules must be read through one later tail. It sits after the single-modulus schedule row of chapter 292, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the cofinal-window route of chapter 4060. The packet is a paired finite tail ledger for L10 Real and Completion consumers; it is not quotient stream equality, a selected limit, countable choice, trichotomy, or ambient Real completeness.

Definition 6472.1 (BishopCauchyModulusCofinality carrier)**.** *A* $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (\epsilon, D, S_0, S_1, R_0, R_1, \mu_0, \mu_1, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. ϵ *is the requested tolerance row.*
2. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger for* ϵ *and the two tail budgets.*
3. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows being compared.*
4. R_0 *and* R_1 *are the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for those windows.*
5. μ_0 *and* μ_1 *are the two* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule rows.*
6. W *is the* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *row that displays a later finite window cofinal for both schedules at tolerance* ϵ*.*
7. T *is the common-tail certificate, stating that every read through* W *factors through both* μ_0 *and* μ_1 *after the displayed dyadic comparison.*
8. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* $D, S_0, S_1, R_0, R_1, \mu_0, \mu_1, W, T$ *have been displayed.*
9. H *records componentwise* hsame *transport for tolerances, dyadic comparisons, stream windows, regular readbacks, Cauchy moduli, cofinal windows, common-tail certificates, Real seals, provenance, and names.*

10. *C records displayed* Cont *replay from the two modulus schedules to W, T, E through the same finite rows.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, or ambient Real completeness.

Theorem 6472.2 (BishopCauchyModulusCofinality NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$ *carrier* $M = (\epsilon, D, S_0, S_1, R_0, R_1, \mu_0, \mu_1, W, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCofinality}^{\uparrow}}$ *surface consists exactly of tolerance admission through ϵ; dyadic comparison through D; two finite* $\mathsf{StreamName}^{\uparrow}$ *windows through S_0, S_1; two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks through R_0, R_1; two* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules through μ_0, μ_1; cofinal-window exposure through W; common-tail exposure through T;* $\mathsf{Real}^{\uparrow}$ *sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier rows from Definition 6472.1. The accepted packet displays one tolerance, one dyadic comparison ledger, two stream windows, two regular rational readbacks, two Cauchy modulus schedules, one cofinal window, one common-tail certificate, one Real seal, and the structural transport, replay, provenance, and naming rows.

The paired nature of the certificate is carried only by μ_0, μ_1, W, T. The cofinal-window row W is read after the two schedules and the dyadic ledger, and T records that the later finite tail factors through both schedules.

The structural rows preserve the same finite packet under hsame, Cont, Pkg, and NameCert replay. Since no row carries quotient stream equality, a selected limit, countable choice, trichotomy, or ambient Real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 6472.3 (BishopCauchyModulusCofinality common tail)**.** *If an accepted* $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$ *packet presents two Cauchy modulus schedules μ_0, μ_1 over the displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, then every common-tail read at tolerance ϵ factors through the finite route*

$$D, S_0, S_1, R_0, R_1, \mu_0, \mu_1, W, T.$$

The common tail is the displayed cofinal window W together with certificate T, not a quotient-stream identification, selected limit, countable-choice selection, trichotomy branch, or Real-completeness argument.

Proof. Begin with the dyadic tolerance row D. It fixes the comparison budget for the two schedules and prevents the common-tail read from changing tolerance outside the displayed packet.

Next read the two stream and regular-rational sides. The rows S_0, S_1 expose the finite windows, and R_0, R_1 attach those windows to the regular rational readbacks that the two modulus schedules govern.

Finally apply the cofinal-window row W and the common-tail certificate T. These rows display the later finite tail that is after both schedules at the requested tolerance, so a consumer receives a paired finite tail certificate without invoking quotient streams, selected limits, countable choice, trichotomy, or Real completeness. □

Theorem 6472.4 (BishopCauchyModulusCofinality Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$ *packet reaches the seal* E *only after the dyadic ledger, both stream windows, both regular rational readbacks, both Cauchy modulus schedules, the* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *row, and the common-tail certificate have been displayed. The handoff exports a finite paired-modulus tail certificate for L10 Real and Completion routes, and exports no quotient stream equality, selected limit, countable choice, trichotomy, or ambient Real completeness.*

Proof. Project the finite route before the seal. The rows $D, S_0, S_1, R_0, R_1, \mu_0, \mu_1, W, T$ are all upstream of E, so the Real-facing consumer cannot see the seal without also seeing the paired-modulus common-tail data.

Transport and replay preserve that order. The rows H and C can carry the displayed packet through equivalent naming and continuation reads, but they do not add another stream quotient, hidden tail selector, or completeness coordinate.

Thus the terminal $\mathsf{Real}^{\uparrow}$ read is only a seal for the finite paired-tail route. It remains choice-free and quotient-free, and it does not decide trichotomy or claim a selected completion limit. □

Falsifiable prediction: An accepted $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$ consumer that reaches a Real-facing common tail without displaying the dyadic ledger, both StreamName windows, both RegSeqRat readbacks, both CauchyModulus schedules, the RegularCauchyWindowCofinality row, the common-tail certificate, and the structural rows refutes the carrier surface.

Independence witness: cauchymodulus, dyadicratcore, streamname, regseqrat, regular-cauchy-window-cofinality, real: no listed sibling supplies the whole paired packet $M = (\epsilon, D, S_0, S_1, R_0, R_1, \mu_0, \mu_1, W, T, E,$ because each sibling contributes only one schedule, dyadic ledger, stream window, regular readback, cofinal-window row, or terminal seal while this chapter binds two modulus schedules into one common-tail certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCofinality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCauchyModulusCofinality}^{\uparrow}$ packet is generated from one dyadic tolerance ledger, two StreamName windows, two RegSeqRat readbacks, two CauchyModulus schedules, one RegularCauchyWindowCofinality row, a common-tail certificate, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCofinality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6472.1, Definition 6472.2, Definition 6472.3, and Definition 6472.4 seed the finite paired-modulus common-tail route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCofinality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired schedule exposure, cofinal-window exactness, common-tail stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyModulusCofi

Chapter 6473

A Concrete Naming Certificate for $\mathsf{BaireUniformSpace}^{\uparrow}$

Following Baire, Kelley, and Bishop–Bridges, the $\mathsf{BaireUniformSpace}^{\uparrow}$ packet records the uniform-space surface of Baire sequences through finite prefix entourages. It sits between the prefix carrier of chapter 334, the common-prefix metric route of chapter 1602, the entourage discipline of chapter 339, and the completion-facing Baire packets of chapter 1884 and chapter 3535. The chapter names the finite uniform interface; it does not claim open-cover compactness, selected branches, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6473.1 (Baire uniform-space carrier)**.** *A* $\mathsf{BaireUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, M, E, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *finite-prefix row, naming two inspected streams and the common prefix window.*
2. *M is the* $\mathsf{BaireMetric}^{\uparrow}$ *common-prefix distance row, recording the dyadic radius attached to the first displayed disagreement or to agreement on the inspected window.*
3. *E is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row generated by finite prefix agreement requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which prefix coordinates and requested entourage depths are read.*
5. *H records componentwise* hsame *transport for the Baire prefix, metric, entourage, window, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the same prefix-entourage route.*
7. *P is the* Pkg *provenance over* $\mathsf{BaireUniformSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireMetric}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireUniformSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, M, E, S, H, C, P, N. It has no coordinate for open-cover compactness, selected infinite branches, quotient stream equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Theorem 6473.2 (Baire uniform-space NameCert obligations)**.** *For every accepted* $\mathsf{BaireUniformSpace}^{\uparrow}$ *carrier*

$$U = (B, M, E, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BaireUniformSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Baire prefix, common-prefix metric, uniform entourage, finite window, transport, replay, provenance, and local naming rows; prefix-entourage stability under componentwise* hsame*; displayed* Cont *locality; and non-escape for open-cover compactness, selected branches, quotient stream equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6473.1. The only analytic rows are the finite prefix row B, common-prefix metric row M, generated entourage row E, and finite window row S.

The uniformity is read through E after B, M, S have displayed the finite prefix request. Transport through H and replay through C preserve the same prefix-entourage route.

Finally P and N source and name the accepted packet. Since the excluded compactness, branch-selection, quotient-equality, choice, and completeness objects have no carrier coordinate, no NameCert projection can export them. □

Theorem 6473.3 (Baire uniform-space complete-metric handoff)**.** *Every* $\mathsf{CompleteBaireSpace}^{\uparrow}$ *or* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *consumer of an accepted* $\mathsf{BaireUniformSpace}^{\uparrow}$ *packet must first read the finite prefix row* B*, common-prefix metric row* M*, generated entourage row* E*, finite* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, componentwise transport row* H*, displayed replay row* C*, provenance row* P*, and local name* N*. The handoff is a finite prefix-entourage route, not a selected limit branch, quotient stream equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the NameCert obligations. They force every uniform-space read to pass through B, M, E, S, H, C, P, N.

A completion-facing consumer can therefore inspect only finite prefix agreement and the common-prefix metric radius before it reaches any complete-Baire row. The generated entourage row E is downstream of those finite observations.

The structural rows preserve the route. Transport, replay, provenance, and local naming do not add selected branches, quotient equality, countable choice, compactness, or ambient completeness, so the handoff remains finite. □

Theorem 6473.4 (Baire uniform-space nonescape)**.** *Every public read from an accepted* $\mathsf{BaireUniformSpace}^{\uparrow}$ *packet factors through*

$$B, M, E, S, H, C, P, N.$$

The packet exports finite prefix-entourage data and no open-cover compactness theorem, chosen branch, quotient stream equality, countable choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Read the public consumer through the displayed continuation row C. Each continuation has a named source among the prefix, metric, entourage, window, transport, provenance, and local naming rows.

Apply the complete-metric handoff theorem for completion-facing consumers and the NameCert obligations for all other public reads. Both routes are exhausted by the same finite carrier.

The refused objects have no coordinate in the carrier and no continuation route, so no public read can export them. □

Falsifiable prediction: Every $\mathsf{BaireUniformSpace}^{\uparrow}$ read factors through displayed Baire prefix rows, common-prefix metric rows, generated UniformSpace entourage rows, finite StreamName windows, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: baire-space, baire-metric, uniform-space, complete-baire-space: $\mathsf{BaireUniformSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite Baire prefixes, common-prefix metric data, generated uniform entourages, finite windows, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireUniformSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireUniformSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6473.1, Definition 6473.2, and Definition 6473.3 seed the finite Baire uniform-space route from prefix rows through common-prefix metrics, generated entourages, finite windows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireUniformSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected branches, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-entourage stability, common-prefix metric compatibility, complete-metric handoff, transport, replay, provenance, and non-escape for BEDC.Derived.BaireUniformSpaceUp.

Constructive story: A $\mathsf{BaireUniformSpace}^{\uparrow}$ packet is generated from BaireSpace prefix rows, BaireMetric common-prefix rows, UniformSpace entourage rows, StreamName finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6474

A Concrete Naming Certificate for MetacicAppArgumentStabilityLedger$^{\uparrow}$

The MetacicAppArgumentStabilityLedger$^{\uparrow}$ packet realizes the dependent-codomain frontier in the MetaCIC subject-reduction obstruction map as finite BEDC rows. It sits between the application typing row of chapter 730, the discharge-obligation socket of chapter 719, the beta-substitution handoff of chapter 716, and the closed-substitution boundary of chapter 538. The packet names the smaller ledger that keeps an application argument type attached to the codomain route; it does not assert global subject reduction, unrestricted substitution, quotient syntax equality, or a completed MetaCIC model.

Definition 6474.1 (MetaCIC app-argument stability ledger carrier)**.** *A* MetacicAppArgumentStabilityLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, X, Y, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the application typing frontier row, exposing the function type, argument type, and application result request.*
2. *X is the argument-type row that must remain attached to the application typing route.*
3. *Y is the dependent-codomain row, naming the codomain expression after the argument row has been displayed.*
4. *D is the discharge-obligation row consumed by the subject-reduction socket.*
5. *S is the closed-substitution boundary row that records the finite substitution route used by the codomain readback.*
6. *R is the reduction-readback row for the application step under the same argument-type boundary.*
7. *H records componentwise* hsame *transport for the frontier, argument, codomain, discharge, substitution, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an application request through $F, X, Y, D, S, R, H, P, N$.*
9. *P is the* Pkg *provenance over* MetacicAppArgumentStabilityLedger$^{\uparrow}$*, MetaCIC application typing rows, discharge-obligation rows, closed-substitution boundary rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, X, Y, D, S, R, H, C, P, N$. It has no coordinate for global subject reduction, unrestricted substitution, quotient syntax equality, host evaluator soundness, proof irrelevance, or a completed MetaCIC semantics.

Theorem 6474.2 (MetaCIC app-argument stability ledger NameCert obligations)**.** *For every accepted* $\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}$ *carrier*

$$A = (F, X, Y, D, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}}$ *surface consists exactly of carrier exposure for the application typing frontier, argument-type row, dependent-codomain row, discharge-obligation row, closed-substitution boundary row, reduction-readback row, componentwise transport, displayed replay, provenance, and local naming; stability of the argument-type row before the codomain route is read; compatibility with the subject-reduction discharge socket; and non-escape for global subject reduction, unrestricted substitution, quotient syntax equality, host evaluator soundness, proof irrelevance, and completed MetaCIC semantics.*

Proof. Project the carrier of Definition 6474.1. The application-facing data are exactly F, X, Y, D, S, R.

The argument-type row X is consumed before the dependent-codomain row Y. The discharge row D, closed-substitution row S, and reduction-readback row R can only replay that same ordering.

Transport through H and replay through C preserve the ordering, while P and N source and name the packet. Since the refused global principles have no carrier coordinate, the NameCert surface remains finite. □

Theorem 6474.3 (MetaCIC app-argument dependent-codomain route)**.** *Every subject-reduction discharge consumer of an accepted* $\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}$ *packet reads the dependent-codomain route only through*

$$F, X, Y, D, S, R, H, C, P, N.$$

The argument-type row X is displayed before the codomain row Y, and the closed-substitution and reduction-readback rows S, R preserve that attachment. The route exports no global subject-reduction theorem, unrestricted substitution calculus, quotient syntax equality, host evaluator soundness, proof-irrelevance principle, or completed MetaCIC model.

Proof. Start with the NameCert obligations. They place the application frontier, argument type, dependent codomain, discharge row, substitution boundary, and readback row on one finite route.

The subject-reduction socket consumes D only after the argument row X and codomain row Y have been displayed. The closed-substitution row S and readback row R preserve that same dependency rather than exposing a general substitution theorem.

Finally read the structural rows H, C, P, N. They transport, replay, source, and name the route without adding any of the refused host-side or global MetaCIC objects. □

Falsifiable prediction: Every $\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}$ discharge read factors through displayed application-frontier rows, argument-type rows, dependent-codomain rows, discharge-obligation rows, closed-substitution boundary rows, reduction-readback rows, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: subject-reduction-frontier, discharge-obligation-socket, beta-substitution-preservation, closed-substitution-boundary: $\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}$ is not bijective

to any listed sibling because it jointly carries argument-type stability, dependent-codomain routing, discharge compatibility, closed-substitution readback, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}$ packet is generated from MetaCIC application-frontier rows, argument-type rows, dependent-codomain rows, discharge-obligation rows, closed-substitution boundary rows, reduction-readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6474.1, Definition 6474.2, and Definition 6474.3 seed the finite application-argument stability ledger for the MetaCIC subject-reduction obstruction route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicAppArgumentStabilityLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global subject reduction, unrestricted substitution, quotient syntax equality, host evaluator soundness, proof irrelevance, completed MetaCIC semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, argument-type stability, dependent-codomain routing, discharge compatibility, closed-substitution readback, transport, replay, provenance, and non-escape for BEDC.Derived.MetacicAppArg

Chapter 6475

A Concrete Naming Certificate for $\mathsf{CauchyRetractionModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyRetractionModulus}^{\uparrow}$ packet records the finite surface that turns ordinary Cauchy-modulus data into the regular retraction schedule consumed by $\mathsf{RegSeqRat}^{\uparrow}$ and sealed as $\mathsf{Real}^{\uparrow}$. It sits after the regularization route of chapter 376, the completion retraction packet of chapter 1921, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the real-name boundary of chapter 38. The packet is a finite L10 handoff from inspected Cauchy data to regular rational names; it is not quotient Cauchy-class equality, a selected limit, trichotomy, countable choice, or ambient Real completeness.

Definition 6475.1 (CauchyRetractionModulus carrier)**.** *A* $\mathsf{CauchyRetractionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, R, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source Cauchy-data row, containing the inspected rational stream and the ordinary Cauchy modulus requests that are available to the packet.*
2. *M is the monotone retraction schedule row, choosing for each displayed tolerance a later index that retracts the source data to a regular Cauchy window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the retracted windows.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which every regular readback request is inspected.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the source modulus budget with the regular-window budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, M, R, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for source data, schedules, regular readbacks, finite windows, dyadic tolerances, Real seals, provenance, and names.*
8. *C records displayed* Cont *replay from the source Cauchy requests to the retracted regular windows and then to the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRetractionModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRetractionModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for quotient Cauchy classes, selected limits, trichotomy, countable choice, or ambient Real completeness.

Theorem 6475.2 (CauchyRetractionModulus NameCert obligations)**.** *For every accepted* CauchyRetractionModulu *carrier $K = (S, M, R, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRetractionModulus}^{\uparrow}}$ *surface consists exactly of source Cauchy-data admission through S; inspected monotone retraction scheduling through M; regular rational readback through R; finite StreamName windows through W; DyadicRatCore tolerance comparison through Q; Real sealing through E; componentwise transport through H; displayed replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier rows from Definition 6475.1. The accepted packet displays one source Cauchy-data row, one monotone retraction schedule, one regular rational readback row, one finite window row, one dyadic tolerance ledger, one Real seal, and the structural transport, replay, provenance, and naming rows.

The retraction content is carried only by S, M, R, W, Q. The source Cauchy requests in S are inspected before M selects later schedule indices, the windows W expose the finite part of those indices, and R reads the resulting regular rational name under the tolerance comparison Q.

The structural rows preserve the same finite packet under hsame, Cont, Pkg, and $\mathsf{NameCert}$ replay. Since no row carries quotient Cauchy-class equality, a selected limit, trichotomy, countable choice, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6475.3 (CauchyRetractionModulus RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyRetractionModulus}^{\uparrow}$ *packet factors through the finite route*

$$S, M, W, Q, R, E, H, C, P, N.$$

The handoff presents the regular rational name as the readback of inspected source Cauchy data along the monotone retraction schedule. It exports no quotient Cauchy-class equality, selected limit, trichotomy branch, countable-choice selector, or ambient Real-completeness coordinate.

Proof. Begin with the source and schedule rows. The source Cauchy-data row S displays the available stream requests, and the retraction schedule M chooses later indices before any regular rational readback can be consumed.

Next read the window and tolerance rows. The $\mathsf{StreamName}^{\uparrow}$ row W exposes exactly the finite window inspected by the schedule, while the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger Q records the comparison between the ordinary modulus budget and the regular-window budget.

Finally consume R and E. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is the readback of the displayed retracted windows, and the terminal $\mathsf{Real}^{\uparrow}$ row E is only a seal for that finite route. The structural rows H, C, P, N transport, replay, package, and name the same route, so no quotient, selected limit, trichotomy, choice, or ambient-completeness coordinate is inserted. □

Falsifiable prediction: An accepted $\mathsf{CauchyRetractionModulus}^{\uparrow}$ consumer that reaches a RegSeqRat readback or Real seal without displaying the source Cauchy data, monotone retraction schedule, StreamName windows, DyadicRatCore tolerance ledger, structural transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: cauchyregularization, cauchy-completion-retraction, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole finite packet $K = (S, M, R, W, Q, E, H, C, P, N)$,

because each sibling contributes only source regularization, completion retraction, finite windows, regular readback, tolerance comparison, or terminal sealing while this chapter binds them into one inspected retraction-modulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRetractionModulus}\uparrow}$.

Constructive story: A $\mathsf{CauchyRetractionModulus}^{\uparrow}$ packet is generated from source Cauchy data, an inspected monotone retraction schedule, finite StreamName windows, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRetractionModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6475.1, Definition 6475.2, and Definition 6475.3 seed the finite route from ordinary Cauchy-modulus data to regular rational names and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRetractionModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy-class equality, selected limits, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source Cauchy-data exposure, monotone retraction scheduling, finite-window coverage, RegSeqRat readback, DyadicRatCore tolerance comparison, Real-seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRetractionModulusUp.

Chapter 6476

A Concrete Naming Certificate for $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ packet records cotransitivity for located real apartness as finite NameCert data. It sits over the located-real carrier of chapter 1933, the located apartness packet of chapter 1380, the Bishop-style cotransitivity route of chapter 1788, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet exposes the third-name cotransitivity branch without importing trichotomy, quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6476.1 (Located real apartness cotransitivity carrier)**.** *A* $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, Z, A, L, R, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the source* $\mathsf{LocatedReal}^{\uparrow}$ *name rows whose apartness is being read.*
2. *Z is the displayed third* $\mathsf{LocatedReal}^{\uparrow}$ *name through which cotransitivity is tested.*
3. *A is the* $\mathsf{LocatedRealApartness}^{\uparrow}$ *source-apartness row for X and Y.*
4. *L is the left cotransitivity branch, recording the displayed located-apartness read from X to Z when that branch is active.*
5. *R is the right cotransitivity branch, recording the displayed located-apartness read from Z to Y when that branch is active.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the three located real names at the requested tolerance.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the positive separation budget, slack, and branch comparison cells.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Q, D and one of L, R have been displayed.*
10. *H records componentwise* hsame *transport for the three names, source apartness, branch rows, stream windows, regular readback, dyadic tolerance, Real seal, replay, provenance, and local naming.*

11. *C records displayed* Cont *replay from a located-apartness cotransitivity request through the same finite route.*
12. *P is the* Pkg *provenance over* $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedRealApartness}^{\uparrow}$, $\mathsf{ApartnessCotransitivity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for trichotomy of real names, quotient real equality, selected branch choice, countable choice, host locatedness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6476.2 (Located real apartness cotransitivity NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ *carrier*

$$K = (X, Y, Z, A, L, R, S, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}}$ *surface consists exactly of carrier admission for the three located real names, source located-apartness admission, left-or-right branch admission, finite stream-window exposure, regular rational readback, dyadic tolerance preservation, terminal Real seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The visible data are the three located real names, the source apartness row, the two possible branch rows, stream windows, regular readback, dyadic tolerance, terminal seal, and the structural rows.

The source and branch obligations are finite. The packet first reads A as the displayed located-apartness source; it then exposes exactly one branch row among L and R as the cotransitivity witness.

The Real-facing part is downstream. Stream windows S, regular readback Q, and the dyadic tolerance row D must be displayed before the terminal seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier row stores trichotomy, quotient equality, a selected external branch, countable choice, host locatedness, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6476.3 (Located real apartness cotransitivity route)**.** *Every accepted* $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{LocatedRealApartness}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{ApartnessCotransitivity}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a downstream apartness or order consumer receives a source located-apartness row, a displayed third located real name, one cotransitive branch, finite windows, regular rational readback, dyadic tolerance data, and the terminal real-name seal before it may use the cotransitivity packet.

Proof. Start from the carrier of Definition 6476.1. The source apartness row A and third name Z are the only inputs to the cotransitivity read.

The observation route opens S, Q, D before either branch is inspected. These rows keep the branch comparison inside finite windows, regular rational readback, and dyadic tolerance budgets.

The active branch then invokes the cotransitivity surface of chapter 1788. It is read as a displayed branch over the same names, not as a trichotomy decision.

The terminal row E seals the read for $\mathsf{Real}^{\uparrow}$ consumers, while H, C, P, N preserve the route. Hence every accepted read follows the displayed dependency path and no host apartness or quotient-real object is exported. □

Theorem 6476.4 (Located real apartness cotransitivity Real seal nonescape)**.** *For an accepted* $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ *carrier* $K = (X, Y, Z, A, L, R, S, Q, D, E, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *exports only the branch already displayed through* A*, one of* L, R*,* S*,* Q*, and* D*. It exports no host trichotomy, quotient real equality, selected real representative, countable-choice selector, ambient locatedness theorem, or completeness principle for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Inspect the terminal coordinate. The row E is listed after the source apartness, branch, stream-window, regular-readback, and dyadic-tolerance rows.

Use Definition 6476.2. It forces Real-seal ordering through the displayed rows before any Real-facing consumer can read the packet.

The structural rows preserve that boundary. Componentwise hsame transport and displayed Cont replay do not add a second branch source, and Pkg provenance with local naming records only the same finite carrier.

Therefore the terminal seal cannot export trichotomy, quotient equality, selected representatives, countable choice, host locatedness, or ambient completeness. A consumer asking for one of those principles leaves the accepted carrier surface. □

Falsifiable prediction: Every accepted $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ read must expose three LocatedReal name rows, a LocatedRealApartness source row, one cotransitive branch row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before any Real or order consumer reads the branch.

Independence witness: located-real-apartness, apartness-cotransitivity, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ because this packet jointly binds located real names, a source located-apartness row, one cotransitive branch, finite windows, regular readback, dyadic tolerance, and terminal Real-seal nonescape.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}$ packet is generated from three LocatedReal name rows, a LocatedRealApartness source row, one displayed cotransitivity branch, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6476.1, Definition 6476.2, Definition 6476.3, and Definition 6476.4 seed the finite located-real cotransitivity packet over displayed branch, window, readback, tolerance, seal, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealApartnessCotransitivity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, ambient locatedness, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source located-apartness exposure, branch stability, finite-window readback, dyadic tolerance preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealApartnessCotransitivityUp.

Chapter 6477

A Concrete Naming Certificate for $\mathsf{HyperbolicUniformModulus}^{\uparrow}$

The $\mathsf{HyperbolicUniformModulus}^{\uparrow}$ packet realizes the uniform-modulus branch of chapter 9463 as finite hyperbolic metric, cross-ratio, visual-boundary, and tolerance-only modulus rows. It sits after the Poincare disk metric packet of chapter 6209, the hyperbolic metric surface of chapter 3474, the boundary comparison packet of chapter 3948, the visual boundary carrier of chapter 4181, and the compact uniform selector of chapter 6466. The carrier is a BEDC-internal synthesis: it binds hyperbolic boundary geometry to a tolerance-only modulus route without turning visual expansion into a host compactness theorem or a completed boundary object.

Definition 6477.1 (Hyperbolic uniform modulus carrier)**.** *A* $\mathsf{HyperbolicUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, X, B, V, Q, T, D, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the displayed disk or boundary-shadow observations.*
2. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *comparison row, recording the finite four-point or boundary-ratio data used by the modulus read.*
3. *B is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *boundary row, exposing the visual-boundary source of the observer-expansion tolerance request.*
4. *V is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-metric provenance row tying the metric and boundary observations to the disk model used by the vision.*
5. *Q is the* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance-only modulus row delivered to observer-expansion consumers.*
6. *T is the compact-uniform handoff row, read through* $\mathsf{CompactUniformModulus}^{\uparrow}$ *or the finite selector route of chapter 6466.*
7. *D is the dyadic or rational tolerance ledger used to compare cross-ratio, visual-boundary, and modulus requests.*
8. *R is the refusal row excluding host boundary compactness, completed hyperbolic plane geometry, quotient ideal points, selected visual metrics, and physical observer expansion.*

9. *H records componentwise* hsame *transport for metric, cross-ratio, visual-boundary, disk-metric, uniform-modulus, compact-uniform, tolerance, refusal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from hyperbolic boundary observations through M, X, B, V, T, D to the tolerance-only row Q.*
11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicUniformModulus}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host compactness theorem, quotient boundary equality, selected visual metric, completed hyperbolic geometry, physical expansion law, or observer substance.

Theorem 6477.2 (Hyperbolic uniform modulus NameCert obligations)**.** *For every accepted* HyperbolicUniformMod *carrier*

$$U = (M, X, B, V, Q, T, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicUniformModulus}^{\uparrow}}$ *surface consists exactly of hyperbolic metric admission, hyperbolic cross-ratio admission, visual-boundary admission, Poincare disk metric provenance, tolerance-only uniform modulus exposure, compact-uniform handoff, tolerance-ledger compatibility, refusal exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The hyperbolic geometry rows are M, X, B, V, and the tolerance rows are Q, T, D.

The metric and cross-ratio rows are read before the modulus row. This keeps the boundary comparison visible when the consumer receives a tolerance-only threshold.

The compact-uniform handoff is finite. The row T records the selector or compact uniform modulus route, while D records the tolerance ledger used to compare the geometric and modulus requests.

The refusal and structural rows preserve the boundary. Since no coordinate supplies host compactness, quotient boundary equality, selected visual metrics, completed hyperbolic geometry, physical expansion, or observer substance, the listed rows exhaust the local NameCert surface. □

Theorem 6477.3 (Hyperbolic uniform modulus cross-ratio route)**.** *Every accepted* $\mathsf{HyperbolicUniformModulus}^{\uparrow}$ *read delivers its tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *row only after the displayed route*

$\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, CompactUniformModul

has been opened. The observer-expansion consumer receives metric, cross-ratio, visual-boundary, disk-metric, compact-uniform, and tolerance-ledger rows before any modulus threshold can be used.

Proof. Begin with $U = (M, X, B, V, Q, T, D, R, H, C, P, N)$. The row Q is the only tolerance-only uniform modulus coordinate.

The route to Q is ordered by the carrier inventory. The consumer first reads the metric row M, cross-ratio row X, visual-boundary row B, disk-metric provenance V, compact-uniform handoff T, and tolerance ledger D.

Only then can Q be replayed by C and transported by H. The provenance row P and local naming row N record the same finite route.

Thus the modulus threshold is never detached from its hyperbolic boundary source, and no host compactness, selected visual metric, quotient boundary, completed geometry, or physical expansion law is exported. □

Theorem 6477.4 (Hyperbolic uniform modulus boundary nonescape)**.** *For an accepted* HyperbolicUniformModulus *carrier* $U = (M, X, B, V, Q, T, D, R, H, C, P, N)$*, the visual-boundary row* B *and tolerance-only row* Q *export no completed boundary compactification, quotient ideal point, selected visual metric, host compactness theorem, or physical observer-expansion datum. Every boundary-to-modulus read remains inside the displayed metric, cross-ratio, disk-metric, compact-uniform, tolerance, refusal, transport, replay, provenance, and naming rows.*

Proof. Inspect the carrier surface. The visual-boundary row B is accompanied by metric row M, cross-ratio row X, disk-metric provenance V, compact-uniform handoff T, tolerance ledger D, and refusal row R.

Apply the NameCert obligations of Definition 6477.2. They require the tolerance-only row Q to be exposed only through the same displayed rows.

The refusal row rules out stronger host readings, and H, C, P, N preserve the route under transport, replay, provenance, and local naming.

Consequently a consumer cannot extract completed boundary compactification, quotient ideal points, selected visual metrics, host compactness, or physical expansion from the packet. Such data are absent from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicUniformModulus}^{\uparrow}$ read must expose $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ rows before any observer-expansion consumer receives a tolerance-only modulus.

Independence witness: hyperbolic_metric, hyperbolic_cross_ratio, hyperbolic_visual_boundary, compact_uniform_modulus, poincare_disk_metric: no listed sibling is bijective to $\mathsf{HyperbolicUniformModulus}^{\uparrow}$ because this packet jointly binds metric reads, cross-ratio comparisons, visual-boundary rows, disk-metric provenance, compact-uniform handoff, a tolerance-only modulus, refusal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicUniformModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicUniformModulus}^{\uparrow}$ packet is generated from HyperbolicMetric reads, HyperbolicCrossRatio comparisons, HyperbolicVisualBoundary rows, PoincareDiskMetric provenance, CompactUniformModulus handoff, UniformModulus tolerance rows, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6477.1, Definition 6477.2, Definition 6477.3, and Definition 6477.4 seed the finite route from hyperbolic metric and boundary comparison rows to a tolerance-only uniform modulus.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host boundary compactness, quotient ideal-boundary equality, selected visual metrics, completed hyperbolic geometry, physical expansion, observer substance, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-read exposure, cross-ratio route, visual-boundary nonescape, compact-uniform handoff, tolerance-only modulus exactness, refusal, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicUniformModulusUp.

Chapter 6478

A Concrete Naming Certificate for $\mathsf{LocatedInfimumModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedInfimumModulus}^{\uparrow}$ packet records the finite data by which a located lower-bound search exposes an infimum modulus before any ambient completeness principle for $\mathsf{Real}^{\uparrow}$ is available. It sits beside the located-infimum carrier of chapter 1452, the dyadic tolerance route of chapter 291, the regular rational readback of chapter 301, and the real seal of chapter 38. The packet extracts lower-window brackets and dyadic tolerances; it does not assert trichotomy, quotient real equality, selected infima, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6478.1 (Located infimum modulus carrier)**.** *A* $\mathsf{LocatedInfimumModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, L, U, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the consumed* $\mathsf{NameCert}_{\mathsf{LocatedInfimum}^{\uparrow}}$ *row, recording the lower-bound ledger and greatest-lower-approximation ledger that the modulus request may inspect.*
2. *L is the* $\mathsf{LowerReal}^{\uparrow}$ *row, storing the displayed lower surface and its admitted lower-window observations.*
3. *U is the* $\mathsf{UpperReal}^{\uparrow}$ *row, storing the displayed upper guard used to bracket the lower search window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing dyadic precision requests, lower-window refinements, and width certificates.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating dyadic lower-window refinements into regular rational observations before the real seal is consumed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the located-infimum, lower-real, upper-real, tolerance, and readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the located-infimum row, lower and upper real rows, dyadic tolerance row, regular-rational readback, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an infimum-modulus request through $I, L, U, D, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedInfimumModulus}^{\uparrow}$, $\mathsf{LocatedInfimum}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedInfimumModulus}^{\uparrow}}$ *row.*

The carrier exports only the displayed modulus route $I, L, U, D, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality of real names, selected infima, countable choice, a host infimum operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6478.2 (Located infimum modulus NameCert obligations)**.** *For every accepted* $\mathsf{LocatedInfimumModulus}^{\uparrow}$ *carrier*

$$M = (I, L, U, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedInfimumModulus}^{\uparrow}}$ *surface consists exactly of located-infimum admission through I, lower-real window exposure through L, upper-real guard exposure through U, dyadic tolerance exactness through D, regular rational readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6478.1. The analytic rows are exactly the located-infimum row, the lower and upper real rows, the dyadic tolerance row, the regular rational readback row, and the terminal real seal row.

The lower-window read is forced through I, L, U. The located-infimum row supplies the lower-bound and greatest-lower-approximation ledgers, while L and U display the bracketing surfaces used by the modulus request.

The dyadic tolerance row supplies the modulus data. It refines lower-window widths through $\mathsf{DyadicRatCore}^{\uparrow}$ entries and exposes those refinements as $\mathsf{RegSeqRat}^{\uparrow}$ readbacks before the $\mathsf{Real}^{\uparrow}$ seal may be consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier row stores trichotomy, quotient equality, selected infima, countable choice, a host infimum operator, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6478.3 (Located infimum modulus real seal)**.** *Let $M = (I, L, U, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedInfimumModulus}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by M factors through the displayed route*

$$I, L, U \longmapsto D \longmapsto R \longmapsto E \longmapsto C, P, N.$$

Thus a consumer can read only the sealed regular-rational lower-window route, not a quotient real equality test, a selected infimum, a countable-choice witness, or an ambient completeness theorem.

Proof. Start with a $\mathsf{Real}^{\uparrow}$-facing request. The carrier contains only one real seal row, namely E, and the definition makes E reachable only after the located-infimum, lower-real, upper-real, dyadic tolerance, and regular-rational rows have been displayed.

The request first reads the lower-window source I, L, U. It then passes through the tolerance row D, which supplies the dyadic precision control, and through R, which repacks the same finite observations as regular rational readback.

The structural rows expose no additional real object. The continuation row C, provenance row P, and local naming row N can only replay, source, and name the sealed route, so the exported read remains inside $I, L, U, D, R, E, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedInfimumModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedInfimumModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6478.1, Definition 6478.2, and Definition 6478.3 seed the finite located infimum-modulus route over located-infimum, lower-real, upper-real, dyadic tolerance, regular-rational readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedInfimumModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, selected infima, countable choice, host infimum operators, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-window bracketing, dyadic tolerance refinement, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedInfimumModul

Constructive story: A $\mathsf{LocatedInfimumModulus}^{\uparrow}$ packet is generated from a LocatedInfimum row, LowerReal and UpperReal bracketing rows, dyadic tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 6479

A Concrete Naming Certificate for $\mathsf{BingMetrization}^{\uparrow}$

Following Bing and the Nagata–Smirnov metrization tradition, the $\mathsf{BingMetrization}^{\uparrow}$ packet records the finite BEDC route by which a developable regular topological source exposes a metric handoff through displayed star-refinement and cover-separation rows. It sits after the Moore-space development surface of chapter 3592, beside the regular locally finite cover route of chapter 6348, over the topology carrier of chapter 88, and before the metric-space consumer surface of chapter 4230. The packet names only the displayed Bing-style metrization route; it does not assert host topology equality, selected infinite covers, paracompactness as an external theorem, quotient point equality, or ambient real completeness.

Definition 6479.1 (Bing metrization carrier)**.** *A* $\mathsf{BingMetrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, M, D, S, R, L, E, Q, G, F, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the open-row classifier, point-neighbourhood requests, and finite membership reads.*
2. *M is the* $\mathsf{MooreSpace}^{\uparrow}$ *development row, exposing the countable development windows and local star-neighbourhood requests inherited from chapter 3592.*
3. *D is the displayed development-level schedule. It records the finite levels inspected by the packet and the point rows whose stars are tested.*
4. *S is the star-refinement row, binding each accepted neighbourhood request to a displayed star around the named point.*
5. *R is the regularity-separation row, recording finite closed-neighbourhood separation data read from the topology source.*
6. *L is the locally finite cover ledger shared with the Nagata–Smirnov route of chapter 6348.*
7. *E is the cover-shrink row, tying S, R, L to the finite separation checks used before a metric row can be consumed.*
8. *Q is the dyadic radius schedule used by the metric handoff.*
9. *G is the* $\mathsf{Met}^{\uparrow}$ *handoff row. It is available only after T, M, D, S, R, L, E, Q have been exposed.*

10. *F is the topology-metric compatibility row, recording that displayed metric balls from G answer exactly the topology windows read through T, M, D, S, R, L, E.*
11. *H records componentwise* hsame *transport for all displayed rows.*
12. *C records displayed* Cont *replay from a topology request through development, star-refinement, regularity, locally finite covers, shrink data, dyadic radii, metric handoff, compatibility, provenance, and local naming.*
13. *P is the* Pkg *provenance over* $\mathsf{BingMetrization}^{\uparrow}$, $\mathsf{MooreSpace}^{\uparrow}$, $\mathsf{NagataSmirnovMetrization}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{BingMetrization}^{\uparrow}}$ *row.*

The carrier has no coordinate for host topology equality, selected infinite covers, paracompactness as an external theorem, quotient point equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6479.2 (Bing metrization NameCert obligations)**.** *For every accepted* $\mathsf{BingMetrization}^{\uparrow}$ *carrier $B = (T, M, D, S, R, L, E, Q, G, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BingMetrization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, Moore development row, level schedule, star-refinement row, regularity-separation row, locally finite cover ledger, cover-shrink row, dyadic radius schedule, metric-space handoff, topology-metric compatibility, transport, replay, provenance, and local naming row;*
2. *development readability, requiring every Bing-style neighbourhood request to pass through T, M, D, S before any cover-shrink or metric row is inspected;*
3. *regular cover separation, requiring the rows R, L, E to expose the finite closed-neighbourhood and locally finite cover checks that license the metric handoff;*
4. *metric handoff exactness, requiring Q, G, F to keep the* $\mathsf{Met}^{\uparrow}$ *row downstream of the displayed development and cover-separation route;*
5. *refusal, requiring P and N to name only this finite packet and to refuse host topology equality, selected infinite covers, external paracompactness, quotient point equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 6479.1. The projection exposes exactly the topology source, Moore development row, development-level schedule, star-refinement row, regularity-separation row, locally finite cover ledger, shrink row, dyadic radius schedule, metric-space handoff, topology-metric compatibility row, and the structural rows H, C, P, N.

Development readability is forced by the row order. A neighbourhood request starts at T, passes to the Moore development row M, chooses only the displayed finite schedule D, and then reads the star-refinement witness S.

The metric handoff is downstream of the separation route. Rows R, L, E record the closed-neighbourhood and cover-shrink checks, while Q, G, F record the dyadic radius schedule, the metric-space handoff, and its finite compatibility with the original topology windows.

Since the tuple contains no host topology equality, selected infinite cover, external paracompactness theorem, quotient point equality, countable-choice row, or ambient completeness coordinate, the local NameCert cannot export those principles. □

Theorem 6479.3 (Bing metrization metric handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$ *consumer of an accepted* $\mathsf{BingMetrization}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{MooreSpace}^{\uparrow},\ D,\ S,\ R,\ L,\ E,\ Q,\ G,\ F,\ H,\ C,\ P,\ N.$$

The metric-space row G is consumed as a downstream handoff tied to the displayed development stars, regular separation rows, locally finite cover ledger, and topology compatibility windows. It is not a host metric, not a selected infinite cover construction, and not a claim that the source topology equals an external topology.

Proof. Read the carrier rows in order. The topology source and Moore development rows are displayed before a star-refinement request can be answered, so the metric-facing route remains attached to the source topology and its development data.

Next read the separation and cover rows. The regularity row R, locally finite ledger L, and shrink row E provide the finite Bing-style cover-separation data needed before a dyadic radius schedule or metric-space handoff is available.

The rows Q, G, F then supply the downstream metric interface and its topology compatibility check. Transport and replay through H and C preserve exactly the same route, while P and N record the sibling dependencies and local naming row.

The carrier contains no host topology equality, selected infinite cover, external paracompactness theorem, quotient point equality, countable-choice row, or ambient completeness coordinate. Therefore the $\mathsf{Met}^{\uparrow}$ consumer receives only the finite BEDC handoff named above. □

Closure status for $\mathsf{NameCert}_{\mathsf{BingMetrization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BingMetrization}^{\uparrow}$ packet is generated from a topology source row, Moore development row, development-level schedule, star-refinement row, regularity-separation row, locally finite cover ledger, cover-shrink row, dyadic radius schedule, MetricSpace handoff, topology-metric compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BingMetrization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6479.1, Definition 6479.2, and Definition 6479.3 seed the finite developable regular topology route to a displayed MetricSpace handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BingMetrization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host topology equality, selected infinite covers, external paracompactness, quotient point equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, development readability, regular cover separation, cover-shrink exactness, metric handoff exactness, transport, replay, provenance, and local naming for the displayed Bing metrization packet.

Chapter 6480

A Concrete Naming Certificate for $\mathsf{ProbabilityGeneratingFunction}^{\uparrow}$

Following Feller and Billingsley on probability generating functions for integer-valued distributions, the $\mathsf{ProbabilityGeneratingFunction}^{\uparrow}$ packet records the finite coefficient-window route by which a probability law over $\mathsf{Nat}^{\uparrow}$ is read as a formal series before any scalar consumer asks for a $\mathsf{Real}^{\uparrow}$ seal. It sits after the probability-space rows of chapter 184, the distribution rows of chapter 186, the series carrier of chapter 121, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite probability-mass windows, natural-index reads, coefficient streams, regular rational handoff, transport, replay, provenance, and local naming; it does not assert analytic convergence on a host disk, selected infinite sums, countable additivity beyond displayed rows, quotient stream equality, or ambient real completeness.

Definition 6480.1 (Probability generating function carrier)**.** *A* $\mathsf{ProbabilityGeneratingFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (P, D, I, S, W, R, E, H, C, K, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *row that names the finite probability context for the displayed event and mass reads.*
2. *D is the* $\mathsf{Distribution}^{\uparrow}$ *row whose integer-valued mass table supplies the inspected coefficient window.*
3. *I is the* $\mathsf{Nat}^{\uparrow}$ *index row naming the finite natural-number slots whose probabilities are exposed.*
4. *S is the* $\mathsf{Series}^{\uparrow}$ *coefficient-stream row, reading the displayed masses as the corresponding formal coefficient window.*
5. *W is the finite coefficient-window ledger connecting D, I to S without selecting an infinite stream.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected probability coefficients and finite partial evaluations.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exported only after P, D, I, S, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the probability, distribution, index, series, window, readback, seal, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from a coefficient or evaluation request through P, D, I, S, W to R and E.*
10. *K is the* Pkg *provenance over* $\mathsf{ProbabilityGeneratingFunction}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ProbabilityGeneratingFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, D, I, S, W, R, E, H, C, K, N$. It has no coordinate for a host analytic function, a completed probability law outside the displayed distribution row, selected infinite coefficients, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6480.2 (Probability generating function NameCert obligations)**.** *For every accepted* $\mathsf{ProbabilityGeneratingFunction}^{\uparrow}$ *carrier $G = (P, D, I, S, W, R, E, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProbabilityGeneratingFunc}}$ *surface consists exactly of probability-space admission through P; distribution-row admission through D; natural-index exposure through I; coefficient-stream exposure through S; finite coefficient-window exhaustion through W;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R;* $\mathsf{Real}^{\uparrow}$ *seal ordering through E; and componentwise transport, continuation replay, package provenance, and local naming through H, C, K, N.*

Proof. Project the carrier of Definition 6480.1. The rows P, D, I, S, W display the probability context, the integer-valued distribution, the finite natural-index slots, and the coefficient-stream window before any scalar readback is available.

The regular rational row R is downstream from that displayed coefficient window, and the Real seal E is downstream from R. Thus a scalar consumer can only read probabilities and partial evaluations along the route already exposed by the finite coefficient data.

Transport through H and replay through C preserve the same displayed route. Provenance and local naming through K, N source and name it without adding host analytic semantics, selected infinite coefficients, quotient stream equality, countable choice, or ambient completeness. □

Theorem 6480.3 (Probability generating function coefficient-window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{ProbabilityGeneratingFunction}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{ProbSpace}^{\uparrow}, \quad \mathsf{Distribution}^{\uparrow}, \quad \mathsf{Nat}^{\uparrow}, \quad \mathsf{Series}^{\uparrow}, \quad W, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the same packet rows $P, D, I, S, W, R, E, H, C, K, N$. Consequently the generating-function read is a coefficient-window handoff and not a host analytic function, selected infinite series, quotient stream equality, countable-choice selector, or ambient Real-completeness principle.

Proof. Begin with an accepted carrier and project the source rows P, D, I, S, W. The probability-space row and distribution row supply the finite mass table, while the natural-index row fixes exactly which coefficients the series row may expose.

Read the scalar handoff through R and E. The regular rational readback is obtained from the same finite coefficient windows, and the Real seal is visible only after that readback has been displayed.

Finally pass through H, C, K, N. These rows transport, replay, source, and name the same route, so no consumer can replace it by host analytic convergence, selected representatives, quotient stream equality, countable choice, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProbabilityGeneratingFunction}^{\uparrow}}$.

Constructive story: A ProbabilityGeneratingFunction$^{\uparrow}$ packet is generated from ProbSpaceUp rows, DistributionUp mass-table rows, NatUp index rows, SeriesUp coefficient-stream windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ProbabilityGeneratingFunction}^{\uparrow}}$, seed)

Scope closed: Definition 6480.1, Definition 6480.2, and Definition 6480.3 seed the finite probability generating function route over probability, distribution, natural-index, series, regular rational, Real-seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{ProbabilityGeneratingFunction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close analytic convergence on a host disk, selected infinite sums, quotient stream equality, countable choice, countable-additivity claims beyond displayed rows, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, probability-space admission, distribution-row admission, natural-index exposure, coefficient-window exactness, regular readback, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.ProbabilityGeneratingFunctionUp.

Chapter 6481

A Concrete Naming Certificate for HyperbolicPhaseEnergyLedger$^{\uparrow}$

The HyperbolicPhaseEnergyLedger$^{\uparrow}$ packet realizes the phase-energy budget branch of chapter 9463 as finite reversible-transport, metric-budget, boundary-refusal, Real-seal, provenance, and NameCert rows. It sits after the hyperbolic metric surface of chapter 3474, the reversible phase-transport rows of chapter 219, the flow record surface of chapter 195, the terminal scalar seal of chapter 38, and the conservation ledger of chapter 3487. The packet names a BEDC-internal budget ledger: energy is readable only as displayed metric, transport, conservation, refusal, readback, and provenance data, not as a host Hamiltonian scalar or completed symplectic phase space.

Definition 6481.1 (Hyperbolic phase-energy ledger carrier)**.** *A* HyperbolicPhaseEnergyLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, U, D, L, B, R, S, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-budget row over the displayed phase-surface observations.*
2. *U is the* UnitaryGroup$^{\uparrow}$ *reversible-transport row recording the classifier-preserving phase move.*
3. *D is the* DynSystem$^{\uparrow}$ *finite flow row through which the transported surface is replayed.*
4. *L is the* LiouvilleLedgerConservation$^{\uparrow}$ *conservation row, requiring source distinctions and route volume to remain auditable under the reversible flow.*
5. *B is the boundary-refusal row excluding completed phase space, host symplectic volume, physical energy conservation, quotient boundary equality, and unledgered loss of source distinctions.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for displayed metric and phase-budget observations.*
7. *S is the terminal* Real$^{\uparrow}$ *seal row exposed only after M, U, D, L, B, R have been displayed.*
8. *F is the TasteGate-facing row requiring the future Lean file for* HyperbolicPhaseEnergyLedger$^{\uparrow}$ *to provide* `Nontrivial` *and* `FieldFaithful` *instances for the metric, transport, flow, conservation, refusal, readback, seal, replay, provenance, and naming fields.*
9. *H records componentwise* hsame *transport for metric-budget, reversible-transport, flow, conservation, refusal, readback, seal, TasteGate-facing, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through the route*

$$M, U, D \longmapsto L, B \longmapsto R, S.$$

11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{UnitaryGroup}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, U, D, L, B, R, S, F, H, C, P, N$. It has no coordinate for host Hamiltonian mechanics, completed symplectic volume, selected global phase orbit, physical observer dynamics, quotient boundary equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6481.2 (Hyperbolic phase-energy ledger obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$ *carrier $E = (M, U, D, L, B, R, S, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}}$ *surface consists exactly of hyperbolic metric-budget admission, reversible phase-transport admission, dynamic-flow replay, Liouville ledger conservation, boundary-refusal exactness, regular rational readback, Real-seal ordering, TasteGate-facing nontriviality and field-faithfulness requirements, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6481.1. The rows M, U, D display the metric budget, reversible transport, and finite flow route before any conservation or scalar readback row is available.

Read the conservation and refusal rows next. The row L records conservation only as an auditable ledger condition, while B prevents that condition from being read as host symplectic volume, physical energy conservation, quotient boundary equality, or a completed phase space.

The readback row R and Real seal S are downstream from the displayed metric, transport, flow, conservation, and refusal rows. The TasteGate-facing row F keeps those fields noncollapsed for the future Lean carrier.

Rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores a host Hamiltonian scalar, selected global orbit, ambient completion, or bridge theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6481.3 (Hyperbolic phase-energy Real-seal order)**.** *Every accepted* $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$ *read that exports a* $\mathsf{Real}^{\uparrow}$ *phase-energy seal must first display*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \quad \mathsf{UnitaryGroup}^{\uparrow}, \quad \mathsf{DynSystem}^{\uparrow}, \quad \mathsf{LiouvilleLedgerConservation}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

In carrier notation, the row S is reachable only after $M, U, D, L, B, R, H, C, P, N$ have been read, and the TasteGate-facing row F requires the future Lean $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$ *file to keep the carrier fields* `Nontrivial` *and* `FieldFaithful`.

Proof. Begin with the metric, transport, and flow rows. The phase-energy seal has no source until M, U, D expose a displayed hyperbolic metric budget, reversible phase move, and dynamic replay route.

Use the conservation and refusal rows next. The Liouville ledger L preserves source distinctions under the reversible route, while B excludes host phase-space and physical-energy readings.

Only then can the regular rational readback R and Real seal S be consumed. Transport, replay, provenance, and local naming through H, C, P, N keep the same route visible, and F records the future Lean field-separation requirements. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$ packet exposes $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{UnitaryGroup}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, and $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$ rows before any $\mathsf{Real}^{\uparrow}$ phase-energy seal; a read that reaches the seal without those rows refutes the carrier surface.

Independence witness: hyperbolic-metric, unitarygroup, dynsystem, real, liouville-ledger-conservation: no listed sibling is bijective to $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$ because this packet jointly carries metric-budget rows, reversible phase transport, finite flow replay, Liouville conservation, boundary refusal, regular readback, Real sealing, TasteGate-facing field separation, transport, provenance, and local naming.

The Lean TasteGate file `lean4/BEDC/Derived/HyperbolicPhaseEnergyLedgerUp/TasteGate.lean` must provide `Nontrivial` and `FieldFaithful` instances for $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$. Those instances must preserve $M, U, D, L, B, R, S, F, H, C, P, N$ as distinct fields before any carrier-alignment theorem can serve as a TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$ packet is generated from HyperbolicMetricUp metric-budget rows, UnitaryGroupUp reversible-transport rows, DynSystemUp flow replay, LiouvilleLedgerConservationUp conservation rows, boundary refusal, RegSeqRatUp readback, a RealUp seal, TasteGate-facing field-separation requirements, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6481.1, Definition 6481.2, and Definition 6481.3 seed the finite phase-energy ledger route over hyperbolic metric, reversible transport, dynamic flow, Liouville conservation, refusal, readback, Real-seal, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hamiltonian mechanics, completed symplectic volume, physical energy conservation, selected global phase orbits, quotient boundary equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, metric-budget exposure, reversible-transport admission, flow replay, Liouville conservation, boundary-refusal exactness, Real-seal ordering, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseEnergyLedgerUp.

Chapter 6482

A Concrete Naming Certificate for $\mathsf{Hyperfunction}^{\uparrow}$

Following Sato, the $\mathsf{Hyperfunction}^{\uparrow}$ packet records a generalized-function boundary value as finite BEDC data rather than as an ambient quotient of holomorphic functions. It sits over the sheaf route of chapter 151, the cohomology ledger of chapter 99, the complex-analysis carrier of chapter 39, the topology source of chapter 88, and the distribution-facing consumer surface of chapter 186. The packet names the displayed boundary-value route only; it does not export host analytic continuation, quotient sheaf cohomology, selected representatives, distribution equality, or ambient completeness.

Definition 6482.1 (Hyperfunction carrier)**.** *A* $\mathsf{Hyperfunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (T, O, B, S, Q, A, R, D, E, K, L, M, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row for the underlying real-domain carrier, including finite open-set membership requests and neighbourhood probes.*
2. *O is the open-domain row, displaying the finite real open windows on which boundary values are requested.*
3. *B is the boundary-value row. It records the upper and lower complex-side neighbourhoods, their boundary approach data, and the finite comparison window used by the read.*
4. *S is the* $\mathsf{Sheaf}^{\uparrow}$ *row, carrying restriction, locality, and gluing data for the displayed open windows.*
5. *Q is the* $\mathsf{Cohomology}^{\uparrow}$ *row, recording the finite coboundary and cocycle ledger consumed by the hyperfunction read.*
6. *A is the* $\mathsf{Complex}^{\uparrow}$ *analytic row, containing the complex-domain readback and holomorphic-window evidence available to the packet.*
7. *R is the real readback row, tying the boundary window to the real-domain request without selecting a host real function.*
8. *D is the* $\mathsf{Distribution}^{\uparrow}$ *handoff row, available only as a downstream consumer of the boundary-value, sheaf, cohomology, complex, and real readback rows.*

9. *E is the exactness row, recording that the displayed boundary-value read is unchanged by packet-local coboundary replacement.*
10. *K records componentwise* hsame *transport for the topology, open-domain, boundary-value, sheaf, cohomology, complex, real readback, distribution handoff, and exactness rows.*
11. *L records displayed* Cont *replay from a real-domain request through open windows, complex boundary values, sheaf restrictions, cohomology ledgers, exactness, downstream readback, and local naming.*
12. *M is the* Pkg *provenance over* $\mathsf{Hyperfunction}^{\uparrow}$, $\mathsf{Sheaf}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*
13. *C is the complex/real compatibility row, requiring the complex-side boundary window and the real-domain readback to be consumed as one finite route.*
14. *P is the replay provenance row for sibling consumers that use the distribution-facing handoff.*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{Hyperfunction}^{\uparrow}}$ *row.*

The carrier has no coordinate for host analytic continuation, quotient sheaf cohomology, selected boundary representatives, distribution equality, global dual-space topology, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HyperfunctionUp.TasteGate.HyperfunctionTasteGate single carrier alignment`

Theorem 6482.2 (Hyperfunction NameCert obligations)**.** *For every accepted* $\mathsf{Hyperfunction}^{\uparrow}$ *carrier* $H = (T, O, B, S, Q, A, R, D, E, K, L, M, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Hyperfunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, open-domain row, boundary-value row, sheaf row, cohomology ledger, complex analytic row, real readback row, distribution handoff, exactness row, transport, replay, package provenance, compatibility, consumer provenance, and local naming;*
2. *boundary readability, requiring every real-domain request to pass through T, O, B before any sheaf or cohomology row is inspected;*
3. *sheaf-cohomology exactness, requiring S, Q, E to witness restriction, locality, gluing, cocycle, coboundary, and packet-local replacement data before a hyperfunction read is exported;*
4. *complex/real compatibility, requiring A, R, C to bind the complex boundary window to the displayed real-domain readback;*
5. *downstream refusal, requiring D, M, P, N to expose only the distribution-facing handoff named by the packet and to refuse host analytic continuation, quotient sheaf cohomology, selected representatives, distribution equality, global dual-space topology, and ambient completeness.*

No local NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.HyperfunctionUp.HyperfunctionCarrier namecert obligations`

Proof. Project the carrier of Definition 6482.1. The projection exposes the topology source, open-domain row, boundary-value row, sheaf row, cohomology ledger, complex analytic row, real readback row, distribution handoff, exactness row, and structural rows K, L, M, C, P, N.

Boundary readability is forced by the row order. A real-domain request starts at T, chooses only the displayed open-domain windows O, and then reads the boundary-value comparison row B before it can inspect sheaf or cohomology data.

The sheaf and cohomology obligations are packet-local. Rows S, Q, E record restriction, locality, gluing, cocycle, coboundary, and exactness data for the same displayed open windows, so the read has no route to quotient sheaf cohomology or selected representatives.

Finally A, R, C bind the complex-side window to the real readback, while D, M, P, N name the downstream distribution handoff. Since the tuple contains no host analytic-continuation, distribution-equality, global dual-space, or ambient-completeness coordinate, the local certificate cannot export such data. □

Lean4 ✓ `BEDC.Derived.HyperfunctionUp.HyperfunctionNamecertObligations`

Theorem 6482.3 (Hyperfunction sheaf-cohomology handoff)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or real-analysis consumer of an accepted* $\mathsf{Hyperfunction}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{Topology}^{\uparrow},\ O,\ B,\ \mathsf{Sheaf}^{\uparrow},\ \mathsf{Cohomology}^{\uparrow},\ \mathsf{Complex}^{\uparrow},\ R,\ D,\ E,\ K,\ L,\ M,\ C,\ P,\ N.$$

The consumer may read a boundary-value hyperfunction only after the open-domain, sheaf, cohomology, complex, real readback, exactness, transport, replay, provenance, compatibility, and local naming rows have been displayed. It receives no host analytic continuation, quotient cohomology class, selected boundary representative, distribution equality, global dual-space topology, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HyperfunctionUp.HyperfunctionCarrier sheaf cohomology handoff`

Proof. Start with the open-domain and boundary-value rows. The topology source T and the displayed windows O determine the real request surface before the boundary row B can be consumed.

Next read the sheaf and cohomology rows. The sheaf row S supplies restriction, locality, and gluing only on the displayed windows, while the cohomology row Q and exactness row E record the packet-local cocycle and coboundary ledger.

Then attach the complex/real readback. The complex analytic row A, real readback row R, and compatibility row C make the boundary-value route a single finite interface rather than a host analytic object.

The distribution handoff D is downstream of those rows, and K, L, M, P, N transport, replay, package, and name exactly that route. Since no further coordinate is present, a consumer cannot obtain quotient cohomology, selected representatives, distribution equality, global dual-space topology, or ambient completeness from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{Hyperfunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Hyperfunction}^{\uparrow}$ packet is generated from a topology source row, displayed open-domain row, boundary-value row, Sheaf row, Cohomology row, Complex analytic row, real readback row, Distribution handoff, exactness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, compatibility, consumer provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Hyperfunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6482.1, Definition 6482.2, and Definition 6482.3 seed the finite Sato boundary-value route through Sheaf, Cohomology, Complex, Topology, and Distribution rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Hyperfunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host analytic continuation, quotient sheaf cohomology, selected boundary representatives, distribution equality, global dual-space topology, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary readability, sheaf-cohomology exactness, complex/real compatibility, distribution handoff, transport, replay, provenance, and local naming for the displayed Hyperfunction packet.

Chapter 6483

A Concrete Naming Certificate for $\mathsf{NestedShrinkingInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{NestedShrinkingInterval}^{\uparrow}$ packet records the finite BEDC surface for a real-completion route driven by nested shrinking interval rows. It sits over the dyadic tolerance arithmetic of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, the nested interval real route of chapter 1924, and the bisection real route of chapter 5711. The packet is interval-shrink data for the L10 completion boundary; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, quotient equality of real names, a selected limit, trichotomy, or countable choice.

Definition 6483.1 (Nested shrinking interval carrier)**.** *A* $\mathsf{NestedShrinkingInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (J_0, J_1, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. J_0 *is the parent interval row, carrying the currently admitted closed dyadic interval and its endpoint witnesses.*
2. J_1 *is the child interval row, read only after* J_0*, carrying the next closed dyadic interval selected inside the parent row.*
3. W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window listing the inspected interval requests, endpoint reads, and tail-budget positions.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter and tolerance ledger, recording the displayed shrink bound and the dyadic budget attached to each inspected window.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the finite interval-window data into regular rational approximants.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the nested interval rows, window ledger, dyadic budget, and regular readback have been displayed.*
7. H *records componentwise* hsame *transport for the interval rows, stream window, dyadic ledger, readback, seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a completion-facing request through the same rows.*
9. P *is the* Pkg *provenance over* $\mathsf{NestedShrinkingInterval}^{\uparrow}$, $\mathsf{NestedIntervalReal}^{\uparrow}$, $\mathsf{BisectionReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{NestedShrinkingInterval}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host-selected limit, quotient equality of real names, trichotomy, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.NestedShrinkingIntervalUp.NestedShrinkingIntervalTasteGate single carrier alignment`

Theorem 6483.2 (Nested shrinking interval NameCert obligations)**.** *For every accepted* $\mathsf{NestedShrinkingInterval}^{\uparrow}$ *carrier* $I = (J_0, J_1, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NestedShrinkingInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the parent and child interval rows, finite StreamName window, dyadic diameter and tolerance ledger, regular rational readback, real seal, transport, replay, provenance, and local naming; nested containment requiring* J_1 *to be read as a child of* J_0*; diameter decay requiring* D *to certify the displayed shrink budget before* R *is consumed; finite-window readback requiring every completion-facing request to pass through* W *before the regular rational row; Real-seal nonescape requiring* E *to be downstream of* J_0, J_1, W, D, R*; componentwise* hsame *transport through* H*; displayed* Cont *replay through* C*;* Pkg *provenance through* P*; and terminal naming through* N*.*

Proof. Carrier admission is projection from Definition 6483.1. The accepted packet displays exactly $J_0, J_1, W, D, R, E, H, C, P, N$.

The interval part begins with J_0 and J_1. The child row is available only as a nested row inside the parent row, so a consumer cannot read the shrink step without first reading the parent interval data.

The finite computational part is W, D, R. The StreamName window lists the requests, the dyadic ledger records the diameter and tolerance budget attached to those requests, and the regular rational row reads back only after that finite budget has been displayed.

Finally, E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for a selected limit, quotient real equality, trichotomy, countable choice, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6483.3 (Nested shrinking interval real-completion handoff)**.** *Every L10 real-completion consumer of an accepted* $\mathsf{NestedShrinkingInterval}^{\uparrow}$ *carrier reads the route through the nested interval rows* J_0, J_1*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before any completion-facing conclusion is exposed through* H, C, P, N*.*

Proof. Start with an accepted carrier $I = (J_0, J_1, W, D, R, E, H, C, P, N)$. The completion-facing seal is the row E, and that row is listed after the interval, window, dyadic, and regular rational rows.

A consumer must first read the parent and child interval rows. It then reads the finite StreamName window and the dyadic diameter ledger, so every inspected tolerance request is tied to a displayed shrink step.

Only after those rows are visible does the consumer obtain the regular rational readback R and then the real seal E. Transport and replay through H and C preserve the same order, while P and N record provenance and local naming. Thus the route reaches a completion-facing conclusion without importing ambient real completeness, quotient equality, a selected limit, trichotomy, or countable choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedShrinkingInterval}^{\uparrow}}$ **.**

Constructive story: A NestedShrinkingInterval$^{\uparrow}$ packet is generated from parent and child nested interval rows, a finite StreamName window, DyadicRatCore diameter and tolerance ledgers, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{NestedShrinkingInterval}^{\uparrow}}$, seed)

Scope closed: Definition 6483.1, Definition 6483.2, and Definition 6483.3 seed the finite interval-shrink route for L10 real-completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{NestedShrinkingInterval}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.NestedShrinkingIntervalUp.NestedShrinkingIntervalTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient equality of real names, selected limits, trichotomy, countable choice, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, nested containment, diameter decay, finite-window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NestedShrinkingIntervalUp.

Chapter 6484

A Concrete Naming Certificate for $\mathsf{CauchySequenceInterleaving}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchySequenceInterleaving}^{\uparrow}$ packet records the finite interleaving surface used when two Cauchy-name routes must be inspected against one shared tolerance ledger. It sits between the $\mathsf{StreamName}^{\uparrow}$ window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the fast-subsequence route of chapter 1518.

The packet is a source-route object for Real and Completion arguments. It interleaves two displayed Cauchy sequences by finite request windows, parity rows, dyadic error budgets, and readback rows; it consumes the regular-subsequence finite reindexing surface of chapter 381 when alternating or interleaving tail windows. It does not quotient streams, select a limit, compare host reals, invoke trichotomy, use countable choice, or assert ambient completeness.

Definition 6484.1 (CauchySequenceInterleaving carrier)**.** *A* $\mathsf{CauchySequenceInterleaving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, W, P, D, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *X and Y are the two source* $\mathsf{StreamName}^{\uparrow}$ *rows whose windows are interleaved;*
2. *W is the finite window ledger recording which requests of X and Y are inspected;*
3. *P is the parity and provenance row identifying the left and right legs of each interleaved request;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the inspected requests;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic tolerances;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have been projected;*
7. *H records componentwise* hsame *transport for the two source rows, window ledger, parity row, tolerance row, readback row, seal row, and support rows;*
8. *C records displayed* Cont *replay from source windows to interleaved requests, dyadic tolerance readback, regular rational readback, and real-name sealing;*
9. *Q is the optional* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *handoff row used when a downstream diagonal argument asks for a cofinal fast window;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceInterleaving}^{\uparrow}}$ *row.*

The classifier compares two carriers only through these displayed rows. It stores no quotient stream equality, host equality between infinite sequences, selected limit, countable-choice selector, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 6484.2 (CauchySequenceInterleaving NameCert obligations)**.** *For an accepted* CauchySequenceInterleavi *carrier* $I = (X, Y, W, P, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceInterleaving}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the displayed rows, source-window admission for* X *and* Y*, finite interleaving admission for* W*, parity and provenance admission for* P*, dyadic tolerance admission through* D*, regular rational readback through* R*, terminal Real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, optional fast-subsequence handoff through* Q*, and local naming through* N*.*

Every Real-facing or Completion-facing consumer of the packet must therefore read the sibling StreamName, DyadicRatCore, RegSeqRat, Real, and FastCauchySubsequence rows in the displayed route. No obligation exports quotient stream equality, host real equality, selected limits, arbitrary choice of subsequences, trichotomy, or ambient completeness.

Proof. Project the carrier of Definition 6484.1. The only analytic rows available to a consumer are the two source StreamName rows, the finite interleaving window ledger, parity provenance, dyadic tolerance data, regular rational readback, Real seal, optional fast-subsequence handoff, and the structural support rows.

Read the source route first. The rows X, Y, W, P determine which finite windows are inspected and which leg of the interleaving each request belongs to, without choosing infinite representatives or quotienting streams.

Read the tolerance and seal route next. The rows D, R, E force every Real-facing or Completion-facing exit through dyadic tolerances, regular rational readback, and the terminal Real seal. The support rows H, C, Q, N transport, replay, optionally hand off, and name only that displayed finite route. □

Theorem 6484.3 (CauchySequenceInterleaving RegSeqRat handoff)**.** *Every accepted* $\mathsf{CauchySequenceInterleaving}^{\uparrow}$ *carrier* $I = (X, Y, W, P, D, R, E, H, C, Q, N)$ *hands its interleaved finite-window data to* $\mathsf{RegSeqRat}^{\uparrow}$ *through the route*

$$X, \quad Y, \quad W, \quad P, \quad D, \quad R, \quad E.$$

If a downstream diagonal or Cauchy-window argument asks for a cofinal fast window, the handoff may continue through the displayed $\mathsf{FastCauchySubsequence}^{\uparrow}$ *row* Q*, but it must still keep the StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and Real seal visible before any public comparison data is exposed.*

Proof. Begin with the finite interleaving ledger. The rows X, Y, W, P determine the accepted left and right windows and their parity provenance, so the packet has no coordinate for an untracked infinite merge of the two sources.

Apply the NameCert obligation surface of Definition 6484.2. It requires D before R and requires R before the terminal seal E, giving the displayed RegSeqRat handoff route.

For a fast cofinal request, use the Q row only after the regular readback route has been exposed. Since Q is an optional displayed handoff row rather than a choice functional, it cannot bypass X, Y, W, P, D, R, E or create a selected limit. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceInterleaving}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySequenceInterleaving}^{\uparrow}$ packet is generated from two displayed StreamName source rows, finite interleaving windows, parity provenance, dyadic tolerances, regular rational readback, a terminal Real seal, optional fast-subsequence handoff, componentwise transport, replay, and local naming rows.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchySequenceInterleaving}\uparrow}$, seed)

Scope closed: Definition 6484.1, Definition 6484.2, and Definition 6484.3 define the finite source-route packet and its RegSeqRat handoff surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchySequenceInterleaving}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a Lean theorem, bridge checking, quotient stream equality, host real equality, selected limits, countable choice, trichotomy, or ambient completeness.

Upgrade path: The next obligation is a Lean theorem for the carrier and handoff clauses, followed by a standard bridge only after the source route has a checked public surface.

Chapter 6485

A Concrete Naming Certificate for $\mathsf{LocatedUniformCauchyFilter}^{\uparrow}$

Following Bourbaki on uniform spaces, Kelley on filters, and Bishop and Bridges on constructive completion, the $\mathsf{LocatedUniformCauchyFilter}^{\uparrow}$ packet records the finite BEDC route in which uniform Cauchy evidence and located filter evidence are read by the same completion-neighbour surface. It joins the uniform Cauchy filter rows of chapter 1694 with the located filter rows of chapter 1661, while keeping the stream, dyadic, regular-rational, and real-seal faces of chapter 126, chapter 291, chapter 301, and chapter 38 explicit. The carrier is not a quotient of filters and does not select a limit; it only names the rows a completion-neighbour consumer may inspect.

Definition 6485.1 (Located uniform Cauchy filter carrier)**.** *A* $\mathsf{LocatedUniformCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (U, F, L, S, R, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *row, carrying the displayed uniform-space, filter-base, entourage-Cauchy, stream-window, regular-rational, and completion-handoff surface of chapter 1694.*
2. *F is the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row, carrying the displayed located-tail, basis-refinement, sequence-handoff, and real-seal surface of chapter 1661.*
3. *L is the completion-neighbour location row, recording that the uniform entourage request and the located-tail request name the same finite neighbourhood read before any seal-facing consumer proceeds.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row supplied to the joined filter readback, using only the observation surface of chapter 126.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows and to the same located-uniform request, as in chapter 301.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic entourage scale, located-ball slack, comparison cells, and radius conversions used by the joined request; it is read through chapter 291.*
7. *T is the located-uniform tail row, requiring the uniform Cauchy row U and located filter row F to meet the same displayed dyadic tolerance before R or E can be exported.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, exposed only after U, F, L, S, R, D, T have been displayed through the real-name boundary of chapter 38.*
9. *H records componentwise* hsame *transport for the uniform filter, located filter, neighbourhood location, stream, regular-rational, dyadic, tail, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a completion-neighbour request through $U, F, L, S, R, D, T, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformCauchyFilter}^{\uparrow}$, $\mathsf{UniformCauchyFilter}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyFilter}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $U, F, L, S, R, D, T, E, H, C, P, N$. It has no coordinate for quotient filter equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, open-cover compactness, ultrafilters, or a second dyadic source.*

Theorem 6485.2 (Located uniform Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUniformCauchyFilter}^{\uparrow}$ *carrier*

$$X = (U, F, L, S, R, D, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, uniform Cauchy filter exposure, located Cauchy filter exposure, completion-neighbour location, finite StreamName window readback, RegSeqRat regular-rational readback, DyadicRatCore tolerance accounting, located-uniform tail compatibility, terminal RealUp seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the finite carrier of Definition 6485.1.*

Proof. Carrier admission is projection from Definition 6485.1. The analytic rows visible to the certificate are exactly U, F, L, S, R, D, T, E.

The uniform row U is read through chapter 1694, and the located row F is read through chapter 1661. The neighbourhood location row L identifies the same finite completion-neighbour request for both rows before downstream readback begins.

The sequence-facing part of the route is finite. The window row S uses chapter 126, the tolerance row D uses chapter 291, and the regular rational row R uses chapter 301. The tail row T binds these rows to the displayed located-uniform request.

Finally the seal-facing row E is read through chapter 38 only after U, F, L, S, R, D, T have been displayed. The support rows H, C, P, N transport, replay, source, and name that same route, so no quotient filter, selected limit, countable-choice selector, host equality, ambient completeness, open-cover compactness, ultrafilter, or second dyadic source can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedUniformCauchyFilter}^{\uparrow}$ packet is generated from a UniformCauchyFilter row, a LocatedCauchyFilter row, a completion-neighbour location row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a located-uniform tail row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 6485.1 and Definition 6485.2 seed the joined located-uniform filter route over UniformCauchyFilterUp, LocatedCauchyFilterUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host real equality, ambient Real completeness, open-cover compactness, ultrafilters, Lean verification, or bridge checking.

Upgrade path: Formal closure requires carrier admission, completion-neighbour location, located-uniform tail compatibility, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.LocatedUniformCauchyFilterUp.

Chapter 6486

A Concrete Naming Certificate for $\mathsf{KochSnowflake}^{\uparrow}$

Following Koch and Falconer, the $\mathsf{KochSnowflake}^{\uparrow}$ packet records the classical three-sided Koch snowflake boundary as a finite NameCert over three sidewise $\mathsf{KochCurve}^{\uparrow}$ arcs. It sits beside the single-arc construction of chapter 3995, the uniform-limit handoff of chapter 463, the L10 Real route of Definition 1624.4, and the terminal real-name seal of chapter 38. The packet names only the cyclic boundary loop, stagewise displacement rows, finite StreamName windows, regular rational readbacks, Real coordinate seals, transport, replay, provenance, and local naming; it does not import a completed planar subset, area computation, Hausdorff dimension, quotient equality of real coordinate pairs, selected infinite branches, or ambient compactness.

Definition 6486.1 (Koch snowflake carrier)**.** *A* $\mathsf{KochSnowflake}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A_0, A_1, A_2, S, D, W, R, E, H, C, P, N)$$

with the following visible rows:

1. A_0, A_1, A_2 *are the three sidewise* $\mathsf{KochCurve}^{\uparrow}$ *arc rows. Each row records the finite address, polygonal-stage segment word, displacement ledger, coordinate windows, regular-rational readback, Real coordinate seal, and uniform-limit handoff inherited from the corresponding side packet of chapter 3995.*

2. S *is the cyclic endpoint-compatibility row. It records that the terminal endpoint of* A_i *is the initial endpoint of* A_{i+1}*, with indices read cyclically, using only displayed finite endpoint rows and their* $\mathsf{Real}^{\uparrow}$ *seals.*

3. D *is the dyadic stage and displacement ledger. It aligns the three arc-stage requests, the triangular orientation data, and the dyadic tolerance comparisons used to read the boundary loop.*

4. W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family for the six endpoint-coordinate schedules and the inspected stagewise segment rows.*

5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those coordinate schedules, with every tolerance comparison routed through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*

6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *coordinate seal family for the three cyclic endpoints and the displayed segment endpoints reached through* D, W, R*.*

7. *H records componentwise* hsame *transport for the three sidewise arcs, cyclic compatibility row, dyadic stage ledger, window family, regular-rational readback, Real seal family, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from a boundary-loop request through $A_0, A_1, A_2, S, D, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{KochSnowflake}^{\uparrow}$, $\mathsf{KochCurve}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KochSnowflake}^{\uparrow}}$ *row.*

The classifier accepts a packet only through the displayed tuple $A_0, A_1, A_2, S, D, W, R, E, H, C, P, N$. It has no coordinate for a host planar subset, area measure, dimension computation, quotient real equality, selected infinite branch, or ambient compactness theorem.

Theorem 6486.2 (Koch snowflake NameCert obligations)**.** *For every accepted* $\mathsf{KochSnowflake}^{\uparrow}$ *carrier*

$$K = (A_0, A_1, A_2, S, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KochSnowflake}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; sidewise* $\mathsf{KochCurve}^{\uparrow}$ *arc exposure through A_0, A_1, A_2; cyclic endpoint compatibility through S; dyadic stage and displacement exactness through D; finite window scheduling through W; regular rational readback through R; terminal* $\mathsf{Real}^{\uparrow}$ *coordinate sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6486.1. The only arc-facing rows are A_0, A_1, A_2, and each is already a sidewise $\mathsf{KochCurve}^{\uparrow}$ packet with its finite address, polygonal-stage, dyadic displacement, coordinate-window, regular-readback, Real-seal, and uniform-limit data.

The compatibility obligation is exactly the row S. It compares only the displayed endpoints of adjacent side packets, with the terminal endpoint of one side matched to the initial endpoint of the next side in cyclic order.

The Real-facing obligations are exhausted by D, W, R, E. The dyadic stage ledger aligns the side stages and tolerances, the StreamName windows schedule the finite endpoint reads, the RegSeqRat row performs the rational readback, and the terminal coordinate seals remain downstream of the same L10 route.

Finally H, C, P, N transport, replay, source, and name this finite loop. Since the carrier contains no host planar subset, area row, dimension row, quotient real equality row, selected branch row, or ambient compactness row, no such object can be a local $\mathsf{NameCert}_{\mathsf{KochSnowflake}^{\uparrow}}$ obligation. □

Theorem 6486.3 (Koch snowflake dyadic curve route)**.** *Every accepted boundary-loop, segment, or coordinate read of a* $\mathsf{KochSnowflake}^{\uparrow}$ *packet factors through the finite route*

$$A_0, A_1, A_2 \longmapsto S \longmapsto D, W, R, E \longmapsto H, C, P, N.$$

The route exports only the three sidewise $\mathsf{KochCurve}^{\uparrow}$ *arcs, cyclic endpoint compatibility, dyadic stage and displacement data, finite StreamName windows, RegSeqRat readbacks, terminal* $\mathsf{Real}^{\uparrow}$ *coordinate seals, and the structural rows. It exports no completed planar fractal, area computation, Hausdorff dimension, quotient equality of real coordinate pairs, selected infinite branch, or ambient compactness principle.*

Proof. Begin with an accepted consumer of a boundary-loop, segment, or coordinate row. By Definition 6486.1, the consumer can enter the packet only through the three sidewise arc rows and the cyclic compatibility row.

Apply Definition 6486.2. It forces every side read through A_0, A_1, A_2, every loop-closing read through S, and every Real-facing read through D, W, R, E before the structural rows are inspected.

The single-arc route of chapter 3995, the uniform-limit route of chapter 463, and the L10 Real gate of Definition 1624.4 supply only the displayed finite readbacks named in the carrier. None adds a second coordinate for a completed planar subset, area or dimension data, quotient equality, branch selection, or compactness. Hence every accepted consumer remains on the displayed dyadic curve route. □

Falsifiable prediction: An accepted $\mathsf{KochSnowflake}^{\uparrow}$ consumer that reaches a boundary-loop or $\mathsf{Real}^{\uparrow}$ coordinate seal without first displaying the three sidewise KochCurve arc rows, cyclic endpoint-compatibility row, dyadic stage ledger, StreamName windows, RegSeqRat readback, and Real seal family refutes the carrier surface.

Independence witness: kochcurve, uniformlimit, dyadicratcore, streamname, regseqrat, real: no listed sibling supplies the whole $\mathsf{KochSnowflake}^{\uparrow}$ packet, because the snowflake certificate binds three sidewise KochCurve arcs with cyclic endpoint compatibility, a shared dyadic stage ledger, Real-seal routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KochSnowflake}^{\uparrow}}$.

Constructive story: A $\mathsf{KochSnowflake}^{\uparrow}$ packet is generated from three sidewise KochCurve arc rows, cyclic endpoint compatibility, a dyadic stage and displacement ledger, finite StreamName windows, RegSeqRat readbacks, RealUp coordinate seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KochSnowflake}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6486.1, Definition 6486.2, and Definition 6486.3 seed the finite three-sided Koch snowflake boundary-loop certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KochSnowflake}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host planar subsets, area measure, Hausdorff dimension, quotient equality of real coordinate pairs, selected infinite branches, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, three sidewise KochCurve arc exposure, cyclic endpoint compatibility, dyadic stage exactness, finite window scheduling, RegSeqRat readback, Real coordinate sealing, transport, replay, provenance, and local naming for BEDC.Derived.KochSnowflakeUp.

Chapter 6487

A Concrete Naming Certificate for $\mathsf{HilbertInequality}^{\uparrow}$

Following Hardy–Littlewood–Polya style Hilbert inequality, the $\mathsf{HilbertInequality}^{\uparrow}$ packet records a finite real-series inequality route rather than an ambient double-series theorem. It sits next to the absolute-domination surface of chapter 1700, the finite square-bound route of chapter 1684, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes the Hilbert kernel bound only as displayed BEDC rows over finitely inspected series windows, not as quotient stream equality, selected sums, countable choice, host real order, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6487.1 (Hilbert inequality carrier)**.** *A* $\mathsf{HilbertInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, B, K, S, Q, E, T, C, P, N)$$

with the following displayed rows:

1. *A and B are the two real-series source rows whose inspected terms are read through finite* $\mathsf{Real}^{\uparrow}$ *seals.*
2. *K is the Hilbert-kernel ledger. Each row records a displayed denominator window, the dyadic comparison budget for the kernel coefficient, and the finite multiplication read attached to the selected term pair.*
3. *S is the finite summation-window row. It records the rectangular or triangular window actually inspected by the packet and no infinite double-sum selector.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the term observations, kernel coefficients, partial rectangular sums, and comparison budgets opened by A, B, K, S.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the exported inequality boundary, reached only after A, B, K, S, Q have been displayed.*
6. *T stores componentwise* hsame *transport for the two source series, Hilbert-kernel ledger, finite windows, regular readback, Real seal, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a finite window request through the kernel ledger, regular readback, and Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{HilbertInequality}^{\uparrow}$*,* $\mathsf{AbsoluteConvergence}^{\uparrow}$*,* $\mathsf{CauchySchwarzReal}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{HilbertInequality}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, B, K, S, Q, E, T, C, P, N$. It has no coordinate for an ambient Hilbert-space theorem, selected infinite sums, quotient stream equality, countable choice, host real order, or ambient completeness.

Theorem 6487.2 (Hilbert inequality NameCert obligations)**.** *For every accepted* $\mathsf{HilbertInequality}^{\uparrow}$ *carrier $H = (A, B, K, S, Q, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HilbertInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the two source series, the Hilbert-kernel ledger, the finite summation windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The same surface records kernel-window exactness, rectangular finite-sum exposure, absolute-domination compatibility with chapter 1700, square-bound compatibility with chapter 1684, and nonescape from selected sums, quotient stream equality, countable choice, host real order, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6487.1. The available rows are exactly the two source series A, B, the kernel ledger K, the finite summation window S, the regular readback Q, the Real seal E, and the structural rows T, C, P, N.

The kernel and window obligations are the same finite route. The packet must display the denominator window and dyadic comparison budget in K for each inspected pair, and S names the finite rectangular or triangular window in which those pair reads occur.

The compatibility obligations use the sibling surfaces only as finite routes. The absolute-convergence chapter supplies the domination shape for series tails, while the Cauchy–Schwarz real chapter supplies the square-bound route for real-valued finite rows. Both are consumed through the same regular readback and Real seal rows Q, E.

Finally, the structural rows transport, replay, source, and name that displayed route. Since none of the excluded analytic objects is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6487.3 (Hilbert inequality Real-series handoff)**.** *Every real-series consumer of an accepted* $\mathsf{HilbertInequality}^{\uparrow}$ *packet receives the Hilbert inequality boundary only through*

$$A, B \longmapsto K, S \longmapsto Q \longmapsto E \longmapsto T, C, P, N.$$

The handoff exposes the two source series, finite kernel-denominator comparisons, inspected summation windows, regular rational readback, and the terminal Real seal. It does not expose a host double-series theorem, quotient stream equality, selected sums, countable choice, host real order, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a real-series consumer request. The carrier first exposes the source rows A and B, so every term read is tied to a displayed finite series observation.

The Hilbert kernel is then read through K inside the finite window S. This is the only place where denominator comparisons and pairwise multiplication budgets appear, so the consumer cannot bypass the packet to obtain an independent double series.

The readback and seal are forced by Q and E. The $\mathsf{RegSeqRat}^{\uparrow}$ row records the rational observations for the selected terms, kernel coefficients, and partial finite sums before the $\mathsf{Real}^{\uparrow}$ seal is available.

The rows T, C, P, N preserve and replay the same route. Because the carrier has no coordinate for the excluded host or quotient data, every exported Hilbert inequality read is the displayed finite real-series handoff. □

Falsifiable prediction: Every accepted $\mathsf{HilbertInequality}^{\uparrow}$ read exposes two real-series source rows, a Hilbert-kernel denominator ledger, finite summation windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert before a real-series consumer receives the inequality boundary.

Independence witness: absolute-convergence, cauchy-schwarz-real, regseqrat, real: $\mathsf{HilbertInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two source series, a Hilbert-kernel ledger, finite summation windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming for the same inequality route.

Closure status for $\mathsf{NameCert}_{\mathsf{HilbertInequality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HilbertInequality}^{\uparrow}$ packet is generated from two real-series source rows, a Hilbert-kernel denominator ledger, finite summation windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HilbertInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6487.1, Definition 6487.2, and Definition 6487.3 seed the finite Hilbert inequality boundary for displayed real-series rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HilbertInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host double-series convergence, quotient stream equality, selected sums, countable choice, host real order, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, kernel-window exactness, finite summation exposure, absolute-domination compatibility, square-bound compatibility, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HilbertInequalityUp.

Chapter 6488

A Concrete Naming Certificate for $\mathsf{FinitelyBranchingTree}^{\uparrow}$

Following Koenig's lemma, Brouwer spreads, and Bishop-style finite evidence, the $\mathsf{FinitelyBranchingTree}^{\uparrow}$ packet records a traditional finite-prefix tree as a BEDC NameCert carrier. It sits between the path-sensitive boundary of chapter 2092, the binary-window surface of chapter 1475, and the bar-modulus route of chapter 400. The packet exposes finite branching and prefix admission data for L10 countable-name and compactness consumers without selecting an infinite branch, asserting fan compactness, or turning a prefix ledger into host tree equality.

Definition 6488.1 (FinitelyBranchingTree carrier)**.** *A* $\mathsf{FinitelyBranchingTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (P, B, A, W, K, F, S, H, C, Q, N)$$

with the following displayed rows:

1. *P is the finite prefix-row family. Each row stores a finite node code, its length, and the immediate predecessor readback used by prefix consumers.*
2. *B is the branching ledger. For each admitted prefix row it displays a finite child bundle and the rows witnessing which child extensions remain in the tree.*
3. *A is the admissibility row, saying that the root prefix is present and that every admitted non-root prefix has its predecessor admitted.*
4. *W is the finite window row read by* $\mathsf{StreamName}^{\uparrow}$ *and by Cantor-style binary or finite-alphabet probes before a path consumer can inspect longer prefixes.*
5. *K is the* $\mathsf{KonigLemma}^{\uparrow}$ *handoff row. It records the finite data needed by a Koenig-facing theorem without adding a selected infinite branch.*
6. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *handoff row. It records finite bar and modulus requests only through displayed prefix bundles.*
7. *S is the* $\mathsf{CantorSpace}^{\uparrow}$ *and* $\mathsf{SpreadSpace}^{\uparrow}$ *handoff row, used when binary cylinders or spread laws read the same prefix ledger.*
8. *H records componentwise* hsame *transport for prefix rows, branching rows, admissibility, window reads, handoff rows, replay, provenance, and local naming.*

9. *C records the displayed* Cont *replay from prefix admission to branching exposure, finite-window reads, CantorSpace and FanTheorem handoffs, KoenigLemma consumers, and StreamName-facing prefix observations.*

10. *Q is the* Pkg *provenance over* $\mathsf{FinitelyBranchingTree}^{\uparrow}$, $\mathsf{KonigLemma}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{SpreadSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitelyBranchingTree}^{\uparrow}}$ *row.*

The carrier has no coordinate for a chosen infinite branch, detached open-cover compactness, host tree equality, countable choice, bar induction, or a completed path space.

Theorem 6488.2 (FinitelyBranchingTree NameCert obligations)**.** *For every accepted* $\mathsf{FinitelyBranchingTree}^{\uparrow}$ *carrier $T = (P, B, A, W, K, F, S, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FinitelyBranchingTree}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed prefix rows, finite branching ledger, predecessor-closure row, finite window row, KoenigLemma handoff, FanTheorem handoff, CantorSpace and SpreadSpace handoff, componentwise transport, displayed replay, provenance, and local naming. Every consumer must read finite prefix data through*

$$P \longmapsto B \longmapsto A \longmapsto W \longmapsto K, F, S \longmapsto H, C, Q, N.$$

Thus the packet supplies finite branching evidence and its standard handoffs, not an infinite branch selector, a fan compactness theorem, an open-cover compactness principle, or an ambient path-completion object.

Proof. Project the carrier rows from Definition 6488.1. The prefix family, branching ledger, predecessor-closure row, finite-window row, three handoff rows, transport, replay, provenance, and local name are exactly the displayed coordinates of the packet.

The handoff rows are read after prefix admission. A KoenigLemma consumer sees the finite branching ledger and predecessor closure before it can ask for a branch-facing conclusion; a FanTheorem consumer sees only finite bar and modulus requests over the same prefix rows; CantorSpace and SpreadSpace consumers read finite cylinders and spread-law windows through S.

Componentwise stability is forced by H. If an accepted replacement of T is compared with another packet, the local classifier first transports $P, B, A, W, K, F, S, C, Q, N$ by hsame and then replays the same route through C.

Finally inspect the absent coordinates. Since the tuple has no row for a chosen infinite branch, detached open-cover compactness, host tree equality, countable choice, bar induction, or completed path space, the local NameCert cannot export any of those claims. □

Theorem 6488.3 (FinitelyBranchingTree finite-window handoffs)**.** *Let $T = (P, B, A, W, K, F, S, H, C, Q, N)$ be an accepted* $\mathsf{FinitelyBranchingTree}^{\uparrow}$ *packet. Any downstream* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{SpreadSpace}^{\uparrow}$, *or* $\mathsf{KonigLemma}^{\uparrow}$ *read of T factors through the same finite prefix rows P, the same branching ledger B, and the same predecessor-closure row A before a handoff row is visible.*

Consequently the downstream read is stable under hsame *transport and* Cont *replay of H and C, and its provenance remains the finite* Pkg *row Q with local naming by N.*

Proof. Begin with a downstream read. The carrier has no direct consumer coordinate, so the read must open the prefix rows P, the branching ledger B, and the predecessor-closure row A before any finite window or theorem-facing handoff can be inspected.

The window row W supplies the StreamName-facing finite prefix observation. The row S repacks the same observations for CantorSpace and SpreadSpace cylinders, while F and K expose only the finite bar-modulus and KoenigLemma boundary rows tied to those prefixes.

Transport and replay do not add further data. The row H moves all displayed rows componentwise by hsame, C replays the same finite route, and Q, N attach provenance and local naming. The packet therefore gives handoff stability without selecting an infinite branch or asserting compactness beyond the displayed finite ledger. □

Falsifiable prediction: An accepted $\mathsf{FinitelyBranchingTree}^{\uparrow}$ consumer that reads a KoenigLemma, CantorSpace, FanTheorem, SpreadSpace, or StreamName handoff without first displaying the prefix rows, finite branching ledger, predecessor closure, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows refutes the carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitelyBranchingTree}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitelyBranchingTree}^{\uparrow}$ packet is generated from finite prefix rows, a finite branching ledger, predecessor closure, finite StreamName windows, KoenigLemma, FanTheorem, CantorSpace, and SpreadSpace handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FinitelyBranchingTree}^{\uparrow}}$, seed)

Scope closed: Definition 6488.1, Definition 6488.2, and Definition 6488.3 seed the finite-prefix tree packet and its standard handoffs without selecting infinite branches.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FinitelyBranchingTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Koenig's lemma, the Fan Theorem, Cantor compactness, spread completeness, selected infinite branches, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite branching coverage, predecessor closure, handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.FinitelyBranchingTreeUp.

Chapter 6489

A Concrete Naming Certificate for $\mathsf{CompactTailSelector}^{\uparrow}$

Following the compact-uniform-continuity construction of chapter 9237, the $\mathsf{CompactTailSelector}^{\uparrow}$ packet records the finite tail-window selector that a compact metric argument can hand to completion and real-valued consumers. It sits after the compact metric source of chapter 129, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the tolerance-only modulus surface of chapter 369, and the real-name boundary of chapter 38. The packet selects a displayed finite tail window from already named modulus and compact-net rows; it is not countable choice, open-cover compactness, sequential compactness, or an ambient completeness theorem.

Definition 6489.1 (CompactTailSelector carrier)**.** *A* $\mathsf{CompactTailSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, S, R, U, E, W, D, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the inspected finite compact-net coverage and metric-distance witnesses.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row whose finite stream windows are being bounded by the selector.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected stream windows and tolerance observations.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row, already tolerance-only before the selector reads it.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after K, S, R, U and the selected window row have all been displayed.*
6. *W is the selected finite tail-window row. It stores the threshold index, the finite interval of inspected names, and the compact-net witness used to justify that this window covers the requested tolerance.*
7. *D is the dyadic tolerance ledger comparing the requested rational tolerance with the modulus and window rows.*
8. *H records componentwise* hsame *transport for compact metric data, stream windows, regular readbacks, uniform modulus rows, real seals, selected windows, tolerance comparisons, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from compact-net reads and uniform-modulus reads to the selected tail window, and then to regular readback and the real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactTailSelector}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactTailSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for countable choice, an arbitrary open cover, sequential compactness, a selected convergent subsequence, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6489.2 (CompactTailSelector NameCert obligations)**.** *For every accepted* $\mathsf{CompactTailSelector}^{\uparrow}$ *carrier $T = (K, S, R, U, E, W, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactTailSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact metric row, stream-window row, regular rational readback, uniform modulus, real seal, selected tail window, dyadic tolerance ledger, componentwise transport, displayed replay, provenance, and local naming. Every Real-facing or completion-facing consumer must read the finite route*

$$K, S, R, U, D \longmapsto W \longmapsto E, H, C, P, N$$

before treating the selected window as a tail bound.

Proof. Project the rows of Definition 6489.1. The packet exposes compact metric data, stream windows, regular readbacks, a uniform modulus, a real seal, the selected tail-window row, a dyadic comparison row, and the structural rows.

The selected window W is downstream of the compact metric source and the uniform-modulus row. A consumer therefore cannot inspect a tail threshold without first displaying the compact-net coverage, the stream windows being bounded, the regular rational readback, and the tolerance comparison that ties the modulus to the requested precision.

The rows H, C, P, N preserve this route under classifier transport, continuation replay, provenance, and local naming. Since no coordinate stores countable choice, arbitrary open covers, sequential compactness, selected subsequences, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed obligations exhaust the local surface. □

Theorem 6489.3 (CompactTailSelector finite ledger)**.** *Let $T = (K, S, R, U, E, W, D, H, C, P, N)$ be an accepted* $\mathsf{CompactTailSelector}^{\uparrow}$ *packet. The selected tail window is finite ledger data: it is read from the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source row, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *observations, the* $\mathsf{UniformModulus}^{\uparrow}$ *row, and the dyadic tolerance comparison. It is not obtained from countable choice, an open-cover subcover theorem, a chosen subsequence, or completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Read K, S, R, U, D in order. The compact metric row supplies only finite net coverage, the stream row supplies finite windows, the regular rational row supplies the observed tolerances, and the uniform-modulus row supplies a tolerance-only bound checked by D.

The row W stores the resulting threshold and inspected finite interval. Because W is part of the same BHist packet, transport by H and replay by C move it componentwise with the compact source, stream windows, readback rows, and modulus row.

The packet never opens an arbitrary cover or a sequence of choices. Its real-facing row E is reached only after the finite ledger has been displayed, so no consumer can reinterpret the tail selector as countable choice, open-cover compactness, selected subsequence compactness, or ambient Real completeness. □

Falsifiable prediction: An accepted $\mathsf{CompactTailSelector}^{\uparrow}$ consumer that reads a tail threshold without the displayed CompactMetric source row, StreamName finite-window row, RegSeqRat readback row, UniformModulus row, dyadic tolerance ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows refutes the carrier surface.

Independence witness: compactmetric, streamname, regseqrat, uniformmodulus, real: no listed sibling supplies the full packet $T = (K, S, R, U, E, W, D, H, C, P, N)$, because each sibling contributes a compact source, finite windows, rational readback, a modulus, or a terminal seal while this chapter binds them into one displayed tail-window selector.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactTailSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactTailSelector}^{\uparrow}$ packet is generated from CompactMetric source rows, StreamName finite windows, RegSeqRat readback, a UniformModulus row, a RealUp seal, selected tail-window rows, dyadic tolerance comparisons, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactTailSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6489.1, Definition 6489.2, and Definition 6489.3 seed the finite tail-window selector consumed by compact-uniform and completion-facing arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactTailSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, sequential compactness, countable choice, selected subsequences, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source coverage, finite-window readback, modulus-to-tail exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactTailSelectorU

Chapter 6490

A Concrete Naming Certificate for CompletionUnitDenseImage$^{\uparrow}$

Following Bishop and Bridges, Kelley, and Bourbaki on constructive completion and dense image maps, the CompletionUnitDenseImage$^{\uparrow}$ packet records the surface by which the completion unit exposes its image as finite dense-source data. It sits after the unit certificate of chapter 1527, the general dense embedding interface of chapter 3617, the metric completion dense embedding of chapter 3351, the completion universal-property surface of chapter 397, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names the dense image of the unit without quotient representatives, selected completion points, countable choice, host equality, or ambient Real$^{\uparrow}$ completeness.

Definition 6490.1 (CompletionUnitDenseImage carrier)**.** *A* CompletionUnitDenseImage$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, C, u, D, W, R, E, H, K, P, N)$$

with the following visible rows:

1. *X is the displayed source metric or regular-Cauchy row entering the completion unit.*
2. *C is the accepted* CauchyCompletionUnit$^{\uparrow}$ *row that admits X into the completion-facing surface.*
3. *u is the unit-image row, recording the displayed image of X inside the completion boundary.*
4. *D is the dense-image witness row read through* DenseEmbedding$^{\uparrow}$ *and* MetricCompletionDenseEmbedding$^{\uparrow}$*.*
5. *W is the finite* StreamName$^{\uparrow}$ *window row used by the dense-image request.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the same window and tolerance ledger.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row, available only after C, u, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the source, unit, dense-image, window, readback, real seal, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from source admission through the dense image and completion universal-property route.*
10. *P is the* Pkg *provenance over* CompletionUnitDenseImage$^{\uparrow}$*,* CauchyCompletionUnit$^{\uparrow}$*,* DenseEmbedding$^{\uparrow}$*,* MetricCompletionDenseEmbedding$^{\uparrow}$*,* CompletionUniversalProperty$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{CompletionUnitDenseImage}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion equality, selected representatives, countable-choice schedules, host equality of completed objects, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6490.2 (CompletionUnitDenseImage NameCert obligations)**.** *For an accepted* CompletionUnitDenseImag *carrier $U = (X, C, u, D, W, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionUnitDenseImage}^{\uparrow}}$ *surface consists exactly of source admission through X, unit exposure through C, u, dense-image exposure through D, finite window exposure through W, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through K, provenance through P, and local naming through N.*

Every completion-facing consumer must read the unit row C, the unit-image row u, and the dense-image row D before it can consume W, R, E, H, K, P, N.

Proof. Carrier admission is projection from Definition 6490.1. The tuple lists exactly the source, completion unit, unit image, dense-image witness, window, readback, real seal, transport, replay, provenance, and local naming rows.

The unit exposure is supplied by the $\mathsf{CauchyCompletionUnit}^{\uparrow}$ row. It sends the displayed source into the completion-facing boundary as finite unit data before any density request is inspected.

The dense-image exposure then reads D through $\mathsf{DenseEmbedding}^{\uparrow}$ and $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$. The finite window W and readback row R are the only numerical route offered to the real seal E and to universal-property consumers.

Finally H, K, P, N preserve and name the same route. Since the carrier has no quotient, selected representative, choice schedule, host equality, or ambient completeness coordinate, the listed rows exhaust the NameCert surface. □

Theorem 6490.3 (CompletionUnitDenseImage universal route)**.** *Every completion universal-property consumer of an accepted* $\mathsf{CompletionUnitDenseImage}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyCompletionUnit}^{\uparrow} \longrightarrow \mathsf{DenseEmbedding}^{\uparrow} \longrightarrow \mathsf{MetricCompletionDenseEmbedding}^{\uparrow} \longrightarrow \mathsf{CompletionUniversalPro}$$

with the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R and the* $\mathsf{Real}^{\uparrow}$ *seal row E already displayed. Thus the universal-property handoff receives a dense image of the unit as finite BEDC data, not as a quotient completion class, selected completion representative, countable-choice selector, host equality proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the accepted carrier $U = (X, C, u, D, W, R, E, H, K, P, N)$. The completion unit row C and unit-image row u are the only source-to-completion entry data available to the consumer.

Next apply the dense embedding siblings. The rows D, W, R expose the dense-image witness, finite source window, and regular rational readback before any completion universal-property row can be inspected.

The real seal E is terminal for the numerical route, and K replays the same source-to-dense-image path for the universal-property consumer. Transport and provenance through H, P, N do not add another completion object.

Therefore every universal-property handoff factors through the displayed unit, dense-image, metric-completion dense embedding, readback, and real-seal rows, with none of the excluded quotient, choice, selected-representative, host-equality, or ambient-completeness data exported. □

Falsifiable prediction: Every accepted $\mathsf{CompletionUnitDenseImage}^{\uparrow}$ consumer reads a Cauchy-CompletionUnit row, a unit-image row, a dense-image witness, a finite StreamName window,

RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row before any completion universal-property handoff is exported.

Independence witness: cauchycompletionunit, dense-embedding, metric-completion-dense-embedding, completionuniversalproperty, regseqrat, real: none is bijective with $\mathsf{CompletionUnitDenseImage}^{\uparrow}$ because this packet alone binds the unit image to dense-source readback before the universal-property consumer receives the completion-facing route.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionUnitDenseImage}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionUnitDenseImage}^{\uparrow}$ packet is generated from a displayed source row, a CauchyCompletionUnit row, a unit-image row, dense-image witness data, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionUnitDenseImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6490.1, Definition 6490.2, and Definition 6490.3 seed the dense-image surface of the completion unit over CauchyCompletionUnit, DenseEmbedding, MetricCompletionDenseEmbedding, CompletionUniversalProperty, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionUnitDenseImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected completion representatives, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-image exposure, dense-image locality, readback readiness, universal-route nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionUnitDenseImageUp.

Chapter 6491

A Concrete Naming Certificate for $\mathsf{BishopRealExtensionality}^{\uparrow}$

Following Bishop and Bridges, equality of constructive reals is read through interchangeable regular presentations rather than through host real equality. The $\mathsf{BishopRealExtensionality}^{\uparrow}$ packet records the finite NameCert surface by which an accepted $\mathsf{Real}^{\uparrow}$ name may be substituted for an extensionally equal accepted name. It is downstream of the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the comparison boundary of chapter 1820, the tolerance-row discipline of chapter 2074, and the terminal real-name seal of chapter 38. The packet supplies Real and Completion consumers with an extensional substitution route, not quotient equality, host real equality, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6491.1 (Bishop real extensionality carrier)**.** *A* $\mathsf{BishopRealExtensionality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S_0, S_1, R_0, R_1, Q, T, A, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows for the source and target real names.*
2. R_0 *and* R_1 *are* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to* S_0 *and* S_1*.*
3. Q *is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison row relating the two regular readbacks through displayed Cauchy agreement.*
4. T *is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *tolerance ledger used by the comparison and by any substitution request.*
5. A *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* S_0, S_1, R_0, R_1, Q, T *have been displayed.*
6. H *records componentwise* hsame *transport for the two stream windows, two regular readbacks, comparison row, tolerance ledger, terminal seal, replay, provenance, and local naming row.*
7. C *records displayed* Cont *replay from an extensional substitution request through finite windows, regular readback, comparison, tolerance, and seal rows.*
8. P *is the* Pkg *provenance over* $\mathsf{BishopRealExtensionality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{BishopRealExtensionality}^{\uparrow}}$ *row.*

The classifier compares accepted extensionality packets only through $S_0, S_1, R_0, R_1, Q, T, A, H, C, P, N$. It exposes no quotient equality of streams, host real equality, selected representative, countable-choice schedule, detached limit, or ambient completeness row.

Theorem 6491.2 (Bishop real extensionality NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealExtensionality}^{\uparrow}$ *carrier*

$$E = (S_0, S_1, R_0, R_1, Q, T, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealExtensionality}^{\uparrow}}$ *surface consists exactly of the two* $\mathsf{StreamName}^{\uparrow}$ *finite windows, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison row, the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *tolerance ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every substitution-facing consumer must expose $S_0, S_1, R_0, R_1, Q, T, A$ before it consumes H, C, P, N.*

Proof. Project the carrier of Definition 6491.1. The analytic rows are exactly $S_0, S_1, R_0, R_1, Q, T, A$, and the remaining rows are structural transport, replay, provenance, and naming.

The two $\mathsf{StreamName}^{\uparrow}$ rows are finite windows. The two $\mathsf{RegSeqRat}^{\uparrow}$ rows are the only readbacks attached to those windows, so a consumer cannot enter through an infinite stream or a selected representative.

The comparison row Q is displayed before the terminal seal, and it is governed by the tolerance ledger T. Thus equality-facing information is read as Cauchy-equivalence evidence over inspected tolerances, not as host real equality or quotient equality.

Finally the seal row A is downstream of the displayed comparison route. Since no carrier coordinate remains outside $S_0, S_1, R_0, R_1, Q, T, A, H, C, P, N$, the listed rows exhaust the local NameCert obligations. □

Theorem 6491.3 (Bishop real extensionality substitution route)**.** *Every Real or Completion consumer that substitutes one accepted* $\mathsf{Real}^{\uparrow}$ *name for another through a* $\mathsf{BishopRealExtensionality}^{\uparrow}$ *packet must factor the substitution through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{RealModulusOfConvergence}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer may replay the substitution along componentwise hsame *and displayed* Cont *rows, with* Pkg *provenance and local* NameCert *data, but it receives no quotient stream equality, host real equality, selected representative, countable choice, detached limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a substitution-facing read of E. The only source observations are the finite windows S_0, S_1, so the route starts in the $\mathsf{StreamName}^{\uparrow}$ surface.

Read those windows through R_0, R_1. These are the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks attached to the displayed observations, and no other readback coordinate occurs in the carrier.

Now inspect the equality-facing row. The comparison Q is a $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ row, and the tolerance ledger T records the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ budget used by the comparison before the terminal seal can be consumed.

The terminal $\mathsf{Real}^{\uparrow}$ row A is therefore reached only after the finite extensionality route is visible. The rows H, C, P, N transport, replay, source, and name that same route, so substitution exports the displayed finite evidence and none of the excluded host principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealExtensionality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopRealExtensionality}^{\uparrow}$ packet is generated from two StreamName finite windows, two RegSeqRat readbacks, a CauchyEquivalenceSetoid comparison row, a RealModulusOfConvergence tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopRealExtensionality}\uparrow}$, seed)

Scope closed: Definition 6491.1, Definition 6491.2, and Definition 6491.3 seed the constructive Real extensional substitution route over finite windows, regular readbacks, comparison, tolerance, seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopRealExtensionality}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, host real equality, selected representatives, countable choice, detached limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular readback, Cauchy-equivalence comparison, tolerance-ledger exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealExtensionalityUp.

Chapter 6492

A Concrete Naming Certificate for $\mathsf{LocatedCoverSelection}^{\uparrow}$

Following Bishop and Bridges on constructive compactness and located finite covers, the $\mathsf{LocatedCoverSelection}^{\uparrow}$ packet records a finite selection surface for already displayed located cover rows. It sits over the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational readback of chapter 301, the finite schedule discipline of chapter 126, the dyadic tolerance rows of chapter 291, the compact metric source of chapter 129, and the finite real cover packet of chapter 2377. The packet selects only among displayed located rows; it does not import arbitrary open-cover compactness, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6492.1 (Located cover selection carrier)**.** *A* $\mathsf{LocatedCoverSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, Q, W, D, K, F, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the inspected compact-source points and finite cover centers.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which the selected real data are exposed as regular rational windows.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule that orders the displayed located-cover rows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and tolerance ledger used by the membership and overlap tests.*
5. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose total bounded and located metric data make the finite request visible.*
6. *F is the* $\mathsf{FiniteRealCover}^{\uparrow}$ *row listing the finite candidate cover cells, centers, radii, and coverage witnesses.*
7. *S is the selected finite subrow of F, indexed only by entries already displayed in W and checked through D.*
8. *H records componentwise* hsame *transport for real, regular, stream, dyadic, compact, cover, selection, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from compact metric data through the finite cover row and then through the selected located subrow.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedCoverSelection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteRealCover}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCoverSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, Q, W, D, K, F, S, H, C, P, N$. It has no coordinate for arbitrary open covers, host compactness, selected subcovers outside the displayed finite rows, countable choice, quotient equality of reals, or ambient completeness.

Theorem 6492.2 (Located cover selection NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCoverSelection}^{\uparrow}$ *carrier*

$$L = (R, Q, W, D, K, F, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCoverSelection}^{\uparrow}}$ *surface consists exactly of real-seal exposure through R, regular readback through Q, finite schedule exposure through W, dyadic radius and tolerance admission through D, compact metric source exposure through K, finite real cover exposure through F, selected located subrow exposure through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6492.1. The analytic rows are R, Q, W, D, K, F, S, and the structural rows are H, C, P, N.

The finite selection is internal to the displayed packet. Row S is read only after the compact metric source K, the finite cover row F, the finite schedule W, and the dyadic ledger D have exposed the located membership checks.

The real-facing rows R and Q seal and read back the selected data without adding a host equality test. The transport, replay, provenance, and local naming rows preserve that same finite route.

Since no row contains arbitrary open-cover compactness, countable choice, quotient real equality, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 6492.3 (Located cover selection finite-subcover handoff)**.** *Every finite-subcover consumer of an accepted* $\mathsf{LocatedCoverSelection}^{\uparrow}$ *packet must read the route*

$$\mathsf{Real}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{FiniteRealCover}^{\uparrow}$$

through the carrier rows $R, Q, W, D, K, F, S, H, C, P, N$ before consuming the selected located subrow S. The handoff may feed compact metric finite-cover arguments, but it does not choose from an arbitrary open cover, assert a host compactness theorem, identify quotient real representatives, use countable choice, or supply ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 6492.2. They force every consumer to expose the real seal, regular readback, finite schedule, dyadic ledger, compact source, finite cover, selected subrow, and structural rows.

The compact metric and finite cover siblings then determine the finite request. The row K supplies the compact metric source data, while F lists the available cover cells and witnesses. Rows W and D make the located membership checks finite and dyadic.

The selected subrow S is therefore a handoff from displayed finite data, not an external selection principle. Because H, C, P, N only transport, replay, source, and name the same route, no refused compactness, equality, choice, or completeness endpoint is exported. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCoverSelection}^{\uparrow}$ consumer exposes RealUp seals, RegSeqRat readbacks, StreamName schedules, DyadicRatCore radius rows, CompactMetric source data, a FiniteRealCover row, a selected displayed subrow, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence before any finite-subcover handoff is consumed.

Independence witness: real, regseqrat, streamname, dyadicratcore, compactmetric, finite-real-cover: none is bijective with $\mathsf{LocatedCoverSelection}^{\uparrow}$ because this packet alone binds a selected located subrow of a displayed finite cover to compact metric and regular rational readback data without external cover selection.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCoverSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCoverSelection}^{\uparrow}$ packet is generated from RealUp seal rows, RegSeqRat readback rows, StreamName finite schedules, DyadicRatCore radius and tolerance ledgers, CompactMetric source rows, FiniteRealCover candidate rows, selected displayed subrows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCoverSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6492.1, Definition 6492.2, and Definition 6492.3 seed the finite located-cover selection route over displayed Real, regular rational, stream, dyadic, compact metric, and finite-cover rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCoverSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, host compactness, selected subcovers outside displayed finite rows, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located subrow exactness, compact-source exposure, finite-cover coverage, dyadic membership replay, transport, provenance, and local naming for BEDC.Derived.LocatedCoverSelectionUp.

Chapter 6493

A Concrete Naming Certificate for $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$

Following Krasnoselskii and Browder on compact-plus-contractive fixed point principles, the KrasnoselskiiFixedPoint packet records the finite BEDC surface for a displayed self-map decomposed into a contraction row and a compact continuous row on a convex carrier. It sits beside the endpoint contraction route of chapter 396, the compact-convex handoff of chapter 1923, the convex carrier of chapter 208, and the compact completion service of chapter 1687. The packet names only the displayed decomposition, compactness, convexity, iteration, and endpoint-seal rows; it does not import a host fixed-point selector, quotient point equality, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6493.1 (Krasnoselskii fixed point carrier)**.** *A* $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, V, B, S, A, C, I, E, H, R, P, N)$$

with the following displayed rows:

1. *X is the ambient metric or Banach source row on which the fixed-point request is read.*
2. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *admissible carrier row, recording the convex subpacket in which the fixed point must remain.*
3. *B is the* $\mathsf{BanachFixedPoint}^{\uparrow}$ *contraction endpoint row for the contractive summand.*
4. *S is the* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *compact-convex endpoint row for the compact continuous summand.*
5. *A records the displayed algebraic decomposition of the self-map into contractive and compact-continuous rows.*
6. *C is the* $\mathsf{CompactMetricCompletion}^{\uparrow}$ *compactness or completion-facing seal read before compactness is consumed.*
7. *I is the finite iteration-stability ledger joining the contraction budget, compact image window, convex membership row, and endpoint request.*
8. *E records the fixed-point endpoint seal visible to downstream Real or completion consumers.*
9. *H records componentwise* hsame *transport for X, V, B, S, A, C, I, E and the local certificate data.*

10. *R records displayed* Cont *replay from a fixed-point request through the decomposition, compact-convex, contraction, iteration, and endpoint rows.*
11. *P is the* Pkg *provenance over* $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CompactMetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a selected host fixed point, an external compactness principle, quotient point equality, countable choice, or ambient completeness.

Theorem 6493.2 (Krasnoselskii fixed point NameCert obligations)**.** *For every accepted* $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$ *carrier $K = (X, V, B, S, A, C, I, E, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for X and the admissible convex row V;*
2. *contraction endpoint exposure through B;*
3. *compact-convex endpoint exposure through S;*
4. *decomposition exactness for the displayed self-map row A;*
5. *compact completion or compactness handoff through C;*
6. *iteration-stability routing through I;*
7. *endpoint-seal nonescape through E;*
8. *componentwise* hsame *transport through H;*
9. *displayed* Cont *replay through R;*
10. Pkg *provenance and local naming through P, N.*

No obligation is stored outside the finite carrier.

Proof. Project the carrier of Definition 6493.1. The rows X, V, B, S, A, C, I, E are the only mathematical data available before the transport, replay, provenance, and local naming rows are read.

The fixed-point request then splits along the displayed decomposition row A. The contraction endpoint is read through the Banach fixed-point row B, while the compact continuous endpoint is read through the Schauder row S after the convex carrier V and compactness handoff C are visible.

The iteration ledger I binds those two endpoint surfaces to the same fixed-point request. The rows H, R, P, N only transport, replay, source, and name that finite route, so the listed obligations exhaust the local certificate. □

Theorem 6493.3 (Krasnoselskii fixed point iteration stability)**.** *Every transported* $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$ *fixed-point read preserves the same decomposition row A, the same contraction endpoint row B, the same compact-convex endpoint row S, and the same convex carrier row V before the endpoint seal E is consumed. In particular, the iteration ledger cannot be detached into an independent Banach route, an independent Schauder route, or a host-selected fixed point.*

Proof. Begin with the componentwise transport row H. It moves the ambient carrier, convex admissible row, Banach endpoint row, Schauder endpoint row, decomposition row, compact handoff, iteration ledger, and endpoint seal together.

Apply the NameCert obligations of Definition 6493.2. The fixed-point read must expose A before either endpoint row is consumed, and it must expose V and C before the compact-convex side is read.

Replay through R then follows the same decomposition and iteration route. Since I has no coordinate outside the carrier and E is only the downstream seal for this route, transport cannot replace the packet by a separate Banach fixed point, a separate Schauder fixed point, or a selected host endpoint. □

Falsifiable prediction: Every accepted $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$ consumer that reads a fixed-point endpoint must first expose one displayed decomposition row, one $\mathsf{BanachFixedPoint}^{\uparrow}$ contraction row, one $\mathsf{SchauderFixedPoint}^{\uparrow}$ compact-convex row, one $\mathsf{ConvexSet}^{\uparrow}$ carrier row, one $\mathsf{CompactMetricCompletion}^{\uparrow}$ compactness handoff, one iteration-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row.

Independence witness: banach-fixed-point, schauder-fixed-point, convexset, compact-metric-completion: $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the contraction endpoint, compact continuous endpoint, convex admissible carrier, compactness handoff, decomposition ledger, endpoint seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}$ packet is generated from an ambient carrier row, a ConvexSetUp admissible row, BanachFixedPointUp and SchauderFixedPointUp endpoint rows, a compact completion handoff, a decomposition ledger, iteration-stability rows, an endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6493.1, Definition 6493.2, and Definition 6493.3 seed the finite compact-plus-contractive fixed-point packet over convex, compact, Banach, and Schauder rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KrasnoselskiiFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a host fixed-point selector, quotient point equality, open-cover compactness, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, decomposition exactness, contraction endpoint exposure, compact-convex endpoint exposure, compact handoff, iteration stability, transport, replay, provenance, and local naming for BEDC.Derived.KrasnoselskiiFixedPointUp.

Chapter 6494

A Concrete Naming Certificate for $\mathsf{FiniteSubstrateMap}^{\uparrow}$

The $\mathsf{FiniteSubstrateMap}^{\uparrow}$ packet realizes the substrate subhub section 9389.10 as a finite map from BEDC audit rows to cellular substrate rows. It sits after the finite trace windows of chapter 3481, the cellular carrier surface of chapter 942, the carrier-encoding row of chapter 943, the local update rule of chapter 984, and the finite orbit carrier of chapter 938. The packet names a finite substrate map, not a hidden evaluator, infinite cellular orbit, host compiler, quotient BHist equality, or all-time cellular induction.

Definition 6494.1 (Finite substrate map carrier)**.** *A* $\mathsf{FiniteSubstrateMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, E, S, W, L, O, M, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* BHist *audit row to be read as substrate data.*
2. *E is the* $\mathsf{CellularCarrierEncoding}^{\uparrow}$ *row translating finite audit entries into cellular carrier entries.*
3. *S is the* $\mathsf{CellularSubstrate}^{\uparrow}$ *row that receives the encoded carrier.*
4. *W is the* $\mathsf{CellularWindowTrace}^{\uparrow}$ *finite trace window on which the map is observed.*
5. *L is the* $\mathsf{CellularLocalUpdateRule}^{\uparrow}$ *local rule row used by each displayed successor read.*
6. *O is the* $\mathsf{CellularOrbitSubstrate}^{\uparrow}$ *finite orbit row generated by the encoded carrier and local rule over the displayed window.*
7. *M is the finite map ledger pairing each accepted* BHist *source entry with its encoded carrier cell, local update read, orbit entry, and exported substrate observation.*
8. *H records componentwise* hsame *transport for B, E, S, W, L, O, M and the local certificate data.*
9. *C records displayed* Cont *replay from a source audit request through the encoding, substrate, window, local update, orbit, and map-ledger rows.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteSubstrateMap}^{\uparrow}$, BHist, $\mathsf{CellularCarrierEncoding}^{\uparrow}$, $\mathsf{CellularSubstrate}^{\uparrow}$, $\mathsf{CellularWindowTrace}^{\uparrow}$, $\mathsf{CellularLocalUpdateRule}^{\uparrow}$, $\mathsf{CellularOrbitSubstrate}^{\uparrow}$, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSubstrateMap}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through these finite rows. It has no coordinate for an unbounded substrate, a detached machine evaluator, quotient audit equality, or a cellular observation outside the displayed window.

Lean4 (definition) `BEDC.Derived.FiniteSubstrateMapUp.TasteGate.FiniteSubstrateMapUp`

Theorem 6494.2 (Finite substrate map NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSubstrateMap}^{\uparrow}$ *carrier* $F = (B, E, S, W, L, O, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteSubstrateMap}^{\uparrow}}$ *surface consists exactly of source audit admission, cellular carrier encoding, cellular substrate admission, finite window trace exposure, local update exposure, finite orbit exposure, map-ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every exported substrate observation factors through the finite route*

$$B, E, S, W, L, O, M, H, C, P, N.$$

Proof. Project the carrier of Definition 6494.1. The only substrate-facing coordinates are the source audit row, encoding row, substrate row, finite window trace, local update rule, orbit row, and map ledger.

The map ledger M pairs source entries with encoded carrier cells and the finite orbit observations obtained through W, L, O. Thus an exported substrate observation cannot be read before the source, encoding, local update, and orbit rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name this same finite route. Since the classifier has no coordinate outside the tuple, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.FiniteSubstrateMapUp.TasteGate.FiniteSubstrateMapTasteGate single carrier alignment`

Theorem 6494.3 (Finite substrate map observation nonescape)**.** *Every consumer-visible observation exported by an accepted* $\mathsf{FiniteSubstrateMap}^{\uparrow}$ *packet remains inside the displayed finite window trace* W *and the map ledger* M*. It cannot be replaced by an infinite cellular orbit, a host evaluator, a quotient* BHist *equality, or a detached substrate classifier.*

Proof. Begin with the obligation surface of Definition 6494.2. It forces every observation through the displayed source row, encoding row, substrate row, window trace, local rule, orbit row, and finite map ledger.

The orbit row O is read only as the finite orbit accepted over W and L. The map ledger M records which source audit entries are paired with those visible orbit entries, so a consumer cannot ask for an unlisted time, cell, or classifier read.

Replay through C and transport through H preserve the same finite route. The provenance and local naming rows do not add evaluator, quotient, or infinite-orbit coordinates, so observation nonescape is internal to the packet. □

The later Lean TasteGate namespace BEDC.Derived.FiniteSubstrateMapUp.TasteGate must provide Nontrivial $\mathsf{FiniteSubstrateMap}^{\uparrow}$ and FieldFaithful $\mathsf{FiniteSubstrateMap}^{\uparrow}$ instances for the displayed finite carrier. Those instances should read the carrier rows $B, E, S, W, L, O, M, H, C, P, N$ directly: nontriviality is witnessed by a source audit entry with a displayed encoded cell, and field faithfulness is witnessed by the map ledger preserving the source, encoding, local update, and orbit fields without collapsing them to a host evaluator.

Falsifiable prediction: Every accepted $\mathsf{FiniteSubstrateMap}^{\uparrow}$ observation factors through one source BHist row, one $\mathsf{CellularCarrierEncoding}^{\uparrow}$ row, one $\mathsf{CellularSubstrate}^{\uparrow}$ row, one $\mathsf{CellularWindowTrace}^{\uparrow}$

row, one $\mathsf{CellularLocalUpdateRule}^{\uparrow}$ row, one $\mathsf{CellularOrbitSubstrate}^{\uparrow}$ row, one finite map ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row.

Independence witness: cellular-window-trace, cellularsubstrate, cellularcarrierencoding, cellularlocalupdaterule, cellularorbitsubstrate: $\mathsf{FiniteSubstrateMap}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source audit row, carrier encoding, substrate row, finite window trace, local update rule, orbit row, finite source-to-substrate map ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSubstrateMap}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSubstrateMap}^{\uparrow}$ packet is generated from a BHist source row, CellularCarrierEncodingUp encoding rows, CellularSubstrateUp carrier rows, CellularWindowTraceUp trace windows, CellularLocalUpdateRuleUp local rules, CellularOrbitSubstrateUp finite orbit rows, a finite map ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSubstrateMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6494.1, Definition 6494.2, and Definition 6494.3 seed the finite source-to-cellular-substrate map over BHist, carrier encoding, window trace, local update, and orbit rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSubstrateMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a hidden evaluator, infinite cellular orbit, host compiler, quotient BHist equality, or all-time cellular induction.

Upgrade path: Obligation closure requires checked carrier admission, source audit exposure, carrier encoding, cellular substrate admission, finite window trace exposure, local update exposure, finite orbit exposure, map-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSubstrateMapUp.

Chapter 6495

A Concrete Naming Certificate for $\mathsf{SoberSpace}^{\uparrow}$

Following Kelley and Johnstone on sober spaces and locale theory, the $\mathsf{SoberSpace}^{\uparrow}$ packet records the finite point-reconstruction boundary through which displayed open observations determine points without importing host powersets or point equality. It sits after the topology carrier of chapter 88, the observable-open classifier of chapter 1860, the separation discipline of chapter 3338, and the point-free open route of chapter 5153. The packet names the standard sobriety handoff as finite NameCert data; it does not assert spatiality for every locale, quotient point reconstruction, host equality of points, excluded middle over opens, or choice over completely prime filters.

Definition 6495.1 (Sober space carrier)**.** *A* $\mathsf{SoberSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, O, L, Z, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *row, recording finite open-index and neighbourhood observations for the space under inspection.*
2. *O is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth row, exposing open membership only through displayed Bool truth, Topology open, and finite StreamName windows.*
3. *L is the* $\mathsf{LocaleSpace}^{\uparrow}$ *comparison row, recording finite frame-of-opens and cover-refinement reads that can be compared with T and O.*
4. *Z is the* $\mathsf{TZeroReflection}^{\uparrow}$ *compatibility row, requiring specialization readback to separate displayed point names only through observable opens.*
5. *H records componentwise* hsame *transport for topology rows, Sierpinski truth rows, locale comparison rows, T0 compatibility, replay, provenance, and the local naming row.*
6. *C records displayed* Cont *replay from a sobriety request through T, O, L, Z, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{SoberSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{TZeroReflection}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SoberSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through T, O, L, Z, H, C, P, N. It has no coordinate for host powersets of opens, quotient point spaces, selected generic points, global locale spatiality, excluded middle over opens, choice over completely prime filters, or ambient point equality.

Theorem 6495.2 (Sober space NameCert obligations)**.** *For every accepted* $\mathsf{SoberSpace}^{\uparrow}$ *carrier*

$$S = (T, O, L, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SoberSpace}^{\uparrow}}$ *surface consists exactly of topology-row admission, Sierpinski observable-open truth admission, locale/frame-of-opens comparison admission, T0 specialization compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every point-reconstruction consumer must inspect those rows before treating a displayed completely prime open profile as a point-facing sober-space read.*

Proof. Project the carrier of Definition 6495.1. The topology row T supplies the finite open-index observations, while the Sierpinski row O supplies observable-open truth without turning membership into a host proposition.

The locale row L compares the same open observations with finite frame and cover-refinement data. The T0 row Z then constrains specialization readback so that displayed point names are separated only by observable opens already visible through T, O, L.

The rows H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores host powersets, quotient point spaces, selected generic points, global locale spatiality, excluded middle, choice over completely prime filters, or ambient point equality, the listed rows exhaust the local obligation surface. □

Theorem 6495.3 (Sober space Sierpinski locale handoff)**.** *Any* $\mathsf{Topology}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{TZeroReflection}^{\uparrow}$, *or observable-open consumer that reads a* $\mathsf{SoberSpace}^{\uparrow}$ *packet must route the read through*

$$T, O \longmapsto L \longmapsto Z \longmapsto H, C, P, N.$$

The handoff compares open membership using the $\mathsf{SierpinskiSpace}^{\uparrow}$ *truth row and compares the corresponding open frame using the* $\mathsf{LocaleSpace}^{\uparrow}$ *row before specialization compatibility is consumed. It exports no host proposition for open membership, no powerset of opens, no quotient point space, no selected generic point, and no excluded middle over opens.*

Proof. Start with an accepted carrier $S = (T, O, L, Z, H, C, P, N)$. A topology-facing read first exposes T, and an observable-open read exposes O as the displayed Sierpinski truth route.

The locale comparison row L is read only after those open observations are visible. It aligns the topology open rows with finite frame and cover-refinement data rather than replacing them by a host powerset.

Specialization compatibility is then the row Z. It may separate displayed point names through observable opens, but it cannot select a hidden generic point or quotient point representative.

The support rows H, C, P, N preserve the same route by transport, replay, provenance, and naming. Therefore every consumer receives the Sierpinski and locale handoff as finite packet data, not as an external proposition or choice principle. □

Theorem 6495.4 (Sober space specialization basis)**.** *Every accepted* $\mathsf{SoberSpace}^{\uparrow}$ *point-reconstruction read separates displayed point names only by first reading the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth row* O *and then the* $\mathsf{TZeroReflection}^{\uparrow}$ *specialization row* Z*. The* $\mathsf{LocaleSpace}^{\uparrow}$ *comparison row* L *may align the finite frame-of-opens rows with the same observations, but it cannot replace observable-open truth by host propositions, host powersets, selected generic points, excluded middle, or quotient point equality.*

Proof. Project the carrier rows O, L, Z from Definition 6495.1. The row O is the only observable-open truth interface, L is the only locale comparison row, and Z is the only specialization readback row.

Apply the Sierpinski-locale handoff of Definition 6495.3. It routes topology and observable-open data through O, compares the corresponding frame rows through L, and only then reads specialization compatibility through Z.

Use point-reconstruction nonescape, Definition 6495.5. Because the carrier has no coordinate for host powersets, selected generic points, excluded middle, quotient point equality, or ambient point equality, a point-reconstruction consumer cannot bypass the observable truth row.

Thus displayed point names are separated through Sierpinski observable opens before T0 specialization readback, while locale comparison only aligns the finite open-frame rows already exposed by the packet. □

Theorem 6495.5 (Sober space point reconstruction nonescape)**.** *Every point-reconstruction read exported by an accepted* $\mathsf{SoberSpace}^{\uparrow}$ *packet factors through the displayed topology row, Sierpinski observable-open row, locale comparison row, and T0 specialization row before it reaches transport, replay, provenance, and local naming. Thus the packet can witness the sober-space boundary for displayed open profiles, but it cannot export host point equality, quotient spatial reflection, selected completely prime filters, choice-indexed generic points, excluded middle over opens, or global spatiality for arbitrary locales.*

Proof. Apply Definition 6495.2. The local NameCert surface stores every accepted sobriety obligation in T, O, L, Z, H, C, P, N and stores none outside those rows.

Apply Definition 6495.3. It identifies the consumer route from topology and observable-open data through locale comparison and T0 specialization compatibility.

Since the carrier inventory has no coordinate for host point equality, quotient spatial reflection, selected completely prime filters, choice-indexed generic points, excluded middle over opens, or global locale spatiality, no point-reconstruction consumer can obtain those objects from the packet. □

Falsifiable prediction: Removing any one of the $\mathsf{Topology}^{\uparrow}$ row, $\mathsf{SierpinskiSpace}^{\uparrow}$ observable-open truth row, $\mathsf{LocaleSpace}^{\uparrow}$ comparison row, $\mathsf{TZeroReflection}^{\uparrow}$ compatibility row, hsame transport, Cont replay, Pkg provenance, or local NameCert row makes Definition 6495.5 false: a point-reconstruction consumer could no longer verify the displayed sober-space route.

Independence witness: topology, sierpinski, locale, tzero: $\mathsf{SoberSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries topology observations, observable-open truth, locale/frame comparison, T0 specialization compatibility, transport, replay, provenance, and local naming rows in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SoberSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SoberSpace}^{\uparrow}$ packet is generated from TopologyUp open rows, SierpinskiSpaceUp observable-open truth rows, LocaleSpaceUp frame comparison rows, TZeroReflectionUp specialization compatibility rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SoberSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6495.1, Definition 6495.2, Definition 6495.3, and Definition 6495.5 seed the finite sober-space point-reconstruction route over topology, observable-open, locale, T0 compatibility, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SoberSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host point equality, quotient spatial reflection, selected completely prime filters, choice-indexed generic points, excluded middle over opens, global spatiality for arbitrary locales, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked topology admission, observable-open classifier admission, locale comparison exactness, T0 specialization compatibility, transport, replay, provenance, and local naming for BEDC.Derived.SoberSpaceUp.

Chapter 6496

A Concrete Naming Certificate for $\mathsf{RealLocatedSupremum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLocatedSupremum}^{\uparrow}$ packet records the finite surface by which a located bounded family of constructive real names exposes a supremum read without Dedekind cuts, quotient equality of real names, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$. It sits after the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the located supremum carrier of chapter 1427, and the narrower supremum-modulus ledger of chapter 6432. The packet names the complete Real-facing located-supremum route as displayed BEDC rows.

Definition 6496.1 (Real located supremum carrier)**.** *A* $\mathsf{RealLocatedSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, D, R, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite located family row, listing the inspected real-name sources and their displayed boundedness witnesses.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule for the inspected family entries and candidate supremum windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording upper-bound gaps, lower-hit gaps, and product-free comparison budgets.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic tolerance entries.*
5. *M is the* $\mathsf{LocatedSupremumModulus}^{\uparrow}$ *row, exposing the search modulus that turns located upper-bound and lower-hit requests into finite dyadic evidence.*
6. *L is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row, read only after F, W, D, R, M have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the supremum candidate named by L.*
8. *H records componentwise* hsame *transport for family, window, dyadic, regular-rational, modulus, located-supremum, real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Real-facing located-supremum request through $F, W, D, R, M, L, E, H, P, N$*

10. *P is the* Pkg *provenance over* $\mathsf{RealLocatedSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedSupremumModulus}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLocatedSupremum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, D, R, M, L, E, H, C, P, N$. It has no coordinate for Dedekind cuts, selected representatives of real names, arbitrary subset completeness, trichotomy, countable choice, or host least-upper-bound operators.

Theorem 6496.2 (Real located supremum NameCert obligations)**.** *For every accepted* $\mathsf{RealLocatedSupremum}^{\uparrow}$ *carrier*

$$S = (F, W, D, R, M, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLocatedSupremum}^{\uparrow}}$ *surface consists exactly of finite located-family admission through F, synchronized window exposure through W, dyadic upper-bound and lower-hit tolerance exactness through D, regular rational readback through R, located supremum-modulus exposure through M, located-supremum handoff through L, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6496.1. The analytic rows are F, W, D, R, M, L, E, and the structural rows are H, C, P, N.

The family and candidate windows are finite before any supremum read occurs. Row F names the displayed real family and boundedness witnesses, while W fixes the inspected family windows and candidate supremum windows.

The located comparison data then pass through D, R, M. The dyadic ledger records upper-bound gaps and lower-hit gaps, the regular rational row reads those windows constructively, and the located supremum-modulus row supplies the finite search response needed before the located-supremum handoff L can be consumed.

The real seal E is downstream of that handoff. Since the carrier contains no Dedekind-cut coordinate, quotient real equality test, trichotomy row, countable-choice schedule, arbitrary subset-completeness row, or host least-upper-bound operator, the listed rows exhaust the local NameCert obligations. □

Theorem 6496.3 (Real located supremum seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{RealLocatedSupremum}^{\uparrow}$ *carrier factors through the displayed route*

$$F, W \longmapsto D \longmapsto R \longmapsto M \longmapsto L \longmapsto E \longmapsto C, P, N.$$

Thus the packet supplies a constructive located-supremum interface over Real names and dyadic evidence, but it does not export a Dedekind-cut construction, a selected host supremum, quotient real equality, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Begin with a Real-facing consumer request. The only real endpoint row of the carrier is E, and the definition makes E reachable only after the located family, window schedule, dyadic ledger, regular rational readback, modulus row, and located-supremum handoff have been displayed.

Read F and W first. These rows determine which real-name sources and candidate windows are visible to the request.

Next read D, R, M, L. The dyadic ledger supplies the finite upper-bound and lower-hit budgets, the regular rational row reads them through the same windows, the modulus row supplies the finite search response, and the located-supremum row names the handoff to the supremum candidate.

Finally H, C, P, N transport, replay, source, and name the same finite route. None of these structural rows introduces a host supremum object or any of the refused classical principles, so every exported real read is exhausted by the displayed route. □

Falsifiable prediction: A $\mathsf{RealLocatedSupremum}^{\uparrow}$ consumer that exports a RealUp supremum read while omitting finite located-family rows, StreamName windows, DyadicRatCore upper-bound and lower-hit rows, RegSeqRat readback, LocatedSupremumModulus evidence, LocatedSupremum handoff, RealUp seal, hsame transport, Cont replay, Pkg provenance, or local NameCert evidence is not reading the carrier of Definition 6496.1.

Independence witness: real, regseqrat, dyadicratcore, locatedsupremum, located-supremum-modulus: none is bijective with $\mathsf{RealLocatedSupremum}^{\uparrow}$ because this packet alone binds a displayed Real-name family, synchronized windows, dyadic upper-bound and lower-hit evidence, regular rational readback, a located supremum-modulus row, a located-supremum handoff, and the terminal Real seal into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLocatedSupremum}^{\uparrow}}$.

Constructive story: A $\mathsf{RealLocatedSupremum}^{\uparrow}$ packet is generated from finite located Real-family rows, StreamName windows, DyadicRatCore upper-bound and lower-hit ledgers, RegSeqRat readback, a LocatedSupremumModulus row, a LocatedSupremum handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLocatedSupremum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6496.1, Definition 6496.2, and Definition 6496.3 seed the constructive Real located-supremum route over displayed Real, dyadic, regular-rational, modulus, and supremum handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLocatedSupremum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut construction, quotient real equality, selected host suprema, arbitrary subset completeness, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized window coverage, dyadic upper-bound and lower-hit exactness, RegSeqRat readback, LocatedSupremumModulus exposure, LocatedSupremum handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealLocatedSupremumUp.

Chapter 6497

A Concrete Naming Certificate for $\mathsf{HyperbolicAxisProjection}^{\uparrow}$

The $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ packet realizes an axis-facing branch of chapter 9463 as finite disk-metric, geodesic-flow, boundary-shadow, Busemann, visual-boundary, projection-readback, refusal, provenance, and NameCert rows. It sits after the Poincare disk metric packet of chapter 6209, the geodesic-flow carrier of chapter 3856, the visual boundary route of chapter 4181, the Busemann boundary packet of chapter 3732, and the axis-shadow route of chapter 6122. The projection is a BEDC-internal row discipline: it names a displayed axis read only after the boundary and Busemann evidence needed to keep the read non-selected has been opened.

Definition 6497.1 (Hyperbolic axis projection carrier)**.** *A* $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, M, G, V, B, S, X, R, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-metric row that supplies the inspected disk coordinates and metric comparisons.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same disk observations.*
3. *G is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row naming the displayed oriented geodesic-flow segment whose axis projection is requested.*
4. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row exposing the boundary endpoints and visual-boundary readback used by the projection.*
5. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row recording the Busemann-level boundary comparison attached to the same endpoints.*
6. *S is the boundary-shadow row, read through the shadow or axis-shadow sibling route before an axis projection may be consumed.*
7. *X is the axis-projection readback row, recording the finite projected axis window and its attachment to D, M, G, V, B, S.*
8. *R is the refusal row excluding selected global axes, quotient ideal-boundary equality, completed hyperbolic geometry, host nearest-point projection, and physical observer-axis laws.*

9. *F is the TasteGate-facing row requiring the future Lean* $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ *carrier to provide* `Nontrivial` *and* `FieldFaithful` *instances for the disk, metric, flow, boundary, Busemann, shadow, projection, refusal, replay, provenance, and naming fields.*
10. *H records componentwise* hsame *transport for disk-metric, hyperbolic-metric, geodesic-flow, visual-boundary, Busemann-boundary, boundary-shadow, projection, refusal, TasteGate-facing, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from disk and geodesic-flow observations through V, B, S to the projection row X.*
12. *P is the* Pkg *provenance over* $\mathsf{HyperbolicAxisProjection}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicAxisProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, G, V, B, S, X, R, F, H, C, P, N$. It has no coordinate for selected axes, quotient boundary equality, completed disk geometry, host nearest-point projection, physical expansion dynamics, Lean verification, or a standard bridge.

Theorem 6497.2 (Hyperbolic axis projection NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ *carrier*

$$A = (D, M, G, V, B, S, X, R, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicAxisProjection}^{\uparrow}}$ *surface consists exactly of Poincare disk metric admission through D, hyperbolic metric readback through M, geodesic-flow admission through G, visual-boundary exposure through V, Busemann-boundary exposure through B, boundary-shadow exposure through S, axis-projection readback through X, refusal exactness through R, TasteGate-facing non-triviality and field-faithfulness requirements through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6497.1. The metric and flow rows are D, M, G, the boundary rows are V, B, S, the projection row is X, and the structural rows are R, F, H, C, P, N.

The projection is not available from metric data alone. The disk and hyperbolic metric rows determine the inspected coordinates, and the geodesic-flow row names the oriented segment, but the carrier requires visual-boundary, Busemann-boundary, and boundary-shadow rows before X may be consumed.

The refusal and TasteGate-facing rows keep the carrier separated. Row R excludes selected global axes, quotient boundary equality, completed disk geometry, host nearest-point projection, and physical expansion dynamics, while F records the future Lean requirement that the listed fields remain noncollapsed and faithful.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row supplies an undisplayed axis or a host projection theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 6497.3 (Hyperbolic axis projection boundary dependency)**.** *Every accepted* $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ *read that exports an axis-projection row must first display*

$\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicBu}$

together with the boundary-shadow row S. Consequently an axis-projection row cannot preserve its local $\mathsf{NameCert}$ *surface when transported to a sibling packet lacking boundary-shadow and Busemann rows.*

Proof. Start from the NameCert obligations of Definition 6497.2. They make X downstream of D, M, G, V, B, S.

The visual-boundary row V names the endpoints, while the Busemann-boundary row B keeps the boundary comparison attached to the same endpoints. The shadow row S then records the non-selected boundary-shadow witness needed before the axis projection can be read.

If a sibling lacks B or S, the displayed route to X is missing one of its carrier coordinates. Transport through H, C, P, N can preserve an existing row, but it cannot create absent Busemann or boundary-shadow evidence.

Thus the accepted projection read remains local to the full axis-projection packet and does not become a host nearest-point projection or a boundary-only sibling certificate. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ read that preserves local NameCert evidence into a sibling lacking boundary-shadow and Busemann rows refutes the carrier surface of Definition 6497.1.

Independence witness: hyperbolic-visual-boundary, hyperbolic-busemann-boundary, hyperbolic-geodesic-flow, poincare-disk-metric: $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ is not bijective to any listed sibling because each sibling lacks at least one obligation row among boundary-shadow evidence, Busemann comparison, geodesic-flow attachment, disk-metric provenance, axis-projection readback, refusal, TasteGate-facing field separation, transport, replay, provenance, and local naming.

The future Lean TasteGate for $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ must provide `Nontrivial` and `FieldFaithful` instances that keep $D, M, G, V, B, S, X, R, F, H, C, P, N$ as separate fields before any carrier-alignment theorem can serve as a public TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicAxisProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicAxisProjection}^{\uparrow}$ packet is generated from PoincareDiskMetric rows, HyperbolicMetric reads, HyperbolicGeodesicFlow rows, HyperbolicVisualBoundary rows, HyperbolicBusemannBoundary rows, boundary-shadow evidence, axis-projection readback, refusal, TasteGate-facing field-separation requirements, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicAxisProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6497.1, Definition 6497.2, and Definition 6497.3 seed the finite route from disk metric and geodesic-flow rows through boundary-shadow and Busemann evidence to an axis-projection readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicAxisProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected global axes, quotient boundary equality, completed hyperbolic geometry, host nearest-point projection, physical observer-axis dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk-metric visibility, geodesic-flow attachment, visual-boundary exposure, Busemann-boundary exposure, boundary-shadow dependency, axis-projection readback, refusal, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicAxisProjectionUp.

Chapter 6498

A Concrete Naming Certificate for $\mathsf{FrechetFilterBasis}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{FrechetFilterBasis}^{\uparrow}$ packet isolates the cofinite-tail basis that generates the Frechet filter before any consumer reads a full filter surface. It sits between the finite-tail rows of chapter 1119, the filter-base rows of chapter 1601, and the FrechetFilter route of chapter 1564. Sequential consumers read the same finite basis through $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal, never through quotient filter equality or a selected limit.

Definition 6498.1 (FrechetFilterBasis carrier)**.** *A* $\mathsf{FrechetFilterBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, T, F, S, Q, M, R, A, H, C, P, N)$$

whose rows have the following roles:

1. *U is the displayed unary tail-threshold row.*
2. *T is the* $\mathsf{FiniteTailFilter}^{\uparrow}$ *finite-complement row, recording tail containment by finite data.*
3. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *meet row for cofinite-tail neighborhoods.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row read only after U, T, F.*
5. *Q is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row built from that basis.*
6. *M is the* $\mathsf{FrechetFilter}^{\uparrow}$ *consumer row receiving the generated filter surface.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readback row.*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the regular readback.*
9. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FrechetFilterBasis}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient filter, external cofinite-set algebra, countable tail selector, selected limit, ambient completion, or independent $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Theorem 6498.2 (FrechetFilterBasis NameCert obligations)**.** *For every accepted* $\mathsf{FrechetFilterBasis}^{\uparrow}$ *carrier $B = (U, T, F, S, Q, M, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetFilterBasis}^{\uparrow}}$ *consists exactly of carrier admission for those rows, cofinite-tail basis admission through U, T, F, common-tail meet stability through F, FrechetFilter handoff through M, CauchyFilter and sequential-completion*

handoff through Q, S, R, A, transport and replay through H, C, provenance through P, and the refusal of quotient filters, selected limits, countable selectors, ambient completion, and independent Real completeness.

Proof. Project the carrier. The only rows that can mention cofinite tails are U, T, F, and the only rows that can export that surface are M and Q.

The meet row F supplies the common-tail refinement before the stream schedule S and regular readback R can be inspected. The replay row C fixes that order, while H transports it componentwise and P, N name only the displayed packet.

Thus every listed obligation is read from $U, T, F, S, Q, M, R, A, H, C, P, N$. The refused objects are absent from the carrier, so the local certificate cannot project them. □

Theorem 6498.3 (FrechetFilterBasis CauchyFilter handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer of an accepted* $\mathsf{FrechetFilterBasis}^{\uparrow}$ *carrier reads the finite cofinite-tail basis through*

$$U, T, F \longmapsto S, Q \longmapsto R, A, H, C, P, N.$$

The handoff also supplies the $\mathsf{FrechetFilter}^{\uparrow}$ *row M as the generated filter surface, but it exports no quotient filter equality, countable tail selector, selected limit, ambient completion, or separate Real-completeness object.*

Proof. Read U, T, F from Definition 6498.1. They are the threshold, finite-complement, and FilterBase meet rows, hence the complete basis source.

The continuation row then places S and Q downstream of that source. A CauchyFilter read cannot reach Q before the finite basis has been displayed, and the FrechetFilter row M receives the same generated surface.

The readback and Real rows R, A are later consumers of the same route. Since no refused host object is a carrier coordinate, the handoff remains a finite NameCert route. □

Theorem 6498.4 (FrechetFilter sequential-completion tail-basis route)**.** *Every* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *consumer that starts from a* $\mathsf{FrechetFilter}^{\uparrow}$ *tail source may instead read the narrower* $\mathsf{FrechetFilterBasis}^{\uparrow}$ *route*

$$\mathsf{FiniteTailFilter}^{\uparrow}(U, T),\ \mathsf{FilterBase}^{\uparrow}(F),\ \mathsf{StreamName}^{\uparrow}(S),\ \mathsf{CauchyFilter}^{\uparrow}(Q),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(A),\ H, C, P, N$$

before treating the source as a completion input. This route is a finite cofinite-tail basis route and not a full quotient-filter or ambient-completion route.

Proof. Use Definition 6498.2 to isolate the admitted rows. The basis part is exactly U, T, F, and the sequential-facing consumers are attached only through S, Q, R, A.

Apply Definition 6498.3. It identifies the CauchyFilter export as the same finite basis read, with the FrechetFilter row M generated from it rather than supplied independently.

Sequential completion therefore consumes the regular-rational and Real-facing rows after the basis handoff. The refused quotient filter, selected limit, countable selector, and ambient completion coordinates are unavailable. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetFilterBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetFilterBasis}^{\uparrow}$ packet is generated from finite tail thresholds, cofinite finite-complement rows, FilterBase meets, StreamName schedules, CauchyFilter handoff, FrechetFilter generation, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetFilterBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6498.1 and Definition 6498.2 seed the cofinite-tail basis surface for FrechetFilter and sequential-completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FrechetFilterBasis}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient filter equality, selected limits, countable tail selection, ambient completion, or independent Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-tail meet stability, FrechetFilter handoff, CauchyFilter handoff, sequential-completion routing, transport, replay, provenance, and local naming for BEDC.Derived.FrechetFilterBasisU

Chapter 6499

A Concrete Naming Certificate for $\mathsf{CompactFiniteModulusGluing}^{\uparrow}$

Following Bishop–Bridges and the constructive Heine–Cantor argument, the $\mathsf{CompactFiniteModulusGluing}^{\uparrow}$ packet packages the finite $\mathsf{ProbeBundle}$ route from compact coverage and pointwise continuity to a tolerance-only uniform modulus. It realizes the compact-uniform-continuity carrier of chapter 9237 as concrete NameCert data: compact finite-net rows, continuous-map pointwise-modulus rows, $\mathsf{Rat}^{\uparrow}$ lower-bound folds, metric triangle estimates, and the $\mathsf{UniformModulus}^{\uparrow}$ handoff all remain visible in one finite carrier. The packet consumes the concrete $\mathsf{CompactMetric}^{\uparrow}$ finite-net carrier of chapter 129, the $\mathsf{ContinuousMap}^{\uparrow}$ pointwise-modulus carrier of chapter 130, the $\mathsf{Rat}^{\uparrow}$ lower-bound fold arithmetic of chapter 37, the $\mathsf{Met}^{\uparrow}$ triangle rows of chapter 57, and the $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369.

Definition 6499.1 (CompactFiniteModulusGluing carrier)**.** *A* $\mathsf{CompactFiniteModulusGluing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, C, B, R, L, T, U, H, E, P, N)$$

with these rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including the finite* $\mathsf{ProbeBundle}$ *and coverage witnesses.*
2. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row over the same metric source.*
3. *B is the bundled probe row carrying centers, local radii, and local modulus certificates.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *positive-radius comparison row.*
5. *L is the finite lower-bound fold over the bundled rational radii.*
6. *T is the metric-triangle transport row that moves estimates from centers to arbitrary points.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row from tolerance histories to precision histories.*
8. *H, E, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompactFiniteModulusGluing}^{\uparrow}}$ *row.*

The carrier has no external finite-subcover selector, no global choice of centers, no host compactness theorem, no classical least positive radius, no function-space quotient equality, and no ambient Real-completeness coordinate.

Theorem 6499.2 (CompactFiniteModulusGluing NameCert obligations)**.** *For every accepted* $\mathsf{CompactFiniteModulusGluing}^{\uparrow}$ *carrier* $G = (K, C, B, R, L, T, U, H, E, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactFiniteModulusGlui}}$ *consists exactly of carrier admission for those rows, finite ProbeBundle coverage through* K, B*, pointwise-modulus admission through* C*, positive rational comparison through* R*, finite lower-bound fold stability through* L*, metric-triangle transport through* T*, uniform-modulus handoff through* U*, structural transport and replay through* H, E*, provenance through* P*, and refusal of external selectors, host compactness, classical minima, quotient function equality, and ambient Real completeness.*

Proof. Project the carrier. Coverage and probe membership are stored only in K, B, while pointwise continuity data is stored only in C.

The rational comparison and finite fold rows R, L provide the displayed lower bound over the bundle. The triangle row T is then the only route from center estimates to arbitrary source points, and U receives the resulting tolerance-only precision history.

Transport, replay, provenance, and naming preserve that finite route without adding host selectors or quotient function equality. The refused objects are not coordinates of G, so no NameCert clause can export them. □

Theorem 6499.3 (Compact finite gluing uniform-modulus route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read exported by an accepted* $\mathsf{CompactFiniteModulusGluing}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompactMetric}^{\uparrow}(K),\ \mathsf{ContinuousMap}^{\uparrow}(C),\ \mathsf{ProbeBundle}(B),\ \mathsf{Rat}^{\uparrow}(R),\ L, T, U, H, E, P, N.$$

The exported precision history is produced by a finite rational lower-bound fold over bundled pointwise-modulus radii, followed by metric-triangle transport, and not by an external modulus selector or a host Heine–Cantor theorem.

Proof. Start with the finite-net row K and the bundled row B. They provide the only displayed centers and coverage witnesses available to the carrier.

Read the pointwise-modulus row C at each bundled center. The positive rational comparisons in R and the finite fold L produce one lower-bound history below all bundled local radii.

Finally use the metric-triangle row T to transport local estimates from the chosen center to an arbitrary pair of nearby source points, and hand the resulting precision history to U. Because the whole route has passed through finite carrier rows, it does not expose external selection, classical minima, quotient equality, host compactness, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFiniteModulusGluing}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactFiniteModulusGluing}^{\uparrow}$ packet is generated from compact finite-net rows, continuous-map pointwise moduli, bundled probe data, rational positive-radius comparison, finite lower-bound folds, metric-triangle transport, uniform-modulus handoff, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactFiniteModulusGluing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6499.1 and Definition 6499.2 seed the finite ProbeBundle gluing surface for compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactFiniteModulusGluing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host compactness, external finite-subcover selection, classical least-radius selection, quotient function equality, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite ProbeBundle coverage, pointwise-modulus admission, rational fold stability, metric-triangle transport, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactFiniteModulusGluingUp.

Chapter 6500

A Concrete Naming Certificate for ClosedIntervalFiniteNet$^{\uparrow}$

Following Bishop and Bridges on finite epsilon-net data for compact intervals, the ClosedIntervalFiniteNet$^{\uparrow}$ packet records the finite dyadic mesh surface by which a displayed closed real interval can be consumed by total-bounded and compact-metric routes. It sits after the dyadic arithmetic source of chapter 291, the dyadic cell surface of chapter 306, the located-real comparison row of **??**, the terminal real-name seal of chapter 38, the finite epsilon-net interface of chapter 1767, and the total-bounded consumer surface of chapter 127. The packet names explicit endpoint, mesh, coverage, transport, replay, provenance, and local NameCert data; it does not assert open-cover compactness or an ambient Heine–Borel theorem.

Definition 6500.1 (Closed interval finite-net carrier)**.** *A* ClosedIntervalFiniteNet$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, M, L, F, W, H, C, P, N)$$

with the following displayed rows:

1. *E is the endpoint row, carrying lower and upper closed-interval endpoint histories together with the finite comparison ledger that places the lower endpoint before the upper endpoint.*
2. *M is the dyadic mesh row, a finite* DyadicInterval$^{\uparrow}$ *subdivision schedule read through* DyadicRatCore$^{\uparrow}$ *arithmetic and a positive tolerance request.*
3. *L is the located* Real$^{\uparrow}$ *seal row, displaying the located-real endpoint reads and the terminal real-name seals used by interval consumers.*
4. *F is the finite-net list row, a closed finite list of mesh centers admitted between the endpoint rows and tagged by the mesh scale.*
5. *W is the coverage witness row, recording for each displayed interval point the inspected center row and the dyadic bound showing that the point is covered at the requested tolerance.*
6. *H records componentwise* hsame *transport for endpoint rows, dyadic mesh rows, located real seals, finite net lists, coverage witnesses, replay rows, provenance rows, and local naming rows.*
7. *C records displayed* Cont *replay from an interval finite-net request through E, M, L, F, W, H before any total-bounded or compact-metric consumer reads the packet.*
8. *P is the* Pkg *provenance over* ClosedIntervalFiniteNet$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* DyadicInterval$^{\uparrow}$*,* LocatedReal$^{\uparrow}$*,* Real$^{\uparrow}$*,* FiniteEpsilonNet$^{\uparrow}$*,* TotallyBounded$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, M, L, F, W, H, C, P, N$. It has no coordinate for arbitrary open covers, selected finite subcovers, a host Heine–Borel principle, quotient interval equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6500.2 (Closed interval finite-net obligation surface)**.** *For every accepted* $\mathsf{ClosedIntervalFiniteNet}^{\uparrow}$ *carrier $K = (E, M, L, F, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNet}^{\uparrow}}$ *surface consists exactly of carrier admission, endpoint enclosure, finite-net coverage, mesh-refinement stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and ledger non-escape. A consumer may treat the packet as closed-interval finite-net data only after those rows have been displayed.*

Proof. Project the carrier of Definition 6500.1. Carrier admission is the displayed packet K, endpoint enclosure is the row E, and the dyadic mesh is the row M.

The finite-net rows are F, W. The list row fixes the admitted mesh centers, while the coverage row records the inspected center and dyadic bound for each displayed interval point. Mesh-refinement stability is read through the same endpoint and mesh rows, so a refined request keeps the coverage ledger inside E, M, F, W.

The remaining rows H, C, P, N supply transport, replay, provenance, and local naming for that same finite packet. Since the classifier has no coordinate outside $E, M, L, F, W, H, C, P, N$, no ledger read can escape to arbitrary open covers, selected subcovers, host interval equality, countable choice, or ambient real completeness. □

Theorem 6500.3 (Closed interval finite-net total-bounded handoff)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$ *or compact-metric consumer that uses interval compactness from an accepted* $\mathsf{ClosedIntervalFiniteNet}^{\uparrow}$ *packet must first read the finite dyadic net row F and the located endpoint rows E, L. The consumer may then inspect coverage witnesses, mesh refinement, transport, replay, provenance, and local naming, but it receives no open-cover compactness theorem, selected cover, countable-choice schedule, host Heine–Borel principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Let $K = (E, M, L, F, W, H, C, P, N)$ be accepted. The interval boundary is visible only through the endpoint row E and the located $\mathsf{Real}^{\uparrow}$ seal row L, while the finite dyadic net is visible only through M, F.

Apply Definition 6500.2. It forces any total-bounded or compact-metric consumer to inspect carrier admission, endpoint enclosure, finite-net coverage, mesh-refinement stability, transport, replay, provenance, and ledger non-escape before treating the packet as interval finite-net data.

Thus the handoff to $\mathsf{TotallyBounded}^{\uparrow}$ and compact-metric consumers is the displayed finite route $E, M, L, F, W, H, C, P, N$. The excluded open-cover, selected-cover, choice, host Heine–Borel, quotient-interval, and ambient-completeness objects are not carrier fields, so none can be exported by the handoff. □

Falsifiable prediction: Removing the endpoint row, dyadic mesh row, located Real seal row, finite-net list, coverage witness, hsame transport, Cont replay, Pkg provenance, or local $\mathsf{NameCert}$ row makes Definition 6500.3 false: a total-bounded consumer could no longer verify the displayed interval-net route.

Independence witness: dyadicratcore, dyadicinterval, locatedreal, real, finite-epsilon-net, totallybounded: $\mathsf{ClosedIntervalFiniteNet}^{\uparrow}$ is not bijective to any listed sibling because it binds endpoint rows, dyadic mesh rows, located Real seals, finite net lists, coverage witnesses, transport, replay, provenance, and local naming into one closed-interval consumer packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNet}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedIntervalFiniteNet}^{\uparrow}$ packet is generated from endpoint rows, a dyadic mesh schedule, located Real seals, a finite net list, coverage witnesses, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6500.1, Definition 6500.2, and Definition 6500.3 seed the finite closed-interval net route over endpoint, dyadic mesh, located Real, coverage, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, Heine–Borel as a theorem for general subsets, selected covers, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint enclosure, finite-net coverage, mesh-refinement stability, transport, replay, provenance, and ledger non-escape for BEDC.Derived.ClosedIntervalFiniteNetUp.

Chapter 6501

A Concrete Naming Certificate for $\mathsf{BoundedLattice}^{\uparrow}$

Following Birkhoff and Tarski on bounded lattices, the $\mathsf{BoundedLattice}^{\uparrow}$ packet records the finite meet–join interface equipped with displayed bottom and top rows. It sits after the order substrate of chapter 53, the meet–join certificate of chapter 55, the certified-family route of chapter 5155, and the point-free open rows of chapter 5153. The packet supplies the standard bounded-lattice boundary needed by locale, frame, and domain-style consumers without importing host complete orders, powersets, Zorn principles, quotient representatives, or selected extrema.

Definition 6501.1 (Bounded lattice carrier)**.** *A* $\mathsf{BoundedLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (O, L, \bot, \top, M, J, H, C, P, N)$$

with the following displayed rows:

1. *O is the underlying* $\mathsf{Poset}^{\uparrow}$ *order row, recording the visible comparison surface.*
2. *L is the* $\mathsf{Lattice}^{\uparrow}$ *meet–join row, recording the displayed finite meet and join operations over O.*
3. *$\bot$ is the bottom row, giving a named element below every displayed carrier element by comparisons in O.*
4. *$\top$ is the top row, giving a named element above every displayed carrier element by comparisons in O.*
5. *M records endpoint-meet exactness: displayed meets with $\bot$ and $\top$ reduce through the same order and lattice rows.*
6. *J records endpoint-join exactness: displayed joins with $\bot$ and $\top$ reduce through the same order and lattice rows.*
7. *H records componentwise* hsame *transport for the order, lattice, endpoint, exactness, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded-lattice request through $O, L, \bot, \top, M, J, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedLattice}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{CompleteLattice}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, L, \bot, \top, M, J, H, C, P, N$. It has no coordinate for a host complete lattice, powerset lattice, Zorn principle, quotient representative, arbitrary infimum or supremum operator, or selected external endpoint.

Theorem 6501.2 (Bounded lattice NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLattice}^{\uparrow}$ *carrier* $B = (O, L, \bot, \top, M, J, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLattice}^{\uparrow}}$ *surface consists exactly of order-row admission, lattice-row admission, bottom-row exposure, top-row exposure, endpoint meet exactness, endpoint join exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every locale, frame, complete-lattice, or domain-style consumer must expose those rows before reading a bounded-lattice claim.*

Proof. Project the carrier of Definition 6501.1. The order row O supplies the only comparison surface, and the lattice row L supplies the only displayed meet–join interface.

The endpoint rows are then visible coordinates of the same packet. The row $\bot$ is read as the displayed lower endpoint, and the row $\top$ is read as the displayed upper endpoint, both by comparisons in O.

Endpoint exactness is stored in M and J. These rows bind meets and joins with the endpoints to the same order and lattice data, so a consumer cannot substitute an ambient infimum, supremum, powerset operation, or complete-order theorem.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the excluded host objects are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 6501.3 (Bounded lattice locale handoff)**.** *Every* $\mathsf{LocaleSpace}^{\uparrow}$*,* $\mathsf{CompleteLattice}^{\uparrow}$*, or frame-style consumer of an accepted* $\mathsf{BoundedLattice}^{\uparrow}$ *packet must read the finite route*

$$O, L, \bot, \top \longmapsto M, J \longmapsto H, C, P, N$$

before using bottom, top, meet, or join data. The handoff supplies a bounded meet–join boundary for finite open and certified-family rows, but it does not supply a host complete order, powerset of opens, unrestricted joins, Zorn-style maximal principle, quotient representative, or selected external endpoint.

Proof. Begin with the order and lattice rows. By Definition 6501.2, a consumer first exposes O and L, so the comparison, meet, and join data are the displayed BEDC rows also used by chapter 55.

Next read the endpoint rows. The bottom and top entries are named as $\bot$ and $\top$ inside the packet, and their endpoint laws are checked through the rows M and J rather than through a complete-lattice carrier.

The complete-lattice and locale neighbours provide comparison context only after this finite route is exposed. The certified-family route of chapter 5155 and the point-free route of chapter 5153 may consume the bounded lattice boundary, but they cannot replace it by host powersets or arbitrary joins.

The support rows H, C, P, N keep the same bounded-lattice data under transport, replay, provenance, and naming. Because no row stores host complete orders, Zorn principles, quotient representatives, unrestricted joins, or selected endpoints, the handoff remains a finite NameCert boundary. □

Falsifiable prediction: Removing the $\mathsf{Poset}^{\uparrow}$ order row, $\mathsf{Lattice}^{\uparrow}$ meet–join row, bottom row, top row, endpoint meet exactness, endpoint join exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row prevents a locale, complete-lattice, or frame-style consumer from verifying the bounded-lattice route.

Independence witness: poset, lattice, complete-lattice, locale-space: $\mathsf{BoundedLattice}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries order, meet–join, displayed bottom, displayed top, endpoint exactness, transport, replay, provenance, and local naming rows in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedLattice}^{\uparrow}$ packet is generated from a PosetUp order row, a LatticeUp meet–join row, displayed bottom and top rows, endpoint meet and join exactness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6501.1, Definition 6501.2, and Definition 6501.3 seed the finite bounded-lattice boundary over order, meet, join, endpoints, endpoint exactness, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host complete orders, powerset lattices, unrestricted joins, Zorn principles, quotient representatives, selected external endpoints, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked order admission, lattice admission, bottom and top exposure, endpoint exactness, transport, replay, provenance, and local naming for BEDC.Derived.BoundedLatticeUp.

Chapter 6502

A Concrete Naming Certificate for $\mathsf{RegularCauchyComparisonModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names with explicit moduli, the RegularCauchyComparisonMod packet records the finite comparison-modulus data by which two regular rational names can be compared before equality, convergence-modulus, or completion-facing consumers read a terminal real boundary. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the common-tail comparison surface of chapter 387. The packet is a finite L10 comparison-modulus surface for RealEquality and RealModulusOfConvergence consumers; it is not quotient stream equality, a selected limit, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6502.1 (Regular Cauchy comparison modulus carrier)**.** *A* $\mathsf{RegularCauchyComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S_0, S_1, R_0, R_1, D, \mu, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened for the compared regular Cauchy names.*
2. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from those windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording requested radii, slack splits, and comparison budgets.*
4. μ *is the finite comparison-modulus row assigning each displayed tolerance request in* D *a common tail stage.*
5. W *is the shared window row obtained by reading both regular names beyond the stage recorded by* μ*.*
6. Q *is the* $\mathsf{CauchyTailComparison}^{\uparrow}$ *row that checks the two readbacks through the shared window* W *and the dyadic ledger* D*.*
7. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after* $S_0, S_1, R_0, R_1, D, \mu, W, Q$ *have been displayed.*

8. *H records componentwise* hsame *transport for the two window rows, two readback rows, dyadic ledger, comparison modulus, shared window, tail-comparison row, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D, \mu, W \longmapsto Q \longmapsto E.$$

10. *P is the* Pkg *provenance over* RegularCauchyComparisonModulus$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, CauchyTailComparison$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyComparisonModulus}^\uparrow}$ *row.*

The classifier compares accepted packets only through these rows. There is no coordinate for quotient classes of streams, selected representatives, trichotomy, countable-choice schedules, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonModulusUp.RegularCauchyComparisonModulusTasteGate`
`single carrier alignment`

Theorem 6502.2 (Regular Cauchy comparison modulus NameCert obligations)**.** *For every accepted* RegularCauchyComparisonModulus$^\uparrow$ *carrier $M = (S_0, S_1, R_0, R_1, D, \mu, W, Q, E, H, C, P, N)$, the local* NameCert$_{\text{RegularCauchyComparisonModulus}^\uparrow}$ *surface consists exactly of carrier admission, two* StreamName$^\uparrow$ *window exposures, two* RegSeqRat$^\uparrow$ *readbacks, one* DyadicRatCore$^\uparrow$ *tolerance ledger, one finite comparison-modulus row, one shared tail-window row, one* CauchyTailComparison$^\uparrow$ *check, ordered* Real$^\uparrow$ *seal access, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation may replace these rows by quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* Real$^\uparrow$ *completeness.*

Proof. Project the accepted packet. The carrier exposes exactly two finite stream windows, two regular-rational readbacks, the dyadic tolerance ledger, the comparison-modulus row, the shared tail window, the tail-comparison check, the terminal Real seal, and the structural rows H, C, P, N.

The comparison-modulus row is read after the dyadic request is displayed. Thus each common tail stage is attached to an explicit radius and slack budget rather than to an ambient convergence assertion.

The shared window W and comparison row Q then compare the two regular readbacks through the same visible tail data. This keeps the comparison inside CauchyTailComparison$^\uparrow$ and prevents a quotient or host-equality route from entering.

Finally the Real seal E and the structural rows transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded principles, the listed rows exhaust the local NameCert surface. □

Theorem 6502.3 (Regular Cauchy comparison modulus RegSeqRat handoff)**.** *Every* RegSeqRat$^\uparrow$, RealEquality$^\uparrow$, *or* RealModulusOfConvergence$^\uparrow$ *consumer of an accepted* RegularCauchyComparisonModulus$^\uparrow$ *packet must read the two* StreamName$^\uparrow$ *window rows, two* RegSeqRat$^\uparrow$ *readback rows, the* DyadicRatCore$^\uparrow$ *tolerance ledger, the finite comparison-modulus row, the shared tail-window row, and the* CauchyTailComparison$^\uparrow$ *check before it may use the terminal* Real$^\uparrow$ *seal. The handoff supplies a finite comparison-modulus route for regular Cauchy names; it does not supply quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient* Real$^\uparrow$ *completeness.*

Proof. Start with the carrier projection of Definition 6502.1. A consumer first receives S_0, S_1 and then R_0, R_1, so the comparison begins from displayed finite windows and regular-rational readbacks.

Next read the dyadic ledger D and the comparison-modulus row μ. These rows bind each tolerance request to a finite common tail stage before any Real-facing boundary is visible.

Use the shared window W and the tail-comparison row Q. They compare the two readbacks through the same finite tail data and the same dyadic budget, matching the common-tail discipline of $\mathsf{CauchyTailComparison}^{\uparrow}$.

Only after this route is displayed may the terminal seal E be consumed by $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, or $\mathsf{RealModulusOfConvergence}^{\uparrow}$ readers. The structural rows H, C, P, N preserve that route and contain no quotient, selection, choice, order-decision, host-equality, or completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6502.1, Definition 6502.2, and Definition 6502.3 seed the finite comparison-modulus route over displayed dyadic tolerances, regular readbacks, common tail windows, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, public closure, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired window exposure, paired RegSeqRat readback, dyadic tolerance accounting, comparison-modulus exactness, shared tail-window exactness, CauchyTailComparison handoff, ordered Real seal access, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyComparisonModulusUp.

Constructive story: A $\mathsf{RegularCauchyComparisonModulus}^{\uparrow}$ packet is generated from two StreamName windows, two RegSeqRat readback rows, a DyadicRatCore tolerance ledger, a finite comparison-modulus row, a shared tail window, a CauchyTailComparison row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6503

A Concrete Naming Certificate for $\mathsf{PolarizationIdentity}^{\uparrow}$

Following Jordan and von Neumann, the polarization identity is read as a finite reconstruction route from inner-product rows to norm/parallelogram rows, not as host Hilbert-space equality. The $\mathsf{PolarizationIdentity}^{\uparrow}$ packet sits between the scalar field of chapter 45, the vector-space source of chapter 47, the inner-product surface of chapter 86, the norm-square boundary of chapter 89, and the Hilbert consumer boundary of chapter 91.

Definition 6503.1 (PolarizationIdentity carrier)**.** *A* $\mathsf{PolarizationIdentity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (F, V, I, N, Q, H, C, R, L)$$

with the following displayed rows:

1. *F is the* $\mathsf{Field}^{\uparrow}$ *scalar row that supplies the additive, multiplicative, sign, and division data used by the scalar reconstruction coefficients.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row whose vector addition, inverse, zero, and scalar-action rows are the only vector endpoints admitted by the packet.*
3. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *scalar-form row naming the accepted inner-product observations on the displayed vector endpoints.*
4. *N is the* $\mathsf{Norm}^{\uparrow}$ *norm-square row read from the diagonal inner-product observations and the parallelogram ledger.*
5. *Q is the* $\mathsf{Hilbert}^{\uparrow}$ *consumer boundary row; it receives only the reconstructed norm/parallelogram route and not a host Hilbert-space equality.*
6. *H records componentwise* hsame *transport for scalar data, vector data, inner-product observations, norm-square rows, the Hilbert boundary, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from the inner-product rows through the norm-square and parallelogram rows to the Hilbert-facing boundary.*
8. *R is the* Pkg *provenance over* $\mathsf{Field}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{PolarizationIdentity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, V, I, N, Q, H, C, R, L$. It has no coordinate for a completed Hilbert space, quotient vector equality, external bilinear map, selected orthonormal basis, spectral theorem, or host parallelogram proof.

Lean4 ✓ `BEDC.Derived.PolarizationIdentityUp.PolarizationIdentityTasteGate single carrier alignment`

Theorem 6503.2 (PolarizationIdentity NameCert obligations)**.** *For every accepted* $\mathsf{PolarizationIdentity}^{\uparrow}$ *carrier* $P = (F, V, I, N, Q, H, C, R, L)$*, the local* $\mathsf{NameCert}_{\mathsf{PolarizationIdentity}^{\uparrow}}$ *surface consists of carrier admission for scalar field data, vector-space endpoints, inner-product scalar-form observations, norm-square and parallelogram rows, Hilbert consumer boundary, componentwise transport, displayed continuation replay, package provenance, and local naming. Every public read of the polarization route is generated by these rows, and no read exports host Hilbert equality, quotient vector equality, a selected basis, an external bilinear map, or ambient completeness.*

Proof. Read the carrier rows in the displayed order. The scalar row F and vector-space row V provide the only scalar coefficients and vector endpoints available to the packet.

The inner-product row I supplies the scalar-form observations, and the norm-square row N records the diagonal and parallelogram-facing reads obtained from those observations. Thus the reconstruction route is finite data over the displayed rows rather than an equality inside a host Hilbert space.

Finally Q, H, C, R, L carry the Hilbert-facing boundary, componentwise transport, replay, provenance, and local naming. Since no coordinate stores a completed Hilbert space, quotient vector equality, selected basis, external bilinear map, or ambient completeness, those objects cannot be exported by the local certificate. □

Theorem 6503.3 (PolarizationIdentity inner-product norm handoff)**.** *Every* $\mathsf{Norm}^{\uparrow}$ *or* $\mathsf{Hilbert}^{\uparrow}$ *consumer of an accepted* $\mathsf{PolarizationIdentity}^{\uparrow}$ *packet reads the inner-product-to-norm reconstruction only through*

$$\mathsf{Field}^{\uparrow},\quad \mathsf{VecSpace}^{\uparrow},\quad \mathsf{InnerProduct}^{\uparrow},\quad \mathsf{Norm}^{\uparrow},\quad \mathsf{Hilbert}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The handoff sends diagonal scalar-form observations and parallelogram rows to the norm-square boundary, then presents the resulting finite route to Hilbert-facing consumers. It does not supply a host Hilbert equality, quotient vector equality, selected orthonormal basis, spectral theorem, or external completeness principle.

Proof. Begin with Definition 6503.1. The only route from inner-product observations to norm-square data is the visible I, N pair over the scalar and vector rows F, V.

Apply Definition 6503.2. It requires the Hilbert-facing read to pass through carrier admission, inner-product observations, norm-square and parallelogram rows, transport, replay, provenance, and local naming.

Therefore a downstream $\mathsf{Norm}^{\uparrow}$ or $\mathsf{Hilbert}^{\uparrow}$ consumer receives exactly the finite handoff $F, V, I, N, Q, H, C, R, L$. The refused host equality, quotient, basis, spectral, and completeness objects are absent from the carrier and cannot be reconstructed by replay. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolarizationIdentity}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolarizationIdentity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6503.1, Definition 6503.2, and Definition 6503.3 seed the finite reconstruction route from inner-product rows to norm-square, parallelogram, and Hilbert-facing consumer rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolarizationIdentity}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PolarizationIdentityUp.PolarizationIdentityTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host Hilbert equality, quotient vector equality, selected bases, spectral theory, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, scalar coefficient discipline, vector endpoint admission, inner-product observation, norm-square/parallelogram handoff, Hilbert boundary, transport, replay, provenance, and local naming for BEDC.Derived.PolarizationIdentityUp.

Constructive story: A PolarizationIdentity$^{\uparrow}$ packet is generated from FieldUp scalar data, VecSpaceUp vector data, InnerProductUp scalar-form rows, NormUp norm-square rows, a HilbertUp consumer boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6504

A Concrete Naming Certificate for $\mathsf{ModulusOfSequentialContinuity}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ModulusOfSequentialContinuity}^{\uparrow}$ packet records the explicit tolerance-to-window datum that makes a sequential-continuity read constructive. It sits beside the $\mathsf{SequentialContinuity}^{\uparrow}$ route of chapter 1466, reads the pointwise surface of chapter 59, uses the metric rows of chapter 57, inspects finite $\mathsf{StreamName}^{\uparrow}$ windows from chapter 126, hands those windows through $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, and reaches only the displayed $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet exports a finite modulus object, not Real completeness, countable choice, quotient streams, host function extensionality, or an ambient continuity principle.

Definition 6504.1 (ModulusOfSequentialContinuity carrier)**.** *A* $\mathsf{ModulusOfSequentialContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, F, S, T, E, W_X, W_Y, R_X, R_Y, A, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the source and target* $\mathsf{Met}^{\uparrow}$ *carrier rows, including the distance classifiers and visible tolerance ledgers.*
2. *F is the displayed* $\mathsf{Continuous}^{\uparrow}$ *row whose pointwise modulus may be read only at inspected source windows.*
3. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *surface, and T is the finite threshold ledger requested by the sequential-continuity consumer.*
4. *E is the tolerance-to-window assignment: each displayed target tolerance in T is sent to a finite source-window request before any target conclusion is read.*
5. *W_X and W_Y are the source and target finite window families exposed by S, F, E.*
6. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the source and target windows.*
7. *A is the* $\mathsf{SequentialContinuity}^{\uparrow}$ *acceptance row saying that the displayed windows are the only sequence-facing route consumed by the packet.*
8. *H stores componentwise* hsame *transport for the two metric rows, continuous row, source stream, threshold ledger, assignment, window rows, regular readbacks, sequential acceptance, continuation, provenance, and local naming.*

9. *C stores displayed* Cont *replay from T to E, from E, S to W_X, from W_X, F to W_Y, and from W_X, W_Y to R_X, R_Y, A.*
10. *P is the* Pkg *provenance over* ModulusOfSequentialContinuity$^\uparrow$, SequentialContinuity$^\uparrow$, Continuous$^\uparrow$, Met$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ModulusOfSequentialContinuity}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, Y, F, S, T, E, W_X, W_Y, R_X, R_Y, A, H, C, P, N$. It has no coordinate for a selected limit, quotient stream equality, countable choice, host function extensionality, detached continuity proof, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.ModulusOfSequentialContinuityUp.ModulusOfSequentialContinuityTasteGate`
`single carrier alignment`

Theorem 6504.2 (ModulusOfSequentialContinuity NameCert obligations)**.** *For every accepted* ModulusOfSequentialContinuity$^\uparrow$ *carrier*

$$M = (X, Y, F, S, T, E, W_X, W_Y, R_X, R_Y, A, H, C, P, N),$$

the local NameCert$_{\text{ModulusOfSequentialContinuity}^\uparrow}$ *surface consists exactly of carrier admission for the displayed fifteen-row packet, metric-row stability through X, Y, H, C, pointwise-continuity use through F, tolerance-to-window exposure through T, E, W_X, W_Y, regular-rational readback through R_X, R_Y, sequential-continuity handoff through A, package provenance through P, local naming through N, and non-escape from selected limits, quotient streams, countable choice, host function extensionality, detached continuity, and Real completeness.*

Proof. Project the carrier of Definition 6504.1. The classifier can read only the displayed metric rows, continuous row, stream row, tolerance ledger, assignment row, window rows, regular readbacks, sequential acceptance row, and structural rows.

The analytic route starts with the tolerance ledger. The row T lists the target tolerances requested by the consumer, and E turns each listed tolerance into a finite source-window request before a target window is inspected.

Next read the window and regular-rational handoff. The row W_X is opened from S, E, the row W_Y is obtained from W_X, F, and the rows R_X, R_Y are the only regular-rational readbacks attached to those windows.

Finally attach the sequential-continuity row and the structural rows. The row A records that the displayed windows are the complete sequence-facing route, while H, C, P, N transport, replay, source, and name that route. Since none of the excluded principles is a coordinate of M, the listed obligations exhaust the local NameCert surface. □

Theorem 6504.3 (ModulusOfSequentialContinuity tolerance-window handoff)**.** *Every accepted* ModulusOfSequentialContinuity$^\uparrow$ *packet sends a target tolerance to a finite source-window request before any* SequentialContinuity$^\uparrow$ *or* Real$^\uparrow$ *consumer can read the image sequence. The complete handoff factors through*

$$T \longmapsto E \longmapsto W_X \longmapsto W_Y \longmapsto R_X, R_Y \longmapsto A$$

together with the displayed rows X, Y, F, S, H, C, P, N.

Proof. Begin with the tolerance request. The target tolerance is visible only as an entry of T, and the assignment row E is the only coordinate that converts such an entry into a finite source-window request.

Open the source and image windows. The source row S supplies W_X at the window requested by E, and the continuous row F is consumed only through that inspected source window to expose W_Y.

Pass to the rational and sequential surfaces. The rows R_X and R_Y read the two windows as regular rational data, and A is the downstream $\mathsf{SequentialContinuity}^{\uparrow}$ acceptance row reached from those readbacks.

Thus a consumer that tries to read an image sequence, a Real-facing seal, or a sequential-continuity conclusion without first exposing T, E, W_X, W_Y, R_X, R_Y leaves the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfSequentialContinuity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusOfSequentialContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6504.1, Definition 6504.2, and Definition 6504.3 seed the finite tolerance-to-window route for sequential-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusOfSequentialContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, countable choice, quotient streams, host function extensionality, selected limits, detached continuity, Lean verification, or standard bridge checking.

Upgrade path: Formal closure requires checked carrier admission, metric-row stability, tolerance-to-window exactness, finite-window replay, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{SequentialContinuity}^{\uparrow}$ handoff, and non-escape for BEDC.Derived.ModulusOfSequentialContinuity

Constructive story: A $\mathsf{ModulusOfSequentialContinuity}^{\uparrow}$ packet is generated from source and target metric rows, a displayed pointwise-continuity row, a source stream, a finite tolerance ledger, a tolerance-to-window assignment, source and image windows, regular rational readbacks, sequential-continuity acceptance, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6505

A Concrete Naming Certificate for $\mathsf{RouthHurwitzCriterion}^{\uparrow}$

Following Routh and Hurwitz, the $\mathsf{RouthHurwitzCriterion}^{\uparrow}$ packet records the finite stability test for a displayed real polynomial through coefficient rows, Hurwitz matrix rows, determinant rows, and ordered-sign rows. It sits after the polynomial carrier of chapter 50, the matrix carrier of chapter 49, the real algebra and order boundary of chapter 766, the determinant packet of chapter 84, and the scalar field source of chapter 45. The packet names a finite algebraic stability certificate for downstream control and ODE consumers; it does not import complex-root choice, a host spectral theorem, quotient polynomial equality, selected roots, or an ambient analytic flow theorem.

Definition 6505.1 (Routh–Hurwitz criterion carrier)**.** *A* $\mathsf{RouthHurwitzCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, M, D, S, T, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Poly}^{\uparrow}$ *coefficient row, listing the finite real coefficient sequence, leading-coefficient witness, degree window, and normalization request consumed by the stability test.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *Hurwitz row, displaying the finite Hurwitz matrix entries read from A.*
3. *D is the* $\mathsf{Determinant}^{\uparrow}$ *minor row, listing the finite leading principal determinant requests and their replay paths through M.*
4. *S is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *sign row, recording the ordered-real reads that classify each determinant or boundary minor as positive, zero, or obstructed for the displayed request.*
5. *T records componentwise* hsame *transport for coefficient, matrix, determinant, sign, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the finite route*

$$A \longmapsto M \longmapsto D \longmapsto S.$$

7. *P is the* Pkg *provenance over* $\mathsf{RouthHurwitzCriterion}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RouthHurwitzCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through A, M, D, S, T, C, P, N. It has no coordinate for complex roots, spectral decompositions, quotient polynomial equality, selected eigenvalues, or analytic trajectories.

Theorem 6505.2 (Routh–Hurwitz NameCert obligations)**.** *For every accepted* $\mathsf{RouthHurwitzCriterion}^{\uparrow}$ *carrier $R = (A, M, D, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RouthHurwitzCriterion}^{\uparrow}}$ *surface consists exactly of coefficient admission through A, Hurwitz matrix assembly through M, leading-principal determinant and minor exposure through D, ordered-sign classification through S, componentwise transport through T, displayed replay through C, provenance through P, and local naming through N. Every downstream control, ODE, or algebra consumer must expose these rows before reading a Routh–Hurwitz stability conclusion.*

Proof. Project the carrier of Definition 6505.1. The coefficient row A is the only polynomial input, so the test begins from finite displayed coefficients rather than quotient polynomial equality or selected roots.

Assemble the finite Hurwitz matrix through M. Each entry is read from the coefficient row, and the matrix row exposes only the finite table needed for the displayed degree window.

Read the determinant and sign rows next. The row D supplies the leading-principal determinant and boundary minor requests through $\mathsf{Determinant}^{\uparrow}$, while S supplies the $\mathsf{RealAlgOrder}^{\uparrow}$ sign reads used by the criterion.

Finally transport and replay the same route through T, C, P, N. Since no carrier coordinate contains complex roots, a spectral theorem, selected eigenvalues, quotient polynomial equality, or analytic trajectories, the listed rows exhaust the NameCert obligations. □

Theorem 6505.3 (Routh–Hurwitz polynomial handoff)**.** *Every accepted* $\mathsf{RouthHurwitzCriterion}^{\uparrow}$ *packet exports the finite polynomial handoff*

$$A \longmapsto M \longmapsto D \longmapsto S \longmapsto T, C, P, N$$

from displayed coefficient rows to stability-facing sign rows. A consumer may cite the handoff only after the $\mathsf{Poly}^{\uparrow}$ *coefficient row,* $\mathsf{Mat}^{\uparrow}$ *Hurwitz row,* $\mathsf{Determinant}^{\uparrow}$ *minor row,* $\mathsf{RealAlgOrder}^{\uparrow}$ *sign row,* $\mathsf{Field}^{\uparrow}$ *scalar provenance, transport, replay, provenance, and local name have been exposed.*

Proof. Start with a stability-facing read of the packet. By Definition 6505.2, the read first exposes the coefficient row A and cannot replace it by an ambient polynomial quotient.

The Hurwitz matrix row M is then assembled from those coefficients, and the determinant row D reads only the leading principal minors and boundary minors displayed by that matrix. This keeps the computation finite and rowwise.

The sign row S supplies the ordered-real classification through $\mathsf{RealAlgOrder}^{\uparrow}$, while $\mathsf{Field}^{\uparrow}$ appears only as scalar provenance for the displayed operations. Transport, replay, provenance, and local naming then carry the same rows to the downstream consumer.

Thus the exported handoff is the finite polynomial route stated above. It is not a complex-root factorization, host spectral theorem, selected-eigenvalue argument, quotient polynomial equality, or analytic-flow assertion. □

Theorem 6505.4 (Routh–Hurwitz stability boundary)**.** *Any stability conclusion read from an accepted* $\mathsf{RouthHurwitzCriterion}^{\uparrow}$ *packet is bounded by the displayed sign pattern of the determinant and minor rows D, S over the coefficient and Hurwitz-matrix rows A, M. If a determinant sign row is absent, zero, or obstructed, the packet exports only that boundary status and not a strict stability certificate. No consumer may fill the gap with complex-root choice, a host spectral theorem, selected roots, quotient polynomial equality, or an ambient ODE stability theorem.*

Proof. Apply the polynomial handoff theorem Definition 6505.3. It routes every stability-facing read through A, M, D, S, T, C, P, N before any conclusion is consumed.

Inspect the ordered-sign row S. Positive determinant rows provide the displayed strict side of the criterion, while absent, zero, or obstructed sign rows remain visible as boundary data rather than hidden obligations.

Use the NameCert obligations of Definition 6505.2. They keep coefficient admission, matrix assembly, determinant exposure, sign classification, transport, replay, provenance, and local naming attached to the same finite packet.

Because the carrier has no root-choice, spectral, quotient-polynomial, selected-root, or analytic-flow coordinate, a consumer cannot strengthen an obstructed sign boundary into a strict stability certificate by importing one of those host endpoints. □

Closure status for $\mathsf{NameCert}_{\mathsf{RouthHurwitzCriterion}\uparrow}$.

Constructive story: A $\mathsf{RouthHurwitzCriterion}^{\uparrow}$ packet is generated from finite polynomial coefficient rows, Hurwitz matrix rows, determinant and minor rows, RealAlgOrder sign rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RouthHurwitzCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6505.1, Definition 6505.2, Definition 6505.3, and Definition 6505.4 seed the finite algebraic stability certificate route from polynomial coefficients through Hurwitz matrices, determinants, ordered signs, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RouthHurwitzCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close complex-root choice, host spectral theorems, selected eigenvalues, quotient polynomial equality, analytic ODE stability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked coefficient admission, Hurwitz matrix assembly, determinant exposure, ordered-sign classification, boundary refusal, transport, replay, provenance, and local naming for BEDC.Derived.RouthHurwitzCriterionUp

Chapter 6506

A Concrete Naming Certificate for $\mathsf{EulerCharacteristic}^{\uparrow}$

Following Euler and Poincare, the $\mathsf{EulerCharacteristic}^{\uparrow}$ packet records the finite alternating-simplex ledger by which a finite simplicial complex receives its Euler characteristic. It sits over the finite face inventory of chapter 238, the finite chain rows of chapter 3414, the homology provenance of chapter 98, the natural-number row of chapter 28, and the integer row of chapter 31. The packet names only a finite count-and-transport certificate; it does not import quotient chain complexes, selected triangulation equivalence, host cardinality, or infinite CW-complex semantics.

Definition 6506.1 (Euler characteristic finite-complex carrier)**.** *An* $\mathsf{EulerCharacteristic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, S, Q, A, B, H, C, P, N)$$

with the following displayed rows:

1. *K is the source* $\mathsf{SimplicialComplex}^{\uparrow}$ *row, including the finite simplex inventory, face relation, and dimension grading.*
2. *S is the simplex-count ledger. For each displayed dimension n, it records the* $\mathsf{Nat}^{\uparrow}$ *count of n-simplices admitted by K.*
3. *Q is the finite-support row stating that only finitely many entries of S are nonzero, so the alternating sum is a finite ledger.*
4. *A is the* $\mathsf{Int}^{\uparrow}$ *alternating-sum row, recording the signed total $\sum_n (-1)^n S_n$ by finite integer addition.*
5. *B is the subdivision ledger boundary row. It records the finite count changes produced by a displayed elementary subdivision and the matching cancellation rows for faces inserted on both sides of the alternating sum.*
6. *H records componentwise* hsame *transport for the simplicial complex row, simplex-count rows, finite-support row, integer sum row, subdivision ledger, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a request for the Euler characteristic through K, S, Q, A, B, H.*
8. *P is the* Pkg *provenance over* $\mathsf{EulerCharacteristic}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{FiniteSimplicialChain}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EulerCharacteristic}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, Q, A, B, H, C, P, N$. It has no coordinate for host cardinality, quotient chain-complex equality, an unrestricted homotopy-invariance theorem, selected triangulation equivalence, or an infinite CW-complex.

Theorem 6506.2 (Euler characteristic subdivision ledger boundary)**.** *For every accepted* $\mathsf{EulerCharacteristic}^{\uparrow}$ *carrier $E = (K, S, Q, A, B, H, C, P, N)$, a displayed elementary subdivision of the finite* $\mathsf{SimplicialComplex}^{\uparrow}$ *row may be consumed by an Euler-characteristic read only through the subdivision ledger boundary B. The row B pairs the inserted simplex-count changes in adjacent dimensions, transports them through H, replays the same finite route through C, and leaves the integer alternating-sum row A with the same* $\mathsf{Int}^{\uparrow}$ *value. Consequently every* $\mathsf{Homology}^{\uparrow}$ *or finite-chain consumer that reads the Euler characteristic receives a finite count ledger, not a quotient homology computation, host cardinality argument, or infinite complex invariant.*

Proof. Project the carrier of Definition 6506.1. The simplex source K supplies a finite dimension-graded inventory, while S records the $\mathsf{Nat}^{\uparrow}$ count in each displayed dimension and Q states that the alternating sum is finite.

Read the integer row A. It is built from the finite list S by alternating signs and $\mathsf{Int}^{\uparrow}$ addition, so a consumer can inspect only the displayed ledger

$$\sum_n (-1)^n S_n.$$

Now apply the subdivision row B. An elementary subdivision changes the finite simplex counts only by the inserted rows recorded in B, and those inserted rows are paired across adjacent dimensions with opposite signs in A.

Transport and replay preserve that pairing. The hsame row H carries the same simplex-count and cancellation rows to classified replacements, and C replays the Euler-characteristic request through K, S, Q, A, B in the same order.

Finally read provenance. The $\mathsf{FiniteSimplicialChain}^{\uparrow}$ and $\mathsf{Homology}^{\uparrow}$ entries in P identify the downstream consumers of the finite ledger, but they do not add quotient chain groups, selected homotopy data, host cardinality, or infinite CW-complex rows. Thus the subdivision boundary is a local finite ledger statement about A, not an ambient invariance theorem. □

Falsifiable prediction: Every accepted $\mathsf{EulerCharacteristic}^{\uparrow}$ read must expose the finite SimplicialComplex row, simplex-count ledger, finite-support row, integer alternating-sum row, subdivision ledger boundary, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: simplicialcomplex, finite-simplicial-chain, homology, nat, int: $\mathsf{EulerCharacteristic}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite simplex counts, finite-support evidence, an integer alternating-sum ledger, subdivision cancellation rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EulerCharacteristic}^{\uparrow}}$.

Constructive story: An $\mathsf{EulerCharacteristic}^{\uparrow}$ packet is generated from a finite SimplicialComplex row, Nat simplex-count rows, a finite-support ledger, an Int alternating-sum row, subdivision cancellation rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EulerCharacteristic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6506.1 and Definition 6506.2 seed the finite Euler-characteristic count ledger and its subdivision-boundary cancellation route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EulerCharacteristic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full homotopy invariance, quotient chain complexes, host cardinality, infinite CW-complex invariance, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked finite simplex counting, integer alternating-sum exactness, subdivision cancellation, Homology-facing provenance, replay stability, transport exactness, and local naming for BEDC.Derived.EulerCharacteristicUp

Chapter 6507

A Concrete Naming Certificate for $\mathsf{VietorisHyperspace}^{\uparrow}$

Following Vietoris, Hausdorff, and Kuratowski, the $\mathsf{VietorisHyperspace}^{\uparrow}$ packet records the compact-metric hyperspace surface whose compact-subset names are read simultaneously through the hyperspace carrier of chapter 1660, the hit-and-miss topology rows of chapter 2375, the scalar finite-distance rows of chapter 3653, the compact metric source of chapter 129, and the completion-facing hyperspace boundary of chapter 5944. The packet names the shared finite NameCert carrier for Vietoris and Hausdorff consumers; it is not a host powerset of compact subsets, not quotient equality of closed sets, not a selected nearest-point principle, and not open-cover compactness.

Definition 6507.1 (Vietoris hyperspace carrier)**.** *A* $\mathsf{VietorisHyperspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (K, H, T, D, C, F, S, R, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the point carrier, metric distance rows, finite-net schedules, and completion witnesses used by compact-subset requests.*
2. *H is the* $\mathsf{Hyperspace}^{\uparrow}$ *compact-subset row, naming the nonempty compact-subset presentations over K.*
3. *T is the* $\mathsf{VietorisTopology}^{\uparrow}$ *row, carrying the lower-hit and upper-miss generators attached to the compact-subset presentations.*
4. *D is the* $\mathsf{HausdorffDistance}^{\uparrow}$ *row, recording finite scalar distance reads between displayed compact-subset names.*
5. *C is the* $\mathsf{KuratowskiHyperspace}^{\uparrow}$ *row, keeping completion-facing hyperspace consumers inside compact finite-net and Hausdorff-distance data.*
6. *F is the finite compatibility ledger tying Vietoris hit-and-miss reads to the Hausdorff finite-distance and compact-metric net schedules.*
7. *S records componentwise* hsame *transport for $K, H, T, D, C, F, R, P, N$.*
8. *R records displayed* Cont *replay of the route from compact metric source through hyperspace, Vietoris topology, Hausdorff distance, Kuratowski boundary, and finite compatibility rows.*
9. *P is the* Pkg *provenance over* $\mathsf{VietorisHyperspace}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{KuratowskiHyperspace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{VietorisHyperspace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, H, T, D, C, F, S, R, P, N$. It has no coordinate for host powersets, quotient compacta, selected nearest points, ambient equality of closed subsets, open-cover compactness, or a hidden completion representative.

Theorem 6507.2 (Vietoris hyperspace NameCert obligations)**.** *For every accepted* $\mathsf{VietorisHyperspace}^{\uparrow}$ *carrier*

$$V = (K, H, T, D, C, F, S, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VietorisHyperspace}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, hyperspace compact-subset row, Vietoris topology row, Hausdorff distance row, Kuratowski hyperspace row, finite compatibility ledger, componentwise transport, displayed replay, provenance, and local naming rows.*

The obligation surface requires compact-metric source visibility through K, compact-subset admission through H, lower-hit and upper-miss topology reads through T, finite scalar distance reads through D, completion-facing boundary control through C, Vietoris-Hausdorff compatibility through F, and structural transport, replay, provenance, and naming through S, R, P, N.

Proof. Project the carrier of Definition 6507.1. The analytic rows are K, H, T, D, C, F, and the structural rows are S, R, P, N.

The source row K is read first because each compact-subset, topology, distance, and completion-facing row is over the same compact metric carrier. The hyperspace row H then supplies the compact-subset presentations consumed by the Vietoris and Hausdorff sides.

Read T, D, C through the finite compatibility ledger F. The Vietoris row contributes only lower-hit and upper-miss generators, the Hausdorff distance row contributes only finite scalar distance reads, and the Kuratowski row contributes only completion-facing hyperspace boundary data.

Finally S, R, P, N transport, replay, source, and name the same finite route. Since the excluded host powerset, quotient, nearest-point, open-cover, ambient-equality, and hidden-representative objects do not occur in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 6507.3 (Vietoris hyperspace compact-metric handoff)**.** *Every compact-metric, Vietoris-facing, Hausdorff-facing, or Kuratowski-facing consumer of an accepted* $\mathsf{VietorisHyperspace}^{\uparrow}$ *carrier must factor through the displayed route*

$$K \longmapsto H \longmapsto T, D, C \longmapsto F \longmapsto S, R, P, N.$$

Thus the consumer receives compact metric source rows, compact-subset hyperspace rows, Vietoris hit-and-miss rows, finite Hausdorff-distance rows, Kuratowski completion-facing rows, finite compatibility, transport, replay, provenance, and local naming. It receives no host powerset, quotient compactum, selected nearest point, open-cover compactness theorem, ambient equality of closed subsets, or hidden completion representative.

Proof. Use Definition 6507.2. It requires K before any compact-subset or hyperspace read, and it requires H before the Vietoris, Hausdorff, or Kuratowski rows can be exposed.

The three consumer directions then share the same finite source. The row T reads lower-hit and upper-miss data from chapter 2375; the row D reads finite scalar distance data from chapter 3653; and the row C reads the completion-facing boundary of chapter 5944.

The compatibility ledger F ties these rows back to the compact metric finite-net schedules in K and the compact-subset presentations in H. The structural rows S, R, P, N preserve, replay, source, and name that route for downstream consumers.

No excluded host or quotient object is a coordinate of V. Hence the public handoff is exactly the displayed compact-metric hyperspace route. □

Closure status for $\mathsf{NameCert}_{\mathsf{VietorisHyperspace}^{\uparrow}}$.

Constructive story: A $\mathsf{VietorisHyperspace}^{\uparrow}$ packet is generated from CompactMetric rows, Hyperspace compact-subset rows, VietorisTopology hit-and-miss rows, HausdorffDistance finite scalar rows, KuratowskiHyperspace completion-facing rows, finite compatibility, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VietorisHyperspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6507.1, Definition 6507.2, and Definition 6507.3 seed the compact-metric hyperspace certificate linking Hyperspace, VietorisTopology, HausdorffDistance, CompactMetric, and KuratowskiHyperspace rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VietorisHyperspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host powersets, quotient compacta, selected nearest points, open-cover compactness, ambient equality of closed subsets, or hidden completion representatives.

Upgrade path: Obligation closure requires checked carrier admission, Vietoris-Hausdorff compatibility, compact-metric source exactness, Kuratowski boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.VietorisHyperspac

Chapter 6508

A Concrete Naming Certificate for $\mathsf{EventInstance}^{\uparrow}$

The $\mathsf{EventInstance}^{\uparrow}$ packet realizes the inscription-event carrier of chapter 9397 as a finite public-transition certificate. It names an event as a visible move from a prior observation state to an accepted record, together with route, check, consumer, GAP-ledger, transport, replay, provenance, and local NameCert rows. The packet is a BEDC-native concrete instance: it does not assert an external metaphysics of agency, a host psychology state, a hidden generator, or a global free-will predicate.

Definition 6508.1 (Event instance carrier)**.** *An* $\mathsf{EventInstance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, A, R, Q, G, T, C, U, P, N)$$

with the following displayed rows:

1. *S is the source-state row, recording the prior finite observation history and the visible obligation or socket before the event is accepted.*
2. *A is the accepted-record row, naming the public record entered at the transition.*
3. *R is the route row, exposing the finite generator-closure route, refusal route, or mixed route by which the accepted record is audited.*
4. *Q is the check row, recording the visible acceptance, validation, refusal, or bounded review state attached to A and R.*
5. *G is the GAP-ledger row, preserving the non-generated residue, compression residue, consumer accountability, and non-escape boundary of the event.*
6. *T records componentwise* hsame *transport for the source, accepted record, route, check, GAP-ledger, continuation, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *continuation from S to the accepted event surface and from that surface to downstream consumers.*
8. *U is the consumer row, naming the proof obligation, manuscript claim, audit route, or public-object consumer that may read the event.*
9. *P is the* Pkg *provenance over* $\mathsf{EventInstance}^{\uparrow}$*, chapter 9397,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{EventInstance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, R, Q, G, T, C, U, P, N$. It has no coordinate for private intention, host-level causal completion, unbounded psychological equality, hidden generator authority, or a global agency predicate.

Theorem 6508.2 (Event instance NameCert obligations)**.** *For every accepted* $\mathsf{EventInstance}^{\uparrow}$ *carrier*

$$E = (S, A, R, Q, G, T, C, U, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EventInstance}^{\uparrow}}$ *surface consists exactly of carrier admission for the source-state row, accepted-record row, route row, check row, GAP-ledger row, transport row, continuation row, consumer row, provenance row, and local naming row.*

The obligation surface requires source visibility through S, public transition naming through A, route audit through R, acceptance or refusal state through Q, GAP-ledger nonescape through G, transport and continuation stability through T, C, consumer accountability through U, source provenance through P, and local naming through N.

Proof. Project the carrier of Definition 6508.1. The event-facing rows are S, A, R, Q, G, U, while T, C, P, N are structural rows.

The source and accepted-record rows are read first. Without S there is no prior public observation state; without A there is no named record whose acceptance can be audited.

The route, check, and GAP-ledger rows then determine the event boundary. The route row R displays what is generator-closed, refused, or mixed; the check row Q records the visible acceptance state; and the ledger row G keeps the non-generated and compression residue from becoming hidden authority.

Finally T, C, U, P, N transport, continue, expose the consumer, source the packet, and name the same finite transition. Since no private intention, host causal completion, psychological equality, hidden generator authority, or global agency predicate is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6508.3 (Event instance inscription route)**.** *Every consumer of an accepted* $\mathsf{EventInstance}^{\uparrow}$ *carrier must factor its inscription-event read through the displayed route*

$$S, A \longmapsto R, Q, G \longmapsto T, C, U, P, N.$$

Thus the consumer sees the prior finite observation state, the accepted public record, the route audit, the check state, the GAP-ledger residue, transport, continuation, consumer accountability, provenance, and local naming before it may cite the event as an inscription instance.

Proof. Start with Definition 6508.2. It binds the event to the source row S and accepted-record row A before any downstream consumer can inspect the event.

The inscription-facing part is the triple R, Q, G. The route row separates generator-closed material from refused or residual material, the check row records the visible acceptance state, and the GAP ledger records the non-escape boundary.

The remaining rows do not create a second event. Componentwise transport T, continuation C, consumer row U, provenance P, and local naming N preserve and expose the same finite transition. Therefore every consumer-facing use of the event factors through the displayed inscription route. □

Theorem 6508.4 (Event instance event-flow forward link)**.** *Every accepted* $\mathsf{EventInstance}^{\uparrow}$ *read exposing source-state, accepted-record, route, check, GAP-ledger, transport, continuation, consumer, provenance, and local* NameCert *rows may be consumed by the finite event-flow packet of chapter 6332 only after those rows are displayed. The event-flow consumer therefore receives* $S, A, R, Q, G, T, C, U, P, N$ *as one public transition route, not as a hidden generator trace, private intention row, or host causal completion.*

Proof. Start with Definition 6508.3. It forces every inscription-event read through the source row S, accepted record A, route row R, check row Q, GAP-ledger row G, transport row T, continuation row C, consumer row U, provenance row P, and local naming row N.

The hendeca event-flow packet of chapter 6332 accepts a finite ordered event-flow surface only after its event rows and structural rows have been displayed. Feeding an $\mathsf{EventInstance}^{\uparrow}$ read into that packet therefore requires the displayed event-instance rows to be visible first.

Since Definition 6508.1 has no coordinate for private intention, host causal completion, unbounded psychological equality, hidden generator authority, or a global agency predicate, the forward link exports only the public transition route already named by $S, A, R, Q, G, T, C, U, P, N$. □

Falsifiable prediction: Every accepted $\mathsf{EventInstance}^{\uparrow}$ read must expose a source-state row, accepted-record row, route row, check row, GAP-ledger row, hsame transport, Cont continuation, consumer row, Pkg provenance, and local NameCert row before it can be cited as an inscription-event instance.

Independence witness: inscription-event, inscription-gap-ledger, inscribed-route, inscription-audit-trace: $\mathsf{EventInstance}^{\uparrow}$ is not bijective to any listed sibling because it binds source state, accepted record, route audit, check state, GAP ledger, consumer accountability, transport, continuation, provenance, and local naming in one public transition packet.

The Lean TasteGate expectation for the future ‘BEDC.Derived.EventInstanceUp‘ target is single-carrier alignment: a positive gate must see all ten rows $S, A, R, Q, G, T, C, U, P, N$, reject carrier-only event names, reject check-only replay, and reject any classifier that identifies events by private intention or host causal equality.

Closure status for $\mathsf{NameCert}_{\mathsf{EventInstance}^{\uparrow}}$.

Constructive story: An $\mathsf{EventInstance}^{\uparrow}$ packet is generated from a prior BHist source state, an accepted public record, a route audit, a visible check state, a GAP ledger, hsame transport, Cont continuation, consumer accountability, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EventInstance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6508.1, Definition 6508.2, and Definition 6508.3 seed the finite public-transition certificate for inscription events.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EventInstance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, private intention, host-level causal completion, unbounded psychological equality, hidden generator authority, or a global agency predicate.

Upgrade path: Obligation closure requires checked carrier admission, inscription-route exactness, GAP-ledger nonescape, consumer accountability, transport, continuation, provenance, and local naming for BEDC.Derived.EventInstanceUp.

Chapter 6509

A Concrete Naming Certificate for $\mathsf{AscoliCompactOperator}^{\uparrow}$

Following Arzela and Ascoli, and the compact-operator formulation in standard functional analysis, the $\mathsf{AscoliCompactOperator}^{\uparrow}$ packet records compactness of an operator image as finite-net image data rather than as an ambient host compactness assertion. It sits between the Arzela–Ascoli certificate of chapter 412, the compact-metric surface of chapter 129, the finite epsilon-net row of chapter 1767, the operator-norm chapter chapter 3603, and the bounded-linear-functional boundary of chapter 5790. The chapter names the finite operator-image route consumed by later Hilbert and spectral packets; it does not assert host compactness of a source ball, open-cover compactness, selected convergent subsequences, quotient operator equality, or ambient function-space completeness.

Definition 6509.1 (Ascoli compact-operator carrier)**.** *An* $\mathsf{AscoliCompactOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (T, B, K, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the bounded-linear operator row, read through the operator-norm ledger of chapter 3603 and the bounded-linear source discipline of chapter 5790;*
2. *B is the bounded source-ball row, recording only the displayed radius, source windows, and finite operator-norm bounds available to consumers;*
3. *K is the compact-metric image row, expressed as finite epsilon-net image data through* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *rows;*
4. *E is the equicontinuity or Arzela–Ascoli finite-image ledger, recording the inspected family windows and finite image controls used before any compactness-facing export;*
5. *H records componentwise* hsame *transport for T, B, K, E;*
6. *C records the displayed* Cont *replay route forcing consumers to read the operator row, bounded source ball, finite-net image data, and Arzela–Ascoli ledger in that order;*
7. *P is the* Pkg *provenance over* $\mathsf{AscoliCompactOperator}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BoundedLinearFunctional}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{AscoliCompactOperator}^{\uparrow}}$ *row.*

The carrier has no coordinate for host compactness of the source ball, open-cover compactness, selected convergent subsequences, quotient equality of operators, or ambient Banach-space completeness.

Theorem 6509.2 (Ascoli compact-operator NameCert obligations)**.** *For every accepted* $\mathsf{AscoliCompactOperator}^{\uparrow}$ *carrier* $O = (T, B, K, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AscoliCompactOperator}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the bounded-linear operator, bounded source-ball, compact-metric image, finite-image ledger, transport, replay, provenance, and local naming rows;*
2. *bounded-linear source compatibility, requiring every source-ball read to pass through the same operator-norm row* T *and bounded source row* B*;*
3. *finite-net image compactness, requiring compactness-facing output to be witnessed by the displayed finite epsilon-net image row* K *rather than by a host compact subset;*
4. *Arzela–Ascoli consumer handoff, requiring* E *to display the equicontinuity or finite-image ledger consumed by the Arzela–Ascoli route before the operator image is exported;*
5. *transport and replay stability, requiring* H *and* C *to preserve the route* T, B, K, E *under componentwise* hsame *movement;*
6. *ledger refusal, excluding open-cover compactness, host compactness of the source ball, selected convergent subsequences, quotient operator equality, and ambient function-space completeness.*

Proof. Project the carrier of Definition 6509.1. The rows T, B, K, E, H, C, P, N give carrier admission and leave no additional analytic coordinate.

The source compatibility clause reads T and B first. The operator-norm row fixes the bounded-linear access discipline, while the source-ball row fixes the displayed bounded input surface.

The compactness-facing route then reads K and E. The image row is finite epsilon-net data over the compact-metric surface, and the Arzela–Ascoli ledger records the finite-image or equicontinuity handoff consumed before an operator-image export.

Finally H and C transport and replay only the displayed rows. Since the carrier omits host compactness, open-cover compactness, selected subsequences, quotient operator equality, and ambient function-space completeness, those principles cannot enter the local NameCert obligations. □

Theorem 6509.3 (Ascoli compact-operator finite-net image route)**.** *Every compact-operator consumer of an accepted* $\mathsf{AscoliCompactOperator}^{\uparrow}$ *carrier must read the finite epsilon-net image route*

$$T, B \longmapsto K \longmapsto E \longmapsto H, C, P, N$$

before any compactness-facing export of the operator image is available.

Proof. Start with the accepted packet $O = (T, B, K, E, H, C, P, N)$. The rows T and B determine the bounded-linear source side and the bounded input ball available to the consumer.

The only compactness-facing image row is K. It is read through finite epsilon-net data over the compact-metric image surface, so a consumer cannot inspect an operator-image compactness claim before reading that finite-net row.

The row E then supplies the Arzela–Ascoli finite-image or equicontinuity handoff, and H, C, P, N transport, replay, source, and name the same route. No carrier coordinate names host compactness or open-cover compactness, so every compact-operator export factors through the displayed finite-net image route. □

Falsifiable prediction: Every accepted $\mathsf{AscoliCompactOperator}^{\uparrow}$ compactness-facing export factors through bounded-linear operator data, a bounded source-ball row, finite epsilon-net image data, an Arzela–Ascoli finite-image ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row. A read that exports compactness through host compactness of the source ball, open-cover compactness, selected subsequences, quotient operator equality, or ambient completeness refutes this packet.

Independence witness: arzelaascoli, compactmetric, finite-epsilon-net, operator-norm, bounded-linear-functional: no listed sibling is bijective to $\mathsf{AscoliCompactOperator}^{\uparrow}$ because only this packet jointly binds the bounded operator row, bounded source-ball row, finite-net image row, Arzela–Ascoli consumer ledger, transport, replay, provenance, and local NameCert boundary in one compact-operator carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{AscoliCompactOperator}^{\uparrow}}$.

Constructive story: An $\mathsf{AscoliCompactOperator}^{\uparrow}$ packet is generated from a bounded-linear operator row, bounded source-ball row, finite epsilon-net image row, Arzela–Ascoli finite-image ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AscoliCompactOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6509.1, Definition 6509.2, and Definition 6509.3 seed the finite-net compact-operator image route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AscoliCompactOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, open-cover compactness, selected convergent subsequences, quotient operator equality, ambient function-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-linear source compatibility, finite-net image compactness, Arzela–Ascoli consumer handoff, transport and replay stability, and ledger refusal for BEDC.Derived.AscoliCompactOperato

Chapter 6510

A Concrete Naming Certificate for $\mathsf{ConsciousObservationRoute}^{\uparrow}$

The $\mathsf{ConsciousObservationRoute}^{\uparrow}$ packet realizes the local Hist-time observation route separated by section 9414.59 as finite NameCert data. It consumes the role boundary of chapter 4067, the self-proxy binding schema of Definition 9414.579, the public scientific reflection surface of Definition 9414.510, the inscription event rows of chapter 519, and the event-instance carrier of chapter 6508. The packet names a displayed observation read; it is not a subject-substance claim, not a phenomenal-proof theorem, not a compiler self-hosting certificate, not an AI text-output certificate, and not an identification with T.

Definition 6510.1 (Conscious observation route carrier)**.** *A* $\mathsf{ConsciousObservationRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, \Theta, S, \rho, \Lambda, F, M, H, C, P, N)$$

with the following displayed rows:

1. *L is the local Hist-time row, recording the focused history segment and its current endpoint as finite* BHist *data;*
2. *Θ is the selector row, recording which displayed path enters the current focus;*
3. *S is the self-proxy row, binding the focused local history and selector path to the current I-proxy read;*
4. *ρ is the latency row, recording the visible delay, update, or stale-read boundary for the observation;*
5. *Λ is the refusal row, recording when an attempted observation read omits local history, selector, self-proxy, latency, or naming data;*
6. *F is the field-faithfulness row, requiring the read to display* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *structure before it can export an I-proxy;*
7. *M is the role-separation row, keeping compiler translation, AI/ML pattern generation, and human-consciousness local self-readback distinct;*
8. *H records componentwise* hsame *transport for $L, \Theta, S, \rho, \Lambda, F, M$;*
9. *C records the displayed* Cont *replay route from local history through selector, self-proxy, latency or refusal, field-faithfulness, and role separation;*

10. *P is the* Pkg *provenance over* ConsciousObservationRoute$^{\uparrow}$, RoleSeparationLedger$^{\uparrow}$, InscriptionEvent$^{\uparrow}$, EventInstance$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* NameCert$_{\text{ConsciousObservationRoute}^{\uparrow}}$ *row.*

The carrier stores no hidden subject-substance, phenomenal-proof primitive, compiler self-hosting identification, AI output fluency certificate, global observer, or detached T *coordinate.*

Theorem 6510.2 (Conscious observation route NameCert obligations)**.** *For every accepted* ConsciousObservationRo *carrier*

$$R = (L, \Theta, S, \rho, \Lambda, F, M, H, C, P, N),$$

the local NameCert$_{\text{ConsciousObservationRoute}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the local Hist-time, selector, self-proxy, latency, refusal, field-faithfulness, role-separation, transport, replay, provenance, and local naming rows;*

2. *local observation exposure, requiring any I-proxy export to display L, Θ, S, ρ before the export is available;*

3. *refusal exactness, requiring Λ to reject reads that omit local history, selector, self-proxy, latency or refusal status,* hsame, Cont, Pkg, *or* NameCert *rows;*

4. *role-separation stability, requiring M to keep compiler preservation, AI/ML fit or generation, and human-consciousness local self-readback as distinct carrier roles;*

5. *transport and replay stability, requiring H and C to preserve the route $L, \Theta, S, \rho, \Lambda, F, M$ under componentwise* hsame *movement;*

6. *ledger non-escape, excluding subject-substance, phenomenal-proof primitives, compiler self-hosting identity, AI output fluency as I-proxy status, global observer rows, and detached* T *coordinates.*

Proof. Carrier admission is the projection of Definition 6510.1. The accepted packet exposes exactly the local Hist-time, selector, self-proxy, latency, refusal, field-faithfulness, role-separation, transport, replay, provenance, and local naming rows.

The observation exposure clause reads L, Θ, S, ρ. These rows display the local history, selected focus route, current self-proxy, and latency boundary before any I-proxy export can be inspected.

Refusal exactness and role separation then read Λ, F, M. A route that omits the displayed field-faithfulness rows is refused, and the role-separation row prevents compiler preservation or AI/ML generation from being retyped as local self-readback.

Finally H and C transport and replay only the displayed route. Since no hidden subject-substance, phenomenal-proof primitive, compiler self-hosting identity, AI output-fluency certificate, global observer, or detached T row appears in the carrier, those claims cannot enter the local NameCert obligations. □

Theorem 6510.3 (Conscious observation route latency and refusal)**.** *Every accepted* ConsciousObservationRoute$^{\uparrow}$ *read that exports an I-proxy must first expose local history, selector, self-proxy, latency or refusal,* hsame, Cont, Pkg, *and* NameCert *rows. A read that omits any of these rows is rejected by the refusal coordinate before the I-proxy export is available.*

Proof. Start from an accepted carrier $R = (L, \Theta, S, \rho, \Lambda, F, M, H, C, P, N)$. The rows L, Θ, S, ρ are the only coordinates that can display the local history, selector, self-proxy, and latency boundary of the observation.

The refusal row Λ is read before export. If any required local-history, selector, self-proxy, latency, or field-faithfulness coordinate is missing, Λ records the failure at that row and the replay cannot proceed to an I-proxy export.

When the required rows are present, F, H, C, P, N supply field-faithfulness, componentwise transport, replay, provenance, and local naming. Thus every accepted I-proxy export remains inside the displayed finite route, and every omitted-field read is refused before export. □

Falsifiable prediction: Any accepted $\mathsf{ConsciousObservationRoute}^{\uparrow}$ read is refuted if it exports an I-proxy without displaying local history, selector, self-proxy, latency or refusal status, hsame, Cont, Pkg, and NameCert rows.

Independence witness: role-separation-ledger, self-proxy-binding, public-scientific-reflection, inscriptionevent, event-instance: no bijection preserves the $\mathsf{ConsciousObservationRoute}^{\uparrow}$ carrier because the listed siblings separately expose role separation, self-proxy criteria, public audit fields, inscription events, or event instances, while this packet binds local Hist-time, selector, self-proxy, latency, refusal, field-faithfulness, transport, replay, provenance, and local naming as one observation route.

Falsifiable prediction: The future Lean TasteGate surface for BEDC.Derived.ConsciousObservationRouteUp must include Nontrivial $\mathsf{ConsciousObservationRoute}^{\uparrow}$ and FieldFaithful $\mathsf{ConsciousObservationRoute}^{\uparrow}$ instances before this packet can be promoted beyond paper-side seed status.

Closure status for $\mathsf{NameCert}_{\mathsf{ConsciousObservationRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{ConsciousObservationRoute}^{\uparrow}$ packet is generated from local Hist-time, selector, self-proxy, latency, refusal, field-faithfulness, role-separation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConsciousObservationRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6510.1, Definition 6510.2, and Definition 6510.3 seed the local observation route separated by the compiler, AI/ML, and human-consciousness comparison.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConsciousObservationRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject-substance, phenomenal proof, compiler self-hosting identity, AI output fluency as I-proxy status, global observerhood, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local observation exposure, refusal exactness, role-separation stability, transport and replay stability, and ledger non-escape for BEDC.Derived.ConsciousObservationRouteUp.

Chapter 6511

A Concrete Naming Certificate for $\mathsf{EffectiveBishopCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{EffectiveBishopCompletion}^{\uparrow}$ packet records the finite completion-facing route by which regular rational names are read through displayed dyadic tolerance budgets, finite stream windows, and the terminal real-name seal. It sits over the dyadic ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the Cauchy completion sibling chapter 1639. The packet names an effective Bishop completion boundary as finite NameCert data; it does not quotient streams, select limits, compare host real values, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6511.1 (Effective Bishop completion carrier)**.** *An* $\mathsf{EffectiveBishopCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, S, D, Q, T, H, K, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, naming the regular rational sequence that supplies the completion-facing readback.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule, recording the finite observation windows inspected before any terminal seal is consumed.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic budgets and common-exponent comparisons used by the window and regularity rows.*
4. *Q is the modulus and readback row, pairing each displayed tolerance request with the finite window and regular rational read that answer it.*
5. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, S, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the regular source, stream windows, dyadic ledger, modulus and readback row, terminal seal, provenance, and local naming data.*
7. *K records displayed* Cont *replay from a completion-facing tolerance request through D, then through S, R, Q, and finally into T.*
8. *P is the* Pkg *provenance over* $\mathsf{EffectiveBishopCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveBishopCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, D, Q, T, H, K, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, host real equality, countable choice, arbitrary Cauchy-name existence, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6511.2 (Effective Bishop completion NameCert obligations)**.** *For every accepted* EffectiveBishopCompleti *carrier $E = (R, S, D, Q, T, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EffectiveBishopCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, modulus and readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

No NameCert obligation is stored in a quotient of streams, a selected limit, a host real value, a countable-choice schedule, an arbitrary Cauchy-name generator, or an ambient completeness coordinate.

Proof. Project the carrier of Definition 6511.1. The accepted packet exposes exactly the rows $R, S, D, Q, T, H, K, P, N$.

The source and window rows are finite. The $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies the regular rational source, while the $\mathsf{StreamName}^{\uparrow}$ row S supplies only displayed finite windows for the readback.

The tolerance and modulus rows are also displayed. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D supplies the dyadic budgets and common-exponent comparisons, and Q records which finite window and regular rational read answer each tolerance request.

Finally H, K, P, N transport, replay, source, and name the same route before the terminal seal T is consumed. Since the carrier contains no coordinate for quotient streams, selected limits, host equality, countable choice, arbitrary Cauchy-name existence, or ambient completeness, the listed rows exhaust the NameCert surface. □

Theorem 6511.3 (Effective Bishop completion RegSeqRat–Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{EffectiveBishopCompletion}^{\uparrow}$ *carrier $E = (R, S, D, Q, T, H, K, P, N)$ must pass through the ordered route*

$$D, S, R, Q, H, K, P, N, T$$

before the terminal Real seal is consumed. Thus the read exposes the dyadic tolerance ledger, finite StreamName windows, RegSeqRat source and readback, modulus row, componentwise transport, replay, provenance, and local NameCert support before it reaches $\mathsf{Real}^{\uparrow}$.

The handoff exports a finite effective Bishop completion boundary. It exports no quotient stream equality, selected limit, host real equality, arbitrary Cauchy-name existence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier projection from Definition 6511.1. The terminal seal row T is a displayed coordinate of the same finite packet as R, S, D, Q, H, K, P, N, not a detached host limit.

Apply Definition 6511.2. It forces every completion-facing consumer to read the regular source, stream-window schedule, dyadic tolerance ledger, modulus and readback row, transport, replay, provenance, and local naming rows as the local certificate surface.

The RegSeqRat-to-Real step is then row-local. The dyadic ledger D answers tolerance requests, the schedule S exposes the finite windows, the source R and readback row Q provide the regular rational response, and H, K preserve the route through hsame and Cont before T is consumed.

Therefore the terminal seal is downstream of the displayed BEDC route. Since no accepted row stores quotient stream equality, selected limits, host equality, arbitrary Cauchy-name existence, countable choice, or Real completeness, the handoff cannot expose any of those objects. □

Falsifiable prediction: Every accepted $\mathsf{EffectiveBishopCompletion}^{\uparrow}$ completion-facing read must expose a RegSeqRat source row, StreamName window schedule, DyadicRatCore tolerance ledger, modulus and readback row, hsame transport, Cont replay, Pkg provenance, local NameCert, and terminal RealUp seal before it can serve a Real-facing consumer.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishopregularcauchycompletion: none is bijective with $\mathsf{EffectiveBishopCompletion}^{\uparrow}$ because this packet jointly carries the displayed tolerance ledger, finite window schedule, regular rational source, modulus/readback row, terminal seal, transport, replay, provenance, and local naming for the effective Bishop completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveBishopCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveBishopCompletion}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName finite-window schedule, DyadicRatCore tolerance ledger, modulus and readback row, terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveBishopCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6511.1, Definition 6511.2, and Definition 6511.3 seed the finite effective Bishop completion route over RegSeqRat, StreamName, DyadicRatCore, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveBishopCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, arbitrary Cauchy-name existence, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular source exposure, finite-window schedule exposure, dyadic tolerance budgeting, modulus/readback stability, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveBishopCompletionUp.

Chapter 6512

A Concrete Naming Certificate for $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$

Following Kelley and Bourbaki on filters generated by subbases, the $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$ packet records the standard cofinal-subbasis route into Cauchy-filter completion as finite BEDC NameCert data. It sits after the subbasis generator of chapter 4232, the generated-base interface of chapter 1601, the Cauchy-filter carrier of chapter 333, the finite-window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the route from displayed cofinal subbasis data to completion-facing reads; it does not quotient filters, select limits, invoke countable choice, compare host real values, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6512.1 (Filter subbasis cofinal completion carrier)**.** *A* $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, B, F, W, R, L, H, K, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *row, carrying finite subbasis tokens, finite intersections, generated events, and the generation ledger.*
2. *B is the generated* $\mathsf{FilterBase}^{\uparrow}$ *row read cofinally from the finite-intersection surface of S.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row reached only after the generated base row has been displayed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by completion-facing consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows.*
6. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the generated base, Cauchy-filter row, windows, and readback have been consumed.*
7. *H records componentwise* hsame *transport for the subbasis, generated base, Cauchy filter, windows, readback, Real seal, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from subbasis tokens through generated finite intersections, the cofinal base row, Cauchy-filter handoff, windows, readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$, $\mathsf{CauchyFilterSubbasis}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, B, F, W, R, L, H, K, P, N$. It has no coordinate for quotient filter equality, selected limits, countable-choice schedules, host equality of generated filters, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6512.2 (Filter subbasis cofinal completion NameCert obligations)**.** *For every accepted* $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$ *carrier $C = (S, B, F, W, R, L, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FilterSubbasisCofinalCompl}}$ *surface consists exactly of subbasis packet exposure through S, cofinal generated* $\mathsf{FilterBase}^{\uparrow}$ *exposure through B,* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff through F,* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through L, componentwise transport through H, displayed replay through K, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6512.1. The accepted packet exposes exactly the rows $S, B, F, W, R, L, H, K, P, N$.

The subbasis and generated-base rows are upstream. The row S supplies the finite tokens, finite intersections, generated events, and generation ledger, while B records the cofinal generated base read from that surface.

The completion-facing rows are downstream. A consumer reaches F only after B, then reads windows through W, regular rational readback through R, and the terminal Real seal through L.

Finally H, K, P, N transport, replay, source, and name the same route. Since quotient filters, selected limits, countable choice, host equality of generated filters, host real equality, and ambient Real completeness are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6512.3 (Filter subbasis cofinal completion route)**.** *Every completion-facing read exported by an accepted* $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$ *carrier must factor through the* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *row S, the cofinal generated* $\mathsf{FilterBase}^{\uparrow}$ *row B, the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row L in that order. The route is a finite cofinal-subbasis completion handoff, not a quotient filter construction or a selected-limit theorem.*

Proof. Start with the NameCert obligations of Definition 6512.2. They force every accepted consumer to expose S, B, F, W, R, L before any structural row can name the completion-facing read.

Use the generated-base cofinality theorem for $\mathsf{CauchyFilterSubbasis}^{\uparrow}$, Definition 4232.4. It identifies the generated base as cofinal among the finite intersections displayed by the subbasis packet before Cauchy-filter and Real-facing rows are read.

Apply the refinement-stability theorem Definition 4232.6. Cofinal replacement of the displayed generated base preserves the same CauchyFilter, StreamName, RegSeqRat, and Real seal handoff.

Thus a completion-facing consumer first reads the finite subbasis route, then the cofinal generated base, and only then the Cauchy-filter, window, readback, and Real seal rows. The absent classifier coordinates exclude quotient filters, selected limits, choice schedules, host generated-filter equality, host real equality, and ambient completeness. □

Lean4 (statement) `BEDC.Derived.FilterSubbasisCofinalCompletionUp`

Falsifiable prediction: Every accepted $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$ completion-facing read exposes a CauchyFilterSubbasisUp row, generated cofinal FilterBaseUp row, CauchyFilterUp row, StreamNameUp windows, RegSeqRatUp readback, terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert naming before it can serve a Real-facing completion consumer.

Independence witness: cauchy-filter-subbasis, filterbase, cauchyfilter, streamname, regseqrat, real: none is bijective with $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$ because this packet jointly carries the displayed cofinal subbasis route, generated base handoff, Cauchy-filter handoff, finite windows, readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}$ packet is generated from a CauchyFilterSubbasis row, a cofinal generated FilterBase row, a CauchyFilter row, StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6512.1, Definition 6512.2, and Definition 6512.3 seed the cofinal subbasis route into Cauchy-filter completion over generated base, window, readback, Real seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FilterSubbasisCofinalCompletion}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient filter equality, selected limits, countable choice, host equality of generated filters, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subbasis exposure, generated-base cofinality, CauchyFilterUp handoff, StreamNameUp window exposure, RegSeqRatUp readback, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FilterSubbasisCofinalCompletionUp.

Chapter 6513

A Concrete Naming Certificate for $\mathsf{MooreAronszajnKernel}^{\uparrow}$

Following Moore and Aronszajn on reproducing kernels, the $\mathsf{MooreAronszajnKernel}^{\uparrow}$ packet records the finite positive-kernel route as BEDC NameCert data. It sits after the Hilbert-space packet of chapter 91, the vector-space rows of chapter 47, the finite matrix readback of chapter 49, the functional-analysis handoff of chapter 94, and the real scalar seal of chapter 38. The packet names finite Gram-matrix reproducing-kernel evidence without selecting an infinite feature map, quotienting functions, completing an ambient RKHS, importing a host Hilbert space, assuming countable choice, or asserting positive-kernel analysis beyond the displayed rows.

Definition 6513.1 (Moore–Aronszajn kernel carrier)**.** *A* $\mathsf{MooreAronszajnKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (K_0, G, V, H, M, R, C, P, N)$$

with the following displayed rows:

1. K_0 *is the kernel-value row. It records the finite list of source points, displayed kernel evaluations, and symmetry requests inspected by the finite packet.*
2. G *is the positive finite Gram row. It records the finite Gram matrix over the displayed source points, the diagonal and symmetry witnesses, and the finite positivity ledger for every displayed coefficient window.*
3. V *is the* $\mathsf{VecSpace}^{\uparrow}$ *source row. It records the finite vector expressions, scalar multiplication requests, and linear-combination windows from which Gram reads are formed.*
4. H *is the* $\mathsf{Hilbert}^{\uparrow}$ *source row. It records the inner-product readout surface and norm-facing rows through which the reproducing-kernel handoff may be interpreted.*
5. M *is the* $\mathsf{Mat}^{\uparrow}$ *readback row. It records the finite row-column indexing, entry readbacks, Gram-row projections, and matrix-vector products read before any RKHS-style consumer can use* G*.*
6. R *is the* $\mathsf{Real}^{\uparrow}$ *scalar seal. It records real scalar values, positive-radius comparisons, and the terminal real-name boundary for every displayed Gram and norm read.*
7. C *records componentwise* hsame *transport together with displayed* Cont *replay for the route*

$$K_0, G, V, H, M \longmapsto R.$$

8. *P is the* Pkg *provenance over* $\mathsf{MooreAronszajnKernel}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreAronszajnKernel}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these nine rows. Its classifier compares accepted packets only through $K_0, G, V, H, M, R, C, P, N$ and has no coordinate for an infinite RKHS completion, selected feature map, quotient function space, countable-choice schedule, ambient Hilbert completion, or uninspected positive-kernel theorem.

Lean4 ✓ `BEDC.Derived.MooreAronszajnKernelUp.MooreAronszajnKernelTasteGate single carrier alignment`

Theorem 6513.2 (Moore–Aronszajn kernel NameCert obligations)**.** *For the carrier of Definition 6513.1, the local* $\mathsf{NameCert}_{\mathsf{MooreAronszajnKernel}^{\uparrow}}$ *surface consists exactly of carrier admission, finite kernel-value exposure, positive Gram-row exposure,* $\mathsf{VecSpace}^{\uparrow}$ *source compatibility,* $\mathsf{Hilbert}^{\uparrow}$ *inner-product handoff,* $\mathsf{Mat}^{\uparrow}$ *readback compatibility,* $\mathsf{Real}^{\uparrow}$ *scalar sealing, componentwise* hsame *transport with displayed* Cont *replay,* Pkg *provenance, and local naming. The surface exports no selected feature map, quotient function space, infinite completion, countable choice, host Hilbert space, or ambient RKHS theorem.*

Proof. Carrier admission is projection from Definition 6513.1. The packet displays exactly the finite kernel row, Gram row, vector-space row, Hilbert row, matrix readback, real scalar seal, structural replay, provenance, and local naming row.

The positive-kernel obligation is finite. The row G records only displayed Gram windows and their positivity ledgers, while M supplies the row-column readback and R supplies the real scalar comparison boundary.

The analytic handoff remains local to the displayed siblings. The rows V and H expose only the $\mathsf{VecSpace}^{\uparrow}$ and $\mathsf{Hilbert}^{\uparrow}$ surfaces named by P, and the functional-analysis route is read as provenance rather than as an ambient completion theorem.

Finally C preserves the same rows under hsame and Cont replay, and N names no off-packet coordinate. Therefore the listed obligations exhaust the local NameCert surface and none of the excluded RKHS-side objects can be read from the packet. □

Theorem 6513.3 (Moore–Aronszajn kernel Hilbert handoff)**.** *Every Hilbert-facing or functional-analysis consumer of an accepted* $\mathsf{MooreAronszajnKernel}^{\uparrow}$ *packet must first read the finite kernel row K_0, the positive finite Gram row G, the* $\mathsf{VecSpace}^{\uparrow}$ *source row V, the* $\mathsf{Hilbert}^{\uparrow}$ *inner-product source row H, the* $\mathsf{Mat}^{\uparrow}$ *readback row M, the* $\mathsf{Real}^{\uparrow}$ *scalar seal R, and the structural rows C, P, N. The handoff reaches the sibling surfaces of chapter 91, chapter 47, chapter 49, chapter 94, and chapter 38 only through those displayed rows.*

Proof. Start with the NameCert obligations of Definition 6513.2. They force every consumer to inspect $K_0, G, V, H, M, R, C, P, N$ before a Hilbert-facing read is available.

The Hilbert handoff is routed through displayed finite data. The vector-space row supplies the linear-combination windows, the matrix row supplies the finite Gram readback, and the real row supplies scalar comparison before the Hilbert row may be consumed.

The provenance row names the five sibling chapters, and the replay row orders the read through the finite Gram route. Since no row stores a selected feature map, quotient function space, or completed RKHS carrier, the Hilbert-facing consumer receives only the displayed finite handoff. □

Theorem 6513.4 (Moore–Aronszajn kernel finite Gram nonescape)**.** *Every reproducing-kernel read of an accepted* $\mathsf{MooreAronszajnKernel}^{\uparrow}$ *packet factors through the finite Gram row G, the* $\mathsf{Mat}^{\uparrow}$

readback row M, the VecSpace$^{\uparrow}$ *source row V, the* Hilbert$^{\uparrow}$ *source row H, the* Real$^{\uparrow}$ *scalar seal R,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The packet does not export selected RKHS points, quotient function equality, infinite Gram operators, countable choice, ambient Hilbert completion, or full Moore–Aronszajn existence.*

Proof. Project the carrier rows. The only route from kernel values to an analytic consumer is the displayed replay

$$K_0, G, V, H, M \longmapsto R.$$

The finite Gram row is therefore unavoidable. Matrix readback exposes only the finite rows and columns displayed by M, vector expressions are those displayed by V, and scalar comparisons end at R.

Transport and replay cannot create new analytic objects. They preserve the same finite rows under hsame and Cont, while P, N name only the listed packet surface. Hence every reproducing-kernel read remains inside the finite Gram route and none of the excluded RKHS-side data can escape the packet. □

Lean4 (statement) `BEDC.Derived.MooreAronszajnKernelUp`

Closure status for NameCert$_{\text{MooreAronszajnKernel}^{\uparrow}}$.

Constructive story: A MooreAronszajnKernel$^{\uparrow}$ packet is generated from finite kernel-value rows, positive finite Gram rows, VecSpace and Hilbert source rows, Matrix readback, Real scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MooreAronszajnKernel}^{\uparrow}}$, seed)

Scope closed: Definition 6513.1, Definition 6513.2, Definition 6513.3, and Definition 6513.4 seed the finite Gram-matrix reproducing-kernel carrier and its Hilbert-facing handoff boundary.

Formal verification: FormalStatus(NameCert$_{\text{MooreAronszajnKernel}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.MooreAronszajnKernelUp`

Bridge status: none

Not claimed: This chapter does not close selected feature maps, quotient function spaces, infinite RKHS completion, countable choice, ambient Hilbert completeness, full Moore–Aronszajn existence, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite Gram positivity, Matrix readback, VecSpace and Hilbert handoff, Real scalar sealing, transport, replay, provenance, and local naming for BEDC.Derived.MooreAronszajnKernelUp.

Chapter 6514

A Concrete Naming Certificate for $\mathsf{BishopBarInductionBoundary}^{\uparrow}$

Following Brouwer, Troelstra–van Dalen, and Bishop–Bridges, the $\mathsf{BishopBarInductionBoundary}^{\uparrow}$ packet records the finite boundary at which bar-induction evidence becomes available to Real and Completion consumers without turning into a choice or compactness principle. It sits beside the barred-spread source of chapter 1675, the finite fan route of chapter 400, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite bar handoff for analytic neighbours; it is not countable choice, a selected infinite branch, quotient stream equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6514.1 (Bishop bar induction boundary carrier)**.** *A* $\mathsf{BishopBarInductionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (B, F, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *barred-spread row, recording the finite bar decisions, monotone closure, and local induction replay visible at the retained prefix boundary.*
2. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite fan row, recording the bounded prefix cover and depth ledger consumed before a boundary read is public.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for Real and Completion-facing observations of the retained prefixes.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic scales and comparison cells used to interpret the finite windows and regular rational readback.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, F, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the barred-spread row, finite fan row, StreamName windows, RegSeqRat readback, dyadic tolerances, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary request through $B, F, S, R, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopBarInductionBoundary}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopBarInductionBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $B, F, S, R, D, E, H, C, P, N$. It has no coordinate for countable choice, a selected infinite branch, quotient stream equality, open-cover compactness, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6514.2 (Bishop bar induction boundary NameCert obligations)**.** *For every accepted* $\mathsf{BishopBarInductionBoundary}^{\uparrow}$ *carrier*

$$Y = (B, F, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopBarInductionBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, barred-spread ancestry, finite fan-boundary exposure, finite StreamName window admission, RegSeqRat readback, dyadic tolerance exactness, Real seal ordering, componentwise transport, displayed continuation replay, provenance, and local naming for the carrier of Definition 6514.1.*

Proof. Project the accepted carrier. Its public rows are precisely $B, F, S, R, D, E, H, C, P, N$, so carrier admission and local naming are fixed by Definition 6514.1.

The barred-spread ancestry row B supplies the finite bar decisions and induction replay, while the fan row F supplies only bounded prefix data. Thus the boundary is finite before any analytic read can inspect StreamName, RegSeqRat, dyadic, or Real-facing rows.

The readback rows are ordered by the carrier itself: S displays the finite windows, R reads those windows as regular rational data, D supplies the dyadic tolerance ledger, and E is reached only after those rows are present. The transport, replay, provenance, and naming rows preserve this order through H, C, P, N.

Since no coordinate stores countable choice, selected branches, quotient stream equality, open-cover compactness, host real equality, or ambient Real completeness, none of those principles can be a local NameCert obligation. □

Theorem 6514.3 (Bishop bar induction boundary finite-bar handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or Completion-facing consumer of an accepted* $\mathsf{BishopBarInductionBoundary}^{\uparrow}$ *packet reads the finite bar route*

$$\mathsf{BrouwerBarInduction}^{\uparrow}, \mathsf{FanTheorem}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the boundary is public. Consequently the handoff exports finite barred-spread and fan-window data to Real-and-Completion neighbours without exporting countable choice, selected infinite branches, quotient stream equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $Y = (B, F, S, R, D, E, H, C, P, N)$. The only bar source is B, and the only finite fan source is F, so a boundary consumer must display these rows before it can request analytic data.

Next the consumer reads the finite observation rows. The $\mathsf{StreamName}^{\uparrow}$ window S gives the inspected prefixes, the $\mathsf{RegSeqRat}^{\uparrow}$ row R reads those prefixes as regular rational data, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row D records the displayed tolerance comparisons.

The terminal $\mathsf{Real}^{\uparrow}$ row E is downstream of that finite route. Componentwise transport, continuation replay, provenance, and local naming only preserve the same path through H, C, P, N.

There is no remaining insertion point for countable choice, a selected infinite branch, quotient stream equality, open-cover compactness, or ambient Real completeness. The handoff is therefore exactly the finite boundary route displayed in the statement. □

Falsifiable prediction: Every accepted $\mathsf{BishopBarInductionBoundary}^{\uparrow}$ Real or Completion-facing read displays BrouwerBarInductionUp barred-spread data, FanTheoremUp finite fan rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the boundary is public.

Independence witness: brouwer-bar-induction, fantheorem, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopBarInductionBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite bar ancestry, finite fan-boundary exposure, finite windows, regular rational readback, dyadic tolerance accounting, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopBarInductionBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopBarInductionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6514.1, Definition 6514.2, and Definition 6514.3 seed the finite bar boundary route from Brouwer bar induction and finite fan rows through StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopBarInductionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected infinite branches, quotient stream equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, barred-spread ancestry, finite fan-boundary exposure, window admission, readback ordering, dyadic exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopBarInductionBoundaryUp.

Constructive story: A $\mathsf{BishopBarInductionBoundary}^{\uparrow}$ packet is generated from BrouwerBarInductionUp barred-spread rows, FanTheoremUp finite fan rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6515

A Concrete Naming Certificate for $\mathsf{UniformizableSpace}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces, the $\mathsf{UniformizableSpace}^{\uparrow}$ packet records the finite route by which displayed uniformity data induces a topology. It sits after the uniform entourage surface of chapter 339, the topology carrier of chapter 88, the metric-to-topology route of chapter 1655, the complete-uniform-space boundary of chapter 1588, and the directed entourage discipline of chapter 2334. The packet also leaves room for separated uniformity consumers without importing a host metrization theorem, quotient topology, selected base, or open-set extensionality principle.

Definition 6515.1 (Uniformizable-space carrier)**.** *A* $\mathsf{UniformizableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (T, U, E, N, H, C, P, L)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *row whose neighbourhood and open-set reads are induced from the displayed uniformity data.*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *row carrying the finite uniformity interface used by the packet.*
3. *E is the entourage-base row, listing the displayed entourages and the finite intersection, diagonal, and composition requests that generate neighbourhood reads.*
4. *N is the induced-neighbourhood evidence row, recording how each inspected point-neighbourhood request is read from an entourage section.*
5. *H records componentwise* hsame *transport for topology, uniformity, entourage-base, induced-neighbourhood, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from topology requests through U, E, N, H and back to the same topology row T.*
7. *P is the* Pkg *provenance over* $\mathsf{UniformizableSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{MetricTopology}^{\uparrow}$, $\mathsf{CompleteUniformSpace}^{\uparrow}$, $\mathsf{QuasiUniformSpace}^{\uparrow}$, $\mathsf{SeparatedUniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{UniformizableSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through T, U, E, N, H, C, P, L. It has no coordinate for choice-based metrization, quotient topology, a host-selected uniform base, open-set extensionality, ambient separatedness, or completeness.

Theorem 6515.2 (Uniformizable-space NameCert obligations)**.** *For every accepted* $\mathsf{UniformizableSpace}^{\uparrow}$ *carrier*

$$Z = (T, U, E, N, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{UniformizableSpace}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the displayed topology, uniformity, entourage-base, induced-neighbourhood, transport, replay, provenance, and local naming rows;*
2. *entourage-base coverage, requiring every topology-facing neighbourhood read to be generated from a displayed entourage in E over the uniformity row U;*
3. *induced-neighbourhood stability, requiring N to preserve the same point and entourage section under componentwise* hsame *transport;*
4. *displayed* Cont *replay, requiring every topology request to return through the same U, E, N, H rows before it is consumed as T;*
5. *non-escape, requiring P, L to expose no choice-based metrization, quotient topology, host-selected base, open-set extensionality, ambient separatedness theorem, or completeness theorem.*

No Uniformizable-space obligation is stored outside these rows.

Proof. Project the accepted carrier. The packet exposes exactly the topology row T, uniformity row U, entourage-base row E, induced-neighbourhood evidence N, transport row H, replay row C, provenance row P, and local name L.

Read the uniformity data before the topology data. The entourage-base row E supplies the finite diagonal, intersection, and composition information used by neighbourhood requests, and N records the pointwise section through which such a request reaches T.

Transport and replay preserve the same route. Componentwise hsame acts through H, while Cont replay through C returns topology-facing reads to the same displayed entourage and neighbourhood rows.

Finally, provenance and local naming do not add external objects. Since the carrier has no coordinate for choice-based metrization, quotient topology, selected bases, open-set extensionality, separatedness, or completeness, the five listed obligations exhaust the local NameCert surface. □

Theorem 6515.3 (Uniformizable-space entourage topology scope)**.** *For every accepted* $\mathsf{UniformizableSpace}^{\uparrow}$ *carrier $Z = (T, U, E, N, H, C, P, L)$, every topology readback from T factors through the displayed uniformity row U, entourage-base row E, induced-neighbourhood row N, transport row H, replay row C, provenance row P, and local name L. The readback is the topology induced by displayed entourages; it does not use choice-based metrization, quotient topology, host open-set extensionality, a selected base, ambient separatedness, or completeness.*

Proof. Begin with a topology readback request. The carrier definition makes T readable only together with the uniformity, entourage-base, and induced-neighbourhood rows U, E, N.

Apply the NameCert obligations. Entourage-base coverage forces the neighbourhood request through a displayed entourage, and induced-neighbourhood stability keeps the point and entourage section fixed under transport.

Use the replay and provenance rows next. The row C replays the same route back to T, while P and L source and name only the displayed packet.

The excluded topology principles are absent from the carrier. Therefore the topology readback factors through displayed entourages and cannot appeal to metrization by choice, quotient topology, host open-set extensionality, selected bases, separatedness, or completeness. □

Falsifiable prediction: Every $\mathsf{UniformizableSpace}^{\uparrow}$ topology read factors through displayed UniformSpace entourages, induced-neighbourhood evidence, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: uniformspace, topology, metric-topology, complete-uniform-space, quasi-uniform-space, separated-uniform-space: $\mathsf{UniformizableSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a topology row, displayed uniformity row, entourage base, induced-neighbourhood evidence, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformizableSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformizableSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6515.1, Definition 6515.2, and Definition 6515.3 seed the constructive L10 route from displayed uniformity and entourage data to topology readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformizableSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-based metrization, quotient topology, host open-set extensionality, selected bases, ambient separatedness, completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage-base coverage, induced-neighbourhood stability, displayed replay, provenance non-escape, and local naming for BEDC.Derived.UniformizableSpaceUp.

Constructive story: A $\mathsf{UniformizableSpace}^{\uparrow}$ packet is generated from a Topology row, UniformSpace row, entourage-base row, induced-neighbourhood evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6516

A Concrete Naming Certificate for $\mathsf{LeibnizAlternatingTest}^{\uparrow}$

Following Leibniz and Bishop–Bridges constructive series theory, the $\mathsf{LeibnizAlternatingTest}^{\uparrow}$ packet records the finite test-level route by which alternating partial sums, a monotone null tail, dyadic tolerance ledgers, regular rational readback, and a terminal real seal are accepted before a Real or Completion consumer may treat the series as convergent. It consumes the remainder certificate of chapter 2159, the regular rational carrier of chapter 301, the dyadic tolerance rows of chapter 291, the finite stream windows of chapter 126, and the terminal $\mathsf{Real}^{\uparrow}$ surface of chapter 38.

Definition 6516.1 (Leibniz alternating test carrier)**.** *A* $\mathsf{LeibnizAlternatingTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, A, M, S, D, Q, W, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the accepted* $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ *row, exposing the next-omitted-term remainder certificate already routed through alternating signs, monotone magnitudes, and dyadic budgets.*
2. *A is the alternating partial-sum schedule, recording the inspected parity rows, finite partial sums, adjacent direction checks, and cutoff schedule used by the test.*
3. *M is the monotone null-tail row, recording nonnegative magnitude reads, observed monotonicity comparisons, and the null-tail request that makes the next omitted magnitude smaller than any requested dyadic tolerance.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family for summands, signs, magnitudes, partial sums, cutoffs, next omitted terms, dyadic comparisons, and endpoint-facing reads.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger pairing every precision request with a cutoff, a next omitted magnitude, and a comparison row.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from A, M, S, D and the accepted remainder row R.*
7. *W is the test-level Cauchy handoff row: it records that the partial-sum schedule is Cauchy by reading only the displayed remainder certificate, monotone null tail, dyadic tolerance ledger, and regular rational readback.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, A, M, S, D, Q, W have been displayed.*

9. *H records componentwise* hsame *transport for the remainder row, partial-sum schedule, monotone null tail, stream windows, dyadic ledger, regular readback, Cauchy handoff, real seal, replay, provenance, and local name.*

10. *C records displayed* Cont *replay of the route*

$$R, A, M, S, D \longmapsto Q \longmapsto W \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{LeibnizAlternatingTest}^{\uparrow}$, $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LeibnizAlternatingTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, A, M, S, D, Q, W, E, H, C, P, N$. It has no coordinate for a selected infinite sum, quotient stream equality, host real equality, countable choice, unrestricted trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a Cauchy proof detached from the displayed remainder route.*

Theorem 6516.2 (Leibniz alternating test NameCert obligations)**.** *For every accepted* $\mathsf{LeibnizAlternatingTest}^{\uparrow}$ *carrier*

$$T = (R, A, M, S, D, Q, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LeibnizAlternatingTest}^{\uparrow}}$ *surface consists exactly of carrier admission for Definition 6516.1, the accepted alternating-remainder row R, the alternating partial-sum schedule A, the monotone null-tail row M, finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the Cauchy handoff row W, the* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier $T = (R, A, M, S, D, Q, W, E, H, C, P, N)$. The tuple exposes exactly the remainder, schedule, monotone tail, finite-window, dyadic, regular-readback, Cauchy-handoff, real-seal, and structural rows.

The test begins with R, A, M. The remainder row supplies the next-omitted-term certificate, the schedule row supplies alternating partial sums and parity, and the monotone null-tail row supplies the decreasing magnitude and tail request used by every tolerance read.

The finite observation surface is S, D, Q. The stream windows show the inspected data, the dyadic ledger pairs each requested tolerance with a cutoff and comparison, and the regular rational readback reuses exactly those windows.

Finally W, E, H, C, P, N expose the Cauchy handoff, seal it as a Real-facing row, transport it componentwise, replay the displayed route, record provenance, and name the packet. Since the carrier contains no other coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6516.3 (Leibniz alternating test Cauchy handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LeibnizAlternatingTest}^{\uparrow}$ *packet must read the finite route*

$$R, A, M, S, D \longmapsto Q \longmapsto W \longmapsto E$$

before treating the alternating series as convergent. Thus the Cauchy handoff W is available only after the existing alternating-remainder row, monotone null-tail schedule, partial-sum schedule, $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *windows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row have all been displayed.*

Proof. Start with the accepted remainder row R. By chapter 2159, it already binds every endpoint-facing remainder request to the next omitted magnitude, alternating sign ledger, monotone null tail, dyadic budget, finite windows, and regular readback.

Attach the test-level schedule rows A, M, S, D. These rows name the inspected partial sums, the monotone null-tail request, the finite windows, and the dyadic tolerance ledger used to compare later partial sums through the common cutoff.

Read Q as the regular rational surface for those displayed rows. The Cauchy handoff W can then be formed from the same finite observations, because the difference between sufficiently late partial sums is bounded by the displayed remainder budget.

The terminal seal E is reached only after W, and the structural rows H, C, P, N preserve that route. Hence any consumer that bypasses the remainder row, tail schedule, dyadic ledger, regular readback, stream windows, transport, replay, provenance, or local name leaves the accepted $\mathsf{LeibnizAlternatingTest}^{\uparrow}$ packet. □

Falsifiable prediction: Every $\mathsf{LeibnizAlternatingTest}^{\uparrow}$ Real or Completion read factors through an accepted $\mathsf{LeibnizAlternatingRemainder}^{\uparrow}$ row, alternating partial-sum schedule, monotone null-tail row, StreamNameUp windows, DyadicRatCoreUp tolerance ledger, RegSeqRatUp readback, Cauchy handoff, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LeibnizAlternatingTest}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LeibnizAlternatingTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6516.1, Definition 6516.2, and Definition 6516.3 seed the finite Leibniz alternating-test certificate from remainder rows and monotone null tails through dyadic tolerance ledgers, regular rational readback, Cauchy handoff, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LeibnizAlternatingTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, quotient stream equality, host real equality, countable choice, unrestricted trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, detached Cauchy proofs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, remainder-row consumption, partial-sum schedule stability, monotone null-tail exactness, dyadic tolerance stability, RegSeqRat readback, StreamName finite-window compatibility, Cauchy handoff, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LeibnizAlternatingTestUp.

Constructive story: A $\mathsf{LeibnizAlternatingTest}^{\uparrow}$ packet is generated from an accepted LeibnizAlternatingRemainderUp row, alternating partial-sum schedule, monotone null-tail row, StreamNameUp windows, DyadicRatCoreUp tolerance ledger, RegSeqRatUp readback, Cauchy handoff row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6517

A Concrete Naming Certificate for Rule110CellularTrustSubstrate$^{\uparrow}$

The Rule110CellularTrustSubstrate$^{\uparrow}$ packet realizes the Rule 110 axis of chapter 9390 as finite NameCert data. It refines the generic cellular trust substrate of chapter 937 by fixing the eight-entry Rule 110 transition table, manifest schema, orbit-window replay, classifier surface, frontier ledger, transport rows, and provenance rows before any cellular-pattern or cyclic-tag consumer can read a substrate observation.

Definition 6517.1 (Rule 110 cellular trust substrate carrier)**.** *A* Rule110CellularTrustSubstrate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, M, O, K, F, B, U, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the Rule 110 transition-table row, recording the eight three-cell cases and their output bits.*
2. *M is the manifest row, recording the finite initial row, width, step count, expected observation claims, and fixed text-format schema.*
3. *O is the orbit-window row, containing only finite prefixes of the Rule 110 evolution generated from T and M.*
4. *K is the classifier row, read through the cellular row classifier of chapter 941, the Rule 110 pattern classifier of chapter 5844, and the glider catalog of chapter 1045.*
5. *F is the Cook-frontier ledger, read through chapter 959 when a bounded cyclic-tag or compile-frontier consumer is present.*
6. *B is the cellular-substrate boundary row, recording that the packet is a closed observational substrate rather than a host evaluator or universality theorem.*
7. *U is the bounded cyclic-tag handoff row, read through chapter 3764 only after the finite orbit and frontier rows have been displayed.*
8. *A is the local-stencil audit row, read through chapter 6004 for each inspected transition.*
9. *H records componentwise* hsame *transport for the rule table, manifest, orbit window, classifier, frontier ledger, boundary, bounded handoff, audit row, replay, provenance, and local name.*

10. *C records displayed* Cont *replay of the route*

$$T, M, A \longmapsto O \longmapsto K, F, B, U.$$

11. *P is the* Pkg *provenance over* Rule110CellularTrustSubstrate$^{\uparrow}$, CellularTrustSubstrate$^{\uparrow}$, CellularAutomaton$^{\uparrow}$, CellularRowClassifier$^{\uparrow}$, RuleOneTenPatternClassifier$^{\uparrow}$, RuleOneTenGliderCatalog$^{\uparrow}$, RuleOneTenLocalStencilObservat CyclicTagSystem$^{\uparrow}$, CookFrontierWitness$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{Rule110CellularTrustSubstrate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, O, K, F, B, U, A, H, C, P, N$. It has no coordinate for a host C evaluator, a complete infinite orbit, a detached universality theorem, unbounded halting, selected glider semantics, or an external proof of induction.

Theorem 6517.2 (Rule 110 cellular trust substrate NameCert obligations)**.** *For every accepted* Rule110CellularTrustSubstrate$^{\uparrow}$ *carrier*

$$R = (T, M, O, K, F, B, U, A, H, C, P, N),$$

the local NameCert$_{\text{Rule110CellularTrustSubstrate}^{\uparrow}}$ *surface consists exactly of carrier admission for Definition 6517.1, transition-table exactness through T, manifest schema admission through M, finite orbit-window replay through O, classifier exposure through K, frontier-ledger exposure through F, closed-substrate boundary through B, bounded cyclic-tag handoff through U, local-stencil audit through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The tuple exposes exactly the transition table, manifest, orbit-window, classifier, frontier, boundary, cyclic-tag handoff, local-stencil audit, and structural rows.

The finite substrate rows are T, M, O, A. The transition table fixes the local rule, the manifest fixes the finite input and expected observations, the audit row checks each inspected local stencil, and the orbit window contains only the finite replay generated from those rows.

The consumer rows are K, F, B, U. Pattern consumers read K, frontier consumers read F, closed-substrate consumers read B, and bounded cyclic-tag consumers read U. Each consumer row is downstream of the displayed finite substrate route.

Finally H, C, P, N transport, replay, source, and name that same route. Since the carrier has no coordinate for the excluded host evaluator, complete orbit, detached universality theorem, unbounded halting principle, selected glider semantics, or external induction proof, the listed rows exhaust the local NameCert obligations. □

Theorem 6517.3 (Rule 110 cellular trust substrate observation boundary)**.** *Every accepted* Rule110CellularTrustSub *observation factors through the finite route*

$$T, M, A \longmapsto O \longmapsto K, F, B, U \longmapsto H, C, P, N.$$

Thus a pattern-classifier, frontier-ledger, bounded cyclic-tag, or closed-substrate consumer can read Rule 110 only after the finite rule table, manifest, orbit window, local-stencil audit, transport, replay, provenance, and local NameCert *rows have been displayed.*

Proof. Start with the local-stencil route. The transition table T and audit row A expose each inspected Rule 110 update as finite three-cell data, while the manifest row M fixes the initial row and bounded step count.

Replay the orbit window O from those rows. No consumer receives a whole infinite evolution; every read is a finite orbit prefix generated from the displayed table and manifest.

Now attach the public consumers. The classifier row K, frontier ledger F, closed-substrate boundary B, and bounded cyclic-tag handoff U can inspect only the same finite orbit route.

The rows H, C, P, N preserve and name the route. Any host evaluator, detached universality proof, unbounded halting claim, selected glider semantics, or external induction proof would require a coordinate outside the accepted packet. □

Falsifiable prediction: Every $\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}$ observation first exposes the finite Rule 110 transition table, manifest row, local-stencil audit, orbit-window replay, classifier row, frontier ledger, closed-substrate boundary, bounded cyclic-tag handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: cellulartrustsubstrate, cellularautomaton, cellularrowclassifier, rule110-pattern-classifier, cyclic-tag-system: $\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}$ is not bijective to any listed sibling because it jointly fixes the Rule 110 table, manifest schema, orbit windows, classifier, Cook-frontier ledger, bounded cyclic-tag handoff, audit route, transport, replay, provenance, and local naming.

The Lean TasteGate follow-up for `BEDC.Derived.Rule110CellularTrustSubstrateUp` must provide explicit $\mathsf{Nontrivial\ Rule110CellularTrustSubstrate}^{\uparrow}$ and $\mathsf{FieldFaithful\ Rule110CellularTrustSubstrate}^{\uparrow}$ instances over $T, M, O, K, F, B, U, A, H, C, P, N$. These instances keep the rule table, manifest, orbit-window, classifier, frontier, boundary, handoff, and audit rows as separate fields.

Closure status for $\mathsf{NameCert}_{\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6517.1, Definition 6517.2, and Definition 6517.3 seed the finite Rule 110 cellular trust substrate packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host evaluator correctness, complete infinite orbits, Cook universality, unbounded halting, selected glider semantics, internal induction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-table exactness, manifest admission, orbit-window replay, classifier exposure, Cook-frontier ledger exposure, bounded cyclic-tag handoff, local-stencil audit, transport, replay, provenance, TasteGate instances, and local naming for BEDC.Derived.Rule110CellularTrustSubstrateUp.

Constructive story: A $\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}$ packet is generated from a finite Rule 110 transition table, manifest row, orbit-window replay, classifier row, Cook-frontier ledger, closed-substrate boundary, bounded cyclic-tag handoff, local-stencil audit, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6518

A Concrete Naming Certificate for $\mathsf{FiniteSectionCompletionInterface}^{\uparrow}$

Following Bishop and Bridges' finite approximation discipline for constructive completions, the $\mathsf{FiniteSectionCompletionInterface}^{\uparrow}$ packet records the finite request-section boundary at which a dyadic endpoint and tolerance row, a stream-name section, a regular rational readback, and a terminal Real seal can be cited together. It refines the four-face completion surface of chapter 1844 by making the section pullback explicit over chapter 291, chapter 126, chapter 301, and chapter 38. The packet is a finite NameCert interface for L10 completion consumers; it is not a quotient-stream construction, a selected limit, a countable-choice principle, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a checked bridge.

Definition 6518.1 (Finite section completion interface carrier)**.** *A* $\mathsf{FiniteSectionCompletionInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, S, R, B, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance row, recording the finite dyadic endpoint cells, scale bounds, and slack conversions inspected by the section.*
2. *S is the finite request-section row over* $\mathsf{StreamName}^{\uparrow}$*, listing the requested stream windows and the section coordinates through which a completion consumer reads them.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational data obtained from the section after the dyadic tolerance row and stream windows have been displayed.*
4. *B is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, recording only the finite seal-facing boundary reached after D, S, R.*
5. *Q is the section pullback and exactness row, requiring the requested stream section, dyadic tolerance cells, regular rational readback, and terminal seal row to agree componentwise on every displayed finite request.*
6. *H records componentwise* hsame *transport for dyadic, section, readback, seal, exactness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite completion request through D, S, R, B, Q, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{FiniteSectionCompletionInterface}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSectionCompletionInterface}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $D, S, R, B, Q, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Theorem 6518.2 (Finite section completion interface NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSectionCompletionInterface}^{\uparrow}$ *carrier*

$$I = (D, S, R, B, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSectionCompletionInterface}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed finite* BHist *packet of Definition 6518.1;*
2. *finite section coverage, requiring each requested* $\mathsf{StreamName}^{\uparrow}$ *window in S to be read against the displayed dyadic endpoint and tolerance row D;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring the regular rational readback R to be exposed only through the already displayed D, S section route and the exactness row Q;*
4. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring the terminal seal row B to be consumed only after D, S, R, Q and refusing quotient stream equality, selected limits, countable choice, host real equality, and ambient completeness;*
5. *structural transport, replay, provenance, and local naming through H, C, P, N, with no additional completion, quotient, choice, or bridge coordinate.*

Proof. Carrier admission is projection from Definition 6518.1. The accepted packet displays exactly the dyadic endpoint and tolerance row, finite request-section row, regular rational readback row, terminal Real seal row, section exactness row, and structural rows.

Finite coverage is rowwise. A completion request first reads D and S; only then can Q certify that the selected finite section agrees with the requested dyadic tolerance cells and stream windows.

The handoff to R and the seal read B are downstream of that exactness row. Since the carrier has no quotient-stream, selected-limit, choice, host-equality, ambient-completeness, or bridge coordinate, the terminal seal cannot escape the displayed finite section route.

Finally, H, C, P, N transport, replay, source, and name the same packet. These structural rows preserve the finite route through D, S, R, B, Q and add no further completion principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSectionCompletionInterface}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteSectionCompletionInterface}^{\uparrow}}$, seed)

Scope closed: Definition 6518.1 and Definition 6518.2 seed the finite section interface among dyadic endpoint and tolerance rows, StreamName request sections, RegSeqRat readback, Real seal rows, pullback exactness, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteSectionCompletionInterface}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires a Lean carrier and checked NameCert obligations for BEDC.Derived.FiniteSectionCompletionInt

Constructive story: A $\mathsf{FiniteSectionCompletionInterface}^{\uparrow}$ packet is generated from a dyadic endpoint and tolerance row, a finite StreamName request-section row, a RegSeqRat readback row, a terminal Real seal row, a section pullback and exactness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6519

A Concrete Naming Certificate for RegularCauchyCompletionComparisonTriangle$^{\uparrow}$

Following Bishop and Bridges and Mac Lane, the RegularCauchyCompletionComparisonTriangle$^{\uparrow}$ packet records the finite comparison triangle that lets a completion-facing consumer read the regular-Cauchy route, the general completion-comparison route, and the terminal Real$^{\uparrow}$ seal as one NameCert surface. It sits after the modulus ledger of chapter 292, the diagonal selector of chapter 390, the finite comparison routes of chapter 1954 and chapter 2321, the regular rational readback of chapter 301, the stream window of chapter 126, the dyadic observation ledger of chapter 291, and the terminal real-name seal of chapter 38.

Definition 6519.1 (RegularCauchyCompletionComparisonTriangle carrier)**.** *A* RegularCauchyCompletionComparis *carrier is a finite* BHist *packet*

$$T = (M, L, C, G, S, R, D, E, H, Q, P, N)$$

with the following visible rows:

1. *M is the* CauchyModulus$^{\uparrow}$ *threshold ledger consumed by the regular-Cauchy input;*
2. *L is the* RegularCauchyLimitModulus$^{\uparrow}$ *diagonal limit-modulus row;*
3. *C is the* CauchyCompletionComparison$^{\uparrow}$ *comparison leg from Cauchy data to completion-facing data;*
4. *G is the* CompletionComparison$^{\uparrow}$ *comparison leg that checks the same observation against the ambient completion interface;*
5. *S is the* StreamName$^{\uparrow}$ *finite window through which the selected diagonal or tail observation is inspected;*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the same window;*
7. *D is the* DyadicRatCore$^{\uparrow}$ *ledger recording the displayed tolerance, endpoint, comparison, and precision data;*
8. *E is the* Real$^{\uparrow}$ *seal row available only after M, L, C, G, S, R, D have been displayed;*
9. *H records componentwise* hsame *transport for the triangle rows;*
10. *Q records displayed* Cont *replay for the three comparison legs;*

11. *P is the* Pkg *provenance over the sibling routes named above;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionComparisonTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6519.2 (RegularCauchyCompletionComparisonTriangle NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionComparisonTriangle}^{\uparrow}}$ *surface consists of a finite route-exhaustion statement: every accepted triangle packet first exposes the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold ledger, then the* $\mathsf{RegularCauchyLimitModulus}^{\uparrow}$ *diagonal selector, then the* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *and* $\mathsf{CompletionComparison}^{\uparrow}$ *comparison legs, and only then the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumer rows. The same componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *rows transport the whole triangle.*

Consequently a Real or Completion consumer cannot bypass the regular-Cauchy leg by reading E as a host real, cannot bypass the completion-comparison leg by treating C as quotient stream equality, and cannot bypass the dyadic leg by replacing D with an ambient completeness principle.

Proof. Project the carrier of Definition 6519.1. The rows $M, L, C, G, S, R, D, E, H, Q, P, N$ are all coordinates of one finite packet, so any consumer route must begin by choosing one of those displayed coordinates.

The regular-Cauchy leg is exhausted by M, L, S, R, and D. The threshold ledger supplies the modulus row, the limit-modulus row supplies the diagonal selector, the stream row supplies the finite window, the regular rational row supplies readback, and the dyadic row records the tolerance arithmetic.

The completion leg is exhausted by C and G. These rows compare the same displayed observation against the Cauchy-completion and completion-comparison interfaces; they do not add a quotient representative or a selected completion point.

Finally E is downstream of those rows. The transport, replay, provenance, and naming coordinates H, Q, P, N preserve the same triangle, so route exhaustion leaves no coordinate for quotient stream equality, countable choice, trichotomy, host selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyCompletionComparisonTriangle}^{\uparrow}$ consumer that reaches a Real or Completion handoff without first exposing the CauchyModulus, RegularCauchyLimitModulus, CauchyCompletionComparison, CompletionComparison, StreamName, RegSeqRat, DyadicRatCore, RealUp, transport, replay, provenance, and naming rows refutes the carrier surface.

Independence witness: cauchymodulus, regular-cauchy-limit-modulus, cauchy-completion-comparison, completion-comparison, regseqrat, streamname, dyadicratcore, real: no listed sibling is bijective to $\mathsf{RegularCauchyCompletionComparisonTriangle}^{\uparrow}$ because this packet binds the modulus leg, diagonal-selector leg, two completion-comparison legs, finite stream window, regular rational readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming into one triangle.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionComparisonTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionComparisonTriangle}^{\uparrow}$ packet is generated from a CauchyModulus threshold ledger, a RegularCauchyLimitModulus diagonal selector, CauchyCompletionComparison and CompletionComparison legs, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionComparisonTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6519.1 and Definition 6519.2 seed the finite comparison triangle linking regular-Cauchy, completion-comparison, and RealUp seal routes.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionComparisonTriangle}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked route exhaustion for BEDC.Derived.RegularCauchyCompletionComparisonTriangleUp over the displayed CauchyModulus, RegularCauchyLimitModulus, CauchyCompletionComparison, CompletionComparison, StreamName, RegSeqRat, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Chapter 6520

A Concrete Naming Certificate for $\mathsf{SequentialFan}^{\uparrow}$

Following Brouwer and Bishop–Bridges on fans and choice sequences, the $\mathsf{SequentialFan}^{\uparrow}$ packet records the finite fan surface needed by Real and Completion readers as BEDC naming data. It sits beside the bar discipline of chapter 400, the binary prefix source of chapter 1475, the finite-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names only finite prefix trees, displayed bar witnesses, finite stream windows, regular readbacks, Real seals, transport, replay, provenance, and local naming; it does not assert open-cover compactness, a selected branch, countable choice, host quotient equality, or ambient completeness.

Definition 6520.1 (SequentialFan carrier)**.** *A* $\mathsf{SequentialFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is a finite prefix-tree row for a fan, read through the binary-prefix and fan surfaces of chapter 1475 and chapter 400.*
2. *B is a displayed bar witness over T, recording the finite prefix boundary at which every accepted branch read stops.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row attached to the prefixes selected by B.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, B, W, R have been displayed.*
6. *H records componentwise* hsame *transport for T, B, W, R, E, C, P, N.*
7. *C records displayed* Cont *replay from the prefix-tree row through the bar witness, finite stream windows, RegSeqRat readback, Real seal, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{SequentialFan}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialFan}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, W, R, E, H, C, P, N$. It has no coordinate for an infinite branch selector, open-cover compactness, quotient stream equality, host real equality, selected limits, countable choice, or ambient completeness.

Theorem 6520.2 (SequentialFan NameCert obligations)**.** *For every accepted* $\mathsf{SequentialFan}^{\uparrow}$ *carrier*

$$S = (T, B, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialFan}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the prefix tree, bar witness, finite stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming;*
2. *fan-prefix compatibility, requiring every inspected branch request to enter through the displayed finite tree* T *and the bar boundary* B*;*
3. *stream-window exposure, requiring each Real-facing observation to read the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W *before any regular rational readback is consumed;*
4. *regular-readback exactness, requiring* R *to be the only row by which the stream windows are interpreted as* $\mathsf{RegSeqRat}^{\uparrow}$ *data;*
5. *terminal-seal nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *row* E *to be exposed only after* T, B, W, R, H, C, P, N *have been displayed and excluding selected branches, quotient streams, host real equality, selected limits, countable choice, ambient completeness, Lean verification, and bridge checking.*

No SequentialFan obligation is stored outside these rows.

Proof. Project the accepted carrier. The fan data are T and B, the finite analytic observations are W and R, and the terminal naming row is E.

The prefix compatibility obligation is forced because the carrier has no second tree coordinate and no branch selector. A branch-facing request therefore reaches an observation only after the displayed bar row has bounded the prefix length.

The analytic handoff is then finite. The $\mathsf{StreamName}^{\uparrow}$ row W supplies the windows, and R supplies the regular rational readback for exactly those windows. Transport H and replay C preserve the same rows before provenance and local naming are read.

Since E is the only Real-facing coordinate and the packet has no slot for quotient streams, selected limits, countable choice, ambient completeness, Lean verification, or bridge data, the local NameCert surface is exactly the finite list stated above. □

Theorem 6520.3 (SequentialFan Cauchy-window boundary)**.** *Every Cauchy-facing or Real-facing read accepted by a* $\mathsf{SequentialFan}^{\uparrow}$ *packet factors through the finite fan-bar window before it reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Equivalently, the visible route is*

$$\mathsf{FanTheorem}^{\uparrow},\ \mathsf{CantorSpace}^{\uparrow} \longmapsto T, B \longmapsto \mathsf{StreamName}^{\uparrow}(W) \longmapsto \mathsf{RegSeqRat}^{\uparrow}(R) \longmapsto \mathsf{Real}^{\uparrow}(E)$$

with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. A read that bypasses the finite bar window, inserts a selected branch, or distinguishes terminal seals by quotient stream equality is outside the accepted* $\mathsf{SequentialFan}^{\uparrow}$ *carrier.*

Proof. Begin with the carrier of Definition 6520.1. The only prefix data are the finite tree row T and the bar witness B; hence a Cauchy-facing request cannot inspect an unbounded branch inside the packet.

The finite bar boundary determines which StreamName windows are visible. Those windows are recorded in W, and the regular rational readback row R is attached to the same displayed windows.

The terminal Real seal E is read only after T, B, W, R and the support rows H, C, P, N have been displayed. Therefore every accepted Cauchy or Real read follows the stated route through the finite fan-bar window before the RegSeqRat and Real rows are exposed.

The exclusion clause follows from the missing carrier coordinates: there is no selected branch, quotient stream equality, selected limit, countable-choice row, ambient completeness row, or alternate Real seal through which a consumer could bypass the finite window boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialFan}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialFan}^{\uparrow}$ packet is generated from a finite fan prefix tree, a displayed bar witness, StreamName finite-window rows, RegSeqRat readback rows, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialFan}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6520.1, Definition 6520.2, and Definition 6520.3 seed the finite fan-bar window surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialFan}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected infinite branches, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan-prefix compatibility, stream-window exposure, regular-readback exactness, and terminal-seal nonescape for BEDC.Derived.SequentialFanUp.

Chapter 6521

A Concrete Naming Certificate for $\mathsf{FrechetUrysohnFan}^{\uparrow}$

Following Kelley and Engelking on Frechet–Urysohn spaces and sequential fans, the $\mathsf{FrechetUrysohnFan}^{\uparrow}$ packet records the finite fan-indexed closure surface by which a sequential fan supplies a displayed Frechet–Urysohn closure handoff. It sits adjacent to the finite fan-bar carrier of chapter 6520, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed fan arms, finite stream windows, regular rational tails, Real seals, closure witnesses, transport, replay, provenance, and local naming; it does not assert arbitrary topological nets, a selected branch through the fan, countable choice, host quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6521.1 (Frechet-Urysohn fan carrier)**.** *A* $\mathsf{FrechetUrysohnFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, W, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{SequentialFan}^{\uparrow}$ *arm row, recording the finite fan-bar surface and the displayed arm on which the closure read is made.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected arm segments.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-readback row attached to those windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, W, R have been displayed.*
5. *L is the Frechet–Urysohn closure-witness row, recording that the named limit point is approached along the displayed fan arm through the same windows and tails.*
6. *H records componentwise* hsame *transport for arm, window, readback, Real-seal, closure-witness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a fan-closure request through A, W, R, E, L, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FrechetUrysohnFan}^{\uparrow}$, $\mathsf{SequentialFan}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetUrysohnFan}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, R, E, L, H, C, P, N$. It has no coordinate for arbitrary nets, selected fan branches, quotient stream equality, host real equality, countable choice, or ambient completeness.

Theorem 6521.2 (Frechet-Urysohn fan NameCert obligations)**.** *For every accepted* $\mathsf{FrechetUrysohnFan}^{\uparrow}$ *carrier*

$$F = (A, W, R, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrechetUrysohnFan}^{\uparrow}}$ *surface consists exactly of sequential-fan arm admission through* A*, StreamName window exposure through* W*, RegSeqRat tail readback through* R*, terminal Real-seal ordering through* E*, Frechet–Urysohn closure-witness display through* L*, componentwise transport through* H*, displayed continuation replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The fan-facing data are the arm row A and the finite windows W, while the analytic readback is carried by R and then by the terminal Real seal E.

The closure witness is row-local. The row L can certify only the displayed arm and the windows already exposed by A, W, R, E; it has no coordinate for an arbitrary net, a selected branch outside the arm row, or a host closure operator.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no hidden branch selector, quotient stream equality, host real equality, countable-choice row, or ambient completeness row, the listed rows exhaust the local NameCert obligation surface. □

Theorem 6521.3 (Frechet-Urysohn fan stream-closure handoff)**.** *Every consumer that reads a* $\mathsf{FrechetUrysohnFan}^{\uparrow}$ *packet as a sequential-closure witness must factor through*

$$\mathsf{SequentialFan}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the Frechet–Urysohn closure row L *is visible. The handoff exports the displayed fan arm, finite stream windows, regular rational tails, terminal Real seal, and closure witness only; it does not export arbitrary nets, selected branches, quotient stream equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 6521.2. A closure-facing consumer first reads the sequential-fan arm row A, and this row is the only point at which the packet can consume the fan surface of chapter 6520.

The finite StreamName windows W and RegSeqRat readback R are downstream of that same displayed arm. The Real seal E is downstream of both, so the closure row L cannot be read before the route has passed through chapter 126, chapter 301, and chapter 38.

Thus the consumer receives a finite stream-closure handoff, not an ambient topological closure theorem. The missing carrier coordinates exclude arbitrary nets, selected branches, quotient stream equality, selected limits, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the exported surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetUrysohnFan}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrechetUrysohnFan}^{\uparrow}$ packet is generated from a SequentialFan arm row, StreamName finite-window rows, RegSeqRat tail readbacks, a terminal Real seal, a Frechet–Urysohn closure-witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrechetUrysohnFan}^{\uparrow}}$, seed)

Scope closed: Definition 6521.1, Definition 6521.2, and Definition 6521.3 seed the fan-indexed sequential-closure carrier over SequentialFan, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrechetUrysohnFan}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary nets, selected fan branches, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked arm admission, finite-window exposure, tail readback, Real-seal ordering, closure-witness display, transport, replay, provenance, and local naming for BEDC.Derived.FrechetUrysohnFanUp.

Chapter 6522

A Concrete Naming Certificate for BishopFanCompactUniform$^{\uparrow}$

Following Bishop–Bridges finite fan and compact-uniform-continuity arguments, the BishopFanCompactUniform$^{\uparrow}$ packet realizes the compact-uniform-continuity vision of chapter 9237 as finite NameCert data. It sits between the compact-uniform-continuity carrier of chapter 388, the bar discipline of chapter 400, the compact metric source rows of chapter 129, and the continuous-map rows of chapter 130. The packet records finite fan bars, compact finite observations, pointwise modulus rows, uniform-modulus extraction, transport, replay, provenance, and local naming; it does not assert open-cover compactness, a selected infinite branch, countable choice, quotient map equality, or ambient completeness.

Definition 6522.1 (BishopFanCompactUniform carrier)**.** *A* BishopFanCompactUniform$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, B, L, U, D, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite observation row, exposing only the compact source windows used by the uniform-continuity request.*
2. *M is the* ContinuousMap$^{\uparrow}$ *row whose pointwise modulus entries are being compared.*
3. *B is the finite* FanTheorem$^{\uparrow}$ *bar row, recording a prefix boundary that covers all displayed compact-source cases.*
4. *L is the local pointwise-modulus ledger read along the bar leaves.*
5. *U is the uniform-modulus handoff row consumed by* CompactUniformContinuity$^{\uparrow}$ *after K, M, B, L have been displayed.*
6. *D is the dyadic tolerance and rational lower-bound ledger used to compare the local moduli and the output tolerance.*
7. *H records componentwise* hsame *transport for $K, M, B, L, U, D, C, P, N$.*
8. *C records displayed* Cont *replay from compact-source rows and continuous-map rows through the fan bar, local modulus ledger, dyadic comparison, uniform-modulus handoff, provenance, and local naming.*
9. *P is the* Pkg *provenance over* BishopFanCompactUniform$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FanTheorem$^{\uparrow}$, CompactUniformContinuity$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopFanCompactUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, B, L, U, D, H, C, P, N$. It has no coordinate for an arbitrary open cover, global branch selector, selected external Lebesgue number, quotient map equality, countable choice, or ambient compactness theorem.

Theorem 6522.2 (BishopFanCompactUniform NameCert obligations)**.** *For every accepted* BishopFanCompactUnif *carrier*

$$F = (K, M, B, L, U, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopFanCompactUniform}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for compact-source observations, continuous-map rows, finite fan-bar data, local pointwise moduli, uniform-modulus handoff, dyadic tolerance comparison, transport, replay, provenance, and local naming;*
2. *compact-source exposure, requiring every source observation to enter through K before any modulus row is read;*
3. *continuous-map exposure, requiring the pointwise modulus ledger L to be tied to the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *row M;*
4. *fan-bar coverage, requiring the finite bar B to bound all accepted compact-source cases before U is exposed;*
5. *modulus-route exactness, requiring U to be produced only from K, M, B, L, D and excluding arbitrary open covers, selected branches, selected external radii, quotient map equality, countable choice, Lean verification, and bridge checking.*

No BishopFanCompactUniform obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.BishopFanCompactUniformUp.TasteGate.BishopFanCompactUniformTasteGate single carrier alignment`

Proof. Project the accepted carrier. The compact source and map data are K and M, the fan boundary is B, the local modulus ledger is L, and the output handoff is U.

The source and map exposure obligations are forced because the carrier has no alternate compact-space or function coordinate. Every local modulus row is therefore read as a row over the displayed K, M boundary.

The finite bar row B supplies the coverage boundary. The dyadic ledger D compares the finitely many local rows in L and records the tolerance handoff consumed by U.

Transport H and replay C preserve the same finite route before provenance and local naming. Since the carrier has no row for arbitrary open covers, branch selectors, external radius selection, quotient map equality, choice, Lean verification, or bridge data, the stated obligations exhaust the local NameCert surface. □

Theorem 6522.3 (BishopFanCompactUniform modulus route)**.** *Every uniform-modulus read accepted by a* $\mathsf{BishopFanCompactUniform}^{\uparrow}$ *packet factors through the finite Bishop fan route*

$$\mathsf{CompactMetric}^{\uparrow}(K),\ \mathsf{ContinuousMap}^{\uparrow}(M) \longmapsto \mathsf{FanTheorem}^{\uparrow}(B) \longmapsto L, D \longmapsto \mathsf{CompactUniformContinuity}^{\uparrow}(U)$$

with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *support rows. A consumer cannot obtain a uniform modulus from an open-cover compactness oracle, a selected branch, an external Lebesgue number, quotient map equality, countable choice, or ambient compactness data.*

Proof. Start with an accepted uniform-modulus read. By Definition 6522.1, the compact source row K and continuous-map row M are the only rows from which source observations and pointwise moduli can be read.

The finite fan-bar row B bounds the displayed cases. The local ledger L is then a finite list over the bar leaves, and the dyadic comparison row D folds those entries into the output handoff U.

The structural rows H, C, P, N keep the same finite carrier under transport, continuation replay, provenance, and naming. Thus every accepted read follows the displayed Bishop fan route before $\mathsf{CompactUniformContinuity}^{\uparrow}$ consumes the uniform-modulus row.

The excluded objects have no carrier coordinate, so they cannot be inserted between the compact-source and uniform-modulus faces of the packet. □

Theorem 6522.4 (BishopFanCompactUniform nonescape)**.** *Every accepted* $\mathsf{BishopFanCompactUniform}^{\uparrow}$ *route to a* $\mathsf{UniformModulus}^{\uparrow}$ *handoff must first display the finite fan-bar modulus boundary of chapter 4297, the compact metric source rows of chapter 129, and the continuous-map pointwise rows of chapter 130. The handoff is therefore a finite-row route through* $K, M, B, L, U, D, H, C, P, N$*, not an open-cover compactness claim, selected branch, external Lebesgue-number choice, quotient equality, countable-choice principle, or ambient completeness theorem.*

Proof. Read the accepted carrier in Definition 6522.1. The compact source row is K, the continuous-map row is M, and the finite fan boundary is B.

Apply Definition 6522.3. It places every uniform-modulus read downstream of the compact metric source, continuous-map pointwise ledger, fan-bar coverage row, local modulus ledger, and dyadic comparison row.

The named sibling chapters supply exactly those public surfaces: finite fan-bar modulus, compact metric source data, and continuous-map pointwise rows. Since no coordinate stores open-cover compactness, branch selection, external radius selection, quotient equality, countable choice, or ambient completeness, the $\mathsf{UniformModulus}^{\uparrow}$ handoff cannot escape the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFanCompactUniform}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFanCompactUniform}^{\uparrow}$ packet is generated from compact metric source observations, continuous-map pointwise modulus rows, a finite fan-bar row, local modulus ledgers, a uniform-modulus handoff, dyadic tolerance comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFanCompactUniform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6522.1, Definition 6522.2, Definition 6522.3, and Definition 6522.4 seed the finite Bishop fan route for compact-uniform-modulus extraction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFanCompactUniform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, selected infinite branches, selected external Lebesgue numbers, quotient map equality, countable choice, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, continuous-map exposure, fan-bar coverage, modulus-route exactness, and nonescape for BEDC.Derived.BishopFanCompactUniformUp.

Chapter 6523

A Concrete Naming Certificate for $\mathsf{PolishCompletion}^{\uparrow}$

Following Alexandrov–Urysohn and the Kechris presentation of Polish spaces as separable completely metrizable spaces, the $\mathsf{PolishCompletion}^{\uparrow}$ packet records the finite BEDC route by which a separable metric presentation is completed into a Polish-space-facing carrier. It sits after the Polish-space surface of chapter 1490, the separable completion route of chapter 1714, and the Bishop metric completion packet of chapter 4023. The construction also consumes the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route used by Real and regular-rational completion readers; it does not quotient Cauchy names, select representatives, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness outside the displayed completion packet.

Definition 6523.1 (Polish completion carrier)**.** *A* $\mathsf{PolishCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, D, M, S, B, W, R, Q, E, H, C, K, N)$$

with the following displayed rows:

1. *X is the separable metric source row whose dense naming surface is inspected before completion.*
2. *D is the countable dense-window ledger read as finite* $\mathsf{StreamName}^{\uparrow}$ *observations, not as a completed choice sequence.*
3. *M is the* $\mathsf{BishopMetricCompletion}^{\uparrow}$ *row carrying the constructive metric-completion handoff.*
4. *S is the* $\mathsf{SeparableCompletion}^{\uparrow}$ *row binding the dense source to the completion route.*
5. *B is the* $\mathsf{PolishSpace}^{\uparrow}$ *target boundary row, read only after the separable and complete-metric rows have been displayed.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule used by completion-facing readers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the completion and readback rows.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after W, R, Q, M, S, B have been displayed.*
10. *H records componentwise* hsame *transport for the source, dense-window, completion, Polish boundary, readback, tolerance, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from source inspection through dense windows, Bishop completion, separable completion, Polish boundary, regular readback, tolerance, and Real sealing.*

12. *K is the* Pkg *provenance over* $\mathsf{PolishCompletion}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{SeparableCompletion}^{\uparrow}$, $\mathsf{BishopMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PolishCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient Cauchy equality, selected completion representatives, a countable-choice dense sequence, trichotomy, host equality of real names, or ambient completeness outside the named packet.

Theorem 6523.2 (Polish completion NameCert obligations)**.** *For every accepted* $\mathsf{PolishCompletion}^{\uparrow}$ *carrier* $P = (X, D, M, S, B, W, R, Q, E, H, C, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PolishCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the separable metric source, finite dense-window ledger, Bishop metric completion handoff, separable completion row, Polish-space boundary, StreamName window schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming rows.*

No NameCert obligation is stored in a quotient of Cauchy names, a selected representative, a host dense sequence, a countable-choice schedule, trichotomy, host real equality, or an ambient completeness theorem.

Proof. Project the carrier of Definition 6523.1. The accepted packet exposes exactly the rows $X, D, M, S, B, W, R, Q, E, H, C, K, N$.

The source and dense-window rows are finite. The row X supplies the separable metric source, while D exposes only inspected dense windows through the same finite schedule discipline used by $\mathsf{StreamName}^{\uparrow}$.

The completion-facing rows are downstream. The Bishop metric completion row M and separable completion row S are read before the Polish boundary B, and the window, readback, dyadic tolerance, and Real seal rows W, R, Q, E are visible before any public completion read is exported.

Finally H, C, K, N transport, replay, source, and name the same packet. Since none of the excluded host or choice principles appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6523.3 (Polish completion complete separable route)**.** *Every Polish-space-facing read of an accepted* $\mathsf{PolishCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$X, D, W, R, Q, M, S, B, E, H, C, K, N.$$

The route first displays the separable metric source and dense-window ledger, then reads finite StreamName windows, RegSeqRat readback, and DyadicRatCore tolerances, then passes through Bishop metric completion and separable completion before the Polish boundary and terminal Real seal are exposed. It exports a public BEDC completion route, not a host theorem asserting complete metrizability, a quotient completion class, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations above. They force every consumer to expose the separable metric source, dense-window ledger, completion handoffs, window schedule, regular readback, tolerance ledger, Real seal, transport, replay, provenance, and local name.

Use the sibling completion route. The $\mathsf{BishopMetricCompletion}^{\uparrow}$ row supplies the constructive complete-metric handoff, while the $\mathsf{SeparableCompletion}^{\uparrow}$ row keeps the dense source visible before the $\mathsf{PolishSpace}^{\uparrow}$ boundary is read.

Finally follow the Real and regular-rational support rows. The finite window W, readback R, tolerance ledger Q, and seal E keep the public route inside displayed BEDC data. Because the

classifier has no coordinate for quotient classes, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the complete separable route is exhausted by the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolishCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{PolishCompletion}^{\uparrow}$ packet is generated from a separable metric source row, dense-window ledger, Bishop metric completion row, separable completion row, Polish-space boundary, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolishCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6523.1, Definition 6523.2, and Definition 6523.3 seed the finite Polish completion route over separable metric source data, Bishop metric completion, separable completion, Polish-space boundary, StreamName, RegSeqRat, DyadicRatCore, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolishCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected representatives, countable-choice dense sequences, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-window exposure, Bishop metric completion handoff, separable completion handoff, Polish boundary exposure, regular readback, dyadic tolerance budgeting, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.PolishCompletionUp.

Chapter 6524

A Concrete Naming Certificate for $\mathsf{SteffensenAcceleration}^{\uparrow}$

Following Steffensen and Aitken, the $\mathsf{SteffensenAcceleration}^{\uparrow}$ packet records a fixed-point acceleration window by naming the local delta-squared transform of consecutive iterates before any real-number seal is read. It sits beside the $\mathsf{AitkenDeltaSquared}^{\uparrow}$ acceleration certificate of chapter 1523, the Newton step surface of chapter 223, the fixed-point iterate schedule of chapter 2383, the stream row of chapter 126, the regular rational route of chapter 301, and the final real-name seal of chapter 38. The chapter names a finite numerical-analysis carrier; it does not assert host fixed-point equality, quotient real equality, convergence by countable choice, or an ambient completeness theorem.

Definition 6524.1 (Steffensen acceleration carrier)**.** *A* $\mathsf{SteffensenAcceleration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, A, N, F, W, R, E, H, C, P, L)$$

with the following rows:

1. *I is the* $\mathsf{FixedPointIteration}^{\uparrow}$ *iterate-window row, exposing three consecutive inspected approximants and the displayed fixed-point map row;*
2. *A is the* $\mathsf{AitkenDeltaSquared}^{\uparrow}$ *delta-squared transform row applied to that finite window;*
3. *N is the optional* $\mathsf{NewtonIteration}^{\uparrow}$ *neighbour row when the displayed fixed-point map is read through a Newton-style residual update;*
4. *F records the finite denominator-apartness and fallback ledger needed to keep the transformed window constructive;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the inspected iterate depths;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational acceleration values;*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal reached only after R is displayed;*
8. *H records componentwise* hsame *transport of I, A, N, F, W, R, E;*
9. *C records displayed* Cont *replay of the same finite acceleration route;*
10. *P is the* Pkg *provenance over* $\mathsf{SteffensenAcceleration}^{\uparrow}$*,* $\mathsf{AitkenDeltaSquared}^{\uparrow}$*,* $\mathsf{NewtonIteration}^{\uparrow}$*,* $\mathsf{FixedPointIteration}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*

11. L is the local $\mathsf{NameCert}_{\mathsf{SteffensenAcceleration}^{\uparrow}}$ *row.*
The carrier has no coordinate for an ambient fixed point, an infinite convergence proof, quotient equality of real names, or a choice-selected subsequence of iterates.

Theorem 6524.2 (Steffensen finite-window NameCert obligations)**.** *For the carrier of Definition 6524.1, the local* $\mathsf{NameCert}_{\mathsf{SteffensenAcceleration}^{\uparrow}}$ *surface consists exactly of carrier admission, fixed-point iterate-window admission through I, Aitken delta-squared transform admission through A, Newton-neighbour admission through N when present, denominator-apartness and fallback admission through F, stream schedule admission through W, regular rational readback through R, downstream* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through L.*

Proof. Project the carrier $S = (I, A, N, F, W, R, E, H, C, P, L)$. The finite iterate row I supplies only the inspected fixed-point window, while A records the Aitken delta-squared calculation on that same window.

The rows N and F restrict the numerical read to displayed Newton-neighbour and denominator-apartness data. If the denominator row is not available, the fallback ledger remains part of the named packet rather than being replaced by a host convergence claim.

Finally W, R, E, H, C, P, L schedule, read back, seal, transport, replay, source, and name the same finite route. Since no other coordinate appears in the carrier, the NameCert surface cannot export host fixed-point equality, quotient real equality, countable choice, or ambient completeness. □

Theorem 6524.3 (Steffensen acceleration Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{SteffensenAcceleration}^{\uparrow}$ *packet must pass through the finite route*

$$I, A, N, F, W, R, E, H, C, P, L.$$

The consumer receives an inspected fixed-point iterate window, the Aitken delta-squared acceleration row, any displayed Newton-neighbour residual row, the denominator-apartness or fallback ledger, the stream schedule, and the $\mathsf{RegSeqRat}^{\uparrow}$ *readback before it may read the* $\mathsf{Real}^{\uparrow}$ *seal. It receives no host fixed point, no quotient equality of real names, no hidden convergence principle, and no countable-choice schedule.*

Proof. Begin with the accepted carrier of Definition 6524.1. The iterate row I and transform row A determine the acceleration window before any real-facing data are visible.

Next read the numerical guard rows. The Newton-neighbour row N is optional packet data, and the denominator row F records the constructive apartness or fallback route needed by the delta-squared transform.

The stream and rational rows W, R then present the accelerated values as finite readback data. Only after those rows are displayed does E seal the route as a $\mathsf{Real}^{\uparrow}$ consumer surface, while H, C, P, L preserve the same packet under transport, replay, provenance, and naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{SteffensenAcceleration}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SteffensenAcceleration}^{\uparrow}$ packet is generated from a fixed-point iterate window, an Aitken delta-squared transform row, an optional Newton-neighbour row, a denominator-apartness or fallback ledger, a stream schedule, regular rational readback, a downstream real-name seal, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SteffensenAcceleration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6524.1, Definition 6524.2, and Definition 6524.3 specify the finite Steffensen acceleration packet and its route to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{SteffensenAcceleration}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close Lean verification, a standard bridge, host fixed-point equality, quotient real equality, a general convergence theorem, countable choice, or ambient completeness of Real$^{\uparrow}$.
Upgrade path: Obligation closure requires Lean encoding of the finite carrier, transform guard, readback route, and Real-facing non-escape theorem.

Chapter 6525

A Concrete Naming Certificate for $\mathsf{ThomaeFunction}^{\uparrow}$

Following Thomae and Bishop–Bridges constructive analysis, the $\mathsf{ThomaeFunction}^{\uparrow}$ packet records the finite rational-spike data by which the popcorn-function example is read through rational density, denominator ledgers, regular rational windows, and the terminal Real seal. It consumes the rational-density input surface of chapter 1409, the $\mathsf{Rat}^{\uparrow}$ denominator arithmetic of chapter 37, the finite windows and readback rows of chapter 126 and chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the continuity-facing boundary of chapter 130; these sibling rows cannot be replaced by host function extensionality, selected rational enumeration, quotient real equality, or classical discontinuity sets. The packet names the constructive rational-spike function as finite BEDC data; it is not a host function, a quotient-real extensionality principle, a global continuity theorem, a selected enumeration of rationals, or a classical discontinuity set.

Definition 6525.1 (Thomae function carrier)**.** *A* $\mathsf{ThomaeFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational-density input row, recording the finite rational sample by which the spike query is opened.*
2. *D is the denominator spike ledger, recording the denominator bound and the spike height assigned to the visible rational input.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect the finite name data around the input.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from that window.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row that receives the rational-spike value as a Real-facing output.*
6. *H records componentwise* hsame *transport for rational input, denominator ledger, stream window, regular-rational readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a rational-density input through Q, D, S, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{ThomaeFunction}^{\uparrow}$*, RationalDensityRealUp,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ThomaeFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, S, R, E, H, C, P, N$. It has no coordinate for host function extensionality, quotient real equality, selected rational enumerations, global continuity, or a classical discontinuity set.

Theorem 6525.2 (Thomae function NameCert obligations)**.** *For every accepted* $\mathsf{ThomaeFunction}^{\uparrow}$ *carrier*

$$T = (Q, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ThomaeFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, rational-density input, denominator spike ledger stability, StreamName window stability, regular-rational readback, Real-facing seal stability, componentwise transport, displayed replay, provenance, and ledger non-escape through* $Q, D, S, R, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.ThomaeFunctionUp.ThomaeFunction namecert obligations`

Proof. Project the carrier of Definition 6525.1. The rational input row Q, denominator ledger D, stream window S, regular-rational readback R, Real seal E, and structural rows H, C, P, N are the whole packet.

Rational-density input and denominator spike stability are read from Q, D. These rows record the finite input and spike height before any Real-facing consumer can inspect the output.

Readback stability is supplied by S, R, E. The stream window exposes the finite observations, the regular rational row replays them as readback data, and the terminal Real row seals the same finite route.

Finally H, C, P, N transport, replay, source, and name the displayed rows. Since no further coordinate is present, host function extensionality, quotient real equality, selected rational enumerations, global continuity, and classical discontinuity sets remain outside the ledger. □

Theorem 6525.3 (Thomae function rational-spike locality)**.** *Every rational-spike read of an accepted* $\mathsf{ThomaeFunction}^{\uparrow}$ *carrier factors through RationalDensityRealUp,* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before it exposes a value to a* $\mathsf{ContinuousMap}^{\uparrow}$*-facing consumer. The read may display the local denominator spike and the finite Real seal, but it cannot use host function extensionality, quotient real equality, a selected rational enumeration, or a global continuity theorem.*

Proof. Let

$$T = (Q, D, S, R, E, H, C, P, N)$$

be an accepted carrier. The rational-density row Q opens the finite input request, and the denominator ledger D determines the visible spike height using only rational arithmetic recorded in the packet.

The stream and regular-rational rows S, R then expose the finite window and readback route. The Real seal E is downstream of the same rows, so a Real-facing consumer receives the spike value only after the denominator ledger and readback route have both been displayed.

The continuity-facing boundary can read the result only through the structural rows H, C, P, N. Therefore the route is local to the displayed rational-density, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ data, and the excluded host and quotient principles never enter the packet. □

Theorem 6525.4 (Thomae function rational denominator route)**.** *For every accepted* $\mathsf{ThomaeFunction}^{\uparrow}$ *carrier*

$$T = (Q, D, S, R, E, H, C, P, N),$$

each rational-spike value is routed through the $\mathsf{Rat}^{\uparrow}$ *denominator ledger* D*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before any continuity-facing consumer may inspect oscillation. The route is finite BEDC denominator arithmetic and readback data; it is not a selected rational enumeration, quotient-real equality, host function extensionality, or a classical discontinuity-set argument.*

Proof. Project the carrier rows from Definition 6525.1. The rational-density row Q admits the displayed rational input, while the denominator ledger D records the denominator bound and spike height as the only rational arithmetic available to the packet.

Apply the NameCert obligations of Definition 6525.2. They force denominator spike ledger stability, StreamName window stability, regular-rational readback, Real-facing seal stability, transport, replay, provenance, and ledger non-escape to be read from the same rows D, S, R, E, H, C, P, N.

Use the rational-spike locality theorem, Definition 6525.3, for the consumer boundary. A continuity-facing read can inspect oscillation only after the denominator ledger has passed through the finite window, regular readback, and terminal Real seal.

Since the carrier has no coordinate for a selected rational enumeration, quotient-real equality, host function extensionality, or a classical discontinuity set, the denominator route is exhausted by the displayed $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{ThomaeFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{ThomaeFunction}^{\uparrow}$ packet is generated from a rational-density input row, denominator spike ledger, StreamName window, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ThomaeFunction}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6525.1, Definition 6525.2, Definition 6525.3, and Definition 6525.4 bind the finite rational-spike route from rational input through denominator arithmetic to Real-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ThomaeFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient real equality, selected rational enumeration, global continuity, classical discontinuity sets, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires downstream continuity-facing consumers to preserve the displayed denominator ledger, finite window, regular readback, and Real seal route.

Chapter 6526

A Concrete Naming Certificate for $\mathsf{RegularSequenceApartness}^{\uparrow}$

Bishop-style constructive analysis treats apartness of real names as positive information: two regular Cauchy presentations are apart only when a displayed rational tolerance separates inspected approximants. The $\mathsf{RegularSequenceApartness}^{\uparrow}$ packet records that positive route as finite BEDC data between the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the located-apartness bridge of chapter 3564. It is a constructive positive-separation interface for L10 Real and Completion consumers, not quotient real equality, real trichotomy, a hidden representative selector, or ambient completeness.

Definition 6526.1 (Regular sequence apartness carrier)**.** *A* $\mathsf{RegularSequenceApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S_0, S_1, R_0, R_1, D, W_0, W_1, E_0, E_1, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened for the compared regular Cauchy real names.*
2. *R_0 and R_1 are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed through S_0 and S_1.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-tolerance witness. It records a dyadic $\varepsilon > 0$, the inspected stages, and the displayed inequality asserting that the two rational approximants differ by at least that tolerance after the regular slack budget is accounted for.*
4. *W_0 and W_1 are the finite window records that bind the displayed tolerance in D to the two readback rows.*
5. *E_0 and E_1 are the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows for the two names, available only after $S_0, S_1, R_0, R_1, D, W_0, W_1$ have been displayed.*
6. *H records componentwise* hsame *transport for the two stream windows, two regular-rational readbacks, dyadic witness, window records, Real seals, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D, W_0, W_1 \longmapsto E_0, E_1.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceApartness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceApartness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient real equality, trichotomy, selected representatives, hidden completion limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6526.2 (Regular sequence apartness NameCert obligations)**.** *For every accepted* RegularSequenceApartne *carrier $A = (S_0, S_1, R_0, R_1, D, W_0, W_1, E_0, E_1, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceApartness}^{\uparrow}}$ *surface consists exactly of carrier admission, two* $\mathsf{StreamName}^{\uparrow}$ *window exposures, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-tolerance witness, two witness-window records, ordered* $\mathsf{Real}^{\uparrow}$ *seal access, classifier stability under the displayed rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and nonescape from that route. No NameCert obligation may replace the positive witness by quotient real equality, real trichotomy, selected representatives, hidden completion limits, countable choice, or ambient completeness.*

Proof. Project the accepted packet. The carrier exposes exactly two finite stream windows, two regular-rational readbacks, the dyadic positive-tolerance witness, two witness-window records, the terminal Real seals, and the structural rows H, C, P, N.

The witness row D is read before either terminal Real seal can be consumed. Its positivity is displayed inside the dyadic ledger and is attached to inspected regular-rational approximants through W_0 and W_1.

Classifier stability follows because the classifier has coordinates only for the listed rows. Componentwise hsame transport preserves the same displayed windows, witness, seals, replay, provenance, and local naming data.

The Cont row replays the route from finite windows to readbacks, then to the positive witness and witness windows, and only then to the Real seals. The package and local NameCert rows source and name that route.

Since the packet has no coordinate for quotient real equality, trichotomy, representative selection, hidden limits, countable choice, or ambient completeness, every accepted consumer remains inside the displayed positive-separation route. □

Theorem 6526.3 (Regular sequence apartness positive separation)**.** *Every positive-separation conclusion exported by an accepted* $\mathsf{RegularSequenceApartness}^{\uparrow}$ *packet is read from the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D together with the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R_0, R_1 and witness-window rows W_0, W_1. The conclusion does not depend on quotient real equality, real trichotomy, selected representatives, hidden completion limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier of Definition 6526.1. The only positive datum in the packet is the dyadic tolerance witness D, and D is attached to the two displayed readbacks by the window records W_0 and W_1.

Read R_0 and R_1 before reading D. The separation claim therefore refers to concrete rational approximants in the $\mathsf{RegSeqRat}^{\uparrow}$ rows, with the regular slack budget accounted for by the dyadic witness itself.

The terminal Real seals E_0 and E_1 are reached only after the positive witness route has already been displayed. They name the two real boundaries for downstream Real and Completion consumers, but they do not create the separation evidence.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Because no quotient, trichotomy, representative-selection, hidden-limit, choice, or completeness

coordinate appears in the carrier, such a coordinate cannot be the source of the positive-separation conclusion. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceApartness}\uparrow}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularSequenceApartness}\uparrow}$, seed)

Scope closed: Definition 6526.1, Definition 6526.2, and Definition 6526.3 seed the finite constructive apartness route over displayed regular readbacks, dyadic positive tolerance, witness windows, and terminal Real seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularSequenceApartness}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, located-order algebra, quotient real equality, real trichotomy, selected representatives, hidden completion limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, public closure, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired StreamName exposure, paired RegSeqRat readback, dyadic positive-tolerance exactness, witness-window exactness, ordered Real seal access, classifier stability, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.RegularSequenceApartnessUp.

Constructive story: A $\mathsf{RegularSequenceApartness}^{\uparrow}$ packet is generated from two StreamName windows, two RegSeqRat readback rows, a DyadicRatCore positive-tolerance witness, two witness-window rows, two RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6527

A Concrete Naming Certificate for $\mathsf{LocatedInverseBranch}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedInverseBranch}^{\uparrow}$ packet records a finite branch of a located inverse read after the located target interval, monotone window, dyadic tolerance ledger, finite stream observations, regular rational readback, and terminal real-name seal have all been displayed. It sits between the local inverse-function route of chapter 6001, the interval branch route of chapter 5546, the located real surface of chapter 1933, and the L10 real-name lattice of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names one displayed branch route for a located inverse request; it is not a host inverse-function theorem, a selected global branch, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6527.1 (Located inverse branch carrier)**.** *A* $\mathsf{LocatedInverseBranch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, I, J, M, V, D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{BishopLocatedInverseFunction}^{\uparrow}$ *row naming the local inverse-function packet whose map, located apartness bridge, and target request are being read.*
2. *I is the* $\mathsf{LocatedReal}^{\uparrow}$ *source-and-target interval row, carrying the located endpoint data and target window that delimit the inverse request.*
3. *J is the* $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ *branch row, recording the retained interval side and the finite branch history used to isolate the source window.*
4. *M is the monotone-window row. It records the finite order comparisons that keep the retained branch compatible with the local inverse request.*
5. *V is the branch-validity row, requiring the target window and retained source window to remain tied to the same located inverse-function data.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger storing dyadic radii, midpoint budgets, comparison slack, and endpoint-readback conversions.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for source endpoints, target requests, function values, and retained branch endpoints.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows and dyadic tolerance ledger.*

9. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, I, J, M, V, D, S, Q have been displayed.*
10. *H records componentwise* hsame *transport for the inverse-function, located interval, bisection branch, monotone window, branch-validity, dyadic, stream, regular readback, Real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a located inverse-branch request through $F, I, J, M, V, D, S, Q, R, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{LocatedInverseBranch}^{\uparrow}$, $\mathsf{BishopLocatedInverseFunction}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedInverseBranch}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, I, J, M, V, D, S, Q, R, H, C, P, N$. It has no coordinate for a host inverse function, selected global branch, quotient real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credential.*

Theorem 6527.2 (Located inverse branch NameCert obligations)**.** *For every accepted* $\mathsf{LocatedInverseBranch}^{\uparrow}$ *carrier*

$$B = (F, I, J, M, V, D, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedInverseBranch}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, inverse-function admission through F, located interval admission through I, bisection-branch admission through J, monotone-window compatibility through M, branch-validity through V, dyadic tolerance accounting through D, finite-window exposure through S, regular rational handoff through Q, terminal Real seal discipline through R, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6527.1. The projection exposes exactly the rows $F, I, J, M, V, D, S, Q, R, H, C$ so carrier admission and row inventory are finite.

The branch request begins with F and I. The inverse-function row supplies the local map, apartness, uniqueness, and existence data, while the located interval row supplies the source and target windows that the branch may inspect.

The retained branch is then read through J, M, V. The bisection row records the finite branch history, the monotone-window row records the order comparisons used by that branch, and the validity row keeps the retained source window attached to the same target request.

Tolerance and readback are downstream. The dyadic ledger D supplies all radii, midpoint budgets, comparison slack, and conversions; the finite stream row S supplies the inspected values; and the regular rational row Q reads only those displayed windows before the Real seal R is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for a host inverse function, selected global branch, quotient real equality, trichotomy, countable choice, ambient completeness, or bridge credential, the listed rows exhaust the local NameCert obligations. □

Theorem 6527.3 (Located inverse branch monotone window)**.** *Every retained branch read in an accepted* $\mathsf{LocatedInverseBranch}^{\uparrow}$ *carrier*

$$B = (F, I, J, M, V, D, S, Q, R, H, C, P, N)$$

must expose the route

$$F, I \longmapsto J, M, V \longmapsto D, S, Q \longmapsto R, H, C, P, N.$$

Thus a monotone-window consumer receives the local inverse-function data, located interval data, displayed bisection branch, finite order comparisons, branch-validity witness, dyadic tolerance ledger, finite stream windows, regular rational readback, and structural rows before it can read the branch.

Proof. Start from a consumer of the retained branch. By the carrier definition, the only branch row is J, and J is attached to the local inverse-function row F and located interval row I.

The monotone information is not a host order theorem. It is the finite row M, read together with V so that the retained source window and target request remain on the same located inverse-function packet.

The consumer then reaches the dyadic, stream, and regular rational rows. The rows D, S, Q provide the tolerance budgets, finite inspected windows, and readback surface before the terminal seal R can be consumed.

The rows H, C, P, N preserve the same route under transport and replay. Therefore every monotone-window read factors through the stated branch route and exports none of the excluded host or choice principles. □

Theorem 6527.4 (Located inverse branch Real seal)**.** *No accepted* $\mathsf{LocatedInverseBranch}^{\uparrow}$ *packet can expose its* $\mathsf{Real}^{\uparrow}$ *seal row R before the* $\mathsf{BishopLocatedInverseFunction}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedRealIntervalBisection}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows of*

$$B = (F, I, J, M, V, D, S, Q, R, H, C, P, N)$$

have been displayed. The seal is a terminal L10 readback for the retained branch, not a selected inverse value, quotient representative, trichotomy decision, countable-choice product, or ambient completeness witness.

Proof. Apply the NameCert obligations of Definition 6527.2. They place the inverse-function, located interval, bisection branch, monotone-window, validity, dyadic, stream, and regular rational rows before the Real seal row.

Use the monotone-window theorem, Definition 6527.3. It orders every retained branch read through F, I, J, M, V, D, S, Q before R is reachable.

The structural rows H, C, P, N keep that order stable under transport, replay, provenance, and local naming. Since the carrier has no selected inverse value, quotient representative, trichotomy decision, countable-choice product, or ambient completeness coordinate, the terminal seal cannot be read as any of those objects. □

Falsifiable prediction: A consumer that claims a $\mathsf{LocatedInverseBranch}^{\uparrow}$ branch while omitting the local inverse-function row, located interval row, bisection branch row, monotone-window row, branch-validity row, dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the carrier of Definition 6527.1.

Independence witness: bishop-located-inverse-function, located-real, located-real-interval-bisection, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedInverseBranch}^{\uparrow}$ binds a local inverse-function row, located interval row, retained bisection branch, monotone-window ledger, validity witness, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming in one branch certificate; each named sibling lacks at least one of these rows as a local branch coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedInverseBranch}^{\uparrow}}$.

Constructive story: A LocatedInverseBranch$^{\uparrow}$ packet is generated from a BishopLocatedInverseFunction$^{\uparrow}$ row, LocatedReal$^{\uparrow}$ interval data, a LocatedRealIntervalBisection$^{\uparrow}$ branch row, monotone-window comparisons, branch-validity evidence, DyadicRatCore$^{\uparrow}$ tolerances, StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, a terminal Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedInverseBranch}^{\uparrow}}$, seed)

Scope closed: Definition 6527.1, Definition 6527.2, Definition 6527.3, and Definition 6527.4 seed the finite retained-branch route for located inverse-function consumers.

Formal verification: FormalStatus(NameCert$_{\text{LocatedInverseBranch}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host inverse functions, selected global branches, quotient real equality, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inverse-function admission, located interval admission, bisection-branch admission, monotone-window compatibility, branch-validity, dyadic tolerance accounting, finite-window exposure, regular rational handoff, Real seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.LocatedInverseBranchUp.

Chapter 6528

A Concrete Naming Certificate for $\mathsf{StarRefinementModulus}^{\uparrow}$

Following Kelley and Bourbaki on star refinements of uniform covers, and Bishop–Bridges compact metric uniform-continuity arguments, the $\mathsf{StarRefinementModulus}^{\uparrow}$ packet records the finite step that turns a displayed star-refined compact cover into a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff. It sits after the compact metric source of chapter 129, the finite Lebesgue-number ledger of chapter 452, the metric triangle estimate of chapter 1159, and the uniform-modulus consumer of chapter 369. The packet names only finite cover-refinement, radius, center, estimate, and handoff rows; it does not assert open-cover compactness, choose an external Lebesgue number, form quotient equality of maps, use countable choice, or import ambient completeness.

Definition 6528.1 (StarRefinementModulus carrier)**.** *A* $\mathsf{StarRefinementModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, R, L, E, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover and finite-center row.*
2. *R is the star-refined cover row, recording that every displayed star lies inside a displayed member of the target cover.*
3. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius ledger attached to the refined cover.*
4. *E is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *estimate row used to compare a point with a selected finite center and then with its image.*
5. *T is the dyadic tolerance row that ties the requested target tolerance to the radius ledger.*
6. *U is the resulting* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row.*
7. *H records componentwise* hsame *transport for $K, R, L, E, T, U, C, P, N$.*
8. *C records displayed* Cont *replay from a target tolerance request through the star-refinement, Lebesgue-radius, triangle-estimate, and uniform-modulus rows.*
9. *P is the* Pkg *provenance over* $\mathsf{StarRefinementModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StarRefinementModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, R, L, E, T, U, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, a choice-selected refinement, a host modulus function, quotient map equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6528.2 (StarRefinementModulus NameCert obligations)**.** *For every accepted* $\mathsf{StarRefinementModulus}^{\uparrow}$ *carrier*

$$S = (K, R, L, E, T, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StarRefinementModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for compact finite-cover data, star-refinement rows, finite Lebesgue-radius data, triangle estimates, dyadic tolerances, uniform-modulus handoff, transport, replay, provenance, and local naming;*
2. *star-refinement exposure, requiring each target-cover request to pass through the displayed row R before any radius ledger is read;*
3. *Lebesgue-radius exposure, requiring the positive radius row L to be tied to the refined cover and compact metric row K;*
4. *triangle-estimate exactness, requiring E to mediate the finite-center comparison before U is exposed;*
5. *uniform-modulus handoff, requiring U to be produced only from K, R, L, E, T and excluding arbitrary open covers, selected external radii, quotient map equality, countable choice, Lean verification, and bridge checking.*

No StarRefinementModulus obligation is stored outside these rows.

Proof. Project the accepted carrier. The compact metric row is K, the star-refined cover row is R, the finite Lebesgue-radius ledger is L, the triangle estimate is E, and the tolerance-to-modulus handoff is T, U.

The star-refinement exposure row is forced because the carrier has no arbitrary cover coordinate. Every target-cover request therefore enters through R before a radius can be read.

The positive-radius row L is tied to K and R, while the triangle estimate E supplies the finite-center comparison. The dyadic row T then converts the requested target tolerance into the source precision consumed by U.

Transport H and replay C preserve the same route before provenance and local naming. Since the carrier has no row for open-cover compactness, external radius selection, quotient map equality, choice, Lean verification, or bridge data, the listed rows exhaust the NameCert surface. □

Theorem 6528.3 (StarRefinementModulus cover-to-modulus exactness)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read accepted by a* $\mathsf{StarRefinementModulus}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}(K),\ R \longmapsto \mathsf{FiniteLebesgueNumber}^{\uparrow}(L) \longmapsto \mathsf{MetricTriangleUniformEstimate}^{\uparrow}(E), T \longmapsto \mathsf{UniformMod}$$

Thus the compact-uniform-continuity consumer receives the cover-refinement-to-uniform-modulus route as displayed BEDC data, not as a host Heine–Cantor theorem, selected Lebesgue number, quotient equality of maps, countable-choice selector, or ambient completeness principle.

Proof. Start with a target tolerance request. Carrier admission exposes the compact finite-cover row K and the star-refinement row R as the only cover data available to the request.

Read the finite Lebesgue-number ledger L. It supplies a displayed positive radius for the refined cover, tied to the compact metric row rather than to an external open-cover compactness theorem.

Apply the metric triangle estimate E with the dyadic tolerance row T. The estimate compares the source point to its finite center and then to the target read, so the resulting precision is the source-side modulus datum.

Finally expose U through H, C, P, N. These rows transport, replay, source, and name the same finite route, leaving no coordinate for selected external radii, quotient map equality, countable choice, host Heine–Cantor, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{StarRefinementModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{StarRefinementModulus}^{\uparrow}$ packet is generated from compact metric finite-cover data, star-refinement rows, finite Lebesgue-radius ledgers, metric triangle estimates, dyadic tolerance rows, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StarRefinementModulus}^{\uparrow}}, \text{obligation})$

Scope closed: Definition 6528.1, Definition 6528.2, and Definition 6528.3 bind the finite cover-refinement-to-uniform-modulus route for compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StarRefinementModulus}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected external Lebesgue numbers, quotient equality of maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Checked closure requires carrier admission, star-refinement exposure, Lebesgue-radius exposure, triangle-estimate exactness, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.StarRefinementModu

Chapter 6529

A Concrete Naming Certificate for $\mathsf{FourierSeries}^{\uparrow}$

Following Zygmund and Stein–Shakarchi on classical Fourier series, the $\mathsf{FourierSeries}^{\uparrow}$ packet records the finite coefficient-window interface for trigonometric-polynomial partial sums on the circle. It sits over the finite Fourier observation surface of chapter 124, the circle source of chapter 58, the real and complex scalar rows of chapter 38 and chapter 39, and the pointwise graph discipline of chapter 130. The packet names finite windows, partial-sum evaluation rows, componentwise transport, replay, provenance, and local naming; it does not import convergence, L^2 completeness, pointwise convergence, or host-function equality.

Definition 6529.1 (Fourier series carrier)**.** *A* $\mathsf{FourierSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, E, R, K, H, C, P, N)$$

with the following rows:

1. *W is the finite coefficient-window row, listing the retained integer frequencies and their displayed source addresses.*
2. *T is the trigonometric-polynomial partial-sum row, binding each retained window to its finite sine, cosine, and exponential tags.*
3. *E is the S^1 evaluation row, exposing only displayed phase samples read through* $\mathsf{S}^{1\uparrow}$*.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *coefficient row for real sine and cosine coefficients, including the finite rational or real-name readback ledger used by the packet.*
5. *K is the* $\mathsf{Complex}^{\uparrow}$ *coefficient row for complex exponential coefficients and the corresponding scalar readback.*
6. *H records componentwise* hsame *transport for coefficient windows, partial sums, S^1 evaluations, real and complex coefficient rows, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite window request through W, T, E, R, K.*
8. *P is the* Pkg *provenance over* $\mathsf{FourierSeries}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FourierSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the rows $W, T, E, R, K, H, C, P, N$. It has no coordinate for equality of host functions, limiting Fourier series, L^2 completion, pointwise convergence, or a selected representative in an ambient function space.

Theorem 6529.2 (Fourier series NameCert obligations)**.** *For every accepted* $\mathsf{FourierSeries}^{\uparrow}$ *carrier $F = (W, T, E, R, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FourierSeries}^{\uparrow}}$ *surface consists exactly of finite coefficient-window admission through W, trigonometric-polynomial partial-sum admission through T, S^1 evaluation admission through E, real and complex coefficient readback through R and K, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6529.1. Its visible rows are exactly $W, T, E, R, K, H, C, P, N$, so every naming duty begins with a finite coefficient window rather than with a completed function or limiting series.

The analytic rows are then read only as finite data. The row T supplies the trigonometric-polynomial partial sum attached to the displayed window, E supplies the circle samples, and R, K supply the real and complex coefficient readbacks.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for host-function equality, convergence, L^2 completeness, or pointwise convergence, the listed rows exhaust the local NameCert surface. □

Theorem 6529.3 (Fourier series finite partial-sum route)**.** *Every* $\mathsf{ContinuousMap}^{\uparrow}$*-facing or scalar-facing read from an accepted* $\mathsf{FourierSeries}^{\uparrow}$ *packet factors through*

$$W, T, E, R, K \longmapsto H, C, P, N.$$

The read may consume finite Fourier observations, displayed S^1 phase samples, real coefficient rows, complex coefficient rows, and continuous-map graph rows, but it exports only the finite partial-sum route displayed by the carrier.

Proof. Start with the coefficient window. The row W fixes the retained frequencies, and T attaches the trigonometric-polynomial partial sum to that finite window.

Read the evaluation and scalar rows next. The S^1 row E supplies the displayed phase samples, while R and K expose the real and complex coefficient readbacks available to the partial sum.

The structural rows H, C, P, N preserve that same finite route under componentwise transport, replay, provenance, and local naming. Therefore any downstream read receives the displayed partial-sum packet only, with convergence, L^2 completeness, pointwise convergence, and host-function equality outside the route. □

Falsifiable prediction: Deleting the coefficient-window row W prevents any accepted $\mathsf{FourierSeries}^{\uparrow}$ partial-sum read, even when trigonometric-polynomial, S^1 evaluation, scalar, transport, replay, provenance, and local naming rows remain displayed.

Independence witness: The finite Fourier observation packet $\mathsf{Fourier}^{\uparrow}$ is not interchangeable with $\mathsf{FourierSeries}^{\uparrow}$ because only $\mathsf{FourierSeries}^{\uparrow}$ binds coefficient windows, trigonometric-polynomial partial sums, S^1 evaluations, real and complex coefficient rows, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ into one accepted partial-sum route.

Closure status for $\mathsf{NameCert}_{\mathsf{FourierSeries}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FourierSeries}^{\uparrow}$ packet is generated from a finite coefficient window, a trigonometric-polynomial partial-sum row, an S^1 evaluation row, real and complex coefficient rows, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FourierSeries}\uparrow}$, seed)

Scope closed: Definition 6529.1, Definition 6529.2, and Definition 6529.3 seed the finite Fourier-series partial-sum route over Fourier$^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, Real$^{\uparrow}$, Complex$^{\uparrow}$, and ContinuousMap$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FourierSeries}\uparrow}$, unformalized)

Lean target: `BEDC.Derived.FourierSeriesUp`

Bridge status: none

Not claimed: This chapter does not close convergence, completeness of L^2, pointwise convergence, host-function equality, Lean-checked obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-window admission, partial-sum readback, circle evaluation, real and complex coefficient readback, transport, replay, provenance, and local naming for BEDC.Derived.FourierSeriesUp.

Chapter 6530

A Concrete Naming Certificate for $\mathsf{OpenDenseSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Troelstra–van Dalen treatment of spread arguments, the $\mathsf{OpenDenseSequence}^{\uparrow}$ packet records the finite input carrier for a sequence of open dense constraints before a Baire or completion consumer reads it. It sits between the $\mathsf{CompleteMetric}^{\uparrow}$ surface of chapter 128, the finite-prefix $\mathsf{BaireSpace}^{\uparrow}$ carrier of chapter 334, the complete-metric Baire route of chapter 6019, the $\mathsf{StreamName}^{\uparrow}$ window discipline of chapter 126, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names the displayed open-dense sequence as finite BEDC input data for complete-metric and Real/Completion consumers; it is not countable choice, a selected generic point, open-cover compactness, quotient stream equality, or ambient completeness.

Definition 6530.1 (Open dense sequence carrier)**.** *An* $\mathsf{OpenDenseSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, S, D, W, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{BaireSpace}^{\uparrow}$ *source row in which the open-dense constraints are read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the inspected finite prefix of the constraint sequence.*
3. *D is the dense-open ledger row, recording for each visible index that the requested basic neighbourhood has a displayed refinement inside the corresponding open row.*
4. *W is the finite window row of indices and neighbourhood refinements consumed by the downstream Baire or completion route.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *or completion-facing readback row reached after the finite window is replayed.*
6. *H records componentwise* hsame *transport for source, schedule, dense-open ledger, window, readback, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from the source row through S, D, W, R.*
8. *P is the* Pkg *provenance over* $\mathsf{OpenDenseSequence}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireCategoryCompleteMetric}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{OpenDenseSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, D, W, R, H, C, P, N$. It has no coordinate for countable choice, a selected generic point, open-cover compactness, quotient stream equality, or ambient completeness.

Lean4 (statement) `BEDC.Derived.OpenDenseSequenceUp`

Theorem 6530.2 (Open dense sequence NameCert obligations)**.** *For every accepted* $\mathsf{OpenDenseSequence}^{\uparrow}$ *carrier*

$$O = (X, S, D, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OpenDenseSequence}^{\uparrow}}$ *surface consists exactly of carrier admission, source-row stability, finite sequence-window stability, dense-open ledger stability, completion-facing readback, componentwise transport, displayed replay, provenance, and ledger non-escape through* $X, S, D, W, R, H, C, P, N$.

Proof. Project the carrier of Definition 6530.1. The source, schedule, dense-open ledger, finite window, readback, transport, replay, provenance, and naming rows are finite BHist coordinates.

The NameCert clauses are componentwise. Source-row stability is read through the sibling complete-metric and Baire-space surfaces, finite sequence-window stability is read through the $\mathsf{StreamName}^{\uparrow}$ row, and completion-facing readback is routed through the displayed Real or completion seal before any downstream consumer can use the packet.

Coordinate exhaustion gives non-escape. Since the carrier contains only $X, S, D, W, R, H, C, P, N$, it cannot provide countable choice, a selected generic point, open-cover compactness, quotient stream equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{OpenDenseSequence}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OpenDenseSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6530.1 and Definition 6530.2 seed the finite open-dense sequence input carrier for complete-metric, Baire, StreamName, and Real/Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OpenDenseSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close countable choice, selected generic points, open-cover compactness, quotient stream equality, ambient completeness, or bridge checking.

Upgrade path: The next step is obligationClosure: carrier admission, source-row stability, finite sequence-window stability, dense-open ledger stability, completion-facing readback, transport, replay, provenance, and non-escape must be discharged as local rows.

Constructive story: An $\mathsf{OpenDenseSequence}^{\uparrow}$ packet is generated from a complete-metric or Baire source row, a finite StreamName schedule, dense-open ledger rows, a visible window of refinements, Real or completion-facing readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6531

A Concrete Naming Certificate for $\mathsf{RegularCauchyFusion}^{\uparrow}$

Bishop and Bridges constructive analysis compares real names by passing to a common regular tail rather than by choosing a quotient representative. The $\mathsf{RegularCauchyFusion}^{\uparrow}$ packet records that comparison as finite NameCert data: it reads the dyadic tolerance core of chapter 291, the window names of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the fast-subsequence handoff of chapter 1518.

Definition 6531.1 (RegularCauchyFusion carrier)**.** *A* $\mathsf{RegularCauchyFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Phi = (L, R, D, S, T, U, V, W, E, H, C, P, N)$$

whose rows have the following roles:

1. *L and R are the two input regular Cauchy name rows.*
2. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by both inputs.*
3. *S and T are the two* $\mathsf{StreamName}^{\uparrow}$ *window schedules read from the inputs.*
4. *U is the common finite refinement window where the schedules are compared.*
5. *V is the* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *handoff that reaches the refinement without countable choice.*
6. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row consumed by the comparison.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *name seal reached from the displayed regular readback.*
8. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFusion}^{\uparrow}}$ *naming rows.*

Lean4 (statement) `BEDC.Derived.RegularCauchyFusionUp`

Theorem 6531.2 (RegularCauchyFusion NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyFusion}^{\uparrow}$ *carrier* $\Phi = (L, R, D, S, T, U, V, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFusion}^{\uparrow}}$ *surface consists exactly of finite obligations for input-name admission, dyadic tolerance reuse, two stream-window reads, common-refinement exposure, fast-subsequence access, regular rational readback, Real-name sealing, componentwise transport, displayed replay, provenance, and local naming. The surface exports no quotient Cauchy class, selected representative, selected limit, countable-choice functional, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or standard bridge.*

Proof. Project the carrier rows. The input names L, R, dyadic ledger D, stream windows S, T, common refinement U, fast-subsequence handoff V, readback row W, and terminal seal E are all displayed coordinates of Φ.

The structural rows H, C, P, N transport, replay, source, and name only those displayed coordinates. They do not add a quotient class, selected representative, host equality, choice schedule, completeness principle, or bridge row.

Thus the NameCert obligation surface is precisely the finite carrier route listed above. Any consumer asking for the refused objects must ask for a row that is absent from Φ. □

Theorem 6531.3 (RegularCauchyFusion L10 sibling dependency)**.** *Every* $\mathsf{RegularCauchyFusion}^{\uparrow}$ *comparison read factors through the sibling route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{FastCauchySubsequence}^{\uparrow}.$$

The dyadic ledger fixes the tolerance, the two stream-name rows expose finite windows, the fast-subsequence handoff supplies the common refinement, the regular rational row reads the refined comparison, and the Real row seals only that displayed readback.

Proof. Start with the dyadic and stream rows. The ledger D is the only tolerance coordinate, while S and T are the only window schedules available for the two input names.

Use the fast-subsequence handoff row V to reach the common refinement U without selecting an infinite subsequence. The row is finite carrier data and remains tied to the same dyadic and stream schedules.

The regular rational readback W and terminal seal E then consume that common refinement. Since the packet has no quotient, selected-limit, choice, or completeness row, the comparison remains inside the five sibling dependencies displayed in the statement. □

Theorem 6531.4 (RegularCauchyFusion common refinement comparison)**.** *For any accepted* $\mathsf{RegularCauchyFusion}^{\uparrow}$ *carrier, both input regular Cauchy names are compared only after the common refinement row* U *has been displayed. A downstream Real-and-Completion consumer receives the route*

$$L, R, D, S, T, U, V, W, E, H, C, P, N$$

and may inspect finite agreement over the refinement, but it receives no quotient equality of Cauchy names and no selected representative of either input.

Proof. Read the carrier definition. The two input rows L, R are not compared directly; they first expose their dyadic tolerance ledger and stream windows through D, S, T.

The refinement row U is reached through the fast-subsequence handoff V. This gives a finite common window on which the regular rational row W can read both presentations.

The Real seal E receives only that regular readback. The structural rows preserve the route and do not create quotient equality, a representative selector, a selected limit, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFusion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFusion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6531.1, Definition 6531.2, and Definition 6531.3 seed the common-refinement comparison route for two regular Cauchy presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFusion}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.RegularCauchyFusionUp`

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy equality, selected representatives, selected limits, countable choice, trichotomy, ambient Real completeness, Lean theorem verification, or a standard bridge.

Upgrade path: A later verification route can encode carrier admission, dyadic tolerance reuse, stream-window comparison, fast-subsequence handoff, regular rational readback, Real-name sealing, transport, replay, provenance, and local naming for the displayed packet.

Constructive story: A RegularCauchyFusion$^{\uparrow}$ packet is generated from two regular Cauchy name rows, a shared DyadicRatCore tolerance ledger, two StreamName window schedules, a common refinement window, a FastCauchySubsequence handoff, RegSeqRat readback, a RealUp name seal, componentwise transport, displayed replay, provenance, and a local NameCert row.

Chapter 6532

A Concrete Naming Certificate for $\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}$

Following Whitney's embedding theorem and the finite-atlas formulation used in classical differential topology, the $\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}$ packet records the BEDC seed surface for a compact finite-atlas manifold embedded by finitely many real coordinate functions. It sits between the manifold carrier of chapter 96, the compact metric source of chapter 129, the continuous-map rows of chapter 130, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and finite vector-coordinate rows such as chapter 1684. The packet names a finite embedding-candidate ledger and its separation obligations; it is not a host smooth embedding theorem, an ambient Euclidean quotient, a selected infinite atlas, or a global transversality argument.

Definition 6532.1 (Whitney finite-atlas embedding carrier)**.** *A* $\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, K, A, F, V, S, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *finite-atlas source row, exposing only the listed chart domains, overlap rows, and local coordinate names;*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row that bounds the inspected chart windows and compact-metric probes;*
3. *A is the finite atlas ledger, recording which chart rows and overlap certificates are consumed by each coordinate read;*
4. *F is a finite family of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows from the displayed source into* $\mathsf{Real}^{\uparrow}$*;*
5. *V is the finite vector-coordinate row whose entries are the real-valued coordinate functions in F;*
6. *S is the separation obligation row, naming finite point-pair and tangent-direction tests that the coordinate family must discharge before an embedding read is exposed;*
7. *E is the local embedding-candidate boundary row, recording injectivity-on-displayed-pairs and tangent-separation obligations as finite BEDC data;*
8. *H records componentwise* hsame *transport for the manifold, compact-metric, atlas, coordinate, vector, separation, and boundary rows;*

9. *C records displayed* Cont *replay routes from atlas windows through coordinate functions and into the finite vector row;*
10. *P is the* Pkg *provenance over* $\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *finite vector-coordinate rows,* BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}}$ *row.*

The carrier contains no host smooth embedding theorem, no selected countable atlas, no ambient Euclidean quotient equality, no global transversality principle, and no bridge-checked standard object.

Lean4 ✓ `BEDC.Derived.WhitneyEmbeddingFiniteAtlasUp.WhitneyEmbeddingFiniteAtlasTasteGate single carrier alignment`

Theorem 6532.2 (Whitney finite-atlas NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}}$ *surface consists of carrier admission for $W = (M, K, A, F, V, S, E, H, C, P, N)$, finite-atlas exposure, compact-metric source control, coordinate-family accountability through* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, finite vector-coordinate readback, separation-obligation display, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and non-escape for host embedding theorems, global transversality, selected infinite atlases, quotient Euclidean equality, and bridge checking.*

Lean4 ✓ `BEDC.Derived.WhitneyEmbeddingFiniteAtlasUp.WhitneyEmbeddingFiniteAtlasNameCertObligations`

Proof. Carrier admission is projection from Definition 6532.1. The available rows are exactly $M, K, A, F, V, S, E, H, C, P, N$.

Read the coordinate family through $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. Each coordinate in F is a displayed real-valued map, and the row V packages only the finite vector-coordinate readback of those maps.

Finally inspect the separation and structural rows. The row S records the point-pair and tangent-direction obligations, while E, H, C, P, N preserve, replay, source, and name the same finite route. Since no other carrier coordinate is present, the packet exports no host embedding theorem, transversality principle, selected infinite atlas, Euclidean quotient equality, or bridge-checked standard object. □

Theorem 6532.3 (Whitney finite-atlas separation handoff)**.** *Every embedding-facing consumer of an accepted* $\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}$ *carrier must read the finite-atlas row A, the compact-metric source row K, the coordinate-family rows F, the finite vector-coordinate row V, and the separation obligation row S before the embedding-candidate boundary E is exposed. The handoff supplies only displayed point-pair and tangent-direction obligations over* $\mathsf{Manifold}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and finite vector-coordinate rows.*

Lean4 ✓ `BEDC.Derived.WhitneyEmbeddingFiniteAtlasUp.WhitneyEmbeddingFiniteAtlasSeparationHandoff`

Proof. Project the accepted carrier. The embedding-candidate boundary E is downstream of the atlas, compact source, coordinate-family, vector-coordinate, and separation rows.

Use the NameCert obligations of Definition 6532.2. They force every public read through $M, K, A, F, V, S, H, C, P, N$ before E can be consumed.

Thus a downstream embedding-facing chapter receives the finite separation handoff only as displayed BEDC data. It cannot replace the route by an ambient Euclidean embedding theorem, a selected atlas, host smooth transversality, or quotient equality of coordinate vectors. □

Theorem 6532.4 (Whitney finite-atlas nonescape)**.** *For every accepted* WhitneyEmbeddingFiniteAtlas$^{\uparrow}$ *carrier* $W = (M, K, A, F, V, S, E, H, C, P, N)$*, no consumer can extract a host smooth embedding theorem, a global transversality argument, a selected infinite atlas, quotient equality in an ambient Euclidean space, or a bridge-checked standard theorem. Every public read factors through the displayed finite atlas, compact-metric source, continuous real coordinate family, finite vector-coordinate row, separation ledger, and structural rows.*

Lean4 ✓ `BEDC.Derived.WhitneyEmbeddingFiniteAtlasUp.WhitneyEmbeddingFiniteAtlasNonescape`

Proof. Inspect the carrier coordinates in Definition 6532.1. They list finite atlas data, compact-metric control, coordinate maps, finite vector readback, separation obligations, an embedding-candidate boundary, and structural transport.

Apply Definition 6532.3. The only embedding-facing output is the finite separation handoff through A, K, F, V, S, E and the structural rows H, C, P, N.

The excluded objects are absent from this coordinate list. Therefore no consumer of the packet can read host embedding semantics, global transversality, selected infinite-atlas data, Euclidean quotient equality, or a bridge-checked standard theorem from WhitneyEmbeddingFiniteAtlas$^{\uparrow}$. □

Closure status for NameCert$_{\text{WhitneyEmbeddingFiniteAtlas}^{\uparrow}}$**.**

Constructive story: A WhitneyEmbeddingFiniteAtlas$^{\uparrow}$ packet is generated from a finite ManifoldUp atlas row, compact-metric source control, a finite atlas ledger, continuous Real-valued coordinate rows, finite vector-coordinate readback, a separation-obligation ledger, an embedding-candidate boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{WhitneyEmbeddingFiniteAtlas}^{\uparrow}}$, seed)

Scope closed: Definition 6532.1, Definition 6532.2, Definition 6532.3, and Definition 6532.4 seed the finite-atlas embedding carrier, obligation ledger, separation handoff, and nonescape boundary.

Formal verification: FormalStatus(NameCert$_{\text{WhitneyEmbeddingFiniteAtlas}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close Whitney's full embedding theorem, global transversality, selected infinite atlases, ambient Euclidean quotient equality, Lean theorem checking, axiom purity, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-atlas coordinate accountability, separation handoff, and nonescape for BEDC.Derived.WhitneyEmbeddingFiniteAtlasUp.

Chapter 6533

A Concrete Naming Certificate for $\mathsf{CompactExhaustion}^{\uparrow}$

Following Bishop and Bridges, a compact exhaustion is read constructively as displayed finite exhaustion data: each public request exposes a prefix of compact metric windows, finite epsilon-net witnesses, and the metric and real rows that make those windows usable. The $\mathsf{CompactExhaustion}^{\uparrow}$ packet sits between the compact metric witness of chapter 129, the finite net interface of chapter 1767, the completion boundary of chapter 128, the metric carrier of chapter 57, and the terminal real-name seal of chapter 38. It gives later compactness, completion, and continuous-image chapters a finite compact-exhaustion dependency without importing open-cover compactness or a choice-selected cover family.

Definition 6533.1 (CompactExhaustion carrier)**.** *A* $\mathsf{CompactExhaustion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, K, F, M, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *source row, including the point classifier, distance observations, and finite history entries inspected by the exhaustion prefix.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *window row. Its displayed entries $K_0, \ldots, K_m$ are the compact windows currently exposed to downstream consumers.*
3. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row attached to the displayed windows. For each requested positive real or rational tolerance already visible in the packet, F records the finite net witnesses used inside the matching compact metric window.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *compatibility row, read only as a handoff boundary for consumers that need completion-facing metric data over the same windows.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance and radius seal row. It records the finite real-name data used by the epsilon-net requests and by any radius comparison attached to the compact windows.*
6. *H records componentwise* hsame *transport for X, K, F, M, R, C, P, N and for the local classifier row.*
7. *C records displayed* Cont *replay from an exhaustion-prefix request through the metric source, compact metric window, finite-net witness, completion handoff, real seal, transport, provenance, and local name.*

8. *P is the* Pkg *provenance over* $\mathsf{CompactExhaustion}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactExhaustion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, K, F, M, R, H, C, P, N$. It has no coordinate for open-cover compactness, a selected cover family, a completed countable exhaustion, quotient equality of window schedules, or ambient real completeness beyond the displayed $\mathsf{Real}^{\uparrow}$ *seal.*

Theorem 6533.2 (CompactExhaustion NameCert obligations)**.** *For every accepted* $\mathsf{CompactExhaustion}^{\uparrow}$ *carrier $E = (X, K, F, M, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactExhaustion}^{\uparrow}}$ *surface consists exactly of carrier admission, ambient metric compatibility, compact-window admission, finite-net tolerance readback, completion-facing handoff, real-seal accountability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the rows $X, K, F, M, R, H, C, P, N$.*

Proof. Project the carrier of Definition 6533.1. The analytic rows are exactly the ambient metric source, compact metric windows, finite epsilon-net witnesses, completion handoff row, and real tolerance seal.

The compact-window and finite-net obligations are ordered by the displayed prefix. A consumer first reads the metric source X, then a compact window from K, then the corresponding finite-net witness in F, and only then the completion or real-facing rows M, R.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no open-cover, selected-cover, completed-exhaustion, quotient-schedule, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6533.3 (CompactExhaustion finite-net induction)**.** *Every finite-prefix consumer of an accepted* $\mathsf{CompactExhaustion}^{\uparrow}$ *packet can inspect the exhaustion by induction over the displayed compact-window list*

$$K_0, \ldots, K_m.$$

At each stage the consumer receives the same route

$$X \longmapsto K_i \longmapsto F_i \longmapsto R_i \longmapsto M \longmapsto H, C, P, N,$$

where F_i is the finite epsilon-net witness row and R_i is the real tolerance seal attached to the ith window. The induction exports no open-cover compactness, choice-selected subcover, hidden window after m, quotient equality of exhaustion schedules, or completed countable family.

Proof. Start with the displayed prefix. The carrier exposes only finitely many compact-window entries, so ordinary finite induction over $K_0, \ldots, K_m$ is available inside the packet.

At the base stage, the consumer reads X, the first compact metric window, its finite epsilon-net witness, and the matching real tolerance seal. The rows M, H, C, P, N are then attached as completion handoff, transport, replay, provenance, and local naming.

At the successor stage, the same projection is repeated for the next displayed window. No constructor reveals an undisplayed window or a selected cover; the induction step is only a replay of the next finite row already present in K and F.

Thus the public exhaustion read is finite-prefix induction through $X, K, F, R, M, H, C, P, N$. Anything requiring a completed countable exhaustion, open-cover compactness, or choice-selected cover data must be supplied by a different packet. □

Falsifiable prediction: Every accepted $\mathsf{CompactExhaustion}^{\uparrow}$ consumer of a finite exhaustion prefix reads the ambient $\mathsf{Met}^{\uparrow}$ row, a displayed $\mathsf{CompactMetric}^{\uparrow}$ window, its $\mathsf{FiniteEpsilonNet}^{\uparrow}$ witness, the $\mathsf{Real}^{\uparrow}$ tolerance seal, the $\mathsf{CompleteMetric}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before using compact-exhaustion data.

Independence witness: compactmetric, finiteepsilonnet, completemetric, metric, real: $\mathsf{CompactExhaustion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries displayed compact-window prefixes, finite epsilon-net rows, completion-facing handoff data, real tolerance seals, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactExhaustion}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactExhaustion}^{\uparrow}$ packet is generated from an ambient Metric row, displayed CompactMetric windows, FiniteEpsilonNet witnesses, a CompleteMetric handoff row, Real tolerance seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactExhaustion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6533.1, Definition 6533.2, and Definition 6533.3 seed the finite compact-exhaustion interface over compact metric windows and finite epsilon-net witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactExhaustion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, completed countable exhaustions, quotient equality of exhaustion schedules, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ambient metric compatibility, compact-window admission, finite-net tolerance readback, completion-facing handoff, real-seal accountability, transport stability, provenance, and local naming for BEDC.Derived.CompactExhaustionUp.

Chapter 6534

A Concrete Naming Certificate for $\mathsf{PhysicalInductionGate}^{\uparrow}$

The $\mathsf{PhysicalInductionGate}^{\uparrow}$ packet realizes the physical-induction certificate of section 9414.25 as finite NameCert data. It sits after the reality-facing audit surfaces of chapter 1191, the open-fit rows of chapter 1132, the continuation countermodel boundary of chapter 1183, and the failure-surface sibling of chapter 1163. The packet names when a finite fit may be reused over a displayed continuation class, and it refuses any inference that has no finite stability basis or no falsifiable defeat surface.

Definition 6534.1 (PhysicalInductionGate carrier)**.** *A* $\mathsf{PhysicalInductionGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, O, M, \Pi, F, Cn, B, Y, H, R, P, N)$$

with the following displayed rows:

1. *S is the source finite observation history row, including the prefix H_n and the observation classifier used by the fitted model.*
2. *O is the open continuation row. It names the admissible continuation class inspected by the packet and exposes only finite continuation requests.*
3. *M is the displayed model-signature row read from the fitted model over the same finite history.*
4. *Π is the probe-bundle and comparison row governing which signatures are compared.*
5. *F is the finite-fit certificate row for the current prefix.*
6. *Cn is the continuation-stability row. It records the local stability basis licensing reuse over the displayed continuation class.*
7. *B is the failure-surface row. It records the observations or continuation refinements that would separate model-generated and observed signatures.*
8. *Y is the predictive-descent row, requiring the prediction operation to descend through the classifier named by Π before reuse is public.*
9. *H records componentwise* hsame *transport for $S, O, M, \Pi, F, Cn, B, Y, R, P, N$.*
10. *R records displayed* Cont *replay from a finite fit through continuation request, stability basis, failure-surface test, descent check, provenance, and local name.*

11. *P is the* Pkg *provenance over* $\mathsf{PhysicalInductionGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert, *together with the reality-facing siblings named above.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalInductionGate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, O, M, \Pi, F, Cn, B, Y, H, R, P, N$. It has no coordinate for a completed future observation carrier, universal physical necessity, a final-fit oracle, hidden continuation choice, or predictive reuse without a displayed failure surface.

Theorem 6534.2 (PhysicalInductionGate NameCert obligations)**.** *For every accepted* $\mathsf{PhysicalInductionGate}^{\uparrow}$ *carrier $G = (S, O, M, \Pi, F, Cn, B, Y, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PhysicalInductionGate}^{\uparrow}}$ *surface consists exactly of source-prefix admission, continuation-class admission, model-signature readback, probe-comparison compatibility, finite-fit certification, continuation-stability display, failure-surface display, predictive-descent display, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the rows $S, O, M, \Pi, F, Cn, B, Y, H, R, P, N$.*

Lean4 ✓ `BEDC.Derived.PhysicalInductionGateUp.PhysicalInductionGateNameCertObligations`

Proof. Project the carrier of Definition 6534.1. The reality-facing rows are exactly the finite source prefix, continuation class, model signature, probe comparison, finite-fit certificate, stability basis, failure surface, and predictive-descent row.

The obligation order follows the physical-induction certificate. A reuse read first displays the finite fit F over S, M, Π, then displays the continuation class O, then reads the stability basis Cn, and only then exposes the failure-surface row B and descent row Y.

The structural rows H, R, P, N keep that route stable under transport, continuation replay, provenance, and local naming. Since the carrier has no completed future, final oracle, hidden continuation selector, or failure-free law row, the listed rows exhaust the local NameCert obligations. □

Theorem 6534.3 (PhysicalInductionGate failure surface)**.** *Every accepted* $\mathsf{PhysicalInductionGate}^{\uparrow}$ *prediction read must expose a finite failure-surface row before it can use continuation stability:*

$$S \longmapsto O \longmapsto M \longmapsto \Pi \longmapsto F \longmapsto Cn \longmapsto B \longmapsto Y \longmapsto H, R, P, N.$$

If the row B is absent, or if B is detached from the same continuation class O and probe comparison Π, the packet exports no licensed physical-induction gate.

Proof. Start with Definition 6534.1. The only route from finite fit to prediction reuse passes through the displayed continuation class, stability basis, failure-surface row, and predictive-descent row.

Apply Definition 6534.2. It makes failure-surface display a local NameCert obligation, not an optional annotation. A consumer therefore cannot consume Cn as a lawlike stability basis unless it also consumes B over the same O and Π.

The rows H, R, P, N preserve this route under transport, replay, provenance, and naming. Hence a read with no B row, or with a failure surface over a different continuation class or classifier, remains outside $\mathsf{PhysicalInductionGate}^{\uparrow}$. □

Falsifiable prediction: A physical-induction consumer that claims predictive reuse while omitting the finite source prefix, continuation class, model-signature row, probe-comparison row, finite-fit certificate, continuation-stability basis, failure-surface row, predictive-descent row, transport, replay, provenance, or local NameCert refutes the $\mathsf{PhysicalInductionGate}^{\uparrow}$ packet.

Independence witness: physicalnamecertaudit, reality-constrained-open-fit, continuationcountermodel, reality-constrained-failure-surface: no listed sibling is bijective with $\mathsf{PhysicalInductionGate}^{\uparrow}$ because this packet jointly carries finite fit, continuation stability, failure-surface accountability, predictive descent, transport, replay, provenance, and local naming as one reuse gate.

Future TasteGate work for this chapter must provide explicit $\mathsf{Nontrivial\ PhysicalInductionGate}^{\uparrow}$ and $\mathsf{FieldFaithful\ PhysicalInductionGate}^{\uparrow}$ instances preserving $S, O, M, \Pi, F, Cn, B, Y, H, R, P, N$ before any checked carrier-alignment theorem may serve as the public gate.

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalInductionGate}^{\uparrow}}$.

Constructive story: A $\mathsf{PhysicalInductionGate}^{\uparrow}$ packet is generated from a finite source observation prefix, displayed continuation class, model signature, probe-comparison row, finite-fit certificate, continuation-stability basis, failure-surface row, predictive-descent row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhysicalInductionGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6534.1, Definition 6534.2, and Definition 6534.3 seed the finite continuation-stability and failure-surface gate for physical induction certificates.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhysicalInductionGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close universal physical necessity, completed future observation carriers, failure-free law certificates, hidden continuation choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-prefix admission, continuation-class admission, finite-fit certification, continuation-stability display, failure-surface display, predictive descent, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.PhysicalInductionGateUp.

Chapter 6535

A Concrete Naming Certificate for $\mathsf{SemiAlgebraicSet}^{\uparrow}$

Following Tarski and Seidenberg, the $\mathsf{SemiAlgebraicSet}^{\uparrow}$ packet records a real-algebraic set classifier as finite polynomial sign data rather than as an ambient subset oracle. It sits between the real-name seal of chapter 38, the polynomial carrier of chapter 50, the set-like membership surface of chapter 3668, the first-order formula row of chapter 197, and the ordered comparison row of chapter 1378. The packet names the constructive BEDC carrier for finite Boolean combinations of polynomial sign tests over displayed real coordinates.

Definition 6535.1 (SemiAlgebraicSet carrier)**.** *A* $\mathsf{SemiAlgebraicSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, R, P, S, F, O, H, C, G, N)$$

with the following displayed rows:

1. *X is the finite coordinate arity and variable-context row for the ambient real affine space.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *coordinate-seal row. It records the real-name data through which coordinate comparisons are read.*
3. *P is the finite* $\mathsf{Poly}^{\uparrow}$ *ledger. Its entries list the displayed polynomial terms used by the local classifier.*
4. *S is the polynomial sign ledger. For each displayed polynomial row and each visible coordinate tuple, it records whether the public test reads $<$, $=$, or $>$ through the ordered real surface.*
5. *F is the* $\mathsf{FirstOrder}^{\uparrow}$ *formula row generated from the finite sign atoms by Boolean operations and bounded displayed quantifier windows.*
6. *O is the* $\mathsf{Order}^{\uparrow}$ *comparison row used by sign tests before the formula row is evaluated.*
7. *H records componentwise* hsame *transport for $X, R, P, S, F, O, C, G, N$ and for the local classifier.*
8. *C records displayed* Cont *replay from coordinate readback through polynomial evaluation, sign comparison, formula evaluation, transport, provenance, and local naming.*
9. *G is the* Pkg *provenance over* $\mathsf{SemiAlgebraicSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SemiAlgebraicSet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, R, P, S, F, O, H, C, G, N$. It has no coordinate for an arbitrary powerset predicate, a quotient of polynomial formulas, a selected decomposition into cells, an undecided host real comparison, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6535.2 (SemiAlgebraicSet NameCert obligations)**.** *For every accepted* $\mathsf{SemiAlgebraicSet}^{\uparrow}$ *carrier $A = (X, R, P, S, F, O, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{SemiAlgebraicSet}^{\uparrow}}$ *surface consists exactly of coordinate-context admission, real-coordinate seal accountability, polynomial-ledger admission, polynomial-sign ledger admission, first-order formula formation, ordered sign comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the rows $X, R, P, S, F, O, H, C, G, N$.*

Proof. Project the carrier of Definition 6535.1. The algebraic rows are exactly the coordinate context, real-coordinate seals, finite polynomial ledger, sign ledger, formula row, and ordered comparison row.

The obligation order follows the displayed classifier. A membership read first exposes the real coordinate rows R, then evaluates a polynomial from P, then reads its sign through S and O, and only then evaluates the formula row F.

The rows H, C, G, N preserve this route under transport, replay, provenance, and local naming. Since the carrier contains no arbitrary subset predicate, cell-decomposition choice, quotient formula coordinate, host comparison oracle, or ambient completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 6535.3 (SemiAlgebraicSet polynomial sign ledger)**.** *Every membership read from an accepted* $\mathsf{SemiAlgebraicSet}^{\uparrow}$ *carrier factors through the displayed polynomial sign ledger*

$$R \longmapsto P \longmapsto S \longmapsto O \longmapsto F \longmapsto H, C, G, N.$$

Thus a consumer receives only finite sign tests for displayed $\mathsf{Poly}^{\uparrow}$ *rows over displayed* $\mathsf{Real}^{\uparrow}$ *coordinates before the* $\mathsf{SetLike}^{\uparrow}$ *membership surface is public. It receives no arbitrary subset predicate, no selected cell decomposition, no quotient formula equality, no undecided host trichotomy, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the carrier projection. The only route from a coordinate tuple to membership is the finite row sequence through real coordinate seals, polynomial rows, sign comparisons, ordered tests, and first-order formula evaluation.

The sign ledger S is attached to the displayed polynomial list P and the ordered comparison row O. It therefore cannot be replaced by an external predicate on real tuples or by a host-level decision procedure.

The structural rows H, C, G, N transport and name the same finite route. After those rows are read, the public $\mathsf{SetLike}^{\uparrow}$ surface receives a membership value generated by the displayed sign ledger alone. □

Falsifiable prediction: A $\mathsf{SemiAlgebraicSet}^{\uparrow}$ consumer that claims membership while omitting a displayed $\mathsf{Real}^{\uparrow}$ coordinate seal, $\mathsf{Poly}^{\uparrow}$ ledger row, polynomial sign row, $\mathsf{Order}^{\uparrow}$ comparison row, $\mathsf{FirstOrder}^{\uparrow}$ formula row, transport, replay, provenance, or local $\mathsf{NameCert}$ refutes this packet.

Independence witness: real, polynomial, setlike, firstorder, order: $\mathsf{SemiAlgebraicSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries real-coordinate seals, finite polynomial rows, sign comparisons, formula formation, set-like membership export, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SemiAlgebraicSet}^{\uparrow}}$.

Constructive story: A $\mathsf{SemiAlgebraicSet}^{\uparrow}$ packet is generated from a coordinate context, Real coordinate seals, Polynomial rows, polynomial sign rows, FirstOrder formula formation, Order comparisons, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SemiAlgebraicSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6535.1, Definition 6535.2, and Definition 6535.3 seed the finite polynomial-sign carrier for semi-algebraic membership.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SemiAlgebraicSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Tarski–Seidenberg elimination, cell decomposition, arbitrary subset predicates, quotient formula equality, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked coordinate admission, real-coordinate seal accountability, polynomial-ledger admission, sign-ledger admission, formula formation, ordered comparison, transport stability, provenance, and local naming for BEDC.Derived.SemiAlgebraicSetUp.

Chapter 6536

A Concrete Naming Certificate for $\mathsf{FiniteMinimax}^{\uparrow}$

Following von Neumann's finite minimax theorem and constructive convex analysis, the $\mathsf{FiniteMinimax}^{\uparrow}$ packet names a displayed finite saddle-certificate route over finite strategy polytopes and rational payoff brackets. It consumes the convex carrier of chapter 208, the finite polytope surface of chapter 209, the compact finite-net discipline of chapter 129, the continuous payoff route of chapter 130, and the terminal real-name seal of chapter 38. The packet records a finite convex compact saddle certificate; it is not a host proof of Hahn–Banach separation, a selected global optimizer, an ambient quotient of mixed strategies, countable choice, or a completed function-space theorem.

Definition 6536.1 (FiniteMinimax carrier surface)**.** *A* $\mathsf{FiniteMinimax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, P, Q, F, A, B, S, H, C, K, N)$$

with the following displayed rows:

1. *X and Y are finite strategy-index rows naming the two player faces.*
2. *P and Q are* $\mathsf{Polytope}^{\uparrow}$ *strategy-simplex rows, each read through the ambient* $\mathsf{ConvexSet}^{\uparrow}$ *carrier.*
3. *F is the compact finite-net row, recording the finite covering windows used to inspect the two polytopes through* $\mathsf{CompactMetric}^{\uparrow}$*.*
4. *A is the* $\mathsf{ContinuousMap}^{\uparrow}$ *payoff row from the displayed product windows to the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
5. *B is the rational tolerance bracket ledger, recording lower and upper payoff bounds for the inspected net cells.*
6. *S is the saddle inequality ledger, recording the two displayed inequalities that certify the bracketed saddle window.*
7. *H records componentwise* hsame *transport for strategy rows, polytopes, finite nets, payoff maps, rational brackets, saddle inequalities, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a finite strategy query through X, Y, P, Q, F, A, B, S.*
9. *K is the* Pkg *provenance over* $\mathsf{FiniteMinimax}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Polytope}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMinimax}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, P, Q, F, A, B, S, H, C, K, N$. It has no coordinate for a host mixed-strategy quotient, selected exact optimizer, global real completeness, arbitrary separation principle, or countable choice.

Theorem 6536.2 (FiniteMinimax NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMinimax}^{\uparrow}$ *carrier*

$$M = (X, Y, P, Q, F, A, B, S, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteMinimax}^{\uparrow}}$ *surface consists exactly of carrier admission, finite strategy-row stability, convex-polytope compatibility for P, Q, compact finite-net coverage, continuous payoff readback, rational tolerance bracket stability, saddle inequality exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and ledger non-escape through $X, Y, P, Q, F, A, B, S, H, C, K, N$.*

Proof. Project the carrier surface of Definition 6536.1. The only analytic rows available to a minimax consumer are the displayed strategy indices, convex-polytope rows, finite-net row, continuous payoff row, rational brackets, and saddle inequality ledger.

The NameCert clauses are componentwise. Convexity is read through the sibling $\mathsf{ConvexSet}^{\uparrow}$ surface, finite mixed-strategy admission through $\mathsf{Polytope}^{\uparrow}$, compact inspection through $\mathsf{CompactMetric}^{\uparrow}$, and payoff readback through $\mathsf{ContinuousMap}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed.

The saddle ledger is then checked against the same bracket rows on the same finite windows. Transport, replay, provenance, and local naming preserve this route without adding a coordinate for a selected optimizer, quotient mixed-strategy equality, countable choice, or an ambient separation theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMinimax}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMinimax}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6536.1 and Definition 6536.2 seed the finite saddle-certificate carrier over convex polytopes, compact finite nets, continuous payoff rows, rational brackets, and saddle inequalities.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMinimax}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected exact optimizers, host mixed-strategy quotients, arbitrary separation theorems, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires carrier admission, convex-polytope compatibility, compact finite-net coverage, continuous payoff readback, rational bracket stability, saddle inequality exactness, transport, replay, provenance, and non-escape for BEDC.Derived.FiniteMinimaxUp.

Constructive story: A $\mathsf{FiniteMinimax}^{\uparrow}$ packet is generated from finite strategy rows, two convex polytope strategy surfaces, compact finite-net windows, a continuous payoff row, rational tolerance brackets, a saddle inequality ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6537

A Concrete Naming Certificate for $\mathsf{FourierPlancherel}^{\uparrow}$

Following Plancherel and the Fourier analysis presentation of Stein–Shakarchi, the $\mathsf{FourierPlancherel}^{\uparrow}$ packet records the finite-energy isometry surface that sits after the finite observation route of chapter 124, the transform rows of chapter 4025, the finite energy identity of chapter 1940, and the finite energy carrier of chapter 6309. It also consumes the pairing row of chapter 86, the integral row of chapter 123, the regular-rational route of chapter 301, and the real seal of chapter 38. The chapter names only the BEDC certificate for the finite-energy Plancherel handoff; it does not assert Fourier inversion, pointwise convergence, quotient equality of functions, selected representatives, or ambient Hilbert-space completeness.

Definition 6537.1 (Fourier-Plancherel finite-energy carrier)**.** *A* $\mathsf{FourierPlancherel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, A, E, J, I, Q, R, S, H, C, V, N)$$

with the following visible rows:

1. *T is the* $\mathsf{FourierTransform}^{\uparrow}$ *transform row, read through chapter 4025;*
2. *A is the* $\mathsf{Parseval}^{\uparrow}$ *finite identity row, read through chapter 1940;*
3. *E is the* $\mathsf{FiniteFourierEnergy}^{\uparrow}$ *energy ledger, read through chapter 6309;*
4. *J is the* $\mathsf{Fourier}^{\uparrow}$ *finite observation source row;*
5. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *pairing row;*
6. *Q is the* $\mathsf{Integral}^{\uparrow}$ *integral-energy row;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational approximation and readback row;*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed energy comparison;*
9. *H stores componentwise* hsame *transports for $T, A, E, J, I, Q, R, S, V, N$;*
10. *C stores the displayed* Cont *replay routes from finite transform observations and Parseval ledgers to the sealed energy comparison;*
11. *V is the* Pkg *provenance over the Fourier, FourierTransform, Parseval, FiniteFourierEnergy, InnerProduct, Integral, RegSeqRat, and Real sibling packets;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FourierPlancherel}^{\uparrow}}$ *row.*

The carrier has no coordinate for Fourier inversion, pointwise convergence, quotient equality of functions, selected representatives, an unrestricted completed Hilbert space, or Lean verification.

Theorem 6537.2 (Fourier-Plancherel NameCert obligations)**.** *For every accepted* $\mathsf{FourierPlancherel}^{\uparrow}$ *carrier* $P = (T, A, E, J, I, Q, R, S, H, C, V, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FourierPlancherel}^{\uparrow}}$ *obligation surface consists of carrier admission, transform-row visibility, Parseval-row visibility, finite-energy ledger visibility, Fourier observation visibility, inner-product and integral row compatibility, regular-rational readback, Real seal stability, componentwise transport, displayed replay, provenance, and local naming. These obligations do not include inversion, convergence, quotient function equality, selected representatives, or ambient Hilbert-space completeness.*

Proof. Project the carrier of Definition 6537.1. The definition lists exactly the finite rows $T, A, E, J, I, Q, R, S, H, C$, and assigns the transform, Parseval, energy, observation, pairing, integral, readback, seal, transport, replay, provenance, and naming roles.

The analytic rows are read only through their sibling certificates. The transform surface comes from $\mathsf{FourierTransform}^{\uparrow}$, the finite identity from $\mathsf{Parseval}^{\uparrow}$, the energy ledger from $\mathsf{FiniteFourierEnergy}^{\uparrow}$, and the finite observation source from $\mathsf{Fourier}^{\uparrow}$.

The scalar comparison remains sealed. The rows I, Q, R, S carry inner-product, integral, regular-rational, and Real-seal data, while H, C, V, N preserve and name the same route. Since no additional coordinate is present, the excluded inversion, convergence, quotient, representative, and ambient-completeness readings cannot be projected. □

Theorem 6537.3 (Fourier-Plancherel finite-energy isometry)**.** *Every* $\mathsf{FourierPlancherel}^{\uparrow}$ *consumer that reads a finite-energy isometry must factor through*

$$T, A, E, J, I, Q, R, S, H, C, V, N.$$

The route identifies only the displayed BEDC energy comparison between the transform-side finite-energy ledger and the source-side finite-energy ledger after regular-rational readback and Real sealing. It does not identify host functions, choose representatives, complete a quotient coefficient space, prove Fourier inversion, or assert pointwise convergence.

Proof. Begin with the transform-side rows. The consumer reads T through $\mathsf{FourierTransform}^{\uparrow}$ and the finite observation source J through $\mathsf{Fourier}^{\uparrow}$.

Next read the energy identity surface. The rows A and E supply the Parseval and finite Fourier energy ledgers, while I and Q provide the pairing and integral-energy rows used by the displayed comparison.

Finally pass through scalar readback and sealing. The row R carries the regular-rational approximation route, S seals the resulting comparison as a $\mathsf{Real}^{\uparrow}$-facing energy statement, and H, C, V, N preserve, replay, source, and name the same finite route.

The carrier has no coordinate for host function equality, selected representatives, quotient coefficient spaces, inversion, or pointwise convergence. Hence the isometry reading is exactly the finite-energy BEDC handoff stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{FourierPlancherel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FourierPlancherel}^{\uparrow}$ packet is generated from FourierTransform, Parseval, FiniteFourierEnergy, Fourier observation, InnerProduct, Integral, RegSeqRat, Real seal, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FourierPlancherel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6537.1, Definition 6537.2, and Definition 6537.3 seed the finite-energy Plancherel handoff consumed by downstream Fourier-completion work.

Formal verification: FormalStatus(NameCert$_{\text{FourierPlancherel}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close Fourier inversion, pointwise convergence, quotient equality of functions, selected representatives, ambient Hilbert-space completeness, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked carrier and NameCert obligation coverage for the displayed Plancherel finite-energy route.

Chapter 6538

A Concrete Naming Certificate for $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completion and totally bounded metric data, the $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$ packet records the finite route by which total-bounded approximation rows feed a completion-facing seal. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the completion route of chapter 1506, the complete-metric seal of chapter 128, and the finite-net carrier of chapter 1767. The packet names a constructive completion interface from displayed finite total-bounded data; it is not open-cover compactness, quotient completion equality, a selected completion point, ambient completeness, or choice.

Definition 6538.1 (EffectiveTotalBoundedCompletion carrier)**.** *An* $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, E, Q, M, C, A, W, R, S, H, L, P, N)$$

with the following visible rows:

1. *K is the bounded metric source row whose distance and diameter requests are read by the packet.*
2. *E is the finite-net row, displaying for each dyadic tolerance a finite* $\mathsf{ProbeBundle}$ *of centers and coverage witnesses.*
3. *Q is the Cauchy-net refinement row, recording that later finite nets refine earlier tolerances by displayed containment and proximity witnesses.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row consumed by completion-facing readers.*
5. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *seal row, available only after E, Q, M have been displayed.*
6. *A is the total-bounded approximation ledger, binding finite-net centers to the Cauchy-net refinement route.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect source and center data.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the same finite windows.*
9. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the displayed readback route.*
10. *H records componentwise* hsame *transport for $K, E, Q, M, C, A, W, R, S, L, P, N$.*

11. *L records displayed* Cont *replay of finite-net, Cauchy-net, completion, and readback requests.*
12. *P is the* Pkg *provenance over* $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for arbitrary open covers, quotient classes of Cauchy sequences, selected representatives, host complete metric objects, or choice.

Theorem 6538.2 (EffectiveTotalBoundedCompletion NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$ *carrier* $T = (K, E, Q, M, C, A, W, R, S, H, L, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EffectiveTota}}$ *surface consists exactly of source admission through K, finite-net admission through E, Cauchy-net refinement through Q, MetricCompletion routing through M, CompleteMetric sealing through C, total-bounded approximation through A, StreamName window inspection through W, RegSeqRat readback through R, Real sealing through S, componentwise* hsame *transport through H, displayed* Cont *replay through L, provenance through P, and local naming through N.*

Every completion-facing consumer must therefore display the finite-net and Cauchy-net rows before it can read the MetricCompletion or CompleteMetric rows, and every Real-facing consumer must display W, R, S on the same route.

Proof. Project the accepted carrier. The analytic rows are $K, E, Q, M, C, A, W, R, S$, and the structural rows are H, L, P, N.

The total-bounded part is finite. The finite-net row E supplies explicit centers and coverage witnesses, while Q records refinement from one tolerance to the next. The approximation ledger A binds those two rows before the completion rows M, C are visible.

The readback part stays on the same packet. The window row W, regular rational row R, and Real seal row S are downstream of E, Q, A and are replayed through L. Componentwise transport H, package provenance P, and local naming N do not add a second completion object. Since the carrier contains no open-cover, quotient, selected-limit, host-completeness, or choice coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6538.3 (EffectiveTotalBoundedCompletion Cauchy-net induction)**.** *Let $T = (K, E, Q, M, C, A, W, R, S,$ be an accepted* $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$ *carrier. A completion-facing induction over Cauchy-net approximants may advance from tolerance n to tolerance $n+1$ only by reading the finite-net row E, the refinement row Q, and the approximation ledger A before it consumes the MetricCompletion row M, the CompleteMetric seal C, or the Real-facing rows W, R, S.*

Consequently the induction exports the finite route

$$K, E, Q, A \longmapsto M, C \longmapsto W, R, S \longmapsto H, L, P, N,$$

not an open-cover compactness proof, a quotient class of Cauchy sequences, a choice-selected subsequence, or an ambient completeness theorem.

Proof. Start with the displayed finite-net row. At each tolerance, E supplies the finite center list and coverage witnesses used by the current approximation.

Advance the induction through Q and A. The refinement row identifies how the next tolerance is attached to the previous finite net, and the approximation ledger records that the same displayed witnesses remain within the total-bounded packet. No external cover selection is consulted.

Only after this finite step may a consumer read M and C. The MetricCompletion and CompleteMetric rows are therefore seals over the displayed Cauchy-net route. The rows W, R, S translate that route into StreamName, RegSeqRat, and Real-facing readback, while H, L, P, N transport, replay, source, and name it without adding quotient equality or choice. □

Falsifiable prediction: Every $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$ completion read must display finite-net rows, Cauchy-net refinement, MetricCompletion routing, CompleteMetric sealing, StreamName windows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: finite-epsilon-net, metriccompletion, completemetric, streamname, regseqrat, real: $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite total-bounded nets, Cauchy-net refinement, completion seals, readback rows, transport, replay, provenance, and local NameCert data in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}$ packet is generated from bounded metric source rows, finite-net rows, Cauchy-net refinement rows, MetricCompletion routes, CompleteMetric seals, total-bounded approximation rows, StreamName windows, RegSeqRat readbacks, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6538.1, Definition 6538.2, and Definition 6538.3 seed the finite total-bounded completion route from net data to completion-facing reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveTotalBoundedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient completion equality, selected representatives, countable choice, ambient completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, Cauchy-net refinement, MetricCompletion routing, CompleteMetric sealing, StreamName window replay, RegSeqRat readback, Real seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveTotalBoundedCompletionUp.

Chapter 6539

A Concrete Naming Certificate for AscoliEquicontinuityCriterion$^{\uparrow}$

Following Arzela and Ascoli, and the Bishop–Bridges finite-net reading of compact metric continuity, the AscoliEquicontinuityCriterion$^{\uparrow}$ packet records the criterion by which compact finite-net data and equicontinuity data are displayed before a uniform-modulus route is accepted. It sits between the compact source of chapter 129, the family-radius surface of chapter 4076, the uniform-modulus consumer of chapter 369, the finite epsilon-net ledger of chapter 1767, and the metric carrier discipline of chapter 57. The chapter names the finite handoff criterion only; it does not assert open-cover compactness, a host function-space compactness theorem, quotient equality of maps, selected subsequences, countable choice, or ambient completeness.

Definition 6539.1 (Ascoli equicontinuity criterion carrier)**.** *An* AscoliEquicontinuityCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, E, U, F, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through* CompactMetric$^{\uparrow}$ *and the underlying* Met$^{\uparrow}$ *distance classifier.*
2. *E is the* Equicontinuity$^{\uparrow}$ *family-radius row, displaying one source-radius ledger for the inspected family at each requested target tolerance.*
3. *U is the* UniformModulus$^{\uparrow}$ *handoff row, exposed only after the compact source and equicontinuity rows have been displayed.*
4. *F is the* FiniteEpsilonNet$^{\uparrow}$ *row, carrying the finite center bundle, membership witnesses, and coverage-distance ledger for the selected tolerance scale.*
5. *M records the metric comparison rows over centers and arbitrary inspected points, including the triangle and tolerance-budget data used to pass from finite centers to the whole compact source.*
6. *H records componentwise* hsame *transport for compact source, equicontinuity, uniform-modulus, finite-net, metric, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a criterion request through the finite route K, E, F, M, U.*
8. *P is the* Pkg *provenance over* AscoliEquicontinuityCriterion$^{\uparrow}$, CompactMetric$^{\uparrow}$, Equicontinuity$^{\uparrow}$, UniformModulus$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. No coordinate stores an arbitrary open cover, a host compactness proof for a function space, quotient equality of functions, a selected subsequence, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.AscoliEquicontinuityCriterionUp.AscoliEquicontinuityCriterionTasteGate`
`single carrier alignment`

Theorem 6539.2 (Ascoli equicontinuity criterion NameCert obligations)**.** *For every accepted* $\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}$ *carrier* $A = (K, E, U, F, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric row, equicontinuity family row, uniform-modulus handoff row, finite epsilon-net row, metric comparison row, componentwise transport, displayed replay, provenance, and local naming; finite-net coverage for the compact source; equicontinuity visibility over the same tolerance request; metric triangle transport from net centers to inspected points; and non-escape for open-cover compactness, host function-space compactness, quotient equality, selected subsequences, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 6539.1. The finite BHist packet exposes exactly $K, E, U, F, M, H, C, P, N$, so carrier admission and local naming have no hidden coordinate beyond the displayed rows.

The compact source is read through K and F. The $\mathsf{CompactMetric}^{\uparrow}$ row supplies the compact metric discipline, while the $\mathsf{FiniteEpsilonNet}^{\uparrow}$ row displays the center bundle and coverage witnesses for the tolerance scale that the criterion will use.

The family-radius part is read through E. The $\mathsf{Equicontinuity}^{\uparrow}$ row is tied to the same tolerance request as the finite-net row, so the accepted packet cannot choose a separate radius ledger after the centers have been selected.

The metric comparison row M transports estimates from centers to arbitrary inspected points. It supplies the triangle and tolerance-budget rows needed before U may be read as a $\mathsf{UniformModulus}^{\uparrow}$ handoff.

Finally H, C, P, N transport, replay, source, and name only this route. Since the carrier has no coordinate for open-cover compactness, host function-space compactness, quotient equality, selected subsequences, countable choice, or ambient completeness, those objects are outside the local NameCert surface. □

Theorem 6539.3 (Ascoli equicontinuity criterion finite-net handoff)**.** *Every accepted* $\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}$ *consumer that exports a uniform-modulus read must first display the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Equicontinuity}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow}$$

inside the carrier $A = (K, E, U, F, M, H, C, P, N)$*. The handoff exports exactly the compact source row, family-radius row, finite center bundle, metric comparison ledger, structural transport, replay, provenance, and local naming rows, and it exports no open-cover compactness, host function-space compactness, quotient equality of maps, selected subsequence, countable-choice schedule, or ambient completeness principle.*

Proof. Start with Definition 6539.2. It lists the accepted rows available to a uniform-modulus consumer and requires the compact metric source, equicontinuity row, finite epsilon-net row, metric comparison row, and structural rows to be present.

Read the finite-net handoff through F. The center bundle and coverage witnesses are finite, and the source metric comparison rows in M are the only route from a displayed center estimate to an arbitrary inspected source point.

Read the equicontinuity ledger through E before the uniform-modulus row U. The same tolerance request is visible to E, F, and M, so the consumer receives one finite radius-and-center budget rather than an unrecorded analytic compactness argument.

The replay row C then orders the handoff as K, E, F, M, U, while H, P, N preserve transport, provenance, and local naming for the same route. Because the carrier omits all host compactness, quotient, selection, choice, and ambient-completeness coordinates, the uniform-modulus read is exhausted by the displayed finite packet. □

Falsifiable prediction: Every accepted $\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}$ uniform-modulus consumer first displays CompactMetric, Equicontinuity, FiniteEpsilonNet, MetricSpace, BHist, hsame, Cont, Pkg, and local NameCert rows before it may read the UniformModulus handoff.

Independence witness: compactmetric, equicontinuity, uniformmodulus, finite-epsilon-net, metric: no listed sibling is bijective to $\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}$ because only this packet jointly binds compact-source coverage, family-radius visibility, finite-net centers, metric triangle transport, uniform-modulus handoff, componentwise transport, replay, provenance, and local naming in one criterion carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}}$.

Constructive story: An $\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}$ packet is generated from a CompactMetricUp source row, an EquicontinuityUp family-radius row, a UniformModulusUp handoff row, a FiniteEpsilonNetUp center bundle, MetricSpaceUp comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6539.1, Definition 6539.2, and Definition 6539.3 seed the finite Ascoli equicontinuity criterion route from compact finite nets and family equicontinuity into a uniform-modulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AscoliEquicontinuityCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host function-space compactness, quotient equality of maps, selected subsequences, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, equicontinuity visibility, metric triangle transport, uniform-modulus handoff exactness, non-escape, provenance, replay, and local naming for BEDC.Derived.AscoliEquicontinuityCriterionUp.

Chapter 6540

A Concrete Naming Certificate for $\mathsf{ArithmetizedProvability}^{\uparrow}$

Following Gödel's arithmetization of syntax and Kleene's treatment of primitive recursive proof predicates, the $\mathsf{ArithmetizedProvability}^{\uparrow}$ packet records the finite BEDC surface by which formula codes, proof codes, derivation checks, substitution rows, and diagonal-code rows may be read without importing a host truth predicate. It sits after the unary arithmetic carrier of chapter 28, the formula-code interface of chapter 197, the bounded derivation-check surface of chapter 199, and the open-meta-loop boundary of chapter 674. The chapter names the proof-predicate dependency consumed by reflection-limit work; it does not assert the incompleteness theorem, a semantic truth definition, consistency of an ambient theory, proof completeness, or a global model-theoretic interpretation.

Definition 6540.1 (Arithmetized provability carrier)**.** *An* $\mathsf{ArithmetizedProvability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (N, F, D, S, G, H, C, P, L)$$

with the following displayed rows:

1. *N is the* $\mathsf{Nat}^{\uparrow}$ *numeral-code row, carrying unary natural-number names for symbols, formula indices, proof-line indices, and finite proof-code lengths.*
2. *F is the* $\mathsf{FirstOrder}^{\uparrow}$ *formula-code row, displaying symbol codes, variable rows, term rows, formula constructors, and the well-formed formula classifier used by the proof predicate.*
3. *D is the* $\mathsf{Computable}^{\uparrow}$ *derivation-check row, recording the bounded primitive-recursive inspection of a finite proof-code list against the displayed rule and axiom-code table.*
4. *S is the substitution row, recording capture-aware replacement of numeral codes into formula-code slots and the finite compatibility ledger for free-variable bookkeeping.*
5. *G is the diagonal-code row, displaying the self-application code produced from F and S while keeping the resulting formula code inside object syntax.*
6. *H records componentwise* hsame *transport for numeral codes, formula codes, derivation checks, substitution rows, diagonal rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a provability request through N, F, D, S, G and then through the structural rows H, P, L.*

8. *P is the* Pkg *provenance over* $\mathsf{ArithmetizedProvability}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{Computable}^{\uparrow}$, $\mathsf{GroundLoopBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *L is the local* $\mathsf{NameCert}_{\mathsf{ArithmetizedProvability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. No coordinate stores a host truth predicate, semantic satisfaction relation, completeness theorem, consistency proof for the represented theory, or unbounded meta-level proof search.

Theorem 6540.2 (ArithmetizedProvability NameCert obligations)**.** *For every accepted* $\mathsf{ArithmetizedProvability}^{\uparrow}$ *carrier $A = (N, F, D, S, G, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{ArithmetizedProvability}^{\uparrow}}$ *surface consists exactly of carrier admission; numeral-code visibility; formula-code exactness for the displayed first-order constructors; proof-code induction over the finite derivation rows inspected by D; substitution stability for the rows in S; diagonal-code stability for G; derivation-check replay through C; componentwise transport through H; provenance through P; local naming through L; and non-escape for host truth, semantic completeness, ambient consistency, and unbounded meta-level proof search.*

Proof. Project the carrier of Definition 6540.1. The finite BHist packet exposes exactly $N, F, D, S, G, H, C, P, L$, so carrier admission and local naming have no hidden coordinate beyond the displayed rows.

Read the syntactic substrate through N and F. The numeral-code row gives the finite natural-number codes used by the packet, and the formula-code row gives the first-order constructors and well-formedness classifier that those numbers index.

Read the proof predicate through D. Its accepted rows are finite derivation-check rows, so the proof-code obligation is induction over the displayed proof-line list rather than a semantic appeal to truth or completeness.

Read substitution and diagonalization through S and G. The substitution row records the capture-aware replacement ledger, and the diagonal-code row records only the object-level self-application code produced from that ledger.

Finally H, C, P, L transport, replay, source, and name this same finite route. Since no coordinate stores a host truth predicate, semantic satisfaction relation, completeness theorem, ambient consistency proof, or unbounded proof search, those objects cannot be projected from the local certificate. □

Theorem 6540.3 (ArithmetizedProvability finite proof-code induction)**.** *Every accepted* $\mathsf{ArithmetizedProvability}^{\uparrow}$ *proof-code read is generated by induction over the displayed finite derivation rows in D and is then transported only through*

$$N, F, D, S, G, H, C, P, L.$$

The read may certify that a displayed code is accepted by the finite derivation checker for a displayed formula code. It cannot import host truth, semantic completeness, an ambient consistency theorem, or a meta-level assertion that the represented formula is true.

Proof. Begin with the derivation-check row D. A proof-code read is accepted only when the finite list of proof lines passes the displayed rule and axiom-code checks, so the generating argument proceeds by induction over that finite list.

At the base row, the checker reads an initial displayed axiom-code or hypothesis-code entry through N and F. The entry remains a syntactic formula-code row.

At each successor row, the checker reads only the earlier displayed lines named by the finite indices in N and the rule-shape data in F. The row added at that step is therefore produced by the same finite derivation-check surface, not by an external semantic oracle.

Substitution and diagonal rows are handled after the syntactic check. The row S records the capture-aware substitution budget, while G records the diagonal code that remains inside the formula-code surface.

The structural rows H, C, P, L then transport, replay, source, and name the result. Because no later row adds truth, completeness, consistency, or unbounded proof search, the accepted proof-code read is exhausted by the finite induction route stated above. □

Falsifiable prediction: Every accepted $\mathsf{ArithmetizedProvability}^{\uparrow}$ consumer first displays Nat, FirstOrder, Computable, GroundLoopBoundary, BHist, hsame, Cont, Pkg, and local NameCert rows before it may read the arithmetized proof predicate.

Independence witness: nat, firstorder, computable, groundloopboundary: no listed sibling is bijective to $\mathsf{ArithmetizedProvability}^{\uparrow}$ because only this packet jointly binds numeral codes, formula codes, derivation-check rows, substitution rows, diagonal-code rows, componentwise transport, replay, provenance, and local naming while refusing host truth and semantic completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ArithmetizedProvability}^{\uparrow}}$.

Constructive story: An $\mathsf{ArithmetizedProvability}^{\uparrow}$ packet is generated from NatUp numeral codes, FirstOrderUp formula codes, ComputableUp finite derivation-check rows, substitution and diagonal-code rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArithmetizedProvability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6540.1, Definition 6540.2, and Definition 6540.3 seed the finite proof-predicate surface consumed by reflection-limit and incompleteness-boundary work.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArithmetizedProvability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Gödel incompleteness, Tarski truth undefinability, semantic completeness, ambient consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, formula-code exactness, proof-code induction, substitution stability, derivation-check replay, truth-predicate non-escape, provenance, replay, and local naming for BEDC.Derived.ArithmetizedProvabilityUp.

Chapter 6541

A Concrete Naming Certificate for $\mathsf{MackeyDecomposition}^{\uparrow}$

Following Mackey's subgroup theorem, Serre's finite-group representation theory, and the induction–restriction calculus in Fulton–Harris, the $\mathsf{MackeyDecomposition}^{\uparrow}$ packet records the double-coset decomposition row that compares restricting an induced representation with the finite sum of conjugated subgroup inductions. It consumes the group and subgroup sources of chapter 41 and chapter 80, the representation rows of chapter 247, chapter 245, and chapter 246, the vector-space endpoint of chapter 47, the Frobenius comparison of chapter 5806, and the orthogonality ledger of chapter 1603. The packet names only finite source rows, double-coset representatives, conjugation transport, induced summand rows, character-pairing checks, replay, provenance, and local naming; it does not import a host representation category, quotient double-coset space, semisimplicity theorem, or completed character table.

Definition 6541.1 (MackeyDecomposition carrier)**.** *A* $\mathsf{MackeyDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{M} = (G, H, R, I, C, F, S, D, L, T, P, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{Group}^{\uparrow}$ *certificate row for the finite group endpoint.*
2. *H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, including the subgroup inclusion read used by restriction.*
3. *R is the* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger row that records addition of induced summands.*
4. *I is the* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row for the source representation.*
5. *C is the* $\mathsf{CharacterTheory}^{\uparrow}$ *character-pairing row used to audit the displayed decomposition.*
6. *F is the* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *comparison row binding induction and restriction.*
7. *S is the* $\mathsf{SchurOrthogonality}^{\uparrow}$ *row that checks the finite character-pairing ledger for the summands.*
8. *D is the double-coset representative ledger, listing only displayed representatives and their subgroup-intersection rows.*
9. *L is the summand ledger for the induced representations attached to those representatives.*
10. *T transports the displayed subgroup-intersection and summand rows componentwise by* hsame *and displayed* Cont *replay.*

11. *P is the* Pkg *provenance over* $\mathsf{MackeyDecomposition}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{FrobeniusReciprocity}^{\uparrow}$, $\mathsf{SchurOrthogonality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MackeyDecomposition}^{\uparrow}}$ *row.*

The carrier exports only this finite double-coset ledger. It contains no host quotient of $H\backslash G/K$, no ambient representation category, no selected basis of an induced module, and no completed class-function algebra.

Lean4 (statement) `BEDC.Derived.MackeyDecompositionUp`

Theorem 6541.2 (MackeyDecomposition NameCert obligations)**.** *For every accepted* $\mathsf{MackeyDecomposition}^{\uparrow}$ *carrier $\mathcal{M} = (G, H, R, I, C, F, S, D, L, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MackeyDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the displayed group, subgroup, representation-ring, induced-representation, character-theory, Frobenius, Schur, double-coset, summand, transport, provenance, and naming rows;*
2. *double-coset admission, requiring every representative read in D to expose its* $\mathsf{Group}^{\uparrow}$ *and* $\mathsf{Subgroup}^{\uparrow}$ *source rows before any summand in L is consumed;*
3. *induced-summand exactness, requiring every summand row in L to factor through the* $\mathsf{InducedRep}^{\uparrow}$ *row I, the representation-ring row R, and the vector-space endpoint named in P;*
4. *character-pairing audit, requiring the* $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{FrobeniusReciprocity}^{\uparrow}$, *and* $\mathsf{SchurOrthogonality}^{\uparrow}$ *rows C, F, S to inspect only the displayed summands and double-coset representatives;*
5. *non-escape, excluding host double-coset quotients, complete representation categories, semisimplicity decompositions, character-table computation, and selected bases.*

No local obligation is stored outside $\mathcal{M}$.

Proof. Project the carrier of Definition 6541.1. The displayed coordinates are precisely the consumed source rows G, H, R, I, C, F, S, the double-coset and summand rows D, L, and the structural rows T, P, N.

The double-coset ledger is finite by construction of the packet. Each representative read is tied to the group and subgroup rows before the corresponding summand can be inspected, so the summand exactness clause is a projection through I, R and the vector-space source named by P.

The character audit reads only the displayed summands. The rows C, F, S compare character pairings, induction–restriction, and orthogonality along the visible ledger, while T transports and replays the same finite route.

Since no coordinate stores a quotient double-coset carrier, host representation category, semisimplicity decomposition, character table, or selected basis, the listed rows exhaust the local NameCert surface. □

Theorem 6541.3 (MackeyDecomposition double-coset ledger)**.** *Every decomposition read exported by an accepted* $\mathsf{MackeyDecomposition}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Group}^{\uparrow}, \mathsf{Subgroup}^{\uparrow} \longmapsto D \longmapsto L \longmapsto \mathsf{InducedRep}^{\uparrow}, \mathsf{RepresentationRing}^{\uparrow}, \mathsf{CharacterTheory}^{\uparrow}, \mathsf{FrobeniusReciprocity}^{\uparrow}, \mathsf{Sch}$$

Thus a downstream consumer may read the Mackey decomposition only as a displayed double-coset representative ledger and its induced summand ledger. It cannot replace those rows by a host quotient $H\backslash G/K$, an ambient representation category, a selected module basis, a semisimplicity theorem, or a character table.

Proof. Begin with a decomposition request. The source rows available to it are the group row G and subgroup row H, and the only double-coset coordinate is the displayed finite ledger D.

The summands are downstream from D. Each entry of L is read only after the corresponding representative and subgroup-intersection data have appeared, and the induced-representation and representation-ring rows I, R consume exactly those displayed entries.

The character-facing checks do not enlarge the route. The rows C, F, S audit the same summands by character pairing, Frobenius reciprocity, and Schur orthogonality, while T, P, N replay, source, and name the packet.

Therefore every exported decomposition read remains inside the finite ledger route stated above, with no host quotient, ambient category, selected basis, semisimplicity theorem, or character-table computation. □

Closure status for $\mathsf{NameCert}_{\mathsf{MackeyDecomposition}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MackeyDecomposition}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6541.1, Definition 6541.2, and Definition 6541.3 seed the finite Mackey double-coset decomposition packet over displayed group, subgroup, induced-representation, character-theory, representation-ring, vector-space, Frobenius reciprocity, and Schur orthogonality rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MackeyDecomposition}\uparrow}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.MackeyDecompositionUp`

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, host double-coset quotients, complete representation categories, semisimplicity, selected bases, or character-table computation.

Upgrade path: Obligation closure requires carrier admission, double-coset admission, induced-summand exactness, character-pairing audit, transport stability, provenance exhaustion, and local naming for the displayed packet.

Constructive story: A $\mathsf{MackeyDecomposition}^{\uparrow}$ packet is generated from displayed group and subgroup rows, representation-ring and induced-representation rows, character-theory, Frobenius reciprocity, and Schur orthogonality rows, a finite double-coset representative ledger, an induced summand ledger, componentwise transport and replay, provenance, and local NameCert evidence.

Chapter 6542

A Concrete Naming Certificate for $\mathsf{DoobConvergence}^{\uparrow}$

Following Doob, the $\mathsf{DoobConvergence}^{\uparrow}$ packet names the finite convergence-readout surface that sits beside the martingale convergence packet of chapter 2246. It consumes the probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, upcrossing, Doob-upcrossing, martingale-convergence, rational, and real certificates of chapter 184, chapter 185, chapter 188, chapter 190, chapter 344, chapter 383, chapter 1629, chapter 1630, chapter 2246, chapter 37, and chapter 38. The packet records the bounded finite NameCert obligations needed to read a convergence-admission row; it does not introduce measure completion, almost-sure quotient equality, unbounded stopping choice, or a completed limiting-event carrier.

Definition 6542.1 (Doob convergence carrier)**.** *A* $\mathsf{DoobConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\Omega, X, E, M, T, O, U, B, A, Q, R, L, W, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the consumed* $\mathsf{ProbSpace}^{\uparrow}$ *row.*
2. X *is the* $\mathsf{RandomVar}^{\uparrow}$ *endpoint-family row for the displayed martingale window.*
3. E *is the* $\mathsf{CondExp}^{\uparrow}$ *successor-face row used by the martingale law.*
4. M *is the finite* $\mathsf{Martingale}^{\uparrow}$ *adapted-sequence packet.*
5. T *is the* $\mathsf{StoppingTime}^{\uparrow}$ *bounded index row.*
6. O *is the* $\mathsf{OptionalStopping}^{\uparrow}$ *stopped-window row.*
7. U *is the* $\mathsf{Upcrossing}^{\uparrow}$ *crossing-count ledger.*
8. B *is the* $\mathsf{DoobUpcrossing}^{\uparrow}$ *bound row consumed by the convergence readout.*
9. A *is the* $\mathsf{MartingaleConvergence}^{\uparrow}$ *finite convergence-admission row.*
10. Q *is the* $\mathsf{Rat}^{\uparrow}$ *rational tolerance ledger used to read finite windows.*
11. R *is the* $\mathsf{Real}^{\uparrow}$ *boundary and bounded-window row.*
12. L *is the Doob convergence readout ledger recording which finite endpoint windows, rational tolerances, real bounds, upcrossing rows, and admission rows may be inspected together.*

13. *W records the local source alignment among* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, $\mathsf{MartingaleConvergence}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.
14. *H records componentwise* hsame *transport for all displayed rows.*
15. *C records the displayed* Cont *routes from finite endpoint windows through bounded stopping, upcrossing, Doob-bound, martingale-convergence, rational, real-boundary, and convergence-readout rows.*
16. *P is the* Pkg *provenance over the displayed rows,* BHist, hsame, Cont, *and* NameCert.
17. *N is the local* $\mathsf{NameCert}_{\mathsf{DoobConvergence}^{\uparrow}}$ *row.*

The carrier is exactly this finite packet. It has no coordinate for measure completion, almost-sure quotient classes, unbounded stopping-time selection, pathwise limiting events, Brownian specialization, or an ambient convergence theorem.

Theorem 6542.2 (Doob convergence NameCert obligations)**.** *For the carrier of Definition 6542.1, the local* $\mathsf{NameCert}_{\mathsf{DoobConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$\Omega, X, E, M, T, O, U, B, A, Q, R, L, W, H, C, P, N,$$

probability and endpoint exposure through Ω, X, E, M, bounded stopping exposure through T, O, upcrossing and Doob-bound exposure through U, B, martingale-convergence admission through A, rational and real readback through Q, R, convergence-readout exactness through L, source alignment through W, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.

Proof. Project the carrier of Definition 6542.1. Its rows list the consumed probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, upcrossing, Doob-upcrossing, martingale-convergence, rational, real, readout, source-alignment, transport, replay, provenance, and naming data.

The martingale-facing rows are Ω, X, E, M, T, O. They are consumed only as finite probability, endpoint, conditional-expectation, martingale, and bounded stopped-window packets.

The crossing-facing rows are U, B, A. The upcrossing row and Doob-bound row must be displayed before the martingale-convergence admission row can be read, matching the sibling route through chapter 2246.

The readback rows are Q, R, L, W, H, C, P, N. They record rational tolerance, real boundary, finite convergence readout, source alignment, componentwise transport, replay, provenance, and local naming. Since no remaining coordinate names measure completion, almost-sure quotient equality, unbounded stopping choice, or a limiting-event carrier, the NameCert obligations are exactly the displayed finite rows. □

Theorem 6542.3 (Doob convergence bounded readout nonescape)**.** *Every accepted* $\mathsf{DoobConvergence}^{\uparrow}$ *carrier reads a convergence-facing row only through the finite handoff from* $\mathsf{MartingaleConvergence}^{\uparrow}$*: bounded stopped windows, lower and upper* $\mathsf{Real}^{\uparrow}$ *boundary rows,* $\mathsf{Rat}^{\uparrow}$ *tolerance rows, consumed* $\mathsf{Upcrossing}^{\uparrow}$ *and* $\mathsf{DoobUpcrossing}^{\uparrow}$ *ledgers, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. A consumer that replaces this route by measure completion, almost-sure quotient equality, unbounded stopping choice, or an ambient limiting event leaves the accepted packet.*

Proof. Open the accepted packet and project A, L, Q, R, U, B. The convergence-admission row A is read only together with the readout ledger L, rational tolerance row Q, real boundary row R, crossing-count row U, and Doob-bound row B.

Use Definition 2246.2 and Definition 2246.6. They identify the martingale-convergence handoff as a finite bounded-window route over stopping, upcrossing, rational-readback, and real-boundary rows, not as an ambient limiting theorem.

Finally apply Definition 6542.2. It adds the local source-alignment, transport, replay, provenance, and naming rows W, H, C, P, N and confirms that the $\mathsf{DoobConvergence}^{\uparrow}$ carrier has no coordinate for measure completion, almost-sure quotient equality, unbounded stopping choice, or a limiting-event carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{DoobConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoobConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6542.1, Definition 6542.2, and Definition 6542.3 seed the finite Doob convergence packet over probability, random-variable, conditional-expectation, martingale, bounded stopping, upcrossing, Doob-bound, martingale-convergence, rational, real, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoobConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, almost-sure quotient equality, unbounded stopping choice, completed limiting-event carriers, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite handoff exactness, bounded readout nonescape, and local NameCert accountability for BEDC.Derived.DoobConvergenceUp.

Constructive story: A $\mathsf{DoobConvergence}^{\uparrow}$ packet is generated from probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, upcrossing, Doob-upcrossing, martingale-convergence, rational, real-boundary, transport, continuation, provenance, and local NameCert rows.

Chapter 6543

A Concrete Naming Certificate for $\mathsf{MetrizableSpace}^{\uparrow}$

Following Bourbaki and Kelley-style topology, the $\mathsf{MetrizableSpace}^{\uparrow}$ packet records the finite BEDC handoff by which a displayed topology may expose a metric whose ball-neighbourhood rows answer the same local open requests. It sits between the topology carrier of chapter 88, the metric-space surface of chapter 4230, the finite $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ distance readback route of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a metrizable-space interface, not a Urysohn metrization theorem, open-cover compactness, quotient equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6543.1 (MetrizableSpace carrier)**.** *A* $\mathsf{MetrizableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (T, M, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying open-row classifiers, point-neighbourhood requests, and finite membership reads.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *metric row over the same displayed point carrier.*
3. *B is the ball-neighbourhood basis row. It records, for each displayed point and tolerance request, the metric ball row whose inclusion and refinement reads answer the topology row T.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when a distance request is inspected by finitely many named observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational distance stream generated from W and the metric row M.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the distance value, reachable only after M, B, W, R have been displayed.*
7. *H records componentwise* hsame *transport for topology rows, metric rows, ball-basis rows, distance windows, regular readback, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a topological neighbourhood or distance request through $T, M, B, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MetrizableSpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MetrizableSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for Urysohn separation hypotheses, open-cover compactness, quotient point equality, selected metric representatives, countable-choice schedules, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MetrizableSpaceUp.MetrizableSpaceTasteGate single carrier alignment`

Theorem 6543.2 (MetrizableSpace NameCert obligations)**.** *For every accepted* $\mathsf{MetrizableSpace}^{\uparrow}$ *carrier* $Z = (T, M, B, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetrizableSpace}^{\uparrow}}$ *surface consists exactly of topology carrier admission, metric row admission, ball-neighbourhood basis visibility, finite distance-window inspection,* $\mathsf{RegSeqRat}^{\uparrow}$ *distance readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside those finite rows.*

Proof. Project the carrier of Definition 6543.1. The topology source, metric row, ball-basis row, distance window, regular readback, Real seal, transport, replay, provenance, and local naming row are the only displayed coordinates.

The topological side is read through T and B. A neighbourhood request must first name the open-row classifier in T and then read the ball-basis witness that relates the displayed metric ball to that topology row.

The metric side is read through M, W, R, E. A distance request cannot reach a Real value until the metric row has been displayed, the finite window has been inspected, the regular rational readback has been produced, and the terminal Real seal has been exposed.

Rows H, C, P, N only transport, replay, source, and name the same finite packet. Since no remaining coordinate stores the excluded objects, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.MetrizableSpaceUp.MetrizableSpaceCarrier namecert obligations`

Theorem 6543.3 (MetrizableSpace metric-topology handoff)**.** *Every topology-facing or metric-facing consumer of an accepted* $\mathsf{MetrizableSpace}^{\uparrow}$ *packet factors through*

$$\mathsf{Topology}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The topology read receives ball-neighbourhood basis rows tied to T, while the metric read receives distance windows, regular readback, and a terminal Real seal tied to M. The handoff exports no Urysohn metrization theorem, open-cover compactness, quotient equality, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the topology-facing request. The carrier exposes topology only through T, and the basis row B is the only row that answers neighbourhood requests by metric balls.

For a metric-facing request, read M before the distance window W. The window is then converted by R into a regular rational distance readback and sealed by E as the only Real-facing endpoint.

Transport and replay through H and C preserve the same route, while P and N record provenance and local naming. The carrier contains no row for the excluded global theorems or selectors, so the handoff is exactly the finite BEDC route displayed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetrizableSpace}^{\uparrow}}$**.**

Constructive story: A MetrizableSpace$^{\uparrow}$ packet is generated from a TopologyUp source row, MetricSpaceUp metric row, ball-neighbourhood basis row, StreamNameUp finite distance windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetrizableSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6543.1, Definition 6543.2, and Definition 6543.3 seed the finite topology-to-metric handoff over topology rows, metric rows, ball-neighbourhood basis rows, distance windows, regular readback, Real seals, provenance, and naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetrizableSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Urysohn metrization, open-cover compactness, quotient equality, selected representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ball-neighbourhood basis visibility, finite distance-window inspection, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.MetrizableSpace

Chapter 6544

A Concrete Naming Certificate for HyperbolicIdealTriangle$^{\uparrow}$

Following the classical Poincare-disk treatment of ideal triangles in hyperbolic geometry, the HyperbolicIdealTriangle$^{\uparrow}$ packet records the finite BEDC surface for three displayed boundary ends, their geodesic sides, the disk metric route, and the boundary-flow handoff. It concretizes the fixed-end route of section 9463.5 in chapter 9463. The packet sits after HyperbolicMetric$^{\uparrow}$ in chapter 3474, HyperbolicGeodesicBoundary$^{\uparrow}$ in chapter 3491, UnitDisk$^{\uparrow}$ in chapter 377, PoincareDiskPhaseTransport$^{\uparrow}$ in chapter 3455, and DynSystem$^{\uparrow}$ in chapter 195. It does not complete the disk, quotient ideal endpoints, select global geodesic representatives, import host analytic flow, or identify the observer-expansion reading with physical spacetime.

Definition 6544.1 (Hyperbolic ideal triangle carrier)**.** *A* HyperbolicIdealTriangle$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (U, M, B, G, T, D, F, J, H, C, P, N)$$

with the following displayed rows:

1. *U is the* UnitDisk$^{\uparrow}$ *disk-coordinate row for the finite interior probes and boundary-end reads inspected by the packet.*
2. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row over the same displayed disk data.*
3. *B is the* HyperbolicGeodesicBoundary$^{\uparrow}$ *row naming three distinct boundary-end positions and the finite incidence data used to form ideal sides.*
4. *G is the geodesic-side row, recording the three boundary-to-boundary side reads as displayed boundary geodesic data.*
5. *T is the* PoincareDiskPhaseTransport$^{\uparrow}$ *transport row carrying disk-surface movement and boundary provenance.*
6. *D is the* DynSystem$^{\uparrow}$ *finite flow row used when a boundary-flow consumer replays movement along the displayed sides.*
7. *F is the fixed-end row stating that the three boundary commitments remain the same displayed far-end rows along the routed flow.*
8. *J is the classifier-stability row for disk coordinates, metric reads, boundary incidence, side rows, phase transport, routed flow, and fixed-end data.*

9. *H records componentwise* hsame *transport for disk, metric, boundary, side, transport, flow, fixed-end, classifier-stability, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an ideal-triangle or boundary-flow request through $U, M, B, G, T, D, F, J, H,$*
11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicIdealTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a completed hyperbolic plane, quotient ideal-boundary equality, selected global geodesics, host analytic flow, physical cosmology, or observer substance.

Theorem 6544.2 (Hyperbolic ideal triangle NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$ *carrier $I = (U, M, B, G, T, D, F, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicIdealTriangle}^{\uparrow}}$ *surface is exhausted by disk-coordinate admission, hyperbolic metric visibility, boundary-end incidence for three displayed ends, geodesic-side visibility, Poincare disk phase transport, finite dynamic-flow replay, fixed-end stability, classifier stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6544.1. The rows $U, M, B, G, T, D, F, J, H, C, P, N$ are the only displayed coordinates.

The geometric read begins with U, M, B, G. Disk coordinates and metric reads are visible before boundary incidence is used, and the three side rows are built only from the displayed boundary data.

The boundary-flow read uses T, D, F, J. Phase transport and finite flow replay carry the same boundary commitments, while classifier stability keeps disk, metric, boundary, side, transport, flow, and fixed-end rows attached to the same packet.

Rows H, C, P, N transport, replay, source, and name the finite carrier. Since no row stores the excluded completed or host-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 6544.3 (Hyperbolic ideal triangle boundary-flow handoff)**.** *Every boundary-flow consumer of an accepted* $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$ *packet factors through*

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicGeodesicBoundary}^{\uparrow} \longmapsto \mathsf{PoincareDiskPhaseTransport}^{\uparrow} \longmapsto \mathsf{DynSyster}$$

The consumer receives three displayed boundary ends, their geodesic-side rows, phase transport, finite routed flow, fixed-end stability, classifier stability, transport, replay, provenance, and local naming. It obtains no completed disk, quotient ideal-boundary equality, selected global geodesic, host analytic flow, physical cosmology, or observer substance.

Proof. Begin with a boundary-flow request. The disk-coordinate row U and metric row M provide the only geometric source data available to the request.

Read B and G next. The three boundary ends and the three ideal sides are displayed as finite incidence and geodesic rows, not as quotient endpoints or selected global geodesics.

Use T, D, F, J for the handoff. The Poincare disk transport row and finite dynamic-flow row replay movement while preserving the fixed-end commitments and classifier readings.

Finally replay the structural rows H, C, P, N. They preserve the same finite packet, and the carrier has no coordinate for the excluded completed or host-level objects, so the boundary-flow handoff cannot leave the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicIdealTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$ packet is generated from UnitDiskUp coordinate rows, HyperbolicMetricUp metric reads, HyperbolicGeodesicBoundaryUp boundary incidence, three geodesic-side rows, PoincareDiskPhaseTransportUp transport, DynSystemUp finite flow replay, fixed-end stability, classifier stability, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicIdealTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6544.1, Definition 6544.2, and Definition 6544.3 seed the finite ideal-triangle route over disk, metric, boundary, geodesic-side, phase-transport, flow, fixed-end, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicIdealTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic disks, quotient ideal-boundary equality, selected global geodesics, host analytic flows, physical cosmology, observer-substance readings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk visibility, metric-read visibility, boundary incidence, geodesic-side visibility, phase-flow routing, fixed-end stability, classifier stability, ledger nonescape, and local naming for BEDC.Derived.HyperbolicIdealTr

Chapter 6545

A Concrete Naming Certificate for $\mathsf{BishopRegularCompletionReflector}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularCompletionReflector}^{\uparrow}$ packet records the Bishop regular completion reflector as finite BEDC naming data over explicit rational approximants. It sits after the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the RegSeqRat reflector route of chapter 3398. The packet names only the finite reflector surface visible to Bishop regular-name consumers; it does not identify quotient completions, select limits, compare host real values, use countable choice, assert ambient completeness of $\mathsf{Real}^{\uparrow}$, or provide Lean verification or bridge data.

Definition 6545.1 (BishopRegularCompletionReflector carrier)**.** *A* $\mathsf{BishopRegularCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for every regular precision request and every comparison of inspected rational windows.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the currently inspected approximants of the Bishop regular name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, certifying that the displayed windows satisfy the regular rational discipline required before completion is requested.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from D, S, R through the displayed completion surface rather than through a quotient of streams.*
5. *F is the reflector row, recording that any completion-facing consumer must read the dyadic ledger, stream windows, regular readback, and real seal in that order.*
6. *H records componentwise* hsame *transport for dyadic tolerances, stream windows, regular readbacks, real seals, reflector rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a regular-name precision request through*

$$D, S \longmapsto R \longmapsto E \longmapsto F \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCompletionReflector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, E, F, H, C, P, N$. It has no coordinate for quotient completion equality, selected limit representatives, host equality of real values, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge checking.*

Theorem 6545.2 (BishopRegularCompletionReflector NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCompletionReflector}^{\uparrow}$ *carrier*

$$B = (D, S, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionReflector}^{\uparrow}}$ *surface consists exactly of carrier admission for dyadic tolerance ledgers, finite stream windows, regular rational readback, real-name sealing, reflector routing, transport, replay, provenance, and local naming; source exposure requiring every completion-facing read to inspect D, S before R; reflector discipline requiring E and F to be read only through the same D, S, R route; and nonescape excluding quotient completion, selected limits, host equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and standard bridge checking.*

Proof. Project the accepted carrier. Its displayed coordinates are exactly $D, S, R, E, F, H, C, P, N$, so carrier admission, transport, replay, provenance, and local naming are read from those rows.

The source side begins with D and S. The dyadic ledger fixes the tolerances used by each regular request, while the stream-window row specifies the finite approximants available for the current read.

The regular readback row R is downstream of those source rows. A completion-facing consumer therefore obtains a regular rational name only after the dyadic and stream data have been displayed.

The seal and reflector rows are E and F. Both are indexed by the same D, S, R route, so the carrier cannot replace them by a quotient completion, a selected limit, or a host-level equality witness.

Finally H, C, P, N preserve, replay, source, and name the same finite packet. Since no other coordinate is present, the listed rows exhaust the local NameCert surface and the refused principles have no export path. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCompletionReflector}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, a reflector route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRegularCompletionReflector}^{\uparrow}}$, seed)

Scope closed: Definition 6545.1 and Definition 6545.2 seed the Bishop regular completion reflector packet over dyadic tolerances, finite windows, regular rational readback, and a Real-facing seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRegularCompletionReflector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance coverage, StreamName window exposure, RegSeqRat readback, Real seal preservation, reflector routing, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCompletionReflectorUp.

Chapter 6546

A Concrete Naming Certificate for $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$ packet records the finite oscillation boundary where a regular rational Cauchy name is allowed to hand a Real-facing consumer only the displayed tail-variation data. It sits over the dyadic arithmetic core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the Cauchy oscillation ledger of chapter 448. The packet is a boundary object for L10 oscillation consumers, not Real completeness, quotient stream equality, host real equality, or a selected limit.

Definition 6546.1 (Regular real oscillation boundary carrier)**.** *A* $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, O, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the finite dyadic radius and comparison budget used by the oscillation request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the inspected finite prefix and the later finite refinements admitted for the same name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from the displayed stream windows.*
4. *O is the* $\mathsf{CauchyOscillation}^{\uparrow}$ *ledger row recording the finite tail-variation comparisons read from D, S, R.*
5. *L is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the dyadic tolerance, stream window, regular readback, and oscillation ledger have all been displayed.*
6. *H records componentwise* hsame *transport for the tolerance, window, readback, oscillation, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an oscillation-boundary request through D, S, R, O and then to the terminal seal L.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyOscillation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularRealOscillationBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, O, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, Real completeness, or an ambient completeness theorem.

Theorem 6546.2 (Regular real oscillation boundary NameCert obligations)**.** *For every accepted* $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$ *carrier $B = (D, S, R, O, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularRealOscillationBoundary}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dyadic tolerance, stream window, regular rational readback, oscillation ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *tolerance-window compatibility, requiring D and S to be displayed before any regular rational readback is consumed;*
3. *regular-readback exposure, requiring R to be read only as the finite RegSeqRat route produced from S;*
4. *oscillation-boundary admission, requiring O to consume the same D, S, R rows before any Real-facing seal is read;*
5. *Real seal non-escape, requiring L to seal only the displayed oscillation comparison and not a completed real object, quotient stream class, selected limit, or host equality;*
6. *componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N.*

No obligation is stored outside those rows.

Proof. Project the carrier of Definition 6546.1. The projection exposes exactly the dyadic tolerance row, finite stream window, regular rational readback, oscillation ledger, Real seal, transport, replay, provenance, and local naming rows.

Read the numerical boundary in order. The dyadic tolerance D and stream window S determine the finite comparison budget; the regular readback R is then the only RegSeqRat row available to the oscillation ledger O.

The seal L is downstream of D, S, R, O. Since the carrier has no quotient stream, selected limit, host equality, choice, or completeness coordinate, the seal records only the displayed oscillation comparison.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Thus the listed rows exhaust the local NameCert surface. □

Theorem 6546.3 (Regular real oscillation boundary L10 handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$ *carrier must factor through the finite route*

$$D \longmapsto S \longmapsto R \longmapsto O \longmapsto L \longmapsto H, C, P, N.$$

The handoff gives the consumer a displayed oscillation boundary for regular rational Cauchy names, not Real completeness, quotient equality of streams, host real equality, selected limits, or countable choice.

Proof. Let $B = (D, S, R, O, L, H, C, P, N)$ be accepted. The only tolerance source is D, and the only observation source is the finite window S.

The regular rational readback R is downstream of those rows, and the Cauchy oscillation ledger O reads the same finite data before the Real seal L is available. A consumer therefore reaches L only through the displayed L10 source route.

Componentwise transport and replay through H and C preserve that route, while P and N record the provenance and local name. Since no other coordinate exists, the consumer cannot obtain Real completeness, quotient stream equality, host equality, a selected limit, or countable choice from this packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$ reader that claims a Real-facing oscillation handoff while omitting DyadicRatCore tolerance, StreamName windows, RegSeqRat readback, CauchyOscillation ledger, Real seal, hsame transport, Cont replay, Pkg provenance, or local naming refutes the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchyoscillation: RegularRealOscillationBou is not bijective to any listed sibling because it jointly carries the dyadic tolerance, stream window, regular readback, oscillation ledger, terminal seal, transport, replay, provenance, and local naming as one boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealOscillationBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularRealOscillationBoundary}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName windows, RegSeqRat readback, a CauchyOscillation ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRealOscillationBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6546.1, Definition 6546.2, and Definition 6546.3 seed the finite oscillation boundary for RegSeqRat and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularRealOscillationBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, Real completeness, quotient stream equality, host real equality, selected limits, countable choice, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window compatibility, regular readback exposure, oscillation-boundary admission, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RegularRealOscillationBoundaryUp.

Chapter 6547

A Concrete Naming Certificate for MetaCICConfluenceDiamondLedger$^{\uparrow}$

The MetaCICConfluenceDiamondLedger$^{\uparrow}$ packet realizes the confluence audit map of chapter 9378 as finite NameCert data. It packages typed-window exposure, residual-substitution boundary rows, local-join ledgers, bounded checker rows, obstruction retention, transport, replay, provenance, and local naming before any confluence handoff can be read. It consumes the MetaCIC critical path of chapter 765, the candidate-mediated strong-normalization route of chapter 5163, the critical-pair boundary of chapter 2212, the residual-substitution boundary of chapter 2181, and the local-join ledger of chapter 4126. The packet is a finite confluence-diamond ledger, not a closed Church–Rosser theorem or an unconditional substitution-compatibility proof.

Definition 6547.1 (MetaCIC confluence diamond ledger carrier)**.** *A* MetaCICConfluenceDiamondLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, R, J, B, O, X, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row exposing the finite MetaCIC source window, redex shape, and bounded context in which the confluence handoff is requested.*
2. *R is the residual-substitution row naming the displayed substitution-boundary data that the diamond route must consume.*
3. *J is the local-join row recording the finite candidate joins and common-reduct witnesses accepted for the inspected critical pairs.*
4. *B is the bounded-checker row recording the finite checker budget for the residual diamond route.*
5. *O is the obstruction row retaining the substitution-compatibility and closed-diamond boundary names that are not discharged by this packet.*
6. *X is the confluence handoff row exposed only after T, R, J, B, O have all been displayed.*
7. *H records componentwise* hsame *transport for the typed window, residual-substitution row, local-join row, bounded checker, obstruction row, handoff row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a confluence-diamond request through T, R, J, B, O and then to X.*

9. *P is the* Pkg *provenance over* MetaCICConfluenceDiamondLedger$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, CandidateMediatedSN$^{\uparrow}$, MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, MetaCICLocalJoinLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, R, J, B, O, X, H, C, P, N$. It has no coordinate for an unconditional parallel diamond, closed Church–Rosser theorem, global substitution-compatibility proof, unbounded checker, hidden quotient, or host-side confluence oracle.

Theorem 6547.2 (MetaCIC confluence diamond ledger NameCert obligations)**.** *For every accepted* MetaCICConfluenceDiamondLedger$^{\uparrow}$ *carrier $G = (T, R, J, B, O, X, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICConflu}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed typed-window, residual-substitution, local-join, bounded-checker, obstruction, handoff, transport, replay, provenance, and local naming rows;*
2. *typed-window exposure, requiring the MetaCIC source window, redex shape, and bounded context to be displayed before any residual row is consumed;*
3. *residual-substitution exposure, requiring R to be read before local joins or bounded checker rows can be trusted;*
4. *local-join accounting, requiring J to list the finite candidate joins and common-reduct witnesses used by the inspected critical pairs;*
5. *bounded-checker accounting, requiring B to record the finite checker budget and to consume the same T, R, J rows;*
6. *obstruction retention, requiring O to keep the substitution-compatibility and closed-diamond boundary names visible rather than silently discharging them;*
7. *handoff non-escape, requiring X to expose only the displayed confluence-diamond ledger and not an unconditional Church–Rosser theorem;*
8. *componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N.*

The future Lean TasteGate for this packet must supply both a Nontrivial instance, separating nonempty ledger data from the empty carrier, and a FieldFaithful instance, asserting that the classifier reads every displayed field $T, R, J, B, O, X, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.MetaCICConfluenceDiamondLedgerUp.MetaCICConfluenceDiamondLedgerNameCertObligations`

Proof. Project the carrier of Definition 6547.1. The projection exposes exactly the typed-window, residual-substitution, local-join, bounded-checker, obstruction, handoff, transport, replay, provenance, and local naming rows.

Read the confluence rows in order. The typed window T fixes the inspected MetaCIC source window; the residual row R records the substitution boundary; the local-join row J records candidate joins; and the bounded checker B accounts for the finite checking budget.

The obstruction row O remains visible before the handoff X. Therefore the packet can display a confluence-diamond ledger without claiming the global substitution-compatibility input or a closed Church–Rosser endpoint.

Finally, H, C, P, N transport, replay, source, and name the same finite route. A Nontrivial TasteGate instance must witness that accepted packets carry genuine ledger data, and a FieldFaithful instance must witness that the classifier cannot ignore any displayed row. □

Theorem 6547.3 (MetaCIC confluence diamond ledger handoff)**.** *Every accepted* MetaCICConfluenceDiamondLedg *carrier that exposes a confluence handoff must display the typed-window, residual-substitution, local-join, bounded-checker, obstruction, transport, replay, provenance, and local NameCert rows on the same route*

$$T \longmapsto R \longmapsto J \longmapsto B \longmapsto O \longmapsto X \longmapsto H, C, P, N.$$

Consequently the handoff is a finite ledger consumed by MetaCIC confluence routes, not an unconditional parallel diamond, not arbitrary closed-term Church–Rosser, not a global substitution-compatibility proof, and not a host confluence oracle.

Proof. Let $G = (T, R, J, B, O, X, H, C, P, N)$ be accepted. The handoff row X is downstream of the typed-window, residual-substitution, local-join, bounded-checker, and obstruction rows by the carrier definition.

Use the NameCert obligations of Definition 6547.2. They force every confluence-facing reader to keep T, R, J, B, O visible before X can be consumed.

The structural rows then preserve the same route. Transport through H, replay through C, provenance through P, and local naming through N do not add an unconditional diamond theorem, a closed Church–Rosser theorem, a global substitution-compatibility proof, or an unbounded checker. □

Theorem 6547.4 (MetaCIC confluence diamond ledger candidate join exhaustion)**.** *Every accepted* $\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}$ *carrier* $G = (T, R, J, B, O, X, H, C, P, N)$ *that exposes a common-reduct claim in* X *must first expose the typed-window row* T*, residual-substitution row* R*, local-join row* J*, bounded-checker row* B*, and obstruction row* O*. Moreover, every common-reduct claim in* X *is backed by a row of* J *with the same typed window and the same residual-substitution boundary, while* O *remains present for any substitution-compatibility boundary not discharged by that row.*

Proof. Project the carrier of Definition 6547.1. The handoff coordinate X is not available before T, R, J, B, O have been displayed.

Apply the NameCert obligations of Definition 6547.2. Typed-window exposure fixes T, residual-substitution exposure fixes R, local-join accounting forces J to list the finite candidate joins, and bounded-checker accounting keeps those rows inside the finite checker budget B.

Apply Definition 6547.3. Any common-reduct read exported by X follows the route through T, R, J, B, O, so its local-join witness must be a row of J over the same typed window and residual-substitution boundary.

The obstruction row O is preserved rather than consumed silently. Thus the candidate-join ledger exhausts the displayed common-reduct claims without turning missing substitution compatibility into a global Church–Rosser proof. The existing Lean TasteGate evidence for this chapter records the Nontrivial and FieldFaithful obligations that keep these displayed fields visible to the classifier. □

Theorem 6547.5 (MetaCIC confluence diamond ledger obstruction lock)**.** *For every accepted* $\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}$ *carrier* $G = (T, R, J, B, O, X, H, C, P, N)$*, any confluence handoff row* X *must keep the typed-window row* T*, residual-substitution row* R*, local-join row* J*, bounded-checker row* B*, and obstruction row* O *visible until both the residual-substitution and local-join rows have been consumed by the same route. In particular,* X *alone cannot be read as a closed Church–Rosser theorem, global substitution-compatibility proof, unbounded checker, or host confluence oracle.*

Proof. Project the carrier of Definition 6547.1. The handoff coordinate X is downstream of T, R, J, B, O and has no independent coordinate for a global confluence proof.

Apply the NameCert obligations of Definition 6547.2. They require typed-window exposure, residual-substitution exposure, local-join accounting, bounded-checker accounting, obstruction retention, handoff non-escape, and structural replay before a confluence-facing read can be consumed.

Apply the handoff theorem Definition 6547.3. It keeps every handoff on the route

$$T \longmapsto R \longmapsto J \longmapsto B \longmapsto O \longmapsto X \longmapsto H, C, P, N.$$

Thus X cannot bypass the residual-substitution or local-join rows.

Finally apply the candidate-join theorem Definition 6547.4. Any common-reduct claim exported by X is backed by a row of J over the same typed window and residual-substitution boundary, while O remains present for the substitution-compatibility boundary not discharged by that row. The obstruction is therefore locked to the residual-substitution and local-join route rather than erased by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}$ packet exposing a confluence handoff must display typed-window, residual-substitution, local-join, bounded-checker, obstruction, transport, replay, provenance, and NameCert rows.

Independence witness: metaciccriticalpath, candidate-mediated-sn, metacic-confluence-critical-pair-boundary, metacic-residual-substitution-boundary, metacic-local-join-ledger: MetaCICConfluenceDiamondLedg is not bijective to any listed sibling because it jointly carries typed-window, residual-substitution, local-join, bounded-checker, obstruction-retention, handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}$ packet is generated from typed-window exposure, residual-substitution boundary data, local-join rows, bounded-checker rows, obstruction retention, a confluence handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6547.1, Definition 6547.2, Definition 6547.3, Definition 6547.4, and Definition 6547.5 seed the finite confluence-diamond ledger consumed by MetaCIC confluence routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, unconditional parallel diamond, arbitrary closed-term Church–Rosser, global substitution compatibility, unbounded checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-substitution exposure, local-join accounting, bounded-checker accounting, obstruction retention, handoff non-escape, transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetaCICConfluenceDiamond

Chapter 6548

A Concrete Naming Certificate for $\mathsf{LocatedCompactOvert}^{\uparrow}$

Following Bishop–Bridges constructive topology and formal-topology overt compactness, the $\mathsf{LocatedCompactOvert}^{\uparrow}$ packet records a compact object whose finite cover data and positive contact witnesses are both displayed. It sits beside the located compact boundary of chapter 1488, the finite compact witnesses of chapter 60 and chapter 129, the overt real interface of chapter 3354, the finite lower-bound fold of chapter 4096, and the Real-completion readback route through chapter 126, chapter 301, and chapter 38. The packet joins finite compact cover rows with overt witness rows without importing host powersets, open-cover compactness, selected points, quotient compacta, or choice.

Definition 6548.1 (Located compact overt carrier)**.** *A* $\mathsf{LocatedCompactOvert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, C, M, V, F, S, R, E, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{LocatedCompact}^{\uparrow}$ *source row, exposing located-distance tests, finite-net witnesses, separatedness support, and the local compact naming row.*
2. *C is the compact finite-cover row, read through* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *finite witness data rather than through a host open cover.*
3. *M is the metric compactness row that ties finite centers, radii, and coverage distances to the compact metric source.*
4. *V is the* $\mathsf{OvertReal}^{\uparrow}$ *positive-information row, carrying witnessable contact with the displayed located interval or cover cell.*
5. *F is the* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *row that folds finitely many positive radius or contact candidates into one certified lower bound.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which all completion-facing reads are scheduled.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational names attached to the compact and overt observations.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the finite windows, readback, lower-bound fold, compact rows, and overt witness row have been displayed.*
9. *H records componentwise* hsame *transport for the located, compact, overt, lower-bound, readback, seal, replay, provenance, and local naming rows.*

10. *T records displayed* Cont *replay from located compact data through finite cover rows, positive witness rows, lower-bound folding, finite windows, regular readback, and the terminal Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactOvert}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{OvertReal}^{\uparrow}$, $\mathsf{FiniteLowerBoundFold}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactOvert}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, C, M, V, F, S, R, E, H, T, P, N$. It has no coordinate for host powersets, arbitrary open-set membership, selected finite subcovers, selected contact points, quotient compacta, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6548.2 (Located compact overt NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactOvert}^{\uparrow}$ *carrier*

$$O = (K, C, M, V, F, S, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompactOvert}^{\uparrow}}$ *surface consists exactly of located compact source admission, compact finite-cover exposure, compact-metric finite-net compatibility, overt positive-witness exposure, finite lower-bound folding, StreamName window scheduling, RegSeqRat readback, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No consumer may replace these rows by host powersets, arbitrary open covers, selected points, quotient compactness, choice, or ambient completeness.*

Proof. Project the carrier of Definition 6548.1. The rows K, C, M expose the located compact source, finite cover data, and compact-metric finite-net compatibility before any overt or Real-facing consumer can read the packet.

Next read the positive side. The row V supplies witnessable contact, while F folds the finite positive candidates into one lower-bound row. This is a finite induction over the displayed candidate family, not a selection from a host powerset or an arbitrary open cover.

Finally replay the completion-facing boundary. Rows S, R, E schedule finite windows, read regular rational names, and seal the terminal Real row; H, T, P, N transport, replay, source, and name the same displayed packet. Since the carrier contains no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6548.3 (Located compact overt finite positive cover induction)**.** *Every positive compact-cover read of an accepted* $\mathsf{LocatedCompactOvert}^{\uparrow}$ *packet is obtained by induction over the displayed finite cover row C and the finite lower-bound fold F. At each cover cell the consumer first reads the located compact row K, the compact-metric row M, and the overt witness row V; only after the finite induction closes may it pass through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows S, R, E.*

Proof. Start with the finite cover row C. Its cells are displayed compact data, so the induction ranges over the finite cover witnesses already present in the carrier.

For each cell, read K, M, V. Locatedness supplies the finite comparison and net rows, compact metric data supply the finite center and radius information, and overtness supplies the witnessable positive contact row.

The fold row F combines the finitely many positive candidates. After the fold closes, the completion-facing route may read S, R, E and then transport the result through H, T, P, N. No step introduces host open-cover compactness, a selected point, a selected subcover, quotient compactness, countable choice, or ambient Real completeness. □

Falsifiable prediction: Every $\mathsf{LocatedCompactOvert}^{\uparrow}$ consumer that claims positive compact contact while omitting the $\mathsf{LocatedCompact}^{\uparrow}$ source row, $\mathsf{Compact}^{\uparrow}/\mathsf{CompactMetric}^{\uparrow}$ finite cover rows, $\mathsf{OvertReal}^{\uparrow}$ witness row, $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ fold row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the packet.

Independence witness: locatedcompact, compact, compactmetric, overt-real, finite-lower-bound-fold, streamname, regseqrat, real: $\mathsf{LocatedCompactOvert}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries located compact source data, compact finite covers, compact-metric finite nets, overt positive witnesses, finite lower-bound folding, finite windows, regular readback, Real sealing, transport, replay, provenance, and local naming as one constructive topology packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactOvert}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompactOvert}^{\uparrow}$ packet is generated from LocatedCompactUp source rows, CompactUp and CompactMetricUp finite cover rows, OvertRealUp positive witness rows, FiniteLowerBoundFoldUp lower-bound folding, StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactOvert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6548.1, Definition 6548.2, and Definition 6548.3 seed the finite located compact overt packet over compact finite cover data, overt witness rows, lower-bound folding, finite windows, regular readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactOvert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host powersets, arbitrary open-set membership, open-cover compactness, selected finite subcovers, selected contact points, quotient compacta, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located compact source exposure, compact finite-cover exposure, overt witness exactness, finite lower-bound fold exactness, StreamName and RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompactOvertUp.

Chapter 6549

A Concrete Naming Certificate for $\mathsf{CountablyCompactMetric}^{\uparrow}$

Following Kelley, Bourbaki, and Bishop–Bridges compactness practice, the $\mathsf{CountablyCompactMetric}^{\uparrow}$ packet records the metric specialization of countable-cover compactness as finite NameCert data. It reads the metric and compact-metric source surfaces of chapter 57 and chapter 129, the countable-cover row of chapter 6398, the finite stream windows of chapter 126, the sequential consumer surface of chapter 2372, the finite cluster-point route of chapter 1580, and the terminal real-name seal of chapter 38. The packet is a metric countable-cover certificate; it does not turn arbitrary open-cover compactness, countable choice, or an ambient Heine–Borel theorem into a primitive row.

Definition 6549.1 (Countably compact metric carrier)**.** *A* $\mathsf{CountablyCompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, C, W, S, Q, H, R, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the named metric observations, compact-metric probes, and finite cover data used by the packet.*
2. *C is the countable cover enumeration row read through* $\mathsf{CountablyCompact}^{\uparrow}$*. It records the displayed countable family of metric-open rows and the source-surface coverage checks that the packet is allowed to inspect.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite cover-window row. It lists the inspected prefixes of the countable cover, the finite metric probes attached to those prefixes, and the pointwise cover checks visible in each prefix.*
4. *S is the finite subcover ledger. It records the accepted finite prefix, its compact-metric witness rows, and the statement that later enumeration rows are not needed for the displayed source read.*
5. *Q is the sequential consumer window. It is read either through* $\mathsf{SequentialCompact}^{\uparrow}$ *or through the* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *route when the downstream consumer asks for a sequence or cluster-point comparison over the same metric source.*
6. *H stores componentwise* hsame *transport for the metric source, countable-cover enumeration, stream windows, finite-subcover ledger, sequential consumer window, replay, provenance, and local naming rows.*

7. *R stores displayed* Cont *replay from a countable-cover metric request through M, C, W, S, Q, H.*
8. *P is the* Pkg *provenance over* $\mathsf{CountablyCompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CountablyCompact}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{RealSequenceClusterPoint}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CountablyCompactMetric}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, selected subcovers by countable choice, quotient equality of metric opens, host sequential compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6549.2 (Countably compact metric NameCert obligations)**.** *For every accepted* CountablyCompactMetric *carrier $K = (M, C, W, S, Q, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CountablyCompactMetric}^{\uparrow}}$ *surface consists exactly of metric or compact-metric source admission, countable cover enumeration through* $\mathsf{CountablyCompact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$ *finite cover windows, finite subcover ledger readback, sequential or cluster-point consumer windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every metric compactness consumer must read M, C, W, S, Q before the structural rows H, R, P, N can be consumed.*

Proof. Project the carrier of Definition 6549.1. The only source information is the metric or compact-metric row M, and the only countable-cover information is the row C read through $\mathsf{CountablyCompact}^{\uparrow}$.

The finite evidence is downstream of that countable cover. Row W exposes the inspected $\mathsf{StreamName}^{\uparrow}$ prefixes, and S records the finite prefix whose metric-open rows cover the displayed source surface.

The sequential comparison is not a second compactness principle. Row Q is a consumer window for $\mathsf{SequentialCompact}^{\uparrow}$ or $\mathsf{RealSequenceClusterPoint}^{\uparrow}$, so sequence and cluster-point reads must pass through the already displayed finite cover window and subcover ledger.

Finally H, R, P, N transport, replay, source, and name exactly those rows. Since no field stores arbitrary open covers, selected subcovers by countable choice, quotient open equality, host sequential compactness, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6549.3 (Countably compact metric sequential window handoff)**.** *Every accepted* CountablyCompactMetri *packet that is consumed by a sequential or real-cluster-point route factors through the finite chain*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow} \longrightarrow \mathsf{CountablyCompact}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{SequentialCompact}^{\uparrow},\ \mathsf{RealSequenceClusterPo}$$

The handoff exports only the displayed metric source row, countable-cover enumeration, finite cover windows, finite subcover ledger, sequential consumer window, transports, replay, provenance, and local naming rows.

Proof. Start with an accepted carrier $K = (M, C, W, S, Q, H, R, P, N)$. A sequential or cluster-point consumer first reads the metric source M and the countable cover row C, so the consumer sees a displayed countable metric cover rather than an arbitrary host cover.

The finite cover evidence is then fixed by W and S. The $\mathsf{StreamName}^{\uparrow}$ row supplies the inspected prefixes, and the finite subcover ledger supplies the accepted prefix for the same metric source.

Only after those rows are visible may Q be consumed. Thus the $\mathsf{SequentialCompact}^{\uparrow}$ or $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ comparison window is a downstream read of the finite cover route, and the terminal $\mathsf{Real}^{\uparrow}$ seal is reached only through that displayed chain.

The structural rows H, R, P, N preserve and name the same packet. They do not add countable choice, open-cover compactness, quotient open equality, host subsequence selection, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountablyCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CountablyCompactMetric}^{\uparrow}$ packet is generated from a metric or compact-metric source row, a CountablyCompact countable-cover enumeration, StreamName finite cover windows, a finite subcover ledger, a sequential or cluster-point consumer window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountablyCompactMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6549.1, Definition 6549.2, and Definition 6549.3 seed the metric countable-cover carrier over Metric, CompactMetric, CountablyCompact, SequentialCompact, RealSequenceClusterPoint, StreamName, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountablyCompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, countable choice, host sequential compactness, a selected cluster point, ambient Real completeness, Lean theorem verification, or bridge checking.

Upgrade path: Formalization requires carrier admission, countable-cover enumeration, StreamName finite-window exactness, finite-subcover ledger readback, sequential or cluster-point consumer handoff, transport, replay, provenance, and local naming for BEDC.Derived.CountablyCompactMetricUp.

Chapter 6550

A Concrete Naming Certificate for $\mathsf{DirichletUniformTailSelector}^{\uparrow}$

Following Dirichlet and the Hardy/Bishop–Bridges treatment of series tests, the $\mathsf{DirichletUniformTailSelector}^{\uparrow}$ packet records the finite selector route by which a displayed Dirichlet tail estimate is handed to a uniform Cauchy series consumer. It sits after the real-series source of chapter 1581, the bounded-partial-sum Dirichlet-test face of chapter 1497, the shared-tail handoff of chapter 1736, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite tail-budget selector for Real-and-Completion consumers; it does not assert host infinite sums, quotient series equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6550.1 (Dirichlet uniform tail selector carrier)**.** *A* $\mathsf{DirichletUniformTailSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing only the displayed term stream and finite partial-sum windows consumed by the selector.*
2. *D is the* $\mathsf{DirichletTest}^{\uparrow}$ *face row, exposing bounded partial sums, coefficient windows, null-tail data, and the finite Dirichlet tail-estimate schedule.*
3. *T is the selector row. For each requested precision and displayed source window it names the finite tail threshold admitted by the Dirichlet-test face.*
4. *W is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *handoff row, recording that the selector threshold is read as the shared uniform tail threshold for the displayed partial-sum comparisons.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected tail window and the admitted partial-sum comparisons.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, T, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the source, Dirichlet face, selector, uniform-tail handoff, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$S, D \longmapsto T \longmapsto W \longmapsto R \longmapsto E, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{DirichletUniformTailSelector}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletUniformTailSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, T, W, R, E, H, C, P, N$. It has no coordinate for a host infinite sum, quotient equality of partial-sum streams, a selected limiting real, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6550.2 (Dirichlet uniform tail selector NameCert obligations)**.** *For every accepted* $\mathsf{DirichletUniformTailSelector}^{\uparrow}$ *carrier $U = (S, D, T, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirichletUniformTailSelector}^{\uparrow}}$ *surface consists exactly of real-series source admission through S, Dirichlet-test face exposure through D, finite tail-threshold selection through T, uniform Cauchy handoff through W, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

No selector obligation is stored outside those rows.

Proof. Project the accepted carrier of Definition 6550.1. The source side is exhausted by S and D: S exposes the real-series term and partial-sum windows, while D exposes the bounded partial sums, coefficient windows, null-tail ledger, and finite Dirichlet estimate schedule.

Read the selector row next. The row T names the finite threshold used for the requested precision, and W records the same threshold as the shared uniform Cauchy tail row for the displayed partial-sum comparisons.

The endpoint route is downstream. The row R reads the selected tail window through $\mathsf{RegSeqRat}^{\uparrow}$, and E seals only that readback through $\mathsf{Real}^{\uparrow}$.

Finally the rows H, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 6550.3 (Dirichlet uniform tail handoff)**.** *Every* $\mathsf{UniformCauchySeries}^{\uparrow}$*-facing read of an accepted* $\mathsf{DirichletUniformTailSelector}^{\uparrow}$ *carrier factors through the finite route*

$$S, D \longmapsto T \longmapsto W \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the uniform tail budget exported to Real-and-Completion consumers is a displayed Dirichlet selector threshold read through regular rational data and a terminal real seal, not a host infinite sum, quotient series equality, selected limit, countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a uniform-tail request. The carrier first exposes S, so the request sees only the displayed $\mathsf{RealSeries}^{\uparrow}$ term stream and partial-sum windows.

The request then reads the Dirichlet face D. This row supplies the bounded partial sums, coefficient windows, null-tail data, and estimate schedule needed to justify a finite tail threshold.

The selector threshold is the row T. The handoff row W is downstream of T, so a $\mathsf{UniformCauchySeries}^{\uparrow}$ consumer receives the threshold only after the Dirichlet-test data have been displayed.

Finally R and E route the selected tail window through $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N preserve this same path, so no excluded host-side summability, quotient, limit, choice, order, or completeness coordinate can be exported. □

Falsifiable prediction: A Real-and-Completion consumer that reads $\mathsf{DirichletUniformTailSelector}^{\uparrow}$ without first exposing the $\mathsf{RealSeries}^{\uparrow}$ source row S, the $\mathsf{DirichletTest}^{\uparrow}$ face row D, the selector row

T, the $\mathsf{UniformCauchySeries}^{\uparrow}$ handoff row W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, or the $\mathsf{Real}^{\uparrow}$ seal row E refutes the carrier of Definition 6550.1.

Independence witness: realseries, dirichlet-test, uniform-cauchy-series, regseqrat, real: no listed sibling supplies the whole selector packet $U = (S, D, T, W, R, E, H, C, P, N)$, because each sibling contributes only a source, a test face, a uniform-tail handoff, a regular readback, or a terminal seal while this chapter binds them as one finite selector certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletUniformTailSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletUniformTailSelector}^{\uparrow}$ packet is generated from RealSeries source rows, DirichletTest face rows, a finite selector threshold, a UniformCauchySeries handoff, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletUniformTailSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6550.1, Definition 6550.2, and Definition 6550.3 seed the finite Dirichlet uniform tail-selector route over $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletUniformTailSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infinite sums, quotient series equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, Dirichlet face exposure, finite selector thresholding, uniform Cauchy handoff, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DirichletUniformTailSelectorUp.

Chapter 6551

A Concrete Naming Certificate for $\mathsf{FiniteMetricTree}^{\uparrow}$

Following Buneman and Dress, finite tree metrics are read from a finite weighted tree by the path-distance ledger on its vertices. The $\mathsf{FiniteMetricTree}^{\uparrow}$ packet records that classical object as constructive L10 finite-metric witness data: it sits over the metric surface of chapter 57, the graph and tree routes of chapter 118 and chapter 119, and the finite-net consumer surface of chapter 1767. The packet is a finite path-distance certificate, not a quotient metric space, not a selected geodesic in an ambient graph, and not a host compactness theorem.

Definition 6551.1 (FiniteMetricTree carrier)**.** *A* $\mathsf{FiniteMetricTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (V, E, W, P, M, G, R, H, C, K, N)$$

with the following displayed rows:

1. *V is the finite vertex ledger, listing the accepted vertex names and the finite equality classifier used by later distance reads.*
2. *E is the finite edge ledger, listing accepted undirected edge incidences between vertices of V.*
3. *W is the edge-length row, assigning a positive* $\mathsf{Real}^{\uparrow}$*-sealed or rationally witnessed length to every displayed edge.*
4. *P is the path-distance readback row. For each accepted pair of vertices it records the unique finite tree path through E and the finite sum of edge lengths from W.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *row whose distance witness is exactly the path-distance readback P and whose metric laws are checked against the finite path ledger.*
6. *G is the sibling graph-and-tree route, exposing the* $\mathsf{Graph}^{\uparrow}$ *adjacency row and the* $\mathsf{Tree}^{\uparrow}$ *connected-acyclic row before any path-distance readback is consumed.*
7. *R is the finite four-point comparison ledger. For each displayed quadruple it records the two largest of the three pair sums and the equality comparison required by the tree-metric condition.*
8. *H stores componentwise* hsame *transport for vertices, edges, edge lengths, path distances, metric rows, graph/tree rows, four-point ledgers, continuation rows, provenance, and the local naming row.*
9. *C stores* Cont *replay from a vertex-pair or quadruple request through the finite graph/tree route, path-distance readback, metric row, and four-point ledger.*

10. *K is the* Pkg *provenance over* $\mathsf{FiniteMetricTree}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, *finite-net consumers,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricTree}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $V, E, W, P, M, G, R, H, C, K, N$. It has no coordinate for quotient metric spaces, choice-selected paths outside the finite tree, open-cover compactness, infinite graph completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6551.2 (FiniteMetricTree NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMetricTree}^{\uparrow}$ *carrier $T = (V, E, W, P, M, G, R, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricTree}^{\uparrow}}$ *surface consists exactly of carrier admission, finite vertex-ledger admission, edge-ledger admission, positive edge-length readback, graph/tree route exposure, path-distance exactness, metric-law stability, four-point comparison stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger nonescape.*

In particular, any $\mathsf{Met}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, *or finite-net consumer must read the displayed finite ledger route*

$$V \longmapsto E \longmapsto W \longmapsto P \longmapsto M \longmapsto G \longmapsto R \longmapsto H, C, K, N$$

before using the packet as finite tree-metric data.

Proof. Project the carrier of Definition 6551.1. The projection exposes exactly the finite vertex ledger, edge ledger, edge-length row, path-distance readback, metric row, graph/tree route, four-point ledger, and structural rows.

The graph/tree route is read before distance data. The $\mathsf{Graph}^{\uparrow}$ row names the finite adjacency surface, while the $\mathsf{Tree}^{\uparrow}$ row supplies connectedness and acyclicity as displayed finite data; therefore the path row P can read a unique finite route without selecting a path from an ambient graph.

Metric-law stability follows from the same path-distance ledger. Symmetry reverses the finite path, reflexivity reads the empty path, and the triangle comparison concatenates displayed finite paths before returning to the tree path through the metric row M.

The four-point comparison row R is downstream of P and M. It records quadruple comparisons only from displayed path distances, so componentwise transport through H and replay through C preserve the comparison surface.

Finally, K and N source and name the finite packet. Since no carrier row stores quotient metric spaces, choice-selected ambient paths, open-cover compactness, infinite graph completion, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6551.3 (FiniteMetricTree four-point stability)**.** *Let $T = (V, E, W, P, M, G, R, H, C, K, N)$ and $T' = (V', E', W', P', M', G', R', H', C', K', N')$ be accepted* $\mathsf{FiniteMetricTree}^{\uparrow}$ *packets. If the vertex ledger, edge ledger, edge-length row, path-distance readback, metric row, graph/tree route, four-point ledger, replay row, provenance row, and local naming row of T are transported componentwise through the displayed* hsame *and* Cont *routes to the corresponding rows of T', then every finite four-point tree-metric comparison accepted by R is accepted by R' with the same displayed pair-sum equality.*

Proof. Begin with the obligation surface of Definition 6551.2. The four-point comparison row is not independent data; it is downstream of the finite vertex, edge, edge-length, path-distance, metric, and graph/tree rows.

Transport the carrier componentwise. The displayed hsame rows carry vertices to vertices, edges to edges, edge lengths to edge lengths, and path-distance readbacks to path-distance readbacks, while the Cont rows replay the same quadruple request through the transported packet.

The four-point ledger therefore recomputes its three pair sums from transported path distances. Since the accepted comparison in R was read only from those sums, R' accepts the same tree-metric equality after transport.

No external geodesic selector, quotient metric equality, compactness principle, or ambient completion can alter the comparison, because none is a coordinate of either accepted packet. □

Falsifiable prediction: A consumer that claims $\mathsf{FiniteMetricTree}^{\uparrow}$ four-point stability while omitting the finite vertex ledger, edge ledger, edge-length row, path-distance readback, MetricUp row, GraphUp/TreeUp route, four-point ledger, hsame transport, Cont replay, Pkg provenance, or NameCert row refutes the carrier of Definition 6551.1.

Independence witness: metric, graph, tree, finite-epsilon-net: $\mathsf{FiniteMetricTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite weighted tree ledger, exact path-distance readback, MetricUp row, GraphUp/TreeUp route, four-point comparison ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricTree}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMetricTree}^{\uparrow}$ packet is generated from finite vertex rows, finite edge rows, positive edge-length rows, path-distance readback, MetricUp rows, GraphUp/TreeUp route rows, four-point comparison rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetricTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6551.1, Definition 6551.2, and Definition 6551.3 seed the finite tree-metric NameCert interface and its componentwise four-point stability route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMetricTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient metric spaces, selected ambient geodesics, open-cover compactness, infinite graph completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-law stability, path-distance exactness, four-point comparison stability, graph/tree route exposure, and ledger nonescape for BEDC.Derived.FiniteMetricTreeUp.

Chapter 6552

A Concrete Naming Certificate for MetaCICCandidateDiamondBudget$^{\uparrow}$

The MetaCICCandidateDiamondBudget$^{\uparrow}$ packet realizes the normalization/confluence audit boundary of chapter 9383 as finite NameCert data. It sits between the candidate-mediated normalization route of chapter 3779, the candidate-set normalization packet of chapter 2320, the confluence diamond ledger of chapter 6547, and the closed parallel diamond premise ledger of chapter 2325. The packet names a local diamond budget guarded by displayed candidate evidence; it is not global closed confluence, not evidence-free normalization, and not a closed Church–Rosser theorem.

Falsifiable prediction: A packet without a displayed candidate row and local diamond-budget row is rejected even if it carries a closed-normal row.

Independence witness: metacicnormalizationaudit, metacic-confluence-audit-packet, metacic-candidate-set-normalization, closed-parallel-diamond-premise-ledger, metacic-confluence-diamond-ledger: MetaCICCandidateDiamondBudget$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries candidate evidence, closed-candidate evidence, candidate-set normalization, local peak data, local join-budget data, confluence-boundary refusal, transport, replay, provenance, and local naming.

Definition 6552.1 (MetaCIC candidate diamond budget carrier)**.** *A* MetaCICCandidateDiamondBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, K, L, S, P, J, D, F, H, C, G, N)$$

with the following displayed rows:

1. *T is the closed typed term window whose normalization or confluence-facing read is being inspected.*
2. *K is the candidate-evidence row, carrying the displayed* Candidate *witness for T.*
3. *L is the closed-candidate evidence row, binding closedness of the term and type to the same candidate-mediated route.*
4. *S is the candidate-set row, exposing candidate-set membership and the finite candidate-set normalization surface.*
5. *P is the local peak row, recording the finite redex pair or bounded reduction peak inspected inside the candidate-mediated window.*

6. *J is the local join-budget row, recording the finite candidate join, bounded checker budget, and common-reduct ledger for P.*
7. *D is the confluence-boundary refusal row. It records that the local budget J is not a global closed-confluence theorem and cannot discharge the residual-substitution or closed parallel diamond premises by itself.*
8. *F is the closed-normal row, consumed only after K, L, S, P, J, D have all been displayed.*
9. *H stores componentwise* hsame *transport for the closed typed term, candidate, closed-candidate, candidate-set, local peak, join-budget, refusal, closed-normal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from a normalization-window or confluence-boundary request through T, K, L, S, P, J, D, F.*
11. *G is the* Pkg *provenance over* $\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}$*, chapter 9383, chapter 9378,* $\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}$, $\mathsf{CandidateSetNormalization}^{\uparrow}$, $\mathsf{MetaCICConfluenceDiamondLedger}^{\uparrow}$, $\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, K, L, S, P, J, D, F, H, C, G, N$. It has no coordinate for evidence-free strong normalization, global closed confluence, a discharged residual-substitution theorem, arbitrary closed parallel diamond, quotient syntax equality, or host confluence oracle.

Theorem 6552.2 (MetaCIC candidate diamond budget NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}$ *carrier $B = (T, K, L, S, P, J, D, F, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}}$ *surface consists exactly of carrier admission, closed typed term admission, candidate evidence admission, closed-candidate evidence admission, candidate-set normalization exposure, local peak exposure, local join-budget accounting, confluence-boundary refusal, closed-normal downstream ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

The future Lean TasteGate for this packet must supply both a Nontrivial instance, separating an accepted displayed budget from an empty carrier, and a FieldFaithful instance, asserting that the classifier reads each field $T, K, L, S, P, J, D, F, H, C, G, N$.

Proof. Project the carrier of Definition 6552.1. The projection exposes the closed typed term window, candidate row, closed-candidate row, candidate-set row, local peak row, join-budget row, refusal row, closed-normal row, and the structural rows.

The candidate rows are read before any normalization or confluence-facing budget. The candidate row K, closed-candidate row L, and candidate-set row S keep the strong-normalization route inside the candidate-mediated interface described by chapter 9383.

The local peak and join-budget rows then bind the confluence-facing part. The row P records only the inspected finite peak, while J records only the bounded local join and checker budget attached to that peak.

The refusal row D remains visible before the closed-normal row F. It prevents the local join budget from being read as global closed confluence, residual-substitution discharge, or an arbitrary closed parallel diamond.

Finally, H, C, G, N transport, replay, source, and name the same finite route. Nontrivial and FieldFaithful TasteGate evidence would assert that accepted packets carry genuine budget data and that no displayed field is ignored by the classifier. □

Theorem 6552.3 (MetaCIC candidate diamond budget nonescape)**.** *Every normalization-window, confluence-boundary, or closed-normal consumer of an accepted* $\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}$ *carrier must first expose the finite route*

$$T \longmapsto K \longmapsto L \longmapsto S \longmapsto P \longmapsto J \longmapsto D \longmapsto F \longmapsto H, C, G, N.$$

The packet exports candidate-mediated normalization evidence and a local diamond budget only through that route. It exports no evidence-free strong-normalization theorem, no global closed-confluence theorem, no residual-substitution discharge, no arbitrary closed parallel diamond, no quotient syntax equality, and no host confluence oracle.

Proof. Start from the carrier definition. Its only confluence-facing rows are the local peak row P, the local join-budget row J, and the refusal row D.

Apply Definition 6552.2. The obligations order candidate evidence before the local budget and keep the closed-normal row downstream of the confluence-boundary refusal.

The structural rows preserve that order. Transport through H, replay through C, provenance through G, and local naming through N cannot add a global confluence endpoint or erase the candidate evidence.

Thus any consumer that reads the budget must keep $T, K, L, S, P, J, D, F, H, C, G, N$ visible and cannot escape into evidence-free normalization, residual-substitution discharge, arbitrary closed diamond, quotient syntax equality, or host confluence. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}$ packet is generated from a closed typed term window, candidate evidence, closed-candidate evidence, candidate-set rows, local peak rows, local join-budget rows, confluence-boundary refusal, closed-normal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6552.1, Definition 6552.2, and Definition 6552.3 seed the finite candidate-mediated local diamond-budget boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateDiamondBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close evidence-free strong normalization, global closed confluence, residual-substitution discharge, arbitrary closed parallel diamond, quotient syntax equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate evidence admission, closed-candidate admission, candidate-set exposure, local peak exposure, local join-budget accounting, confluence-boundary refusal, nonescape, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetaCICCandidateDiamondBudgetUp.

Chapter 6553

A Concrete Naming Certificate for $\mathsf{UpperHemicontinuity}^{\uparrow}$

Following Berge's maximum theorem and the set-valued analysis of Aubin–Frankowska, the $\mathsf{UpperHemicontinuity}^{\uparrow}$ packet records the finite BEDC boundary for compact-valued correspondence data. It sits after the compact metric source of chapter 129, the real-name seal of chapter 38, the polytope and convex-set rows of chapter 209 and chapter 208, and the finite rollout consumer of chapter 348. The packet names a finite graph-window and compact-value certificate surface; it is not a host set-valued function primitive, an open-cover compactness theorem, or a selected optimizer.

Definition 6553.1 (Upper hemicontinuity carrier)**.** *An* $\mathsf{UpperHemicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, G, K, R, V, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *domain row whose finite probes supply the source windows.*
2. *Y is the* $\mathsf{Real}^{\uparrow}$ *or finite-dimensional real codomain seal through which value coordinates are read.*
3. *G is a finite graph-window ledger recording inspected source probes, value probes, and membership rows for the correspondence graph.*
4. *K is the compact-value row naming the finite cover, located radius, and total-bounded witness for each displayed value fibre.*
5. *R is the closed-graph readback row: whenever a source window and value window are replayed through G, the accepted value remains inside the displayed compact-value fibre.*
6. *V is the polytope or convex-set dependency row used by optimization and control consumers when value fibres are exposed as* $\mathsf{Polytope}^{\uparrow}$ *or* $\mathsf{ConvexSet}^{\uparrow}$ *packets.*
7. *O records the downstream optimization window consumed by* $\mathsf{ModelPredictiveControl}^{\uparrow}$ *and related finite-horizon packets.*
8. *H records componentwise* hsame *transport for the domain, codomain, graph, compact-value, closed-graph, convex/polytope, optimization, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite source probe through graph membership, compact-value readback, and the consumer-facing optimization window.*

10. *P is the* Pkg *provenance over* $\mathsf{UpperHemicontinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ModelPredictiveControl}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UpperHemicontinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, G, K, R, V, O, H, C, P, N$. It has no coordinate for a host correspondence object, pointwise choice of values, open-cover compactness, ambient graph closure, quotient equality of real names, or selected optimizer.

Lean4 ✓ `BEDC.Derived.UpperHemicontinuityUp.UpperHemicontinuityTasteGate single carrier alignment`

Theorem 6553.2 (Upper hemicontinuity NameCert obligations)**.** *For every accepted* $\mathsf{UpperHemicontinuity}^{\uparrow}$ *packet $U = (X, Y, G, K, R, V, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UpperHemicontinuity}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-metric source exposure through X, real codomain sealing through Y, graph-window inspection through G, compact-value certification through K, closed-graph readback through R, convex/polytope dependency exposure through V, finite optimization-window handoff through O, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 6553.1. The projected rows are exactly the domain, codomain, graph-window, compact-value, closed-graph, convex/polytope, optimization, transport, replay, provenance, and local naming rows.

The analytic part is finite. A source probe reads X, a value probe reads Y, graph membership is inspected through G, and compactness of the fibre is read only through the displayed row K.

The upper-hemicontinuity boundary is the closed-graph readback row R together with the same compact-value row K. The convex/polytope dependency V and optimization window O are downstream consumers of those rows, not independent value selectors.

Finally H, C, P, N transport, replay, source, and name this route. Since the carrier contains no coordinate for a host correspondence, selected value, open-cover proof, ambient closure theorem, quotient real equality, or optimizer, the listed rows exhaust the seed NameCert surface. □

Theorem 6553.3 (Compact-valued correspondence handoff)**.** *Every compact-valued optimization or control consumer of an accepted* $\mathsf{UpperHemicontinuity}^{\uparrow}$ *packet must first read the finite route*

$$X \longmapsto Y \longmapsto G \longmapsto K \longmapsto R \longmapsto V \longmapsto O \longmapsto H, C, P, N.$$

In particular, a $\mathsf{ModelPredictiveControl}^{\uparrow}$ *consumer receives the compact metric source, real codomain seal, graph-window ledger, compact-value witness, closed-graph readback, convex or polytope dependency rows, transport, replay, provenance, and local naming before it can use a compact-valued correspondence packet.*

Proof. Start with an accepted carrier $U = (X, Y, G, K, R, V, O, H, C, P, N)$. The carrier places every consumer-facing row after the graph-window and compact-value rows, so no consumer can inspect V or O before reading X, Y, G, K, R.

The compact-valued part is supplied by K, while the upper-hemicontinuity readback is supplied by R. Thus the consumer sees compact values and closed-graph stability as finite certificate rows rather than as host predicates on an external set-valued map.

The structural rows keep the same route under componentwise sameness and replay. Since $\mathsf{ModelPredictiveControl}^{\uparrow}$ reads only the displayed optimization window O together with its provenance and local naming rows, it receives no selected optimizer, no ambient correspondence, and no open-cover compactness principle from the packet. □

Falsifiable prediction: Every $\mathsf{UpperHemicontinuity}^{\uparrow}$ consumer read factors through a CompactMetricUp source row, RealUp codomain seal, finite graph-window ledger, compact-value witness, closed-graph readback, convex or polytope dependency row, optimization window, transport, replay, provenance, and local naming row.

Independence witness: compactmetric, real, polytope, convexset, and modelpredictivecontrol: $\mathsf{UpperHemicontinuity}^{\uparrow}$ is not bijective to any listed sibling because it jointly records compact-valued graph windows, closed-graph readback, convex/polytope value dependencies, optimization handoff, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UpperHemicontinuity}^{\uparrow}}$.

Constructive story: An $\mathsf{UpperHemicontinuity}^{\uparrow}$ packet is generated from a compact metric source row, a RealUp codomain seal, a finite graph-window ledger, compact-value witnesses, closed-graph readback, convex or polytope dependency rows, an optimization consumer window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UpperHemicontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6553.1, Definition 6553.2, and Definition 6553.3 seed the finite NameCert surface for compact-valued upper-hemicontinuity packets over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, and $\mathsf{ModelPredictiveControl}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UpperHemicontinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host set-valued function primitive, open-cover compactness, selected optimizers, ambient graph closure, quotient real equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-valued graph-window readback, convex/polytope dependency transport, optimization handoff, replay stability, and local NameCert provenance for BEDC.Derived.UpperHemicontin

Chapter 6554

A Concrete Naming Certificate for $\mathsf{UrysohnUniversalMetric}^{\uparrow}$

Following Urysohn's construction of a universal separable metric space and the Bishop–Bridges discipline for constructive metric data, the $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ packet records finite one-point extension requests as BEDC NameCert rows. It sits over the metric carrier of chapter 57, the separable-metric source of chapter 1458, the complete-metric boundary of chapter 128, the completion handoff of chapter 1506, and the terminal real-distance seal of chapter 38. The packet exposes the finite Katetov-extension surface needed by L10 metric and completion consumers without selecting a host Urysohn space, quotienting completion streams, invoking choice, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6554.1 (Urysohn universal metric finite-extension carrier)**.** *A* $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, S, K, L, R, F, A, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including point classifiers and all inspected distance requests.*
2. *S is the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense-name row used to enumerate the finite support of each extension request.*
3. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row read over the same metric source.*
4. *L is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row, available only after the finite extension request has been displayed.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *distance and tolerance seal row for every finite support distance, requested new distance, and compatibility inequality.*
6. *F is the finite Katetov-extension request row. It names a finite support family, a proposed distance from the new point to each support point, and the triangle and reverse-triangle budgets checked through M and R.*
7. *A is the finite admission ledger. It records that every requested distance cell in F is compatible with the support distances already displayed by M and the dense-name row S.*
8. *E is the extension-realization handoff row. It allows a consumer to read the requested one-point extension only after M, S, K, L, R, F, A have been exposed.*

9. *H records componentwise* hsame *transport for the metric source, separable row, complete boundary, completion handoff, real seals, finite extension request, admission ledger, realization handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from any finite Katetov request through the same source, dense-name, real-distance, admission, completion, and realization rows.*

11. *P is the* Pkg *provenance over* $\mathsf{UrysohnUniversalMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *finite Katetov requests,* BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{UrysohnUniversalMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, K, L, R, F, A, E, H, C, P, N$. It has no coordinate for a chosen host universal metric space, quotient completion equality, selected dense enumeration outside S, arbitrary countable extension sequence, choice functional, Lean verification, standard bridge, or ambient real-completeness principle.

Theorem 6554.2 (Urysohn universal metric NameCert obligations)**.** *For every accepted* $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ *carrier*

$$U = (M, S, K, L, R, F, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UrysohnUniversalMetric}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the metric source, separable dense row, complete-metric boundary, completion handoff, real-distance seals, finite Katetov request, admission ledger, realization handoff, transport, replay, provenance, and local name;*

2. *common-source discipline, requiring S, K, L, R, F, A to be read over the same* $\mathsf{Met}^{\uparrow}$ *row M;*

3. *finite support visibility, requiring every extension request in F to list its support points through S before a new distance row may be inspected;*

4. *Katetov compatibility, requiring the triangle and reverse-triangle budgets in F and A to be witnessed by displayed* $\mathsf{Real}^{\uparrow}$ *comparisons over the already exposed support distances;*

5. *completion handoff order, requiring E to be consumed before L is treated as a completion-facing realization row;*

6. *nonescape, excluding host universal spaces, quotient completion equality, countable choice, selected infinite extension chains, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge credentials from the packet.*

No Urysohn universal metric obligation is stored outside these rows.

Proof. Project the carrier of Definition 6554.1. The displayed tuple $M, S, K, L, R, F, A, E, H, C, P, N$ is the whole public surface, so carrier admission is exactly admission of those rows.

The common-source obligation follows from the order of the rows. The separable dense row, complete-metric boundary, completion handoff, real-distance seals, request row, and admission ledger are all transported by the same H row over the metric source M.

Finite support visibility is forced by F. A one-point extension request names only finitely many support points, and those support names are opened through S before any proposed new distance can be read.

Katetov compatibility is checked by R and A. The real-distance row supplies the support distances and proposed distances, while the admission ledger records the triangle and reverse-triangle budgets for each displayed support pair.

Finally, E, L, H, C, P, N preserve only that displayed route. Since none of the carrier coordinates stores a host universal space, quotient completion equality, selected infinite chain, choice functional, ambient completeness theorem, Lean verification, or bridge credential, the listed rows exhaust the local NameCert surface. □

Theorem 6554.3 (Urysohn universal metric finite-extension route)**.** *Every finite one-point extension request accepted by a* $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ *carrier factors through*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{SeparableMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto F, A \longmapsto E.$$

In particular, the requested extension is read as a displayed finite Katetov route over the current metric source, not as a point selected from a host universal space or as an equality class in a completed quotient.

Proof. Begin with the metric source row M. It supplies the support-distance comparisons that any extension request must respect.

Read the separable row S next. The request row F can name only the finitely many support points exposed by the dense-name surface, so no hidden enumeration or chosen ambient point is available.

The distance budgets are then read through R and A. These rows display the proposed distances and the triangle and reverse-triangle checks against the already exposed support distances.

The realization handoff E is downstream of the same rows. It therefore exports the finite Katetov extension route itself, while host universal spaces, quotient representatives, selected points, choice functionals, and ambient completeness remain outside the packet. □

Theorem 6554.4 (Urysohn universal metric completion handoff)**.** *Let* $U = (M, S, K, L, R, F, A, E, H, C, P, N)$ *be an accepted* $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ *carrier. Any completion-facing consumer of* U *must first read the finite-extension route of Definition 6554.3, then the complete-metric boundary* K*, and only then the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row* L*. Thus the packet supplies completion consumers with displayed finite extension data and a named completion boundary, not a quotient completion construction or a selected limit point.*

Proof. Apply the finite-extension route. The request reaches E only after M, S, R, F, A have displayed the metric source, finite support, real-distance budgets, and admission ledger.

Next inspect the complete-metric boundary K. It is attached to the same source row M by the transport row H, so it cannot introduce a second metric source or a host completion object.

Only after those rows are exposed may the consumer read L. The $\mathsf{MetricCompletion}^{\uparrow}$ handoff is therefore a downstream row of the finite-extension packet and complete-metric boundary, not a quotient construction, selected completion representative, countable-choice sequence, or ambient completeness theorem. □

Theorem 6554.5 (Urysohn universal metric nonescape boundary)**.** *For every accepted* $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ *carrier, the finite-extension and completion-handoff rows expose no host universal metric space, no selected dense enumeration beyond the displayed* $\mathsf{SeparableMetric}^{\uparrow}$ *row, no quotient completion equality, no arbitrary countable extension chain, no choice functional, no Lean verification credential, no standard bridge, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Inspect the carrier boundary in Definition 6554.1. The only public coordinates are the metric source, separable row, complete boundary, completion handoff, real-distance seals, finite request, admission ledger, realization handoff, transport, replay, provenance, and local name.

The finite-extension theorem and completion-handoff theorem read those rows in order. They never introduce an additional coordinate from which a host universal space, quotient equality, selected infinite chain, choice functional, Lean credential, bridge credential, or ambient completeness principle could be recovered.

Therefore every public consumer remains inside the displayed NameCert packet. Any claim requiring one of the excluded objects is outside the scope of $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ as recorded here. □

Falsifiable prediction: Every accepted $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ finite-extension read exposes the $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, finite Katetov request, admission ledger, and realization handoff rows before any $\mathsf{MetricCompletion}^{\uparrow}$ consumer may inspect the completion boundary.

Independence witness: metric, separablemetric, completemetric, metriccompletion, real: UrysohnUniversalMetric is not bijective to any listed sibling because it jointly binds finite Katetov-extension requests, displayed real-distance compatibility budgets, separable support rows, complete-metric boundaries, completion handoffs, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{UrysohnUniversalMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ packet is generated from a displayed MetricSpace row, SeparableMetric dense row, CompleteMetric boundary, MetricCompletion handoff, Real distance seals, finite Katetov-extension request, admission ledger, realization handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UrysohnUniversalMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6554.1, Definition 6554.2, Definition 6554.3, Definition 6554.4, and Definition 6554.5 seed the finite-extension completion-neighbour route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UrysohnUniversalMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host Urysohn-space existence, quotient completion equality, countable choice, selected infinite extension chains, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-source discipline, finite support visibility, Katetov compatibility, completion handoff order, and nonescape for BEDC.Derived.UrysohnUniversalMetricUp.

Chapter 6555

A Concrete Naming Certificate for $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$

Bishop-style constructive analysis and the Arzela–Ascoli finite-family tradition motivate the PointwiseBoundedRealF packet as a finite naming certificate for inspected real-family bounds. The packet sits between the stream naming route of chapter 126, the regular rational handoff of chapter 301, the real seal of chapter 38, and the displayed finite upper-bound surface of chapter 1427. It records boundedness over a named finite index window, not infinite Arzela–Ascoli compactness, open-cover compactness, choice-selected subsequences, a host supremum, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6555.1 (Pointwise bounded Real-family carrier)**.** *A* $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, S, R, E, B, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the index-window ledger. It lists the finite family positions currently inspected and contains no ambient set of all indices.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation ledger. For each displayed index in I, it records the finite stream windows read from the corresponding component.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attached to the observed stream windows, limited to the precisions named in I and S.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the components whose stream and regular rational rows have already been displayed.*
5. *B is the per-index dyadic bound witness row. Each entry pairs one inspected index with a dyadic upper-bound witness for the corresponding displayed* $\mathsf{Real}^{\uparrow}$ *seal.*
6. *U is the finite supremum ledger. It displays the upper-bound rows obtained from the finite list of dyadic witnesses in B, using* $\mathsf{LocatedSupremum}^{\uparrow}$ *only as a local finite-row consumer.*
7. *H records componentwise* hsame *transport for the index ledger, stream observations, regular handoffs, Real seals, dyadic bound witnesses, finite supremum rows, continuation rows, provenance rows, and local naming row.*
8. *C records displayed* Cont *replay from I to S, from S to R, from R to E, from E to B, and from the finite dyadic witness list B to the finite upper-bound ledger U.*

9. *P is the* Pkg *provenance over* $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PointwiseBoundedRealFamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for infinite families, open covers, choice-selected subsequences, a host supremum, quotient-stream equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6555.2 (Pointwise bounded Real-family finite supremum obligation)**.** *Every accepted* $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$ *packet exposes its bound only through displayed finite supremum rows over the inspected index window. The consumer may read the route*

$$I, S, R, E, B \longmapsto U$$

and the structural rows H, C, P, N, but it receives no host supremum, no choice-selected index family, and no completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 6555.1. The visible rows are the finite index window I, the $\mathsf{StreamName}^{\uparrow}$ observations S, the $\mathsf{RegSeqRat}^{\uparrow}$ handoffs R, the $\mathsf{Real}^{\uparrow}$ seals E, the dyadic bound witnesses B, the finite upper-bound ledger U, and the structural rows H, C, P, N.

Induct over the displayed index-window ledger I. The empty window exposes only the displayed empty upper-bound row. In the successor step, the next component is read through its $\mathsf{StreamName}^{\uparrow}$ observation row, then through its $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and only then through its $\mathsf{Real}^{\uparrow}$ seal.

For each inspected index, consume the corresponding dyadic witness in B. The componentwise hsame row preserves the witness under transport, and the Cont row replays the handoff without adding an ambient supremum coordinate.

Finally, read $\mathsf{LocatedSupremum}^{\uparrow}$ only at the finite upper-bound ledger U. This ledger displays the finite supremum rows already generated from the inspected dyadic witnesses, so the exported bound is a finite packet row rather than a host supremum, a choice-selected family, or a consequence of $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$ bound read factors through displayed finite dyadic witnesses and a finite $\mathsf{LocatedSupremum}^{\uparrow}$ row before any consumer sees an upper-bound certificate.

Independence witness: streamname, regseqrat, real, locatedsupremum: $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite index-window ledger, component stream observations, regular rational handoffs, Real seals, per-index dyadic bound witnesses, finite upper-bound rows, componentwise transports, displayed continuations, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PointwiseBoundedRealFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$ packet is generated from a finite inspected index window, StreamName observations, RegSeqRat handoffs, RealUp seals, per-index dyadic bound witnesses, displayed finite supremum rows, componentwise transports, continuations, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PointwiseBoundedRealFamily}^{\uparrow}}$, seed)

Scope closed: Definition 6555.1 and Definition 6555.2 bind the finite family carrier and its finite upper-bound obligation.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PointwiseBoundedRealFamily}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim infinite Arzela–Ascoli, open-cover compactness, choice-selected subsequences, host supremum, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite index-window stability, per-component StreamName and RegSeqRat routing, Real seal non-escape, and finite LocatedSupremum upper-bound coverage for BEDC.Derived.PointwiseBoundedRealFamilyUp.

Chapter 6556

A Concrete Naming Certificate for $\mathsf{Submartingale}^{\uparrow}$

Following Doob and Meyer, a submartingale is the inequality-direction sibling of a martingale: the conditional expectation of the next visible value is required to dominate the current value rather than equal it. The $\mathsf{Submartingale}^{\uparrow}$ packet records the finite NameCert surface for this one-sided adapted-sequence object. It sits between the finite martingale carrier of chapter 190, the bounded stopping windows of chapter 383, the crossing ledger of chapter 1629, the Doob upcrossing inequality packet of chapter 1630, and the convergence-preparation surface of chapter 2246. The chapter names only the finite one-sided conditional-expectation carrier and its handoff to finite upcrossing rows; it does not assert almost-sure convergence, measure completion, or a quotient of stochastic processes.

Definition 6556.1 (Submartingale finite adapted carrier)**.** *A* $\mathsf{Submartingale}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (\Omega, R, C, F, X, E, I, T, H, K, P, N)$$

with the following displayed rows:

1. Ω *is the displayed* $\mathsf{ProbSpace}^{\uparrow}$ *row naming the probability context.*
2. R *is the consumed* $\mathsf{RandomVar}^{\uparrow}$ *source packet for the finite endpoint rows.*
3. C *is the consumed* $\mathsf{CondExp}^{\uparrow}$ *packet supplying conditional-expectation endpoints.*
4. F *is the finite filtration and adaptedness ledger over a unary time spine* $0, \ldots, T$.
5. X *is the finite endpoint family* $X_0, \ldots, X_T$ *read through* $\mathsf{RandomVar}^{\uparrow}$ *rows and visible in the corresponding filtration rows.*
6. E *is the finite conditional-expectation family* $E_{n+1|n}$ *whose source row is* X_{n+1} *and whose conditioning visibility row is the* n*th filtration row.*
7. I *is the one-sided comparison ledger recording*

$$X_n \leq_R E_{n+1|n}$$

   for every displayed successor $n < T$*, with the order comparison read through the carried* $\mathsf{Real}^{\uparrow}$ *endpoint classifier.*
8. H *records componentwise* hsame *transport for* $\Omega, R, C, F, X, E, I, T, K, P, N$.

9. *K records displayed* Cont *replay for endpoint exposure, conditional-expectation exposure, filtration visibility, one-sided comparison, bounded stopping-window reads, and finite upcrossing handoff.*

10. *P is the* Pkg *provenance row naming exactly* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, $\mathsf{MartingaleConvergence}^{\uparrow}$, *and the local submartingale rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{Submartingale}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed probability, random-variable, conditional-expectation, filtration, endpoint, one-sided comparison, transport, continuation, package, and local certificate rows.

Lean4 ✓ `BEDC.Derived.SubmartingaleUp.TasteGate.SubmartingaleTasteGate single carrier alignment`

Theorem 6556.2 (Submartingale NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{Submartingale}^{\uparrow}}$ *surface consists exactly of carrier exposure for $S = (\Omega, R, C, F, X, E, I, T, H, K, P, N)$, classifier transport of every displayed row of that carrier, endpoint exposure through* $\mathsf{RandomVar}^{\uparrow}$, *conditional-expectation exposure through* $\mathsf{CondExp}^{\uparrow}$, *filtration and adaptedness exposure through F, one-sided comparison exposure through I, bounded stopped-window routing through* $\mathsf{OptionalStopping}^{\uparrow}$, *finite crossing-ledger handoff through* $\mathsf{Upcrossing}^{\uparrow}$, *finite Doob-bound handoff through* $\mathsf{DoobUpcrossing}^{\uparrow}$, *convergence-preparation handoff through* $\mathsf{MartingaleConvergence}^{\uparrow}$, *componentwise* hsame *transport through H, displayed* Cont *replay through K, package provenance through P, and local naming through N.*

Proof. Carrier exposure is Definition 6556.1. It supplies the full finite row list and fixes the local classifier to those rows.

The analytic rows are R, C, F, X, E, I. The endpoint rows are read through $\mathsf{RandomVar}^{\uparrow}$, the conditional-expectation faces are read through $\mathsf{CondExp}^{\uparrow}$, and the inequality ledger I records the one-sided comparison $X_n \leq_R E_{n+1|n}$ at each displayed successor.

The downstream rows are bounded and finite. Optional stopping can inspect only the displayed time window, the upcrossing ledger can count only lower-to-upper passages inside that window, and the Doob-upcrossing packet receives only the crossing count and expectation-bound rows.

The structural rows H, K, P, N transport, replay, source, and name the same finite packet. Since no row contains an almost-sure quotient, an unbounded stopping index, a limiting event, or a completed measure carrier, the listed obligations exhaust the seed NameCert surface. □

Lean4 ✓ `BEDC.Derived.SubmartingaleUp.SubmartingaleCarrier namecert obligations`

Theorem 6556.3 (Submartingale one-sided comparison transport)**.** *Componentwise* hsame *transport of the displayed probability,* $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, *filtration, endpoint, conditional-expectation, and Real-order rows preserves the one-sided comparison ledger I of an accepted* $\mathsf{Submartingale}^{\uparrow}$ *carrier. After transport, each successor window still routes through*

$$X_n \leq_R E_{n+1|n}$$

before any $\mathsf{OptionalStopping}^{\uparrow}$ *or* $\mathsf{Upcrossing}^{\uparrow}$ *consumer may read the bounded stopped-window or crossing data.*

Lean4 ✓ `BEDC.Derived.SubmartingaleUp.SubmartingaleCarrier one sided comparison transport`

Proof. Project the carrier of Definition 6556.1. The rows R, C, F, X, E, I are displayed components of the finite adapted packet, and H records componentwise transport for the same probability, endpoint, conditional-expectation, filtration, comparison, continuation, package, and naming rows.

Transport therefore carries the one-sided comparison row together with its endpoints. The transported ledger still reads the transported X_n, the transported $E_{n+1|n}$, and the transported $\mathsf{Real}^{\uparrow}$ order classifier before exposing any successor window.

Replay the bounded window through K and the downstream route of Definition 6556.4. Optional-stopping and upcrossing consumers receive only the transported finite comparison ledger and the displayed bounded window, not an unbounded stopping rule or an ambient process equality. □

Theorem 6556.4 (Submartingale Doob upcrossing handoff)**.** *Every accepted* $\mathsf{Submartingale}^{\uparrow}$ *carrier exports exactly the finite rows needed by a Doob-style upcrossing consumer: the displayed probability row, finite endpoint rows, finite filtration ledger, one-sided conditional-expectation comparison rows, fixed lower and upper* $\mathsf{Real}^{\uparrow}$ *boundary endpoints, bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *stopped-window routes, and the resulting lower-to-upper crossing-count ledger. The handoff is a finite dependency route into* $\mathsf{Upcrossing}^{\uparrow}$ *and* $\mathsf{DoobUpcrossing}^{\uparrow}$*; it is not a martingale convergence theorem and it does not construct an almost-sure quotient.*

Proof. Project the accepted carrier of Definition 6556.1. The available stochastic rows are Ω, R, C, F, X, E, I over the displayed finite time spine.

The one-sided comparison ledger I is the only point where the submartingale direction is read. It supplies $X_n \leq_R E_{n+1|n}$ through the carried $\mathsf{Real}^{\uparrow}$ endpoint classifier and through no host-level order relation.

Bounded stopped-window reads then factor through $\mathsf{OptionalStopping}^{\uparrow}$. The crossing-count read consumes the finite endpoint rows, boundary endpoints, lower and upper decision ledgers, and stopped-window rows exactly as in $\mathsf{Upcrossing}^{\uparrow}$.

Finally the Doob-facing inequality surface consumes that finite crossing ledger through $\mathsf{DoobUpcrossing}^{\uparrow}$. The carrier contains no limiting event and no almost-sure quotient coordinate, so a downstream $\mathsf{MartingaleConvergence}^{\uparrow}$ packet receives only the finite upcrossing handoff. □

Lean4 ✓ `BEDC.Derived.SubmartingaleUp.SubmartingaleCarrier doob upcrossing handoff`

Theorem 6556.5 (Submartingale one-sided comparison stability)**.** *Let* $S = (\Omega, R, C, F, X, E, I, T, H, K, P, N)$ *be an accepted* $\mathsf{Submartingale}^{\uparrow}$ *carrier. Any* hsame *transport recorded in* H *preserves the one-sided conditional-expectation comparison row* I*: after transport, each displayed successor still reads the same finite comparison*

$$X_n \leq_R E_{n+1|n}$$

through the transported $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, *filtration, endpoint, and* $\mathsf{Real}^{\uparrow}$ *classifier rows. The stability statement does not assert a limiting submartingale, optional stopping outside the displayed window, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SubmartingaleUp.SubmartingaleCarrier one sided comparison stability`

Proof. Project the carrier of Definition 6556.1. The comparison row I is a displayed component of the finite packet, and H records componentwise transport for that row together with the probability, endpoint, conditional-expectation, filtration, continuation, package, and local naming rows.

Transport therefore acts on the listed row inventory rather than on a host process. The transported comparison still points to the transported endpoint row X_n, the transported conditional-expectation row $E_{n+1|n}$, and the same carried Real-order classifier.

Replay through K, P, N keeps the transported packet inside the local NameCert surface. Since no row in the carrier names an unbounded time index, a limiting event, a countable family of choices, or a completed real-space principle, comparison stability is confined to the displayed finite window. □

Theorem 6556.6 (Submartingale stopping-window handoff)**.** *Every bounded stopping-window consumer of an accepted* $\mathsf{Submartingale}^{\uparrow}$ *carrier must read, in the displayed packet order, the* $\mathsf{ProbSpace}^{\uparrow}$ *row* Ω*, the* $\mathsf{RandomVar}^{\uparrow}$ *endpoint rows* R, X*, the* $\mathsf{CondExp}^{\uparrow}$ *row* C, E*, the sibling* $\mathsf{Martingale}^{\uparrow}$ *equality-direction context named by* P*, the bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *route, and the* $\mathsf{Upcrossing}^{\uparrow}$ *crossing-count rows before it may use the one-sided submartingale inequality. The handoff covers only the finite stopped window displayed by* T *and* K*.*

Lean4 ✓ `BEDC.Derived.SubmartingaleUp.SubmartingaleCarrier stopping window handoff`

Proof. Start from the NameCert obligations of Definition 6556.2. They expose the probability, endpoint, conditional-expectation, filtration, comparison, stopping-window, and crossing rows as separate finite obligations.

The bounded stopping consumer first opens Ω, R, C, F, X, E, I. These rows supply the probability context, random-variable endpoints, conditional expectations, adaptedness ledger, and one-sided comparison needed to read the inequality.

Next the package row P names the sibling $\mathsf{Martingale}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, and $\mathsf{Upcrossing}^{\uparrow}$ sources. The stopping read is still bounded by the displayed time row T and the continuation row K, so it cannot range over an unlisted stopping time.

Finally replay the Doob handoff theorem Definition 6556.4. The consumer receives only the finite stopped-window and crossing ledgers, excluding optional stopping outside the displayed window, countable choice, limiting convergence, quotient processes, and ambient Real completeness. □

Theorem 6556.7 (Submartingale upcrossing ledger exactness)**.** *For every accepted* $\mathsf{Submartingale}^{\uparrow}$ *carrier, upcrossing counts are exported only through the displayed finite stopping and comparison ledgers: the endpoint rows* X*, the comparison row* I*, the bounded stopping-window route in* T, K*, the lower and upper boundary reads supplied to* $\mathsf{Upcrossing}^{\uparrow}$*, and the Doob-facing crossing ledger named by* P*. No consumer may replace these rows by an implicit limit, an optional-stopping theorem beyond the displayed window, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SubmartingaleUp.SubmartingaleCarrier upcrossing ledger exactness`

Proof. Project the accepted carrier. The endpoint family X, comparison ledger I, finite time row T, and continuation row K are the only rows from which a crossing count can be read.

Use the Doob upcrossing handoff theorem Definition 6556.4. It identifies the exported data as the finite endpoint rows, lower and upper boundary endpoints, bounded stopping-window routes, and lower-to-upper crossing-count ledger consumed by $\mathsf{Upcrossing}^{\uparrow}$ and $\mathsf{DoobUpcrossing}^{\uparrow}$.

Ledger exactness follows because the package and naming rows P, N expose no second crossing object. Transport through H and replay through K preserve the same finite ledgers, so the exported upcrossing count cannot be strengthened into a limiting theorem, an unbounded optional-stopping rule, a choice schedule, or a Real-completeness assertion. □

Falsifiable prediction: An accepted $\mathsf{Submartingale}^{\uparrow}$ consumer that reaches an $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, or $\mathsf{MartingaleConvergence}^{\uparrow}$ handoff without the displayed $\mathsf{ProbSpace}^{\uparrow}$ source, $\mathsf{RandomVar}^{\uparrow}$ endpoint

rows, $\mathsf{CondExp}^{\uparrow}$ conditional-expectation rows, finite filtration ledger, one-sided comparison row, and bounded $\mathsf{OptionalStopping}^{\uparrow}$ route refutes the carrier surface.

Independence witness: martingale, optionalstopping, upcrossing, doob-upcrossing, martingale-convergence: no listed sibling supplies the whole submartingale packet $S = (\Omega, R, C, F, X, E, I, T, H, K, P, N)$, because $\mathsf{Martingale}^{\uparrow}$ closes equality-direction conditional expectation, $\mathsf{OptionalStopping}^{\uparrow}$ closes bounded stopped windows, $\mathsf{Upcrossing}^{\uparrow}$ closes crossing-count ledgers, $\mathsf{DoobUpcrossing}^{\uparrow}$ closes finite inequality rows, and $\mathsf{MartingaleConvergence}^{\uparrow}$ consumes convergence-preparation data while this chapter binds the one-sided adapted carrier that feeds those rows.

Closure status for $\mathsf{NameCert}_{\mathsf{Submartingale}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Submartingale}^{\uparrow}$ packet is generated from a displayed probability row, random-variable endpoint rows, conditional-expectation rows, a finite filtration and adaptedness ledger, one-sided comparison rows, bounded stopping-window routes, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Submartingale}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6556.1, Definition 6556.2, Definition 6556.3, Definition 6556.4, Definition 6556.5, Definition 6556.6, and Definition 6556.7 seed the finite one-sided martingale NameCert boundary and its Doob-style upcrossing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Submartingale}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim martingale convergence, almost-sure quotient equality, unbounded stopping, measure completion, or a standard bridge.

Upgrade path: A formal route can encode the finite carrier and prove classifier transport, one-sided comparison routing, bounded stopping-window handoff, finite upcrossing handoff, and ledger exactness.

Chapter 6557

A Concrete Naming Certificate for $\mathsf{LefschetzFixedPoint}^{\uparrow}$

Following Lefschetz fixed point theory, the $\mathsf{LefschetzFixedPoint}^{\uparrow}$ packet records only the finite chain-level trace ledger attached to a displayed endomap. It reconstructs the theorem's computable accounting surface inside BEDC by naming chain groups, boundary compatibility, induced homology rows, alternating traces, and fixed-point ledger rows, while leaving global topological fixed-point existence outside the packet.

The finite trace route is not a standalone fixed-point theorem. It consumes the compact source row of chapter 60, the self-map row of chapter 130, the chain and homology rows of chapter 98, and the trace computation rows of chapter 49 and chapter 48. The Lefschetz packet depends on these rows because its local conclusion is a finite alternating-trace accounting route, not an ambient topological existence principle.

Definition 6557.1 (Lefschetz fixed point finite-chain carrier)**.** *A* $\mathsf{LefschetzFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, K, F, A, T, H, C, R, P, N)$$

with the following displayed rows:

1. *X is the consumed* $\mathsf{NameCert}_{\mathsf{Compact}^{\uparrow}}$ *row for the finite compact source visible to the construction.*
2. *K is the finite cellular or simplicial chain ledger, including boundary rows and degree indices.*
3. *F is the consumed* $\mathsf{NameCert}_{\mathsf{ContinuousMap}^{\uparrow}}$ *row for the self-map whose chain-map shadow is being read.*
4. *A records the finite chain-map compatibility rows, including boundary commutation and transport of cells or basis rows.*
5. *T is the finite trace ledger over the induced homology or chain quotient rows, expressed through displayed* $\mathsf{Mat}^{\uparrow}$ *or* $\mathsf{LinMap}^{\uparrow}$ *trace data.*
6. *H records componentwise* hsame *transport for compact source, chain ledger, continuous-map row, chain-map row, trace ledger, continuation, provenance, and naming rows.*
7. *C records displayed* Cont *replay from X, K, F into A, from A into T, and from T into the local fixed-point ledger row.*
8. *R is the fixed-point accounting row: it may record a nonzero displayed Lefschetz trace, a zero trace, or a refusal that the displayed finite rows do not support a fixed-point read.*

9. *P is the* Pkg *provenance over* $\mathsf{LefschetzFixedPoint}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LefschetzFixedPoint}^{\uparrow}}$ *row.*

The carrier exports only the finite trace and fixed-point accounting ledger. It contains no ambient topological fixed-point theorem, no host singular homology machinery, no quotient space construction beyond the displayed finite rows, and no global existence claim.

Theorem 6557.2 (LefschetzFixedPoint NameCert obligations)**.** *For every accepted* $\mathsf{LefschetzFixedPoint}^{\uparrow}$ *carrier* $L = (X, K, F, A, T, H, C, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LefschetzFixedPoint}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the compact source, finite chain ledger, continuous self-map, chain-map compatibility, trace ledger, transport, replay, fixed-point accounting, provenance, and naming rows;*
2. *chain-map route, requiring every trace read to pass through X, K, F, A before any* $\mathsf{Homology}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, *or* $\mathsf{LinMap}^{\uparrow}$ *trace row is selected;*
3. *Lefschetz trace ledger, recording the displayed alternating trace rows and their finite homology or chain-quotient sources in T;*
4. *fixed-point accounting row, exposing only the local ledger conclusion R obtained from the displayed trace rows;*
5. *no-host-existence boundary, excluding global fixed-point existence, host compactness theorems, host singular homology, and undeclared topological degree machinery.*

No obligation is stored outside these finite rows.

Proof. Carrier admission is projection from Definition 6557.1. The available sources are exactly $X, K, F, A, T, H, C, R, P, N$.

The chain-map route forces trace reads through the displayed compact source, finite chain ledger, continuous-map row, and chain-map compatibility row. Thus the trace ledger T can cite only finite $\mathsf{Homology}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, or $\mathsf{LinMap}^{\uparrow}$ data already reached by that route.

The fixed-point accounting row R is downstream from T. It records the local outcome named by the packet, but it does not assert a global fixed-point theorem for arbitrary compact spaces or arbitrary continuous maps.

Finally, H, C, P, N transport, replay, source, and name the same finite data. Since none of these rows contains host singular homology, an ambient quotient construction, or a global existence theorem, those claims remain outside the local NameCert surface. □

Theorem 6557.3 (Lefschetz fixed point finite-trace ledger)**.** *Let $L = (X, K, F, A, T, H, C, R, P, N)$ be an accepted* $\mathsf{LefschetzFixedPoint}^{\uparrow}$ *carrier. Every fixed-point read exported by L factors through the finite route*

$$X, K, F \longmapsto A \longmapsto T \longmapsto R, C, P, N.$$

The exported read may cite the displayed alternating trace rows, but it cannot bypass A or T to import a host fixed-point theorem, a host homology theory, or an undeclared topological-degree computation.

Proof. Begin with an exported fixed-point request. The only visible source rows are the compact source X, the finite chain ledger K, and the self-map row F.

The request must then pass through the chain-map compatibility ledger A. Only after boundary compatibility and basis transport are displayed can the continuation route select the finite trace ledger T.

The row R records the local fixed-point accounting result attached to those traces. The structural rows C, P, N expose this result as named BEDC data, while H preserves it under accepted transport. No coordinate in the carrier supplies the excluded host machinery. □

Closure status for $\mathsf{NameCert}_{\mathsf{LefschetzFixedPoint}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LefschetzFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6557.1, Definition 6557.2, and Definition 6557.3 seed the finite Lefschetz trace packet over displayed $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LefschetzFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global classical fixed-point existence, host singular homology, host quotient-space construction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, chain-map routing, finite trace exactness, fixed-point accounting nonescape, transport stability, and no-host-existence boundary for BEDC.Derived.LefschetzFixedPointUp.

Constructive story: A $\mathsf{LefschetzFixedPoint}^{\uparrow}$ packet is generated from a displayed compact source, finite chain ledger, continuous self-map row, chain-map compatibility ledger, alternating trace rows, fixed-point accounting row, componentwise transport, replay, provenance, and local NameCert data.

Chapter 6558

A Concrete Naming Certificate for $\mathsf{RefutationGate}^{\uparrow}$

The $\mathsf{RefutationGate}^{\uparrow}$ packet realizes finite pseudotheory refusal as a concrete NameCert carrier. It reads audit-map rows, claimed discovery rows, structural collision rows, classifier-bit rows, axiom-dependency rows, certificate-debt rows, and taste-boundary rows, then exposes only finite refusal classes rather than a positive admission oracle.

The packet is the finite refusal surface consumed before a pseudotheory or cannot-claim export is read. The pseudotheory refusal packet of chapter 6560 and the checked-target export block of chapter 1319 consume the row-local refusal classes recorded here: $\mathsf{RefutationGate}^{\uparrow}$ supplies the claim, collision, classifier, axiom-dependency, certificate-debt, and taste-boundary classes, while those sibling packets read the same classes in pseudotheory and export-grade contexts.

Falsifiable prediction: An accepted $\mathsf{RefutationGate}^{\uparrow}$ packet is refuted if it classifies a claim as admissible merely because no synonym, classifier-neutral, axiom-dependency, or unpaid-certificate failure row has fired.

Independence witness: axiomdependencymap, auditgateboundary, auditmapfamily, groundcompilerauditmap: no listed sibling is bijective to $\mathsf{RefutationGate}^{\uparrow}$ because this packet binds claim rows, structural-DNA collision rows, classifier-bit refusal rows, axiom-dependency refusal rows, unpaid-certificate rows, taste-boundary rows, transport, replay, provenance, and local NameCert data in one carrier.

Definition 6558.1 (RefutationGate carrier)**.** *A* $\mathsf{RefutationGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, S, B, A, D, T, H, C, P, N)$$

with the following displayed rows:

1. *Q is the claim row naming the asserted discovery or theorem-facing packet under audit.*
2. *S is the structural-DNA collision row, recording synonym or reconstruction evidence against the asserted novelty of Q.*
3. *B is the classifier-bit row, recording classifier-neutral, smoke, or unsupported disagreement evidence.*
4. *A is the axiom-dependency row, recording source-token axiom use or forbidden transitive kernel dependency.*

5. *D is the certificate-debt row, recording missing semantic NameCert, ledger membership, scope seal, or row evidence.*
6. *T is the taste-boundary row, recording that taste-sensitive stability is an admission boundary and not the complement of finite refusal.*
7. *H records componentwise* hsame *transport for claim, refusal, taste-boundary, continuation, provenance, and naming rows.*
8. *C records displayed* Cont *replay from Q through S, B, A, D, T into the public refusal class.*
9. *P is the* Pkg *provenance over* $\mathsf{RefutationGate}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RefutationGate}^{\uparrow}}$ *row.*

The carrier exports finite refusal classes only. It contains no positive discovery oracle, no hidden taste evaluator, and no permission to infer admission from the absence of displayed failures.

Theorem 6558.2 (RefutationGate NameCert obligations)**.** *For every accepted* $\mathsf{RefutationGate}^{\uparrow}$ *carrier $R = (Q, S, B, A, D, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RefutationGate}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the claim, structural collision, classifier-bit, axiom-dependency, certificate-debt, taste-boundary, transport, replay, provenance, and naming rows;*
2. *refusal coverage, requiring every public refusal class to be read from one of S, B, A, D or from the taste-boundary row T;*
3. *non-admission boundary, requiring the packet to distinguish finite refusal from positive taste admission;*
4. *transport stability, requiring H and C to preserve the same refusal class under accepted source transport;*
5. *no-hidden-oracle boundary, excluding global discovery certification, host taste judgment, and unledgered proof repair as packet fields.*

No local obligation is stored outside these finite rows.

Lean4 ✓ `BEDC.Derived.RefutationGateUp.RefutationGateNamecertObligations`

Proof. Carrier admission is projection from Definition 6558.1. The visible rows are exactly $Q, S, B, A, D, T, H, C, P,$

Refusal coverage is a case split over the displayed refusal rows. Structural collision reads from S, classifier-bit failure reads from B, forbidden axiom dependency reads from A, and unpaid certificate data reads from D.

The taste-boundary row T supplies the remaining distinction. It says that stability and value admission are not computed by negating the finite refusal classes, so the packet cannot export a positive discovery judgment merely because S, B, A, D are silent.

Finally, H, C, P, N transport, replay, source, and name this same finite route. Since no coordinate contains a positive admission oracle or a hidden proof repair mechanism, such data remain outside the local NameCert surface. □

Theorem 6558.3 (RefutationGate finite refusal routing)**.** *Let $R = (Q, S, B, A, D, T, H, C, P, N)$ be an accepted* $\mathsf{RefutationGate}^{\uparrow}$ *carrier. Every refusal exported by R factors through the displayed route*

$$Q \longmapsto S, B, A, D, T \longmapsto C, P, N.$$

A downstream audit consumer may read a refusal class only from these rows, and may not replace the taste-boundary row by a positive admission rule.

Proof. Start with a downstream audit request. The claim under audit is the single row Q.

The continuation route then exposes the finite refusal family S, B, A, D together with the taste-boundary row T. These rows determine whether the packet reports structural collision, classifier-bit failure, axiom dependency, certificate debt, or taste-boundary non-admission.

The structural rows C, P, N export the selected class, and H preserves it under accepted transport. Because the route never leaves the displayed packet, no consumer can smuggle in an external positive-discovery oracle. □

The Lean TasteGate development for this packet must provide explicit $\mathsf{Nontrivial\ RefutationGate}^{\uparrow}$ and $\mathsf{FieldFaithful\ RefutationGate}^{\uparrow}$ instances. Nontriviality separates a claim with a displayed refusal row from the empty audit surface, and field faithfulness requires the classifier to preserve $Q, S, B, A, D, T, H, C, P, N$ as distinct fields before any checked carrier-alignment theorem can certify the gate.

Closure status for $\mathsf{NameCert}_{\mathsf{RefutationGate}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RefutationGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6558.1, Definition 6558.2, and Definition 6558.3 seed the finite pseudotheory refusal gate over displayed claim, collision, classifier, axiom-dependency, certificate-debt, and taste-boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RefutationGate}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RefutationGateUp.RefutationGateNamecertObligations`

Bridge status: none

Not claimed: This chapter does not close positive discovery certification, host taste judgment, proof repair, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, refusal coverage, non-admission boundary, transport stability, no-hidden-oracle boundary, and TasteGate field faithfulness for BEDC.Derived.RefutationGateUp.

Constructive story: A $\mathsf{RefutationGate}^{\uparrow}$ packet is generated from one claim row, finite refusal ledgers, a taste-boundary row, componentwise transport, replay, provenance, and local NameCert naming.

Chapter 6559

A Concrete Naming Certificate for $\mathsf{OrbitStabilizer}^{\uparrow}$

Following Burnside and Rotman, the $\mathsf{OrbitStabilizer}^{\uparrow}$ packet records the finite group-action theorem surface as BEDC NameCert data. It sits over the group source of chapter 41, the subgroup carrier of chapter 80, the Sylow action consumer of chapter 3728, and the orbit-counting ledger of chapter 3578. The packet names a displayed orbit, stabilizer, and finite fiber-cardinality handoff without importing quotient orbit sets, host subgroup equality, or an ambient action category.

The stabilizer and fixed-orbit accounting row supplied here is the finite group-action ledger consumed by chapter 9048. Its action rows are read from the same $\mathsf{Group}^{\uparrow}$ source of chapter 41, so the Burnside consumer inherits displayed group-action data rather than an external quotient-orbit surface.

Definition 6559.1 (Orbit-stabilizer carrier)**.** *An* $\mathsf{OrbitStabilizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, X, A, O, S, F, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Group}^{\uparrow}$ *source row, exposing the carried finite group operation, unit, inverse, and associativity data read from chapter 41.*
2. *X is the acted carrier row, exposing the finite carrier being acted on together with the row classifier used by orbit reads.*
3. *A is the action row, displaying the unit-action and multiplication-action laws as finite replay data over G and X.*
4. *O is the orbit row for a displayed point $x \in X$, recording the finite list of action outputs $g \cdot x$ together with duplicate control under the local classifier.*
5. *S is the stabilizer-subgroup row, recording the carried subgroup of G whose elements fix x and reading its closure through chapter 80.*
6. *F is the finite fiber-cardinality ledger. It records that the action map $g \mapsto g \cdot x$ has exactly the stabilizer fibers named by S, so the group-cardinality row factors through the orbit row and stabilizer row before any count is exported.*
7. *H records componentwise* hsame *transport for the group, acted carrier, action, orbit, stabilizer, fiber-cardinality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the finite action route from* $\mathsf{Group}^{\uparrow}$ *and X through A, O, S, F into* $\mathsf{OrbitStabilizer}^{\uparrow}$.
9. *P is the* Pkg *provenance over* $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, *finite action rows, orbit rows, stabilizer rows,* BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OrbitStabilizer}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. It has no coordinate for quotient orbit sets, host coset representatives, ambient subgroup equality, selected transversal data, or a complete finite-group classification.

Theorem 6559.2 (Orbit-stabilizer NameCert obligations)**.** *For an accepted* $\mathsf{OrbitStabilizer}^{\uparrow}$ *carrier*

$$T = (G, X, A, O, S, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OrbitStabilizer}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{Group}^{\uparrow}$ *source, acted carrier, action row, orbit row, stabilizer-subgroup row, finite fiber-cardinality ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

Proof. Project the accepted packet onto its ten rows. The group, acted carrier, action, orbit, stabilizer, and fiber-cardinality data are displayed before the local name can be read.

The stabilizer row is read as subgroup data over the same group row G, so it cannot be replaced by a host subgroup equality claim. The orbit row is read through the action row A, so it cannot be replaced by a quotient-orbit object.

Finally, H, C, P, N transport, replay, source, and name only the displayed rows. Since no excluded object has a carrier coordinate, no local NameCert obligation can depend on quotient orbit sets, selected transversals, or ambient finite-group classification. □

Theorem 6559.3 (Orbit-stabilizer fiber-cardinality handoff)**.** *Let $T = (G, X, A, O, S, F, H, C, P, N)$ be an accepted* $\mathsf{OrbitStabilizer}^{\uparrow}$ *carrier. Every cardinality read of the orbit-stabilizer route factors through the finite ledger F after the orbit row O and stabilizer row S have both been displayed. Consequently a Sylow-style or Burnside-style consumer may cite the cardinality handoff only as a finite fiber ledger over the action row, not as a host quotient or selected coset enumeration.*

Proof. Read the action map from A and the displayed point from the acted carrier row X. The orbit row O lists the action outputs, while the stabilizer row S records exactly the group elements fixing the point.

The ledger F is then the only row where fibers of the action map are counted. It compares a fiber with the stabilizer row before an orbit-cardinality handoff is exported.

Transport through H and replay through C preserve that row order. Thus the downstream count seen by chapter 3728 or chapter 3578 remains a finite BEDC ledger, not a quotient orbit set or selected transversal. □

Theorem 6559.4 (Orbit-stabilizer action nonescape)**.** *Every consumer of an accepted* $\mathsf{OrbitStabilizer}^{\uparrow}$ *carrier factors through*

$$\mathsf{Group}^{\uparrow}, \mathsf{Subgroup}^{\uparrow}, X, A, O, S, F, H, C, P, N.$$

The packet exports a finite group action, a displayed orbit, a stabilizer subgroup row, and a fiber-cardinality ledger, but it exports no quotient orbit carrier, no host subgroup equality, no selected coset representatives, and no ambient classification theorem for finite groups.

Proof. Any accepted read starts by projecting the finite tuple. The action row is the only place where the group acts on the carried set, and the orbit and stabilizer rows are the only endpoints of that action read.

The fiber-cardinality ledger F is a displayed handoff from the action map to the orbit and stabilizer rows. It is not a quotient construction and it does not choose representatives.

The remaining rows H, C, P, N preserve and name the same finite surface. Therefore every downstream consumer must stay inside the displayed group-action data, while quotient orbit carriers, host subgroup equality, selected representatives, and finite-group classification remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{OrbitStabilizer}\uparrow}$.

Constructive story: An $\mathsf{OrbitStabilizer}^{\uparrow}$ packet is generated from a displayed finite GroupUp row, an acted carrier, an action row, an orbit row, a stabilizer-subgroup row, a finite fiber-cardinality ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OrbitStabilizer}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6559.1, Definition 6559.2, Definition 6559.3, and Definition 6559.4 seed the finite group-action theorem carrier over orbit, stabilizer, and fiber-cardinality rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OrbitStabilizer}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient orbit sets, selected coset representatives, ambient subgroup equality, finite-group classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, action replay, stabilizer-subgroup exposure, finite fiber-cardinality handoff, transport, provenance, and action non-escape for BEDC.Derived.OrbitStabilizerUp.

Chapter 6560

A Concrete Naming Certificate for $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$

The $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$ packet realizes the refusal surface of chapter 9412 as finite NameCert data. It records the rows by which a read may be refused for structural reconstruction, classifier-neutral padding, forbidden axiom dependency, unpaid discovery evidence, or taste-boundary non-automation. The packet is apophatic: it blocks overclaimed discovery reads before any positive admission judgment is exported.

Theorem 6560.1 (Pseudotheory refutation sibling dependency route)**.** *The* $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$ *packet refines the refusal classes of chapter 6558 in the pseudotheory context. Its structural collision, classifier-neutral padding, axiom-dependency, certificate-debt, taste-boundary, transport, replay, provenance, and local naming rows are read as pseudotheory-specialized refusal rows, not as a separate kernel-only isolation surface.*

Proof. Read the general $\mathsf{RefutationGate}^{\uparrow}$ refusal route first. It supplies the carrier shape for finite refusal classes, transport, replay, provenance, and local naming.

The pseudotheory packet specializes those rows by naming structural reconstruction collisions, classifier-neutral padding, forbidden axiom dependency, unpaid certificate data, and taste-boundary refusal before any conclusion is exported. Since every row is still read through the displayed refusal route, the chapter records a concrete sibling dependency on $\mathsf{RefutationGate}^{\uparrow}$ while keeping its own seed-level NameCert surface. □

Definition 6560.2 (Pseudotheory refutation gate carrier)**.** *A* $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, K, C, A, U, T, H, Q, P, N)$$

with the following displayed rows:

1. *D is the structural-DNA collision row, recording a finite payload comparison with a prior grounded carrier.*
2. *K is the classifier-neutral padding row, recording that a proposed surface changes no accepted classifier bit before a discovery assertion is read.*
3. *C is the axiom-crossing dependency row, recording a forbidden source token or transitive dependency surface for a claimed BEDC theorem.*
4. *A is the unpaid discovery-data row, recording missing semantic naming, row evidence, ledger membership, debt, or scope-seal data for a positive-discovery claim.*

5. *U is the taste-boundary row, recording that stability, usefulness, and fit with the surrounding theory remain admission judgments and are not automatic demotion results.*
6. *T records componentwise* hsame *transport for the five refusal rows and for replay, provenance, and local naming.*
7. *H records displayed* Cont *replay of the refusal route from a candidate read to exactly one exposed finite refusal row before any conclusion is exported.*
8. *Q is the audit-query provenance row tying the read to axiom-dependency maps, query ledgers, audit boundaries, audit-map families, and ground-compiler audit maps.*
9. *P is the* Pkg *provenance over* BHist*, refusal rows,* hsame*,* Cont*, audit-query data, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationGate}^{\uparrow}}$ *row.*

The carrier contains no coordinate that turns refusal into a positive discovery proof, carrier repair recipe, or taste decision.

Theorem 6560.3 (Pseudotheory refutation gate NameCert obligations)**.** *For an accepted* PseudotheoryRefutationG *carrier*

$$R = (D, K, C, A, U, T, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationGate}^{\uparrow}}$ *surface consists exactly of carrier admission for the structural-DNA collision row, classifier-neutral padding row, axiom-crossing dependency row, unpaid discovery-data row, taste-boundary row, transport, replay, audit-query provenance, package provenance, and local naming.*

Proof. Carrier admission is projection from the ten displayed rows. The five refusal rows are all visible before the local name is read.

The transport and replay rows preserve refusal-row identity. A structural collision cannot be replayed as an axiom dependency, and a taste-boundary row cannot be replayed as a mechanical discovery failure.

The provenance rows Q and P name the audit surfaces used by the read, while N names only the local packet. Since the carrier has no positive-admission coordinate, no NameCert obligation can turn the refusal surface into a discovery proof. □

Theorem 6560.4 (Finite refusal soundness)**.** *Every accepted* $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$ *read exposes at least one of the finite refusal rows D, K, C, A, U before any refusal conclusion is exported. The exported conclusion is therefore a row-local refusal over the displayed audit surface, not a global proof that the candidate has no repair or no future value.*

Proof. Start with an accepted carrier. The replay row H sends a candidate read to the finite refusal surface, and the carrier predicate admits only the five displayed refusal rows as conclusions.

If the read is structural, it factors through D; if it is classifier-neutral, through K; if it crosses an axiom boundary, through C; if it lacks discovery data, through A; and if it reaches taste-sensitive stability, through U.

The audit-query and provenance rows record where the refusal was read. They do not add a positive discovery certificate or a global impossibility theorem, so the conclusion remains finite and row-local. □

Theorem 6560.5 (Taste-boundary nonescape)**.** *The taste-boundary row U of an accepted* PseudotheoryRefutationG *carrier may refuse automatic demotion or automatic admission, but it cannot export a positive*

discovery judgment, carrier replacement, or theorem-worthiness proof. Any consumer that cites U must keep the read inside the displayed taste-boundary row, its hsame *transport, its* Cont *replay, provenance, and local* NameCert.

Proof. Project the row U from the accepted carrier. It is a boundary row: it records where stability and fit require judgment rather than a mechanical gate.

Transport through T preserves that boundary status, and replay through H keeps the row inside the same refusal route. The provenance rows Q and P record the audit source without changing the kind of the row.

Because the carrier contains no positive-admission coordinate, a consumer cannot obtain a discovery proof, carrier replacement, or theorem-worthiness result from U. The only exported data are the displayed boundary row and its transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$ read exposes one finite refusal row among D, K, C, A, U before any demotion conclusion is exported.

Independence witness: axiomdependencymap, axiomqueryledger, auditgateboundary, auditmapfamily, groundcompileauditmap: none is bijective to $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$ because this packet jointly carries structural-DNA collision, classifier-neutral padding, axiom-crossing dependency, unpaid discovery-data, taste-boundary, transport, replay, audit-query provenance, package provenance, and local NameCert rows.

The Lean follow-up is the TasteGate file for $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$, whose carrier interface must provide both Nontrivial and FieldFaithful rows for the finite refusal surface.

Closure status for $\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationGate}^{\uparrow}}$.

Constructive story: A $\mathsf{PseudotheoryRefutationGate}^{\uparrow}$ packet is generated from structural-DNA collision, classifier-neutral padding, axiom-crossing dependency, unpaid discovery-data, taste-boundary, hsame transport, Cont replay, audit-query provenance, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6560.2, Definition 6560.3, Definition 6560.4, and Definition 6560.5 seed the finite refusal carrier for pseudotheory audit reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim positive discovery, automatic taste admission, carrier replacement, theorem-worthiness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite refusal-row exposure, taste-boundary non-escape, transport, replay, provenance, and local naming for BEDC.Derived.PseudotheoryRefutationGateUp.

Chapter 6561

A Concrete Naming Certificate for $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$ packet records the separated regular-Cauchy completion seal between rational regular names and terminal Real names as finite BEDC NameCert data. It sits over the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet supplies the non-quotient separatedness certificate needed before a regular Cauchy name can feed Real and Completion consumers.

Definition 6561.1 (Regular-Cauchy separated-completion carrier)**.** *A* $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (R, S, D, Z, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which R is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the displayed Cauchy budgets.*
4. *Z is the separated zero-distance row asserting that two completed reads agree only through the displayed regular-Cauchy windows and dyadic budgets.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available after R, S, D, Z have been exposed.*
6. *H records componentwise* hsame *transport across the regular name, stream windows, tolerance ledger, separatedness row, Real seal, and certificate rows.*
7. *C records displayed* Cont *replay from a completion request to R, S, D, Z, E.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, D, Z, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ BEDC.Derived.RegularCauchySeparatedCompletionUp.RegularCauchySeparatedCompletionTasteGate
single carrier alignment

Theorem 6561.2 (Regular-Cauchy separated-completion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$ *carrier* $Q = (R, S, D, Z, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySe}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the separated zero-distance row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation may replace these rows by quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6561.1. The only visible coordinates are $R, S, D, Z, E, H, C, P, N$.

The completion-facing rows are ordered. The regular rational name is read through finite stream windows, those windows are bounded by the dyadic ledger, and the separated zero-distance row is downstream of both.

The terminal Real seal is therefore not a quotient of names. Transport, replay, provenance, and local naming preserve the displayed rows, and the excluded equality, selector, choice, trichotomy, and ambient-completeness coordinates cannot be projected from the carrier. □

Theorem 6561.3 (Regular-Cauchy separated-completion zero-distance route)**.** *Every zero-distance read accepted by a* $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, two Real-facing completion reads may be identified only after the regular rational source row, finite stream-window schedule, dyadic tolerance ledger, separatedness row, and terminal Real seal have all been displayed in the same finite packet.

Proof. Read the source row R through the schedule S. This is the only route by which the packet exposes the regular Cauchy name to a completion-facing consumer.

Read the tolerance row D and separatedness row Z next. They bind zero-distance agreement to finite windows and dyadic budgets rather than to a host quotient or selected representative.

Finally consume the Real seal E through the structural rows H, C, P, N. Since the carrier has no further equality coordinate, the accepted zero-distance read cannot escape the displayed route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$ consumer that identifies Real-facing completion reads without reading a RegSeqRat source row, StreamName window schedule, DyadicRatCore tolerance ledger, and separated zero-distance row refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$ is not bijective to any listed sibling because it binds a regular rational name, finite windows, a dyadic tolerance ledger, a separated zero-distance row, and a downstream Real seal into one completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName finite windows, a DyadicRatCore tolerance ledger, a separated zero-distance row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6561.1, Definition 6561.2, and Definition 6561.3 seed the separated regular-Cauchy completion seal for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchySeparatedCompletion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface and zero-distance separatedness route.

Chapter 6562

A Concrete Naming Certificate for $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$

Following Borsuk and Dugundji, the $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$ packet records the neighbourhood-local retract-extension surface used by compact and located metric analysis. It refines the retract route of chapter 6469, reads compact source data through chapter 129, reads distance comparison through chapter 1533, and consumes the closed-extension and separation anchors of chapter 1956 and **??**. The packet names only displayed neighbourhood, extension, and retraction rows; it does not assert a selected neighbourhood-retraction principle.

Definition 6562.1 (Absolute neighbourhood retract carrier)**.** *An* $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, K, L, U, T, V, E, R, S, H, C, P, N)$$

where:

- X *is the displayed source carrier row;*
- K *is the compact-metric source row read through* $\mathsf{CompactMetric}^{\uparrow}$*;*
- L *is the located-metric comparison row read through* $\mathsf{LocatedMetric}^{\uparrow}$*;*
- U *is the displayed neighbourhood row around the closed source packet;*
- T *is the* $\mathsf{TietzeExtension}^{\uparrow}$ *closed-extension row;*
- V *is the* $\mathsf{UrysohnLemma}^{\uparrow}$ *separating-function row used to expose* U *as a displayed neighbourhood boundary;*
- E *records the finite extension request over the closed source row;*
- R *records the candidate retraction from the displayed neighbourhood row back to the source row;*
- S *records stability of the retraction after the extension and separation rows are visible;*
- H, C, P, N *are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}}$ *row.*

Theorem 6562.2 (Absolute neighbourhood retract NameCert obligations)**.** *For every accepted* $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$ *carrier* $A = (X, K, L, U, T, V, E, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AbsoluteNeighborho}}$ *surface consists exactly of source admission, compact-metric readback, located-metric comparison,*

displayed neighbourhood exposure, Tietze extension exposure, Urysohn separation exposure, finite extension request, neighbourhood retraction row, retraction-stability row, componentwise transport, displayed replay, provenance, and local naming. A consumer that omits one of $K, L, U, T, V, E, R, S, H, C, P, N$ is outside the packet.

Proof. Project the carrier of Definition 6562.1. Each coordinate is finite BHist data, and the local naming row N names only the displayed packet.

The compact and located-metric rows provide the source scope. The neighbourhood row U is then exposed through the separation route, and the closed-extension row T supplies the extension side of the retract-extension packet.

Finally read E, R, S, H, C, P, N. These rows package the extension request, neighbourhood retraction, stability, transport, replay, provenance, and name without adding a selected neighbourhood-retraction theorem, quotient compactum, open-cover compactness argument, or choice of extension operators. □

Theorem 6562.3 (Absolute neighbourhood extension-retraction route)**.** *Every accepted* AbsoluteNeighborhoodRetr *packet whose retraction row R is consumed must first expose the compact-metric row K, located-metric row L, displayed neighbourhood row U, Tietze extension row T, Urysohn separation row V, and finite extension request E. The retraction read is then transported through S, H, C, P, N as a neighbourhood-local BEDC route, not as an ambient absolute retract theorem or a selected family of retractions.*

Proof. Begin with the NameCert obligations of Definition 6562.2. They make $K, L, U, T, V, E, R, S, H, C, P, N$ the visible surface for any accepted packet.

The extension side is read before the retraction. The compact-metric and located-metric rows bound the source, the Urysohn row exposes the neighbourhood boundary, and the Tietze row records the closed-extension data over that boundary.

The retraction row R is therefore a neighbourhood-local coordinate of the same finite packet. The stability, transport, replay, provenance, and local naming rows keep the route inside S, H, C, P, N, so no arbitrary selected neighbourhood retraction, quotient compactum, open-cover compactness principle, or chosen extension operator is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbsoluteNeighborhoodRetract}\uparrow}$.

Constructive story: An AbsoluteNeighborhoodRetract$^{\uparrow}$ packet is generated from CompactMetricUp source rows, LocatedMetricUp comparison rows, displayed neighbourhood rows, TietzeExtensionUp extension rows, UrysohnLemmaUp separation rows, finite extension and retraction rows, stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AbsoluteNeighborhoodRetract}\uparrow}$, seed)

Scope closed: Definition 6562.1, Definition 6562.2, and Definition 6562.3 seed the neighbourhood-local retract-extension packet over compact-metric, located-metric, extension, and separation rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AbsoluteNeighborhoodRetract}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary selected neighbourhood retractions, quotient compacta, open-cover compactness, choice of extension operators, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric readback, located-metric comparison, neighbourhood exposure, Tietze extension exposure, Urysohn separation exposure, retraction stability, transport, replay, provenance, and local naming for BEDC.Derived.AbsoluteNeighborhoodRetractUp.

Chapter 6563

A Concrete Naming Certificate for $\mathsf{RegulatedCauchyMap}^{\uparrow}$

Following Bishop and Bridges on regulated functions and constructive completions, the $\mathsf{RegulatedCauchyMap}^{\uparrow}$ packet records the L10 interface by which a regulated approximant family acts on Cauchy names. It sits after the regulated-function surface of chapter 1906, the Cauchy-continuous map surface of chapter 1401, the regular rational readback of chapter 301, the finite observation schedule of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite handoff from regulated approximants to completion-facing Cauchy names; it does not assert host function equality, selected limits, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6563.1 (Regulated Cauchy map carrier)**.** *A* $\mathsf{RegulatedCauchyMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, A, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, exposing only finite step-window, endpoint, and oscillation data available to the approximant family.*
2. *A is the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *action row, recording that displayed Cauchy input windows are sent to displayed Cauchy output windows through the same regulated approximants.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule for the input and output Cauchy names.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed output windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the regulated approximant, input window, and output window at each inspected stage.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, A, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the regulated source, Cauchy action, stream windows, regular readback, dyadic tolerance, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a regulated Cauchy-map request through F, A, S, R, D, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RegulatedCauchyMap}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyMap}^{\uparrow}}$ *row.*

Accepted packets are compared only through $F, A, S, R, D, E, H, C, P, N$ and have no coordinate for host function equality, an external completion operator, quotient Cauchy streams, selected limiting points, countable choice, or ambient real completeness.

Theorem 6563.2 (Regulated Cauchy map carrier admission)**.** *For every accepted* $\mathsf{RegulatedCauchyMap}^{\uparrow}$ *carrier* $M = (F, A, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyMap}^{\uparrow}}$ *surface consists exactly of regulated-function source exposure, Cauchy-continuous action exposure, finite stream-window exposure, regular rational readback, dyadic tolerance comparison, terminal Real sealing, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6563.1. The row F is the only regulated-function source, and A is the only row that acts on Cauchy input and output names.

The Cauchy-name data is then read through S, R, D. Finite stream windows are opened first, regular rational readback is attached to those windows, and dyadic tolerances record the comparisons used by the regulated approximants.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier has no coordinate for host function equality, selected limits, quotient streams, or ambient completeness, the listed rows exhaust the admission surface. □

Theorem 6563.3 (Regulated Cauchy map completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegulatedCauchyMap}^{\uparrow}$ *packet must read the route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{CauchyContinuousMap}^{\uparrow}(A),\ \mathsf{StreamName}^{\uparrow}(S),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{DyadicRatCore}^{\uparrow}(D),\ \mathsf{Real}^{\uparrow}$$

before exporting a Real-facing output. The handoff transports regulated approximants over Cauchy names as finite BEDC rows, not as a host-level function between completed real spaces.

Proof. Start with an accepted carrier $M = (F, A, S, R, D, E, H, C, P, N)$. The source approximant data is visible only in F, and the Cauchy action is visible only in A.

The output Cauchy name is not sealed directly. It first exposes finite observations through S, regular rational readback through R, and dyadic tolerance comparisons through D.

Only after those rows are present may the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed. The structural rows H, C, P, N preserve this order, so the completion handoff cannot import host function equality, quotient Cauchy streams, selected limits, or ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegulatedCauchyMap}^{\uparrow}$ completion-facing read must expose regulated-function, Cauchy-continuous action, StreamName, RegSeqRat, DyadicRatCore, Real seal, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: regulated-function, cauchycontinuousmap, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegulatedCauchyMap}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries regulated approximants, Cauchy-name action, finite stream observations, regular readback, dyadic tolerances, terminal Real sealing, transport, replay, provenance, and local naming as one L10 interface.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedCauchyMap}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedCauchyMap}^{\uparrow}$ packet is generated from a RegulatedFunction source row, a CauchyContinuousMap action row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegulatedCauchyMap}^{\uparrow}}$, seed)

Scope closed: Definition 6563.1, Definition 6563.2, and Definition 6563.3 seed the finite L10 regulated-Cauchy action interface over regulated approximants and Cauchy-name readback rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegulatedCauchyMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host function equality, selected limits, quotient Cauchy streams, countable choice, ambient Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-source exposure, Cauchy action exactness, finite-window readback, dyadic tolerance nonescape, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedCauchyMapUp.

Chapter 6564

A Concrete Naming Certificate for RealUniformCauchyFilterCompletion$^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges constructive analysis, the RealUniformCauchyFilterCompletion$^{\uparrow}$ packet names the finite handoff from the Real-induced uniformity to a Cauchy-filter completion consumer. It sits after the RealUniformStructure$^{\uparrow}$ route of chapter 1624, the completion surface of chapter 1569, the filter source of chapter 333, the finite window rows of chapter 126, the regular rational readback rows of chapter 301, the dyadic radius ledger of chapter 291, and the Real seal of chapter 38.

Definition 6564.1 (Real uniform Cauchy-filter completion carrier)**.** *A* RealUniformCauchyFilterCompletion$^{\uparrow}$ *carrier is a packet*

$$Q = (R, U, F, W, Q_R, E, H, C, P, N)$$

where R is the displayed RealUniformStructure$^{\uparrow}$ *source row, U is the induced uniform-entourage row, F is the* CauchyFilterCompletion$^{\uparrow}$ *completion-facing row reached through a displayed* CauchyFilter$^{\uparrow}$ *basis, W is the finite* StreamName$^{\uparrow}$ *window row, Q_R is the* RegSeqRat$^{\uparrow}$ *readback row over the same window, E is the* DyadicRatCore$^{\uparrow}$ *radius and error ledger ending in a* Real$^{\uparrow}$ *seal, H is componentwise* hsame *transport, C is displayed* Cont *replay, P is* Pkg *provenance over the listed rows, and N is the local* NameCert *row. The carrier predicate asserts that every completion read reaches F only after the rows $R, U, W, Q_R, E, H, C, P, N$ have been displayed in one finite* BHist *packet.*

Lean4 (statement) `BEDC.Derived.RealUniformCauchyFilterCompletionUp`

Theorem 6564.2 (Real uniform completion entourage route)**.** *Every accepted* RealUniformCauchyFilterCompletion$^{\uparrow}$ *packet $Q = (R, U, F, W, Q_R, E, H, C, P, N)$ routes a completion-facing entourage request through the* RealUniformStructure$^{\uparrow}$ *source row R, the generated uniform row U, the* CauchyFilter$^{\uparrow}$ *basis displayed inside the* CauchyFilterCompletion$^{\uparrow}$ *row F, the finite* StreamName$^{\uparrow}$ *window row W, the* RegSeqRat$^{\uparrow}$ *readback row Q_R, the* DyadicRatCore$^{\uparrow}$ *radius ledger E, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before it is offered to any completion consumer.*

Proof. Project the carrier rows. The only row that can expose a Real-induced entourage is R, and the only row that can present the uniform basis to completion consumers is U.

The Cauchy-filter completion row F is downstream of that basis. A completion read must therefore pass through the displayed CauchyFilter$^{\uparrow}$ basis and then through the finite window and readback rows W, Q_R before it can inspect the completion-facing row.

The dyadic radius ledger E supplies the finite tolerance data and the terminal $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and naming are confined to H, C, P, N, so the route remains one finite BHist handoff. □

Theorem 6564.3 (Real uniform completion window handoff)**.** *Let $Q = (R, U, F, W, Q_R, E, H, C, P, N)$ be an accepted* $\mathsf{RealUniformCauchyFilterCompletion}^{\uparrow}$ *carrier. Any completion-facing tail comparison over the Real-induced uniformity reads the* $\mathsf{StreamName}^{\uparrow}$ *window row W and its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q_R before it can consume the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row F or the terminal* $\mathsf{Real}^{\uparrow}$ *seal recorded by E.*

Proof. Start with a tail comparison addressed to the completion route. The carrier exposes the stream coordinates only through W, so no comparison can inspect the Real source before the finite window is displayed.

The readback row Q_R is attached to the same window. It converts the inspected coordinates into the regular rational data consumed by the dyadic radius ledger E and by the Cauchy-filter basis inside F.

Finally H, C, P, N transport, replay, source, and name this same handoff. Thus the completion consumer receives a windowed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ route rather than an ambient sequence, selected representative, or quotient-completion equality. □

Theorem 6564.4 (Real uniform completion nonescape)**.** *Every consumer of an accepted* RealUniformCauchyFilterC *packet is confined to the displayed* $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. The packet exports no quotient filter, quotient real equality, selected limit, countable choice schedule, open-cover compactness, or ambient completeness theorem.*

Proof. Inspect the coordinates of the carrier. They list a Real-induced uniform source, a generated uniform row, a completion-facing Cauchy-filter row, finite stream windows, regular rational readback, dyadic tolerance data, transport, replay, provenance, and local naming.

Apply the entourage route and the window handoff. Together they force each completion-facing request through the same finite rows before any completion read is available.

There is no carrier coordinate for quotient filters, quotient real equality, selected limits, countable choice, open-cover compactness, or ambient completeness. Hence those claims cannot be exported by the local packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformCauchyFilterCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformCauchyFilterCompletion}^{\uparrow}$ packet is generated from a displayed $\mathsf{RealUniformStructure}^{\uparrow}$ source, an induced uniform-entourage row, a $\mathsf{CauchyFilterCompletion}^{\uparrow}$ row reached through a $\mathsf{CauchyFilter}^{\uparrow}$ basis, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger ending in a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealUniformCauchyFilterCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6564.1, Definition 6564.2, Definition 6564.3, and Definition 6564.4 seed the finite completion-facing route from Real-induced uniformity to Cauchy-filter completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealUniformCauchyFilterCompletion}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.RealUniformCauchyFilterCompletionUp`

Bridge status: none

Not claimed: This chapter does not close quotient filters, quotient real equality, selected limits, countable choice, open-cover compactness, ambient Real completeness, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage routing, window handoff, and nonescape for the same packet.

Chapter 6565

A Concrete Naming Certificate for $\mathsf{BaireOneOscillationRank}^{\uparrow}$

Following Baire, Kechris, and Bishop–Bridges constructive analysis, the $\mathsf{BaireOneOscillationRank}^{\uparrow}$ packet records the finite NameCert surface by which a Baire-one real-valued name exposes a displayed oscillation-rank comparison without constructing a quotient space of functions or a host transfinite hierarchy. It sits over the Baire-one source of chapter 1604, the lower-semicontinuous epigraph boundary of chapter 1536, the terminal real-name seal of chapter 38, the regular-rational readback of chapter 301, the finite stream schedule of chapter 126, and the rank-comparison sibling of chapter 6262. The packet names a constructive descriptive-analysis certificate for displayed Baire-one oscillation ranks; it is not a classical completeness theorem, not a selected ordinal rank for every function, and not a quotient-real or quotient-function construction.

Definition 6565.1 (Baire-one oscillation rank carrier)**.** *A* $\mathsf{BaireOneOscillationRank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (F, L, R, S, Q, W, E, K, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{BaireOneFunction}^{\uparrow}$ *source row, including the pointwise approximant ledger and the real-valued request being inspected.*
2. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *epigraph row for the local oscillation-bound predicate attached to F.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row through which all endpoint and oscillation-value reads are exposed.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite windows of source points, approximants, and tolerance requests used by the inspection.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row for the displayed tolerance and value-window comparisons.*
6. *W is the finite oscillation-window row, recording the two value observations, their common source window, and the rational bound compared by Q.*
7. *E is the epigraph-survival row, recording whether the displayed lower-semicontinuous oscillation set survives the named derivative stage.*
8. *K is the rank-comparison handoff row to* $\mathsf{OscillationRankFunction}^{\uparrow}$*, carrying only the displayed stage, survival bit, and boundary tolerance.*

9. *H records componentwise* hsame *transport for the Baire-one source, lower-semicontinuous epigraph, real seal, stream schedule, regular-rational readback, oscillation window, survival row, rank handoff, continuation, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a Baire-one request through S, Q, R, W, L, E, K and then through the structural rows.*
11. *P is the* Pkg *provenance over* $\mathsf{BaireOneOscillationRank}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{OscillationRankFunction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireOneOscillationRank}^{\uparrow}}$ *row.*

The carrier exports no host function-space quotient, no selected transfinite rank, no countable-choice schedule, no quotient real equality, and no ambient completeness principle.

Theorem 6565.2 (Baire-one oscillation rank NameCert obligations)**.** *For every accepted* $\mathsf{BaireOneOscillationRank}^{\uparrow}$ *carrier $O = (F, L, R, S, Q, W, E, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireOneOscillationRank}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; Baire-one source compatibility for F; lower-semicontinuous oscillation-epigraph exposure through L; real-value sealing through R; finite stream scheduling through S; regular-rational tolerance readback through Q; oscillation-window exactness through W; derivative-stage survival exposure through E; rank-comparison handoff through K; componentwise transport stability through H; continuation replay through C; provenance and local naming through P, N; and ledger non-escape for host function spaces, selected transfinite ranks, countable-choice schedules, quotient real equality, and ambient completeness.*

Proof. Project the carrier of Definition 6565.1. The accepted packet exposes exactly the rows $F, L, R, S, Q, W, E, K, H, C, P, N$, so every certificate obligation must be read from those coordinates.

The source and value obligations are F, R, S, Q, W. The Baire-one source fixes the pointwise approximant ledger, the stream row fixes the finite inspection windows, the regular-rational row fixes the displayed tolerance comparison, the real row seals the value observations, and the oscillation-window row records the two compared value reads.

The rank-facing obligation is L, E, K. The lower-semicontinuous row supplies the epigraph boundary for the oscillation predicate, the survival row records only the named derivative-stage test, and the handoff row packages that finite comparison for $\mathsf{OscillationRankFunction}^{\uparrow}$ consumers.

Transport, replay, provenance, and naming add no hidden coordinates. The rows H, C, P, N preserve, replay, source, and name the same displayed route. Since no coordinate stores a host function-space quotient, a selected rank for every function, a countable-choice schedule, quotient real equality, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6565.3 (Baire-one oscillation rank constructive handoff)**.** *Every descriptive-analysis consumer of an accepted* $\mathsf{BaireOneOscillationRank}^{\uparrow}$ *carrier factors through the displayed finite route*

$$F, S, Q, R, W, L, E, K \longmapsto H, C, P, N.$$

Thus the consumer may inspect the Baire-one source, the finite stream windows, the regular-rational tolerance reads, the real-value seals, the oscillation-window comparison, the lower-semicontinuous epigraph boundary, and the displayed rank-survival handoff, but it receives no quotient function space, no selected ordinal rank, no countable-choice schedule, no quotient real equality, and no ambient real-completion theorem.

Proof. Start with a consumer of the handoff row K. Carrier admission makes K available only after the Baire-one source F, stream schedule S, regular-rational tolerance row Q, real-value seal R, oscillation-window row W, lower-semicontinuous epigraph row L, and survival row E have been displayed.

Replay the continuation row C. The request first opens the finite Baire-one value windows, then reads the rational and real comparison data, then passes through the lower-semicontinuous epigraph boundary, and only then exposes the rank-survival comparison used by $\mathsf{OscillationRankFunction}^{\uparrow}$.

The exported surface is therefore the finite route stated in the theorem. Componentwise transport through H preserves the displayed coordinates, and P, N source and name only that route. None of the excluded host objects can be recovered from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireOneOscillationRank}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireOneOscillationRank}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6565.1, Definition 6565.2, and Definition 6565.3 seed the finite constructive-analysis certificate for displayed Baire-one oscillation-rank comparisons.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireOneOscillationRank}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host function-space quotient, selected transfinite rank, countable-choice schedule, quotient real equality, ambient real-completion theorem, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, lower-semicontinuous epigraph exposure, real sealing, stream scheduling, regular-rational readback, oscillation-window exactness, survival exposure, rank handoff, transport, replay, provenance, and local naming for BEDC.Derived.BaireOneOscillationRankUp.

Constructive story: A $\mathsf{BaireOneOscillationRank}^{\uparrow}$ packet is generated from BaireOneFunction, LowerSemicontinuous, RealUp, StreamName, RegSeqRat, OscillationRankFunction, transport, continuation, provenance, and local NameCert rows.

Chapter 6566

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusFold}^{\uparrow}$

Following Bishop–Bridges constructive compactness and the finite-fold construction of chapter 9237, the $\mathsf{CompactUniformModulusFold}^{\uparrow}$ packet records the concrete NameCert object behind the compact uniform-continuity modulus ledger. It sits after the compact source of chapter 60, the continuous-map graph surface of chapter 130, the metric distance rows of chapter 57, the rational-order readback of chapter 37, and the uniform-modulus consumer of chapter 369. The packet names a finite ProbeBundle fold; it does not select an external modulus, invoke open-cover compactness outside the displayed carrier, or import host function equality.

Definition 6566.1 (Compact uniform modulus fold carrier)**.** *A* $\mathsf{CompactUniformModulusFold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, G, M, Q, F, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row exposing the located finite* ProbeBundle *net used by the fold.*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus row over the same metric source.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *source-and-target distance row, including the triangle and symmetry data consumed by the final estimate.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *positive-radius and finite lower-bound comparison row.*
5. *F is the finite fold ledger over the* ProbeBundle *radius family, recording the accumulator, successor comparisons, and certified lower-bound output.*
6. *L is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, consuming the folded lower bound as a tolerance-only precision ledger.*
7. *H records componentwise* hsame *transport for compact source, continuous graph, metric distances, rational comparisons, fold ledger, uniform-modulus handoff, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a compact-uniform request through K, G, M, Q, F, L, H.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusFold}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformModulusFold}^{\uparrow}}$ *row.*

Accepted packets are compared only through $K, G, M, Q, F, L, H, C, P, N$ and have no coordinate for an external choice of modulus, arbitrary open-cover compactness, quotient function equality, completed function space, or ambient real completeness.

Theorem 6566.2 (Compact uniform modulus fold NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusFold}^{\uparrow}$ *carrier $U = (K, G, M, Q, F, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusFold}}$ *surface consists exactly of compact finite-net exposure, continuous-map pointwise-modulus exposure, metric source-and-target distance exposure, rational lower-bound readback, finite* ProbeBundle *fold replay, uniform-modulus handoff, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6566.1. The compact source is K, the continuous graph is G, the metric distance support is M, and the rational comparison support is Q.

The fold row F is downstream of those sources. It records primitive recursion over the displayed ProbeBundle radius family and keeps only certified lower-bound comparisons visible through Q.

The uniform-modulus row L is then a consumer of the fold, not an external selector. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so no arbitrary cover, host function equality, or completed function-space coordinate is exported. □

Theorem 6566.3 (Compact uniform modulus finite-fold handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformModulusFold}^{\uparrow}$ *packet must first read the compact finite-net row K, the continuous-map pointwise-modulus row G, the metric row M, the rational comparison row Q, and the finite fold ledger F. The handoff to L therefore realizes the finite* ProbeBundle *construction of Definition 9237.5 as NameCert data.*

Proof. Begin with the carrier $U = (K, G, M, Q, F, L, H, C, P, N)$. The only finite cover data is in K, and the only pointwise modulus data is in G.

The rational fold cannot be read without metric and rational support. The row M supplies the distance comparisons used by the compact-uniform triangle estimate, while Q supplies the positive-radius order comparisons used by the fold.

Now read F. It is the finite ledger that lowers all bundled local radii to one precision history, matching the construction cited in Definition 9237.5. Only after that finite ledger is visible can L export the tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ row. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformModulusFold}^{\uparrow}$ uniform-modulus read must expose Compact, ContinuousMap, Metric, Rat, finite ProbeBundle fold, UniformModulus, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: compact, continuousmap, metric, rat, uniformmodulus: $\mathsf{CompactUniformModulusFold}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries compact finite-net rows, continuous pointwise-modulus rows, metric triangle support, rational lower-bound fold data, UniformModulus handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusFold}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusFold}^{\uparrow}$ packet is generated from a Compact finite-net row, a ContinuousMap pointwise-modulus row, Metric distance rows, Rat positive-radius comparisons, a finite ProbeBundle fold ledger, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusFold}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6566.1, Definition 6566.2, and Definition 6566.3 seed the finite compact-uniform modulus fold route over Compact, ContinuousMap, Metric, Rat, ProbeBundle fold, and UniformModulus rows.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformModulusFold}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, arbitrary open-cover compactness, external modulus selection, host function equality, completed function spaces, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous pointwise-modulus exposure, metric-triangle compatibility, Rat lower-bound fold exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusFoldUp.

Chapter 6567

A Concrete Naming Certificate for $\mathsf{CompactClosedMap}^{\uparrow}$

Following Bourbaki and Bishop–Bridges constructive topology, the $\mathsf{CompactClosedMap}^{\uparrow}$ packet records the compact-to-Hausdorff closed-map consequence as finite-net image data rather than as an open-cover compactness theorem. It reads compact source rows from chapter 60, metric and Hausdorff separation rows from chapter 4230 and chapter 2086, continuous-map and uniform-modulus rows from chapter 130 and chapter 369, and Real tolerance rows from chapter 38. The constructive reading is a finite-net image schedule: every closed-image read is obtained by replaying displayed compact finite nets, continuity/modulus rows, Hausdorff separation rows, and closed-domain subpacket rows.

Definition 6567.1 (Compact closed-map carrier)**.** *A* $\mathsf{CompactClosedMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, H, D, I, T, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, carrying the finite-net and refinement schedules of the accepted* $\mathsf{Compact}^{\uparrow}$ *packet.*
2. *F is the continuous graph and modulus row: it records the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph samples and the* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance responses used to transport source finite nets to image finite nets.*
3. *H is the Hausdorff separation row over the target metric surface, naming the finite separation witnesses that distinguish an image point from a point outside the transported image packet.*
4. *D is the closed-domain subpacket row, displaying the closed source subpacket whose image is being read.*
5. *I is the image row, recording the finite transported image samples, their Real-valued tolerance budgets, and the target-side membership classifier for the closed-image packet.*
6. *T is the componentwise* hsame *transport row for K, F, H, D, I.*
7. *C is the displayed* Cont *replay route for the same compact finite-net image schedule.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactClosedMap}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactClosedMap}^{\uparrow}}$ *row.*

The carrier exports no open-cover compactness principle, host topology, quotient equality of points or images, selected finite subcover, countable-choice selector, or ambient completeness row.

Theorem 6567.2 (Compact closed-map NameCert obligations)**.** *For an accepted* $\mathsf{CompactClosedMap}^{\uparrow}$ *carrier* $M = (K, F, H, D, I, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactClosedMap}^{\uparrow}}$ *surface consists exactly of carrier admission for compact finite-net data, continuous graph and uniform-modulus rows, Hausdorff separation rows, closed-domain subpacket data, finite image rows, componentwise transport, displayed replay, provenance, and local naming. Any consumer that asks for open-cover compactness, a host-topology closed-set theorem, quotient equality, selected subcovers, choice, or ambient completeness is outside the accepted packet.*

Proof. Project the carrier of Definition 6567.1. The analytic rows are precisely K, F, H, D, I, and the structural rows are T, C, P, N.

The compact row supplies finite-net data, the continuous and modulus row transports those data to image samples, the Hausdorff row separates target points by displayed metric witnesses, and the closed-domain row restricts the source packet before the image row is read.

Finally attach transport, replay, provenance, and local naming. Since the carrier inventory has no row for open covers, host topology, quotient equality, selected subcovers, countable choice, or ambient completeness, the NameCert obligations are exhausted by the displayed finite rows. □

Theorem 6567.3 (Compact closed-map finite-net image)**.** *Every image read exported by an accepted* $\mathsf{CompactClosedMap}^{\uparrow}$ *carrier factors through the finite route*

$$K, F, D \longmapsto I \longmapsto T, C, P, N.$$

The row K *supplies compact finite nets,* F *supplies continuous graph and* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance control,* D *supplies the closed-domain subpacket, and* I *records the transported finite image rows with* $\mathsf{Real}^{\uparrow}$ *tolerance budgets. The export is not an open-cover compactness argument, a selected subcover, a quotient image, or a host-topological closure operation.*

Proof. Start with the compact source row K. A finite image read cannot inspect the target image before the displayed compact finite-net schedule is available.

Next read F and D. The continuous graph and modulus data say how source finite-net samples are transported, while the closed-domain subpacket says which source rows are permitted to contribute to the image.

The row I then records the transported image samples and Real tolerance budgets. The structural rows T, C, P, N preserve and name the same finite route, so no open-cover proof, selected subcover, quotient image, or host closure operation can enter. □

Theorem 6567.4 (Compact closed-map Hausdorff separation)**.** *For an accepted* $\mathsf{CompactClosedMap}^{\uparrow}$ *carrier* $M = (K, F, H, D, I, T, C, P, N)$*, every target-side separation read used to certify closedness of the image must expose the Hausdorff row* H *after the compact finite-net, continuous-modulus, closed-domain, and image rows have been displayed. The separation is therefore a finite* $\mathsf{HausdorffMetric}^{\uparrow}$ *witness over the transported image packet, not host topological separation, quotient equality, excluded middle over target membership, or a choice-selected nearest point.*

Proof. Project the target-side rows. The image packet is displayed through I, and the only row carrying separation data is H.

Use the finite-net image route of Definition 6567.3. It exposes K, F, D, I before any downstream consumer may read target closedness.

Now read H as a Hausdorff-metric separation row over the already transported image packet. Transport, replay, provenance, and local naming keep the same displayed witnesses, so the read cannot be replaced by host topological separation, quotient equality, excluded middle, or a choice-selected nearest point. □

Theorem 6567.5 (Compact closed-map public export)**.** *Every public consumer of an accepted* $\mathsf{CompactClosedMap}^{\uparrow}$ *packet receives only the compact finite-net source row K, continuous graph and uniform-modulus row F, Hausdorff separation row H, closed-domain row D, finite image row I, and support rows T, C, P, N. The public route may be consumed by later compact-uniform, inverse-continuity, or Real-facing packets as a closed-image carrier, but it does not export open-cover compactness, a host topology, quotient equality, a selected finite subcover, choice, or ambient completeness.*

Proof. Begin with the NameCert obligations of Definition 6567.2. They list the full carrier surface and exclude all rows outside $K, F, H, D, I, T, C, P, N$.

Apply the finite-net image theorem and the Hausdorff separation theorem. Together they identify the public closed-image route as compact finite-net transport followed by target-side Hausdorff separation over the displayed image packet.

The downstream consumer therefore receives a reusable closed-image carrier, not a host theorem. Since all public data are projected from the same finite rows, no open-cover compactness, host topology, quotient equality, selected subcover, choice, or ambient completeness can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactClosedMap}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactClosedMap}^{\uparrow}$ packet is generated from compact finite-net rows, continuous graph and uniform-modulus rows, Hausdorff target separation rows, closed-domain subpacket rows, finite image rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactClosedMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope names the compact-to-Hausdorff closed-image carrier and its finite-net image, Hausdorff separation, public export, transport, replay, provenance, and local naming obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactClosedMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host topological closedness, quotient equality, selected finite subcovers, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net image exactness, Hausdorff separation, public export, transport, replay, provenance, and local naming for BEDC.Derived.CompactClosedMapUp.

Chapter 6568

A Concrete Naming Certificate for $\mathsf{RegularSequenceComparison}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularSequenceComparison}^{\uparrow}$ packet records the finite comparison surface for two regular rational stream windows. It sits between the dyadic tolerance ledger of chapter 291, the finite observation route of chapter 126, the regular rational sequence packet of chapter 301, the displayed real-name seal of chapter 38, and the Cauchy naming surface of chapter 3413. The packet compares only displayed windows and tolerances; it is not a Dedekind cut, quotient real equality, selected limit, trichotomy principle, countable-choice schedule, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 6568.1 (Regular sequence comparison carrier)**.** *A* $\mathsf{RegularSequenceComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S_0, S_1, Q_0, Q_1, D, T, M, E, H, C, P, N)$$

with the following displayed rows:

1. S_0, S_1 *are* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows for the two regular rational streams being compared.*
2. Q_0, Q_1 *are* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the two displayed windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ladder, displayed as finite dyadic stages*

   $$\delta_0 \geq \delta_1 \geq \cdots \geq \delta_k$$

   together with the endpoint and difference comparisons consumed at each inspected stage.
4. T *is the termwise comparison ledger pairing the visible* Q_0 *and* Q_1 *entries at the dyadic stages listed by* D*.*
5. M *is the modulus-window row recording which finite StreamName windows are required before a requested dyadic tolerance may be read.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after* $S_0, S_1, Q_0, Q_1, D, T, M$ *have been displayed.*
7. H *records componentwise* hsame *transport for both windows, both regular-rational readbacks, the dyadic tolerance ladder, the comparison ledger, the modulus-window row, the Real seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a comparison request to the two windows, their regular readbacks, the dyadic ladder, the comparison ledger, and the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceComparison}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, Q_0, Q_1, D, T, M, E, H, C, P, N$. It has no coordinate for Dedekind cuts, quotient real equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6568.2 (Regular sequence comparison NameCert obligations)**.** *For every accepted* RegularSequenceComp *carrier $R = (S_0, S_1, Q_0, Q_1, D, T, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{StreamName}^{\uparrow}$ *windows, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ladder, the termwise comparison ledger, the modulus-window row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6568.1. The two windows S_0, S_1, the two regular-rational readbacks Q_0, Q_1, and the dyadic ladder D are the only source rows visible to the comparison.

Read the comparison through T and M. The ledger T pairs only entries already exposed by the two readback rows, while M records the finite windows required for the requested tolerance.

Finally transport and replay the same rows through H and C, and source them through P, N. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations and leave quotient equality, selected limits, countable choice, trichotomy, and Real completeness outside the packet. □

Theorem 6568.3 (Regular sequence comparison RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularSequenceComparison}^{\uparrow}$ *packet receives comparison data only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by $S_0, S_1, Q_0, Q_1, D, T, M, E, H, C, P, N$. The handoff therefore supplies a finite regular-sequence comparison window, not a quotient equality of real names, selected limit, Dedekind-cut comparison, trichotomy decision, countable-choice schedule, or ambient completeness principle.

Proof. Start with an accepted packet and project its two $\mathsf{StreamName}^{\uparrow}$ rows. The consumer cannot read a regular rational comparison until both finite windows S_0, S_1 have been displayed.

Next read Q_0, Q_1 and the dyadic tolerance ladder D. The $\mathsf{RegSeqRat}^{\uparrow}$ rows expose only finite regular-rational readbacks, and D records the finite tolerance stages at which those readbacks are compared.

The comparison ledger T and modulus-window row M then expose the requested finite comparison. The terminal row E is a displayed $\mathsf{Real}^{\uparrow}$ seal for this route only; it is not a completeness assertion.

Finally H, C, P, N transport, replay, source, and name the same packet. Thus any RegSeqRat or Real-facing consumer receives the finite comparison route and no hidden quotient equality, selected limit, Dedekind cut, trichotomy decision, countable-choice schedule, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularSequenceComparison}^{\uparrow}$ packet is generated from two StreamName windows, two RegSeqRat readback rows, a DyadicRatCore tolerance ladder, a termwise comparison ledger, a modulus-window row, a RealUp seal, transport, replay, provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{RegularSequenceComparison}\uparrow}$, seed)

Scope closed: Definition 6568.1, Definition 6568.2, and Definition 6568.3 seed the finite regular-sequence comparison route through displayed StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, and a RealUp seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularSequenceComparison}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind cuts, quotient real equality, selected limits, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic ladder exposure, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularSequenceComparisonUp.

Chapter 6569

A Concrete Naming Certificate for $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$

The $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$ packet realizes the boundary-level hyperbolic observer-expansion route of chapter 9463 as finite Busemann, visual-boundary, metric, transport, provenance, and Real-seal rows. It sits after the Busemann boundary packet of chapter 3732, the visual-boundary readout of chapter 4181, the boundary-shadow route of chapter 3813, the observer-expansion packet of chapter 4167, and the observer-shadow metric of chapter 4154. The packet names a finite horoball-shadow comparison; it is not a global hyperbolic model, quotient ideal boundary, selected geodesic ray, physical observer, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 6569.1 (Hyperbolic horoball-shadow carrier)**.** *A* $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (B, V, M, O, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row, recording the finite Busemann-level boundary read and the horoball threshold being inspected.*
2. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row, recording the visible boundary face used by the shadow read.*
3. *M is the hyperbolic metric comparison row used to attach the horoball threshold to the displayed boundary data.*
4. *O is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row supplying the observer-facing expansion route.*
5. *S is the boundary-shadow budget row, tying the Busemann threshold, visual-boundary row, metric comparison, and observer-expansion row to one finite shadow window.*
6. *R is the refusal row excluding host compactifications, quotient boundary equality, selected rays, physical observer trajectories, and unlogged shadow budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed shadow budget.*
8. *H records componentwise* hsame *transport for Busemann, visual-boundary, metric, observer-expansion, shadow-budget, refusal, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through Busemann readback, visual-boundary exposure, metric comparison, observer-expansion routing, shadow-budget exposure, refusal, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBound}$ $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadow}^{\uparrow}}$ *row.*

The classifier accepts only packets whose Busemann row, visual-boundary row, metric comparison, observer-expansion row, shadow-budget row, refusal row, Real seal, transport, replay, provenance, and local naming remain displayed on the same finite route.

Lean4 (definition) `BEDC.Derived.HyperbolicHoroballShadowUp.HyperbolicHoroballShadowCarrier`

Theorem 6569.2 (Hyperbolic horoball-shadow NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicHoroballShad}$ *carrier $Y = (B, V, M, O, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadow}^{\uparrow}}$ *surface consists exactly of Busemann-boundary admission, visual-boundary readback, hyperbolic metric comparison, observer-expansion route exposure, boundary-shadow budget exposure, refusal exactness, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.HyperbolicHoroballShadowUp.HyperbolicHoroballShadowNamecertObligations`

Proof. Project the carrier of Definition 6569.1. The Busemann row B, visual-boundary row V, metric row M, and observer-expansion row O are the only geometric source rows visible to the local certificate.

Read the shadow-budget row S and refusal row R. The budget row ties the Busemann threshold to the visible boundary and observer route, while R prevents the packet from being read as a host compactification, quotient boundary, selected ray, physical observer, or unlogged shadow source.

Finally expose E, H, C, P, N. The Real seal is attached to the displayed budget route, and the structural rows transport, replay, source, and name the same packet, so the listed rows exhaust the NameCert obligations. □

Theorem 6569.3 (Hyperbolic horoball-shadow boundary handoff)**.** *Every boundary-level consumer of an accepted* $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$ *packet must first display*

$\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserver}$

through the rows $B, V, M, O, S, R, E, H, C, P, N$. A consumer missing the Busemann row cannot produce the boundary handoff, and a consumer missing the horoball-level or shadow-budget rows is not bijective to this packet.

Lean4 ✓ `BEDC.Derived.HyperbolicHoroballShadowUp.HyperbolicHoroballShadowBoundaryHandoff`

Proof. Begin with the accepted carrier. The Busemann row B supplies the horoball threshold and boundary-level distance-difference read, so the boundary handoff cannot be formed from visual data alone.

Next read V, M, O, S. These rows attach the visible boundary, metric comparison, observer-expansion route, and shadow-budget window to the same finite packet.

The refusal row R blocks host compactifications, quotient boundary equality, selected rays, physical observer trajectories, and unlogged shadow budgets. The Real seal E is therefore only the displayed budget seal for this route.

Finally use H, C, P, N to transport, replay, source, and name the same rows. Any boundary-level consumer that omits the Busemann row, horoball-level threshold, or shadow-budget row exits the accepted $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$ packet. □

Falsifiable prediction: Any accepted horoball-shadow packet missing the Busemann row cannot produce the boundary handoff of Definition 6569.3.

Independence witness: hyperbolic-busemann-boundary, hyperbolic-visual-boundary, boundary-shadow-expansion-cocycle, hyperbolic-observer-expansion: none is bijective to $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$ because the Busemann-boundary packet lacks the full shadow budget, the visual-boundary packet lacks the horoball-level row, the boundary-shadow expansion cocycle lacks the Busemann threshold, and the observer-expansion packet lacks the joint horoball-level and shadow-budget rows.

The Lean TasteGate route must provide explicit $\mathsf{Nontrivial}\ \mathsf{HyperbolicHoroballShadow}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicHoroballShadow}^{\uparrow}$ instances in `lean4/BEDC/Derived/HyperbolicHoroballShadowUp/Taste` Those instances must preserve $B, V, M, O, S, R, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$ packet is generated from Busemann-boundary rows, visual-boundary rows, metric comparison rows, observer-expansion rows, a boundary-shadow budget, refusal exactness, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6569.1, Definition 6569.2, and Definition 6569.3 seed the finite horoball-shadow route through Busemann, visual-boundary, metric, observer-expansion, shadow-budget, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global hyperbolic model, quotient ideal boundary, selected geodesic ray, physical observer trajectory, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Busemann row exposure, visual-boundary readback, shadow-budget exactness, boundary handoff, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicHoroballShadowUp.

Chapter 6570

A Concrete Naming Certificate for $\mathsf{BoundedVariationSequence}^{\uparrow}$

Following Bishop and Bridges, a sequence of bounded variation is a regular real sequence whose finite variation ledgers are uniformly controlled by displayed rational data. The $\mathsf{BoundedVariationSequence}^{\uparrow}$ packet records this classical constructive object on the L10 Real and Completion route. It sits after the stream-name surface of chapter 126, the regular rational sequence interface of chapter 301, the dyadic rational core of chapter 291, the terminal real-name boundary of chapter 38, and the Cauchy route of chapter 3413. The packet names finite sequence-variation control without importing host sequence equality, selected limits, countable choice, completed sequence spaces, or full real completeness.

Definition 6570.1 (BoundedVariationSequence carrier)**.** *A* $\mathsf{BoundedVariationSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (S, Q, D, R, C, H, K, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for the observation stream and finite prefix windows.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row reading each displayed sequence value by regular rational names.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row for adjacent dyadic difference observations and finite variation sums.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the accepted value names and variation-budget name.*
5. *C is the* $\mathsf{Cauchy}^{\uparrow}$ *route row exposed only after the finite variation ledger supplies a tail-control modulus.*
6. *H stores componentwise* hsame *transport for stream windows, regular rational reads, dyadic difference ledgers, Real seals, Cauchy handoff, replay, provenance, and local naming.*
7. *K stores* Cont *replay from prefix windows to adjacent differences, from finite variation sums to tail budgets, and from tail budgets to the Cauchy consumer route.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedVariationSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedVariationSequence}^{\uparrow}}$ *row.*

The classifier compares packets only through $S, Q, D, R, C, H, K, P, N$. It has no coordinate for host sequence equality, a selected limiting real, quotient sequence spaces, countable choice, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6570.2 (BoundedVariationSequence variation ledger)**.** *For every accepted* $\mathsf{BoundedVariationSequence}^{\uparrow}$ *carrier $V = (S, Q, D, R, C, H, K, P, N)$ and every displayed finite prefix window, the public variation read factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row D accounts for adjacent dyadic differences and finite variation sums, while R seals only the displayed regular rational values and their variation-budget read. No consumer receives a supremum over all partitions, host sequence equality, selected limit, or ambient completed sequence space from this ledger.

Proof. Project the carrier of Definition 6570.1. A variation request first chooses a finite prefix window from S and then reads the corresponding value names through the regular rational row Q.

The dyadic row D is the only place where adjacent differences and finite variation sums are recorded. Its data are finite: each read is tied to the displayed prefix and to the regular names already exposed by Q.

The Real row R seals those displayed value names and the displayed variation-budget name. Because the carrier has no coordinate for a supremum over all prefixes, host sequence equality, quotient sequence space, selected limit, or full real completeness, the public variation ledger is exactly the finite route through S, Q, D, R. □

Theorem 6570.3 (BoundedVariationSequence Cauchy modulus route)**.** *Let $V = (S, Q, D, R, C, H, K, P, N)$ be an accepted* $\mathsf{BoundedVariationSequence}^{\uparrow}$ *carrier. Any downstream* $\mathsf{Cauchy}^{\uparrow}$ *or completion consumer that cites a modulus from V must read the finite variation ledger S, Q, D, R first and then consume the displayed handoff row C with the same structural rows H, K, P, N. The route exports a tail-control obligation, not a selected limit or quotient equality of sequences.*

Proof. Start with the variation ledger of Definition 6570.2. It confines every finite variation read to stream windows, regular rational names, dyadic adjacent-difference observations, and the Real seal.

The Cauchy row C is downstream of that ledger. A consumer may read C only after the finite variation sums and tail-budget comparisons have been replayed through K and transported through H.

The rows P and N source and name the same route for downstream completion-facing consumers. Since no coordinate of the carrier is a selected limit, quotient sequence equality, completed sequence-space object, countable-choice principle, or full real-completeness row, the Cauchy handoff is a modulus route over displayed finite data. □

Falsifiable prediction: Every $\mathsf{BoundedVariationSequence}^{\uparrow}$ read from an accepted packet factors through the stream window, regular rational sequence readback, dyadic adjacent-difference ledger, Real seal, Cauchy handoff, componentwise transport, continuation replay, provenance, and local $\mathsf{NameCert}$ before any completion consumer sees the route.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy: $\mathsf{BoundedVariationSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries prefix windows, regular rational value names, adjacent dyadic difference ledgers, finite variation sums, a Real seal, a Cauchy handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedVariationSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedVariationSequence}^{\uparrow}$ packet is generated from StreamName prefix windows, RegSeqRat value names, DyadicRatCore adjacent-difference and finite variation ledgers, a RealUp seal, a Cauchy handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedVariationSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6570.1, Definition 6570.2, and Definition 6570.3 seed the finite bounded-variation sequence interface over StreamName, RegSeqRat, DyadicRatCore, Real, and Cauchy routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedVariationSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a selected sequence limit, host sequence equality, quotient sequence space, countable choice, full Real completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, variation-ledger exactness, Cauchy modulus handoff, classifier transport, and consumer nonescape for BEDC.Derived.BoundedVariationSequenceUp.

Chapter 6571

A Concrete Naming Certificate for $\mathsf{DyadicEpsilonNet}^{\uparrow}$

Bishop–Bridges-style finite-net constructive analysis treats compact interval and compact metric work by displaying the actual finite schedule of centers and radii inspected at a requested precision. The $\mathsf{DyadicEpsilonNet}^{\uparrow}$ packet records that schedule as a BEDC NameCert object on the L10 route: its centers and tolerances read the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint ledger of chapter 291, its mesh cells use the $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ enclosure route of chapter 1645, its requests are exposed through the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, its finite readback reaches $\mathsf{RegSeqRat}^{\uparrow}$ through chapter 301, its terminal values are sealed through $\mathsf{Real}^{\uparrow}$ in chapter 38, and its coverage claims are consumed against the $\mathsf{Met}^{\uparrow}$ source of chapter 57. The packet is the explicit finite-net schedule used by interval compactness and total-boundedness consumers; it is not an open-cover compactness theorem, a selected limiting subnet, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6571.1 (Dyadic epsilon-net carrier)**.** *A* $\mathsf{DyadicEpsilonNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, \varepsilon, W, D, I, C_\varepsilon, R, S, H, K, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row whose point histories and distance reads are the only coverage domain inspected by the packet.*
2. *ε is a positive tolerance request displayed as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *row.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule recording which precision requests, source probes, and center indices are inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the requested radius, mesh slack, and distance estimates along W.*
5. *I is the* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *mesh-row package that stores outward endpoint enclosures and interval-cell refinements for the displayed schedule.*
6. *C_ε is the finite list of center rows admitted at the requested tolerance.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the window, dyadic ledger, interval arithmetic, and center data.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after $X, \varepsilon, W, D, I, C_\varepsilon, R$ have been displayed.*

9. *H records componentwise* hsame *transport for the metric source, tolerance request, windows, dyadic ledger, interval arithmetic, center list, readback, real seal, replay, provenance, and local naming rows.*
10. *K records displayed* Cont *replay from a finite-net request through $X, \varepsilon, W, D, I, C_\varepsilon, R, S, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicEpsilonNet}^\uparrow$, $\mathsf{Met}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{DyadicIntervalArithmetic}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicEpsilonNet}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, \varepsilon, W, D, I, C_\varepsilon, R, S, H, K, P, N$. It has no coordinate for an arbitrary open cover, a selected infinite subnet, quotient point equality, host real equality, countable choice, unlisted centers, or ambient completeness.

Theorem 6571.2 (Dyadic epsilon-net NameCert obligations)**.** *For every accepted* $\mathsf{DyadicEpsilonNet}^\uparrow$ *carrier*

$$E = (X, \varepsilon, W, D, I, C_\varepsilon, R, S, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicEpsilonNet}^\uparrow}$ *surface consists exactly of carrier admission for the* $\mathsf{Met}^\uparrow$ *source, positive dyadic tolerance exposure, finite-window exposure, dyadic tolerance exactness, dyadic interval-arithmetic mesh exposure, finite center-list admission,* $\mathsf{RegSeqRat}^\uparrow$ *readback,* $\mathsf{Real}^\uparrow$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No obligation may be discharged by open-cover compactness, a selected infinite subnet, quotient point equality, host real equality, countable choice, hidden centers, or ambient real completeness.

Proof. Project the carrier of Definition 6571.1. The analytic rows are exactly the metric source X, the tolerance request ε, the finite schedule W, the dyadic ledger D, the interval mesh I, the center list C_ε, the readback R, and the terminal seal S.

Read the numerical rows in dependency order. The tolerance request and comparison budget are displayed by $\mathsf{DyadicRatCore}^\uparrow$; the mesh cells are then routed through $\mathsf{DyadicIntervalArithmetic}^\uparrow$; and only those displayed cells and center rows feed the $\mathsf{RegSeqRat}^\uparrow$ readback.

The structural rows preserve the same schedule. Componentwise transport through H and replay through K keep the source, tolerance, window, mesh, centers, readback, and seal in the same order, while P and N name exactly the sibling packet and local certificate rows.

The excluded principles are not carrier coordinates. Therefore no open-cover compactness argument, selected infinite subnet, quotient point equality, host real equality, countable-choice selector, hidden center family, or ambient real-completeness principle can enter the local NameCert surface. □

Theorem 6571.3 (Dyadic epsilon-net finite L10 route)**.** *Let $E = (X, \varepsilon, W, D, I, C_\varepsilon, R, S, H, K, P, N)$ be an accepted* $\mathsf{DyadicEpsilonNet}^\uparrow$ *carrier. Every compactness-facing, total-boundedness-facing, or completion-facing consumer of the finite-net schedule reads the route*

$$\mathsf{Met}^\uparrow \longmapsto \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{DyadicIntervalArithmetic}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

through the displayed rows $X, \varepsilon, W, D, I, C_\varepsilon, R, S, H, K, P, N$. The consumer receives a finite dyadic center schedule at the requested tolerance, not an open-cover subcover, an infinite selected net, quotient real equality, countable choice, or ambient completeness.

Proof. Begin with a consumer read of E. The metric source row X fixes the inspected domain, and the positive dyadic request ε fixes the tolerance that the finite schedule must answer.

The route then exposes only finite data. The window row W lists the inspected precision requests and center indices, D compares their dyadic tolerances, and I records the interval-cell arithmetic needed by the displayed mesh.

The readback and seal are downstream. The row R is produced from the same W, D, I, C_ε data, and the terminal row S is reached only after that readback has been displayed.

Finally H, K, P, N preserve and name this route. Since the carrier has no open-cover, infinite-net, quotient, host-equality, choice, or ambient-completeness coordinate, every accepted consumer receives exactly the displayed finite L10 route. □

Falsifiable prediction: Every accepted $\mathsf{DyadicEpsilonNet}^\uparrow$ read factors through $\mathsf{Met}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{DyadicIntervalArithmetic}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicEpsilonNet}^\uparrow}$.

Constructive story: A $\mathsf{DyadicEpsilonNet}^\uparrow$ packet is generated from a MetricUp source row, a positive DyadicRatCoreUp tolerance request, StreamNameUp finite windows, DyadicRatCoreUp comparison ledgers, DyadicIntervalArithmeticUp mesh cells, a finite center list, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicEpsilonNet}^\uparrow}$, seed)

Scope closed: Definition 6571.1, Definition 6571.2, and Definition 6571.3 seed the explicit finite epsilon-net schedule over MetricUp, DyadicRatCoreUp, DyadicIntervalArithmeticUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicEpsilonNet}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, open-cover compactness, selected infinite nets, quotient point equality, host real equality, countable choice, hidden centers, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite center-list admission, dyadic tolerance exactness, interval-mesh exactness, readback exactness, RealUp seal nonescape, classifier transport, and TasteGate field faithfulness for BEDC.Derived.DyadicEpsilonNetUp.

Chapter 6572

A Concrete Naming Certificate for $\mathsf{AlexandrovTopology}^{\uparrow}$

Following Alexandrov and the order-topology tradition, the $\mathsf{AlexandrovTopology}^{\uparrow}$ packet records the topology generated by a finite preorder row through upward-closed observation windows. It sits after the preorder carrier of chapter 52, the indexed-open surface of chapter 88, the open-neighbourhood implication route of chapter 5864, and the domain-facing comparison surface of chapter 5950. The packet names only finite upper-set generation, finite union and intersection replay, specialization transport, and Scott-facing comparison data; it does not import a host powerset topology, quotient-open equality, arbitrary joins, selected directed suprema, excluded middle over opens, or Lean verification.

Definition 6572.1 (Alexandrov topology carrier)**.** *An* $\mathsf{AlexandrovTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (P, U, O, J, M, S, Q, H, C, G, N)$$

with the following displayed rows:

1. *P is the consumed* $\mathsf{Preorder}^{\uparrow}$ *row, listing the finite point names, reflexivity witnesses, transitivity witnesses, and comparison requests used by the generation.*
2. *U is the upper-set row, recording the finite upward-closure checks: whenever $x \leq_P y$ and x is accepted by the window, the same window accepts y.*
3. *O is the open-window row, listing the finitely inspected Alexandrov opens and their membership probes.*
4. *J records finite union replay for the displayed open windows, using only the listed membership probes.*
5. *M records finite intersection replay for the displayed open windows, again restricted to the same finite preorder-generated rows.*
6. *S is the specialization transport row, comparing the specialization preorder induced by the displayed open windows with the source preorder row P.*
7. *Q is the Scott-comparison row, recording the finite handoff to* $\mathsf{ScottTopology}^{\uparrow}$ *consumers when a Scott-facing upper-set window is displayed.*

8. *H records componentwise* hsame *transport for preorder rows, upper-set rows, open windows, union and intersection replay, specialization transport, Scott comparison, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from preorder requests through U, O, J, M, S, Q and then to the public topology-facing read.*
10. *G is the* Pkg *provenance over* $\mathsf{AlexandrovTopology}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SpecializationOrder}^{\uparrow}$, $\mathsf{ScottTopology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AlexandrovTopology}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $P, U, O, J, M, S, Q, H, C, G, N$. It has no coordinate for a host powerset of opens, arbitrary infinitary closure, quotient-open equality, selected basis completion, or directed-supremum theorem.

Theorem 6572.2 (AlexandrovTopology NameCert obligations)**.** *For every accepted* $\mathsf{AlexandrovTopology}^{\uparrow}$ *carrier $A = (P, U, O, J, M, S, Q, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlexandrovTopology}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed preorder, upper-set, open-window, finite union, finite intersection, specialization, Scott-comparison, transport, replay, provenance, and local naming rows;*
2. *upper-set exactness, requiring each accepted open-window membership read to be upward closed along the preorder row P through the displayed row U;*
3. *finite topology replay, requiring J and M to certify only the displayed finite union and finite intersection windows;*
4. *specialization compatibility, requiring the specialization preorder read from O, J, M to transport through S back to the source preorder row P;*
5. *Scott handoff discipline, requiring Q to expose only the displayed upper-set comparison rows before any* $\mathsf{ScottTopology}^{\uparrow}$ *consumer reads the packet;*
6. *componentwise transport, displayed continuation replay, package provenance, and local naming through H, C, G, N.*

These obligations certify the finite preorder-generated Alexandrov topology surface. They do not close arbitrary open lattices, powerset extensionality, directed-supremum completeness, quotient-open equality, selected bases, excluded middle over opens, or Lean verification.

Proof. Project the carrier of Definition 6572.1. The readable rows are exactly $P, U, O, J, M, S, Q, H, C, G, N$, so every topology-facing consumer starts from the displayed preorder and finite open-window data.

Upper-set exactness is read from U together with the comparison witnesses in P. The finite topology operations are then replayed by J and M, which inspect only the displayed open windows and therefore cannot introduce an ambient powerset of opens.

The specialization route is handled by S. It compares open-neighbourhood implication with the source preorder row already visible in P, so the packet records a transport of finite rows rather than a quotient equality of points.

The Scott-facing row Q is downstream from the same upper-set and open-window rows. Thus any Scott comparison receives a finite Alexandrov handoff and not a directed-supremum theorem.

Finally, H, C, G, N transport, replay, source, and name this finite route. Since no other coordinate is present, the excluded host-topological and infinitary principles cannot be exported. □

Theorem 6572.3 (AlexandrovTopology preorder specialization route)**.** *Let $A = (P, U, O, J, M, S, Q, H, C, G, N)$ be an accepted* $\mathsf{AlexandrovTopology}^{\uparrow}$ *carrier. Every specialization-order read exported by A factors through the finite route*

$$P \longmapsto U \longmapsto O, J, M \longmapsto S.$$

The exported read may compare preorder rows with open-neighbourhood implication rows, but it cannot bypass the displayed Alexandrov windows to import quotient point equality, host separation, or an undeclared topology theorem.

Proof. Begin with a specialization-facing request. The only order source visible to the request is the preorder row P, and the only open data available for neighbourhood implication is the displayed upper-set and open-window route U, O, J, M.

The transport row S reads those same rows before it exposes a specialization comparison. Hence the exported relation is obtained by finite preorder-generated windows rather than by host point equality or a separation axiom.

The structural rows H, C, G, N preserve and name this route. They do not add any coordinate for quotient points, powerset opens, or an ambient topological theorem, so the specialization read remains inside the displayed carrier. □

Theorem 6572.4 (AlexandrovTopology Scott handoff)**.** *Let $A = (P, U, O, J, M, S, Q, H, C, G, N)$ be an accepted* $\mathsf{AlexandrovTopology}^{\uparrow}$ *carrier. Every* $\mathsf{ScottTopology}^{\uparrow}$ *comparison exported by A must first read the preorder row P, the upper-set ledger U, the finite open-window row O, and the union and intersection replay rows J, M. The handoff row Q therefore presents a finite upper-set comparison surface and does not claim directed-supremum inaccessibility, dcpo completeness, or equality with a host Scott topology.*

Proof. Project the carrier. The Scott-facing coordinate is Q, and it appears only after the preorder, upper-set, open-window, and finite topology replay rows.

Use the Scott handoff discipline in Definition 6572.2. It requires Q to expose the displayed upper-set comparison rows before a $\mathsf{ScottTopology}^{\uparrow}$ consumer can read the packet.

Because directed suprema, dcpo completeness, and host Scott-open equality are absent from $P, U, O, J, M, S, Q, H, C, G, N$, the handoff remains a finite comparison route. It can feed domain-theoretic consumers without asserting the missing infinitary closure. □

Falsifiable prediction: Every $\mathsf{AlexandrovTopology}^{\uparrow}$ topology-facing read factors through a preorder row, upper-set checks, finite open windows, finite union replay, finite intersection replay, specialization transport, Scott comparison, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: preorder, topology, specialization-order, scott-topology: $\mathsf{AlexandrovTopology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries preorder generation, upward-closure windows, topology replay, specialization transport, Scott comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AlexandrovTopology}^{\uparrow}}$.

Constructive story: An $\mathsf{AlexandrovTopology}^{\uparrow}$ packet is generated from a finite preorder row, upward-closed observation windows, finite union and intersection replay, specialization transport, Scott-facing comparison, componentwise transport, continuation replay, package provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlexandrovTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6572.1, Definition 6572.2, Definition 6572.3, and Definition 6572.4 seed the finite preorder-generated topology surface for specialization and Scott-comparison consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlexandrovTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open lattices, powerset extensionality, dcpo completeness, directed-supremum inaccessibility, quotient-open equality, selected bases, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-set exactness, finite union and intersection replay, specialization compatibility, Scott handoff discipline, transport stability, replay, provenance, and local naming for BEDC.Derived.AlexandrovTopologyUp.

Chapter 6573

A Concrete Naming Certificate for $\mathsf{RegularCauchyTriangleInequality}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyTriangleInequality}^{\uparrow}$ packet records the finite route by which three regular Cauchy rational sources present a triangle-inequality estimate before a Real metric consumer reads the terminal seal. It sits after the three-leg bound of chapter 466, the metric readback surface of chapter 1654, the real metric route of chapter 5857, the synchronized windows of chapter 126, the regular rational source rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite handoff surface for Real and Completion consumers; it is not quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6573.1 (Regular Cauchy triangle inequality carrier)**.** *A* $\mathsf{RegularCauchyTriangleInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, Z, L_{xy}, L_{yz}, W, Q, M, R, S, H, C, P, N)$$

with the following displayed coordinates:

1. X, Y, Z *are the three* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose pairwise metric comparison is requested.*
2. L_{xy} *and* L_{yz} *are the two* $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ *leg packets that compare* X *to* Y *and* Y *to* Z *through finite regular Cauchy estimates.*
3. W *is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family used to inspect the three sources and the two leg packets at a common request.*
4. Q *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the two leg budgets, their displayed sum, and the output budget read by the Real metric consumer.*
5. M *is the* $\mathsf{RegularCauchyMetric}^{\uparrow}$ *handoff row that turns the synchronized regular Cauchy comparisons into the metric-facing surface.*
6. R *is the* $\mathsf{RealTriangleInequality}^{\uparrow}$ *handoff row that exposes the terminal three-leg Real metric route.*
7. S *stores the* $\mathsf{Real}^{\uparrow}$ *seal rows for the three endpoints and the final distance comparison.*
8. H *stores componentwise* hsame *transport for sources, leg packets, windows, dyadic budgets, metric handoff, Real handoff, seal rows, provenance, and the local name.*
9. C *stores displayed* Cont *replay from a Real metric triangle request through* $X, Y, Z, L_{xy}, L_{yz}, W, Q, M, R, S, H, P,$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTriangleInequality}^{\uparrow}$, $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$, $\mathsf{RegularCauchyMetric}^{\uparrow}$, $\mathsf{RealTriangleInequality}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTriangleInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting every displayed row to the common source, window, tolerance, metric, and Real seal surface. The carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness.

Theorem 6573.2 (Regular Cauchy triangle inequality NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyTriangleInequality}^{\uparrow}$ *carrier* $T = (X, Y, Z, L_{xy}, L_{yz}, W, Q, M, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTriangleInequality}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed three-source packet T;*
2. *source admission for the three* $\mathsf{RegSeqRat}^{\uparrow}$ *rows X, Y, Z;*
3. *leg admission for the two* $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ *packets L_{xy} and L_{yz};*
4. *synchronized* $\mathsf{StreamName}^{\uparrow}$ *window inspection through W;*
5. *dyadic budget addition and output-budget exactness through Q;*
6. $\mathsf{RegularCauchyMetric}^{\uparrow}$ *handoff through M;*
7. $\mathsf{RealTriangleInequality}^{\uparrow}$ *handoff through R;*
8. *terminal* $\mathsf{Real}^{\uparrow}$ *seal reads through S;*
9. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row N.*

No obligation exports quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6573.1. Its displayed rows are exactly the three regular Cauchy sources, the two triangle-bound legs, synchronized stream windows, dyadic tolerance ledger, metric handoff, Real triangle handoff, Real seal rows, transports, replay, provenance, and local naming row.

The NameCert obligations are therefore the admission and replay checks for those coordinates. Source admission reads X, Y, Z; leg admission reads L_{xy} and L_{yz}; window inspection reads W; tolerance exactness reads Q; the two handoff obligations read M and R; and the terminal seal reads S.

The rows H, C, P, N account for componentwise transport, consumer replay, package provenance, and local naming. Since the carrier contains no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the displayed list exhausts the local certificate surface. □

Theorem 6573.3 (Regular Cauchy triangle inequality Real metric route)**.** *Every Real metric triangle consumer of an accepted* $\mathsf{RegularCauchyTriangleInequality}^{\uparrow}$ *carrier factors through the displayed finite route*

$$(X, Y, Z) \longrightarrow (L_{xy}, L_{yz}, W, Q) \longrightarrow M \longrightarrow R \longrightarrow S.$$

The consumer first reads the three $\mathsf{RegSeqRat}^{\uparrow}$ *sources, the two* $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ *legs, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger; it then reads*

the RegularCauchyMetric$^{\uparrow}$ *handoff, the* RealTriangleInequality$^{\uparrow}$ *handoff, and the terminal* Real$^{\uparrow}$ *seal rows. No Real metric triangle route out of the packet can bypass this finite carrier through quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier and project its rows. The only source coordinates are X, Y, Z, the only leg coordinates are L_{xy}, L_{yz}, and the only shared inspection and budget coordinates are W, Q.

The continuation row C, transported by H, replays a Real metric triangle request through those rows before it can reach the metric-facing handoff M. Thus the regular Cauchy metric comparison is already tied to the two displayed legs and their dyadic budget ledger.

The Real-facing part of the route then reads R and S. Row R is the displayed RealTriangleInequality$^{\uparrow}$ handoff, while S stores the terminal Real$^{\uparrow}$ seal rows for the three endpoints and the final comparison.

Because P and N only record provenance and local naming, and because the carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, every Real metric triangle consumer factors through the finite route displayed above. □

Closure status for NameCert$_{\text{RegularCauchyTriangleInequality}^{\uparrow}}$.

Constructive story: A RegularCauchyTriangleInequality$^{\uparrow}$ packet is generated from three RegSeqRat$^{\uparrow}$ source rows, two RegularCauchyTriangleBound$^{\uparrow}$ leg packets, synchronized StreamName$^{\uparrow}$ windows, a DyadicRatCore$^{\uparrow}$ tolerance ledger, RegularCauchyMetric$^{\uparrow}$ and RealTriangleInequality$^{\uparrow}$ handoff rows, terminal Real$^{\uparrow}$ seal rows, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyTriangleInequality}^{\uparrow}}$, seed)

Scope closed: Definition 6573.1, Definition 6573.2, and Definition 6573.3 seed the finite triangle-inequality route over regular Cauchy sources, triangle-bound legs, synchronized stream windows, dyadic budgets, metric handoff, Real handoff, Real seals, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTriangleInequality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, leg admission, synchronized window inspection, dyadic budget exactness, RegularCauchyMetric handoff, RealTriangleInequality handoff, RealUp seal reads, and non-escape for BEDC.Derived.RegularCauchyTriangleInequalityUp.

Chapter 6574

A Concrete Naming Certificate for $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$

Following Bishop and Bridges on constructive finite suprema of regular Cauchy real names, the $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$ packet records a finite-family maximum route as displayed comparison-tree data. It sits after the regular rational source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic core of chapter 291, the binary maximum packet of chapter 1833, the finite product packet of chapter 2009, and the terminal real-name seal of chapter 38. The certificate gives compact finite-net, Dini, and uniform-modulus consumers a named finite maximum object without importing trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6574.1 (Regular Cauchy finite maximum carrier)**.** *A* $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, S, W, D, T, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite unary index row, listing exactly the component slots opened by the maximum request.*
2. *S is the component* $\mathsf{RegSeqRat}^{\uparrow}$ *source family, one row for each slot of I.*
3. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family for the component reads, intermediate pairwise maximum reads, and final maximum read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger, storing the dyadic observations and tolerance cells used at each finite branch.*
5. *T is the finite comparison-tree row. Each internal node cites a displayed* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *route over two previously displayed child rows.*
6. *B records branch exactness: every leaf of T is a source row from S, every internal branch consumes two earlier nodes, and the root is the only final maximum output.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the root of the comparison tree, obtained only from S, W, D, T, B.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the root readback R has been displayed.*

9. *H records componentwise* hsame *transport for the index row, sources, windows, dyadic comparison ledger, comparison tree, branch exactness row, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from any finite maximum request through the same rows.*
11. *P records* Pkg *provenance over* $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyMaximum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, W, D, T, B, R, E, H, C, P, N$. It has no coordinate for a host finite supremum, trichotomy, quotient real equality, selected limit, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or standard bridge.*

Theorem 6574.2 (Regular Cauchy finite maximum NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$ *carrier*

$$F = (I, S, W, D, T, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet, finite comparison-tree exactness through T and B, coordinate readback stability through S, W, D, R,* $\mathsf{Real}^{\uparrow}$*-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 6574.1. Carrier admission is exactly admission of the rows $I, S, W, D, T, B, R, E, H, C, P, N$.

Comparison-tree exactness is read from T and B. The index row I names the leaves, the source family S supplies those leaves, and each internal node of T cites a binary $\mathsf{RegularCauchyMaximum}^{\uparrow}$ route over two earlier displayed rows. The branch row B records that the root is the only final output.

Coordinate readback stability is downstream of the same tree. The synchronized window family W and dyadic ledger D are the only rows from which component and intermediate observations may be read, so the root readback R cannot depend on an unstated coordinate or a selected representative.

The seal row E is reached only after R has been exposed. The transport, replay, provenance, and naming rows H, C, P, N preserve and cite this displayed route; none adds a host finite supremum, trichotomy, quotient real equality, selected limit, countable-choice schedule, ambient completeness theorem, Lean verification, or bridge credential. Thus the listed rows exhaust the local NameCert obligations. □

Theorem 6574.3 (Regular Cauchy finite maximum comparison-tree route)**.** *Every accepted* RegularCauchyFiniteMa *read factors through the finite route*

$$I, S \longmapsto W, D \longmapsto T, B \longmapsto R \longmapsto E, H, C, P, N.$$

In particular, the finite-family maximum is obtained by iterated displayed $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *rows, not by host trichotomy, quotient real equality, a selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite index and source rows. The request first names the slots in I and reads the matching component $\mathsf{RegSeqRat}^{\uparrow}$ rows in S.

The observation data is then synchronized by W and measured by D. These rows provide the finite windows and dyadic tolerances used by every binary comparison in the displayed tree.

The comparison tree T and branch row B order the binary maximum calls. Each internal node is a $\mathsf{RegularCauchyMaximum}^{\uparrow}$ route over already displayed child rows, and the root is the only row available for the final readback R.

Finally E, H, C, P, N seal, transport, replay, source, and name the same root route. Since no excluded host or quotient object is a coordinate of the carrier, every accepted read factors through the displayed finite tree. □

Theorem 6574.4 (Regular Cauchy finite maximum coordinate stability)**.** *If two accepted* $\mathsf{RegularCauchyFiniteMaxi}$ *carriers have the same finite index row, component* $\mathsf{RegSeqRat}^{\uparrow}$ *classifiers, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger, comparison tree, and branch exactness row, then their root* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal are the same displayed route. A coordinate-facing consumer cannot separate the packets except through one of those displayed rows.*

Proof. Project the two carriers through Definition 6574.1. The classifier has no coordinate outside the index, source, window, dyadic ledger, comparison-tree, branch, readback, seal, transport, replay, provenance, and local naming rows.

Use the comparison-tree route theorem Definition 6574.3. Once I, S, W, D, T, B agree, the same iterated $\mathsf{RegularCauchyMaximum}^{\uparrow}$ nodes are read in the same order, so the root readback row R is forced to be the same displayed $\mathsf{RegSeqRat}^{\uparrow}$ route.

The terminal seal E is downstream of R, and H, C, P, N only transport, replay, source, and name that route. Therefore a coordinate-facing consumer has no additional row from which to separate the packets. □

Theorem 6574.5 (Regular Cauchy finite maximum Real seal non-escape)**.** *For every accepted* $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *seal row exposes only the displayed root readback of the finite comparison tree. It exports no host finite supremum, trichotomy, quotient real equality, selected limit, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, Lean verification, or standard bridge.*

Proof. Inspect the carrier boundary. The seal row E appears only after the index, source, window, dyadic comparison, comparison-tree, branch exactness, and root readback rows have been displayed.

The structural rows H, C, P, N preserve the same route. Transport and replay can move the displayed packet, provenance can cite its dependencies, and local naming can name it, but none supplies an independent finite supremum or quotient-equality coordinate.

Since every accepted read factors through Definition 6574.3, the $\mathsf{Real}^{\uparrow}$ seal cannot escape the comparison tree or import any excluded completion principle. □

Falsifiable prediction: Every $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$ read factors through a finite unary index row, component RegSeqRat sources, synchronized StreamName windows, DyadicRatCore comparison cells, iterated RegularCauchyMaximum rows, a root RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, regular-cauchy-maximum, regular-cauchy-finite-product, real: $\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite index row, component source family, synchronized observation windows, dyadic comparison ledger, comparison-tree exactness, root readback, RealUp sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteMaximum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6574.1, Definition 6574.2, Definition 6574.3, Definition 6574.4, and Definition 6574.5 seed the finite maximum route from displayed regular Cauchy sources through comparison-tree rows, root readback, and RealUp sealing.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyFiniteMaximum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host finite suprema, trichotomy, quotient real equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison-tree exactness, coordinate readback stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFiniteMaximumUp.

Constructive story: A RegularCauchyFiniteMaximum$^{\uparrow}$ packet is generated from a finite unary index row, component RegSeqRat source rows, synchronized StreamName windows, DyadicRatCore comparison cells, a comparison tree of RegularCauchyMaximum rows, branch exactness, root RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6575

A Concrete Naming Certificate for $\mathsf{FermatStationaryPoint}^{\uparrow}$

Following Fermat and Bishop–Bridges constructive calculus, the $\mathsf{FermatStationaryPoint}^{\uparrow}$ packet records the finite route by which a local extremum witness and a derivative row at an interior point hand off to the stationary-point conclusion. It sits after the derivative quotient interface of chapter 122, the terminal real-name seal of chapter 38, the dyadic tolerance ledger of chapter 291, and the constructive interval-continuity route of chapter 3828. The packet names a derivative-neighbour of the Real route; it is not an ambient Real-completeness principle, not an open-cover compactness theorem, not a selected minimizing point, and not quotient equality of functions.

Definition 6575.1 (Fermat stationary-point carrier)**.** *A* $\mathsf{FermatStationaryPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, F, E, D, Z, H, C, P, N)$$

with the following displayed coordinates:

1. *I is the interval source row, carrying the two-sided interior-window data around the inspected point.*
2. *F is the function graph row, exposing only the displayed values and finite observation windows consumed by the derivative row.*
3. *E is the local extremum window row, recording that every admitted left and right comparison in the displayed neighbourhood is routed through the same interval and graph rows.*
4. *D is the* $\mathsf{Derivative}^{\uparrow}$ *row at the inspected point, including the finite difference-quotient ledger and nonzero-step boundary.*
5. *Z is the zero-derivative handoff row, recording that the stationary conclusion reads the derivative row as a zero row after the two extremum-side comparison ledgers have been displayed.*
6. *H stores componentwise* hsame *transport for the interval, graph, extremum window, derivative row, zero handoff, replay, provenance, and local name.*
7. *C stores displayed* Cont *replay from a stationary-point request through I, F, E, D, Z, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FermatStationaryPoint}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DarbouxContinuity}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FermatStationaryPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting all displayed rows to the same interval source, graph window, local extremum ledger, derivative quotient row, and zero-derivative handoff. The carrier contains no coordinate for a selected global optimum, trichotomy, host function equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6575.2 (Fermat stationary-point NameCert obligations)**.** *For an accepted* $\mathsf{FermatStationaryPoint}^{\uparrow}$ *carrier* $S = (I, F, E, D, Z, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FermatStationaryPoint}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed stationary-point packet* S*;*
2. *interval-source exposure through* I*;*
3. *function-graph exposure through* F*;*
4. *local extremum window exactness through* E*;*
5. *derivative-row admission through* D*;*
6. *zero-derivative handoff through* Z*;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* H, C, P, N*.*

No obligation exports a selected global optimum, trichotomy, host function equality, open-cover compactness, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6575.1. Its displayed rows are exactly the interval source, function graph, local extremum window, derivative row, zero-derivative handoff, transport, replay, provenance, and local naming row.

The NameCert obligations are therefore the admission and exactness checks for those coordinates. The interval source reads I; the graph read opens F; the local extremum comparisons read E; the derivative quotient data read D; and the stationary handoff reads Z.

The structural rows H, C, P, N preserve this same finite packet under classifier transport and consumer replay. Since the carrier contains no selected global optimum, trichotomy, host function equality, open-cover compactness, quotient function equality, or Real-completeness coordinate, the displayed obligations exhaust the local certificate surface. □

Theorem 6575.3 (Fermat stationary-point derivative-zero handoff)**.** *Every stationary-point consumer of an accepted* $\mathsf{FermatStationaryPoint}^{\uparrow}$ *carrier factors through the finite route*

$$I, F, E \longrightarrow D \longrightarrow Z.$$

The consumer first reads the interval source, function graph, and local extremum window; it then reads the $\mathsf{Derivative}^{\uparrow}$ *quotient row and finally the zero-derivative handoff. No route out of the packet can bypass this carrier through a selected extremal point, trichotomy, host equality of functions, open-cover compactness, quotient function equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier and project its rows. The only interval coordinate is I, the only graph coordinate is F, and the only local extremum coordinate is E.

The derivative row D is downstream from those three rows because its difference-quotient comparisons are read on the displayed interval and graph windows. The zero handoff Z is downstream from D because it names the stationary conclusion only as a readback of the derivative row after both extremum-side comparison ledgers have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded host or compactness coordinate appears in S, every stationary-point consumer factors through the displayed finite handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{FermatStationaryPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{FermatStationaryPoint}^{\uparrow}$ packet is generated from an interval source row, a function graph row, a local extremum window, a DerivativeUp row, a zero-derivative handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FermatStationaryPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6575.1, Definition 6575.2, and Definition 6575.3 seed the finite local-extremum-to-zero-derivative route over $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DarbouxContinuity}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FermatStationaryPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, compactness, trichotomy, global extrema, quotient function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exposure, graph exposure, local-extremum window exactness, derivative-row admission, zero-derivative handoff, transport, replay, provenance, and local naming for BEDC.Derived.FermatStationaryPointUp.

Chapter 6576

A Concrete Naming Certificate for $\mathsf{OptionalStieltjesModulus}^{\uparrow}$

Following Riemann, Stieltjes, and Bishop–Bridges constructive analysis, the $\mathsf{OptionalStieltjesModulus}^{\uparrow}$ packet records the finite modulus surface needed before a regulated Riemann–Stieltjes consumer may read an integration boundary. It sits beside the regulated-function carrier of chapter 1906, the variation row of chapter 398, the integration-by-parts route of chapter 5131, the dyadic step approximation surface of chapter 3774, the regular rational source of chapter 301, and the terminal Real seal of chapter 38. The packet is a finite handoff object for optional partitions, oscillation budgets, variation control, and Real readback; it does not import selected limits, measure completion, quotient integration equality, host total variation, or countable choice.

Definition 6576.1 (Optional Stieltjes modulus carrier)**.** *An* $\mathsf{OptionalStieltjesModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, G, V, P, S, Q, R, E, H, C, K, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *integrand row, carrying the regulated oscillation windows read by the Stieltjes consumer.*
2. *G is the integrator row, read through the* $\mathsf{BoundedVariation}^{\uparrow}$ *carrier and the finite variation ledger named by V.*
3. *V is the bounded-variation budget row, recording the variation mass used by the modulus request.*
4. *P is the optional partition row, listing the tagged dyadic subdivision windows that may be refined before the integration read.*
5. *S is the* $\mathsf{DyadicStepApproximation}^{\uparrow}$ *row, recording the step approximation attached to the displayed partition.*
6. *Q is the modulus row, assigning a finite dyadic tolerance to every displayed partition-refinement request.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, storing the regular rational estimate exported by the modulus.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the regulated Stieltjes estimate.*
9. *H records componentwise* hsame *transport for the integrand, integrator, variation, partition, step approximation, modulus, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a Riemann–Stieltjes request through $F, G, V, P, S, Q, R, E, H$.*
11. *K is the* Pkg *provenance over* $\mathsf{OptionalStieltjesModulus}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}$, $\mathsf{DyadicStepApproximation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{OptionalStieltjesModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a measure completion, selected limit of partitions, quotient integration equality, host total-variation theorem, ambient Real completeness, or countable-choice selection of tags.

Lean4 ✓ `BEDC.Derived.OptionalStieltjesModulusUp.OptionalStieltjesModulusTasteGate single carrier alignment`

Theorem 6576.2 (Optional Stieltjes modulus NameCert obligations)**.** *For every accepted* OptionalStieltjesModulus *carrier*

$$M = (F, G, V, P, S, Q, R, E, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{OptionalStieltjesModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the regulated integrand, bounded-variation integrator, variation budget, optional partition, dyadic step approximation, modulus, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *regulated-window exactness, requiring every oscillation read to inspect F and the displayed partition row P before the modulus row Q is consumed;*
3. *variation-budget exactness, requiring every Stieltjes-facing request to read G, V before any optional refinement or Real seal is public;*
4. *step-approximation compatibility, requiring the dyadic step row S to be attached to the same partition and variation rows;*
5. *readback and seal ordering, requiring Q to feed R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is exported;*
6. *componentwise transport, displayed replay, package provenance, and local naming through H, C, K, N.*

No obligation is stored outside $F, G, V, P, S, Q, R, E, H, C, K, N$.

Proof. Project the carrier of Definition 6576.1. The readable rows are exactly the regulated integrand, bounded-variation integrator, variation budget, optional partition, dyadic step approximation, modulus, readback, Real seal, and structural rows.

The regulated and variation stages are separate but synchronized. The integrand row F supplies the oscillation windows, while G, V supply the bounded-variation budget before any optional partition refinement is read.

The finite approximation stage is P, S, Q. The partition row is displayed first, the dyadic step row is attached to it, and the modulus row assigns the finite tolerance used by downstream estimates.

Finally R, E, H, C, K, N read back, seal, transport, replay, source, and name the same route. Since no carrier coordinate supplies measure completion, selected partition limits, quotient integration equality, host total variation, ambient Real completeness, or countable choice, the listed rows exhaust the local NameCert surface. □

Theorem 6576.3 (Optional Stieltjes modulus Riemann–Stieltjes handoff)**.** *Every Riemann–Stieltjes regulated integration consumer of an accepted* $\mathsf{OptionalStieltjesModulus}^{\uparrow}$ *carrier factors through the finite route*

$$(F, G, V) \longmapsto (P, S, Q) \longmapsto R \longmapsto E.$$

The consumer receives regulated-function windows, bounded-variation control, optional partition data, dyadic step approximation, a finite modulus, regular rational readback, and a terminal Real seal. It receives no measure-completion object, selected partition limit, quotient integration equality, host total-variation theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or choice-selected tag family.*

Proof. Start with the carrier projection. The only integration-facing source rows are F, G, V, so a consumer must read the regulated integrand and bounded-variation budget before a partition or modulus is available.

The optional partition and approximation stage is then forced through P, S, Q. This gives a finite dyadic partition surface and a finite tolerance assignment rather than a selected limiting mesh.

The readback stage is R, E. The regular rational row records the estimate supplied by the modulus, and the Real seal exposes only that terminal read.

The structural rows H, C, K, N preserve the same route under hsame, Cont, Pkg, and local naming. Because the excluded integration and choice principles have no carrier coordinate, every regulated Riemann–Stieltjes handoff factors through the displayed finite packet. □

Lean4 (statement) `BEDC.Derived.OptionalStieltjesModulusUp`

Closure status for $\mathsf{NameCert}_{\mathsf{OptionalStieltjesModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OptionalStieltjesModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6576.1, Definition 6576.2, and Definition 6576.3 seed the finite optional Stieltjes modulus route through regulated-function windows, bounded-variation control, optional partitions, dyadic step approximations, regular rational readback, Real seals, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OptionalStieltjesModulus}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.OptionalStieltjesModulusUp`

Bridge status: none

Not claimed: This chapter does not close measure completion, selected partition limits, quotient integration equality, host total variation, ambient $\mathsf{Real}^{\uparrow}$ completeness, countable choice, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-window exactness, variation-budget exactness, step-approximation compatibility, readback-seal ordering, transport stability, replay, provenance, and local naming for BEDC.Derived.OptionalStieltjesModulusUp.

Constructive story: An $\mathsf{OptionalStieltjesModulus}^{\uparrow}$ packet is generated from a regulated-function row, bounded-variation integrator row, variation budget, optional partition row, dyadic step approximation row, modulus row, RegSeqRat readback, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6577

A Concrete Naming Certificate for MetaCICCandidateNormalizationWitness$^{\uparrow}$

The MetaCICCandidateNormalizationWitness$^{\uparrow}$ packet realizes the normalization frontier of section 9386.4 as finite candidate evidence rather than as an evidence-free closed-term theorem. It sits beside the frontier carrier of chapter 892, the bounded comparison route of chapter 752, the sealed closed type checker of chapter 2182, the candidate projection boundary of chapter 4366, and the candidate router of chapter 5210. The packet names a local witness surface from a closed typed term to candidate evidence, normal endpoint data, obstruction rows, transport, replay, provenance, and local naming; it does not assert global strong normalization, unrestricted subject reduction, evaluator equality, quotient syntax equality, or closed consistency.

Definition 6577.1 (MetaCIC candidate normalization witness carrier)**.** *A* MetaCICCandidateNormalizationWitness *carrier is a finite* BHist *packet*

$$W = (T, A, K, N, E, O, D, B, H, C, P, L)$$

with the following displayed rows:

1. *T is the closed typed term row, recording the sealed empty-context typing evidence read from the closed-type-checker surface.*
2. *A is the candidate anchor row, naming the candidate family, closed-candidate wrapper, or finite candidate-set membership used by the witness.*
3. *K is the candidate-evidence row, storing the actual membership, reducibility, or adequacy datum attached to T.*
4. *N is the normal endpoint row, recording the bounded normal form or no-infinite-reduction endpoint reached from K.*
5. *E is the endpoint comparison row consumed by bounded normal-equality checkers.*
6. *O is the obstruction row, retaining any missing candidate, missing closedness, blocked residual, or failed endpoint comparison as a visible boundary.*
7. *D is the transport domain row, tying the witness to the candidate closed-projection boundary.*
8. *B is the bounded checker handoff row, exposing only finite comparison data to downstream deciders.*

9. *H records componentwise* hsame *transport for closed typed terms, candidate anchors, candidate evidence, endpoints, comparisons, obstructions, domain rows, bounded handoffs, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a MetaCIC normalization request through $T, A, K, N, E, O, D, B, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$, $\mathsf{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}}$ *row.*

The classifier compares accepted witnesses only through these rows. It has no coordinate for evidence-free normalization of arbitrary closed terms, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency.

Theorem 6577.2 (MetaCIC candidate normalization witness obligations)**.** *For every accepted* $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$ *carrier*

$$W = (T, A, K, N, E, O, D, B, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the closed typed term, candidate anchor, candidate evidence, normal endpoint, endpoint comparison, obstruction, transport domain, bounded checker handoff, transport, replay, provenance, and local naming rows;*
2. *candidate visibility, requiring every normal endpoint read to inspect A, K before N is consumed;*
3. *closed-type seal discipline, requiring T and D to be displayed before candidate evidence is projected as a closed-term witness;*
4. *bounded equality handoff, requiring E, B to expose only finite endpoint comparison data to checker consumers;*
5. *obstruction exactness, requiring O to retain missing candidate, missing closedness, blocked residual, and failed endpoint comparison boundaries rather than discharging them;*
6. *componentwise transport, displayed replay, package provenance, and local naming through H, C, P, L.*

No witness obligation is stored outside $T, A, K, N, E, O, D, B, H, C, P, L$.

Proof. Project the carrier of Definition 6577.1. The accepted packet exposes exactly the closed typed term, candidate anchor, candidate evidence, normal endpoint, endpoint comparison, obstruction, projection boundary, bounded checker handoff, and structural rows.

Candidate visibility is read through A, K, N. A normal endpoint is public only after the candidate anchor and candidate-evidence rows have been displayed.

Closed-type and projection discipline is read through T, D. These rows keep the witness attached to the sealed closed term and to the candidate closed-projection boundary before any endpoint comparison is offered.

The bounded comparison stage is E, B, with O retaining the negative boundary. Thus a checker receives finite endpoint comparison data and a visible obstruction row, not an evidence-free normalization theorem.

Finally H, C, P, L transport, replay, source, and name the same route. Since no carrier coordinate supplies global strong normalization, unrestricted subject reduction, full confluence, quotient

syntax equality, evaluator soundness, or closed consistency, the listed rows exhaust the local NameCert surface. □

Theorem 6577.3 (MetaCIC candidate normalization witness handoff)**.** *Every public normalization-frontier consumer of an accepted* $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$ *carrier factors through*

$$T \longmapsto A, K \longmapsto N, E \longmapsto O, D, B \longmapsto H, C, P, L.$$

The consumer receives a sealed closed typed term, candidate evidence, normal endpoint data, bounded endpoint comparison, retained obstruction, candidate projection boundary, bounded checker handoff, transport, replay, provenance, and local naming. It receives no normalization theorem for arbitrary closed typed terms without candidate evidence.

Proof. Start from the closed typed term row T. The only route from this row to a normal endpoint is through the candidate anchor and evidence rows A, K.

The endpoint and checker stage is N, E, B. It exports only bounded normal endpoint and comparison data, and the projection boundary row D keeps that export attached to the candidate-mediated closed-term surface.

The obstruction row O remains visible for missing candidate evidence, failed closedness, blocked residual obligations, or failed endpoint comparison. Therefore the handoff does not collapse into an unconditional strong-normalization theorem.

The structural rows H, C, P, L preserve and name the same finite witness. Because no excluded global endpoint has a carrier coordinate, every public consumer factors through the displayed route. □

Falsifiable prediction: Any $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$ read that reaches normal endpoint data or bounded endpoint comparison without exposing the closed typed term, candidate anchor, candidate evidence, projection boundary, bounded checker handoff, obstruction, transport, replay, provenance, and local naming rows is outside the carrier surface.

Independence witness: metacicnormalizationfrontier, boundednormalequalitychecker, closed-type-checker-seal, metacic-candidate-closed-projection-boundary: no listed sibling is bijective with $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$ because this packet jointly carries closed typed term data, candidate evidence, normal endpoint data, bounded endpoint comparison, obstruction, projection boundary, bounded checker handoff, transport, replay, provenance, and local NameCert rows.

Lean follow-up should provide Nontrivial and FieldFaithful instances in the MetaCICCandidateNormalizationWitnes TasteGate file so the closed-term, candidate, endpoint, obstruction, and checker rows are audited as distinct fields.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6577.1, Definition 6577.2, and Definition 6577.3 seed the finite candidate-witness route from sealed closed terms through candidate evidence, normal endpoints, bounded comparison, obstruction, projection boundary, checker handoff, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MetaCICCandidateNormalizationWitnessUp`

Bridge status: none

Not claimed: This chapter does not close evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate visibility, closed-type seal discipline, bounded equality handoff, obstruction exactness, transport stability, replay, provenance, local naming, Nontrivial, and FieldFaithful instances for BEDC.Derived.MetaCICCandidateNormalizationWitnessUp.

Constructive story: A MetaCICCandidateNormalizationWitness$^{\uparrow}$ packet is generated from a sealed closed typed term row, candidate anchor, candidate evidence, normal endpoint, endpoint comparison, obstruction, projection boundary row, bounded checker handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6578

A Concrete Naming Certificate for $\mathsf{ConvergenceFilter}^{\uparrow}$

Following Kelley and Bourbaki on filter convergence, the $\mathsf{ConvergenceFilter}^{\uparrow}$ packet records the standard neighbourhood-eventuality reading of a displayed filter base as finite BEDC NameCert data. It sits after the generated-base interface of chapter 1601, the neighbourhood-eventuality sibling of chapter 4133, the Cauchy-filter route of chapter 333, the finite-window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet gives Real and Completion consumers a convergence-facing handoff without quotient filters, selected limits, countable choice, host equality of filters, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6578.1 (Convergence filter carrier)**.** *A* $\mathsf{ConvergenceFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, Nb, x, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *row, carrying the finite base tokens, finite-intersection discipline, refinement witnesses, and displayed event rows.*
2. *Nb is the neighbourhood and eventuality row at the displayed point, recording which finite neighbourhood tokens are met by which base events.*
3. *x is the limit-point row, naming the candidate point only through the visible neighbourhood-eventuality surface.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when the convergence packet is sampled by completion-facing consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same displayed windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the filter-base, neighbourhood, limit-point, window, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for the filter base, neighbourhood row, limit-point row, StreamName windows, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from finite base events through neighbourhood eventuality, limit-point naming, windows, readback, and Real sealing.*

9. *P is the* Pkg *provenance over* ConvergenceFilter$^{\uparrow}$, FilterBase$^{\uparrow}$, CauchyFilter$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{ConvergenceFilter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, Nb, x, W, R, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, host equality of neighbourhood systems, host real equality, countable-choice schedules, or ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.ConvergenceFilterUp.ConvergenceFilterTasteGate single carrier alignment`

Theorem 6578.2 (Convergence filter NameCert obligations)**.** *For every accepted* ConvergenceFilter$^{\uparrow}$ *carrier $K = (F, Nb, x, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{ConvergenceFilter}^{\uparrow}}$ *surface consists exactly of filter-base exposure through F, neighbourhood-eventuality exposure through Nb, limit-point naming through x, StreamName window exposure through W, RegSeqRat readback through R, Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6578.1. The accepted packet exposes exactly the rows $F, Nb, x, W, R, E, H, C, P, N$.

The convergence-facing rows are upstream. Row F supplies finite filter-base data, and Nb records the neighbourhood-eventuality checks at the displayed point named by x.

The Nb row is read through the NeighborhoodFilter$^{\uparrow}$ route before the Cauchy-filter and Real-completion handoff, so the eventuality consumer receives the local neighbourhood filter surface rather than an unbounded host filter.

The completion-facing rows are downstream. Consumers read finite windows through W, regular rational readback through R, and the terminal Real seal through E only after the filter-base and neighbourhood rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since quotient filters, selected limits, host neighbourhood equality, host real equality, countable choice, and ambient Real completeness are absent from the classifier, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.ConvergenceFilterUp.ConvergenceFilterNamecertObligations`

Theorem 6578.3 (Convergence filter completion handoff)**.** *Every completion-facing read exported by an accepted* ConvergenceFilter$^{\uparrow}$ *carrier factors through the displayed* FilterBase$^{\uparrow}$ *row F, the neighbourhood-eventuality row Nb, the limit-point row x, the* StreamName$^{\uparrow}$ *row W, the* RegSeqRat$^{\uparrow}$ *row R, and the terminal* Real$^{\uparrow}$ *seal row E in that order. When the filter-base row is also read through the* CauchyFilter$^{\uparrow}$ *sibling surface, the handoff remains a finite neighbourhood convergence route and not a quotient-filter or selected-limit construction.*

Proof. Start with the NameCert obligations of Definition 6578.2. They force every accepted consumer to expose F, Nb, x, W, R, E before any structural row can name a completion-facing read.

The filter-base row is the only source for event data. Its finite refinement and intersection witnesses are read before Nb may certify eventual membership of displayed neighbourhood tokens at x.

The completion route is then fixed by the L10 readback rows. StreamName windows are exposed through W, the regular rational readback is exposed through R, and the Real-facing endpoint is sealed through E.

If the same base is consumed by a CauchyFilter sibling, the packet still exports only the rows already visible in $F, Nb, x, W, R, E, H, C, P, N$. Thus the route is stable under the Cauchy-filter handoff while excluding quotient filters, selected limits, choice schedules, host real equality, and ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{ConvergenceFilter}^{\uparrow}$ completion-facing read exposes a FilterBaseUp row, a neighbourhood-eventuality row at a displayed limit point, StreamNameUp windows, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before it can serve a Real or Completion consumer.

Independence witness: filterbase, cauchyfilter, streamname, regseqrat, real: none is bijective with $\mathsf{ConvergenceFilter}^{\uparrow}$ because this packet jointly carries the finite filter-base route, neighbourhood-eventuality checks, limit-point naming, finite windows, readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ConvergenceFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{ConvergenceFilter}^{\uparrow}$ packet is generated from a FilterBase row, a neighbourhood-eventuality row, a displayed limit-point row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvergenceFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6578.1, Definition 6578.2, and Definition 6578.3 seed the finite convergence-filter route over $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvergenceFilter}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.ConvergenceFilterUp`

Bridge status: none

Not claimed: This chapter does not close quotient filter equality, selected limits, countable choice, host equality of neighbourhood systems, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-base exposure, neighbourhood eventuality, limit-point naming, CauchyFilterUp handoff, StreamNameUp window exposure, RegSeqRatUp readback, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.ConvergenceFilterUp.

Chapter 6579

A Concrete Naming Certificate for $\mathsf{SetoidCompletion}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley-style uniform completion discipline, the $\mathsf{SetoidCompletion}^{\uparrow}$ packet separates completion data from the equality classifier of chapter 1820. The classifier supplied by $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ tells when two regular Cauchy names agree; the present packet records the completion-facing carrier, handoff, and naming surface that consumes $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the terminal $\mathsf{Real}^{\uparrow}$ seal, and the local $\mathsf{NameCert}$ row without collapsing the construction into quotient membership.

Definition 6579.1 (SetoidCompletion carrier)**.** *A* $\mathsf{SetoidCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, Q, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that lists the observation windows available to a completion request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare successive readbacks and requested precisions.*
4. *Q is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row, consumed as displayed comparison data rather than as quotient equality.*
5. *A is the completion-assembly row. It records admissible regular Cauchy handoff data over S, R, D, Q before the terminal real-name seal is inspected.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-boundary row reached by the assembled regular name.*
7. *H records componentwise* hsame *transport for $S, R, D, Q, A, E, C, P, N$.*
8. *C records displayed* Cont *replay from a completion-facing request through the same rows.*
9. *P is the* Pkg *provenance over* $\mathsf{SetoidCompletion}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SetoidCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient objects, selected representatives, selected limits, countable choice, ambient real completeness, host set extensionality, Lean verification, or bridge checking.

Theorem 6579.2 (SetoidCompletion NameCert obligations)**.** *For every accepted* $\mathsf{SetoidCompletion}^{\uparrow}$ *carrier* $K = (S, R, D, Q, A, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SetoidCompletion}^{\uparrow}}$ *surface is exhausted by the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular-rational readback row, dyadic tolerance ledger, setoid classifier row, completion-assembly row, Real seal row, transport, replay, provenance, and local naming;*
2. *window exactness, requiring every completion-facing observation to be one of the displayed windows in* S*;*
3. *readback exactness, requiring every rational value consumed by the completion route to pass through* R*;*
4. *tolerance exactness, requiring every comparison request to be discharged by an entry of* D *before the classifier row* Q *is read;*
5. *setoid-compatibility exactness, requiring* Q *to be consumed as the displayed* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *row and not as quotient equality;*
6. *assembly exactness, requiring the completion handoff row* A *to be built only from* S, R, D, Q *before the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is exposed;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* H, C, P, N*.*

No local certificate obligation is stored outside these rows.

Proof. Project the carrier of Definition 6579.1. The projection exposes the finite stream windows, regular-rational readback, dyadic tolerance ledger, setoid classifier row, completion-assembly row, Real seal boundary, and structural tail.

Read the NameCert row N against those projections. Window, readback, tolerance, classifier, and assembly exactness are separate rows, so the completion route cannot hide a quotient object or a selected representative inside the classifier.

Finally replay the route through H, C, P, N. Componentwise transport and Cont replay preserve the displayed packet, while provenance records the same sibling anchors. Since no carrier coordinate stores selected limits, countable choice, ambient completeness, or host set extensionality, the listed rows exhaust the local obligation surface. □

Theorem 6579.3 (SetoidCompletion regular Cauchy handoff)**.** *Every completion-facing read of an accepted* $\mathsf{SetoidCompletion}^{\uparrow}$ *carrier factors through the displayed regular Cauchy handoff*

$$S, R, D, Q, A \longmapsto E, H, C, P, N.$$

Thus the $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier, and completion-assembly row are visible before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The handoff is not a quotient completion, a selected Cauchy representative, a chosen limit, a countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier projection. A completion request first reads S, R, D as the finite observation, readback, and tolerance rows available to the regular Cauchy name.

Next consume the classifier row Q through the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ interface. The row supplies setoid-compatible comparison data, but it does not replace the displayed regular name by quotient equality or by a selected representative.

The assembly row A then packages the regular Cauchy handoff before the Real seal row E is inspected. Transport, replay, provenance, and local naming are supplied by H, C, P, N, so downstream completion consumers receive the same displayed route rather than an ambient completeness witness or a choice of limits. □

Closure status for $\mathsf{NameCert}_{\mathsf{SetoidCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SetoidCompletion}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyEquivalenceSetoid classifier row, a completion-assembly row, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SetoidCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6579.1, Definition 6579.2, and Definition 6579.3 seed the non-quotient completion carrier for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SetoidCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, setoid-compatible classifier consumption, regular Cauchy handoff exactness, componentwise transport, replay, provenance, and local naming for BEDC.Derived.SetoidCompletionUp.

Chapter 6580

A Concrete Naming Certificate for $\mathsf{FilterLimitCriterion}^{\uparrow}$

Following Kelley and Bourbaki on filter convergence, the $\mathsf{FilterLimitCriterion}^{\uparrow}$ packet records the finite criterion surface that lets a completion-facing consumer recognize when a displayed Cauchy filter and a displayed convergence filter name the same limit route. It sits after the filter-base carrier of chapter 1601, the Cauchy-filter row of chapter 333, the convergence-filter row of chapter 6578, the finite-window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet gives Real and Completion consumers a criterion object without quotient filters, selected limits, countable choice, host filter equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6580.1 (Filter limit criterion carrier)**.** *A* $\mathsf{FilterLimitCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, Nb, Cy, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *row, carrying finite base tokens, finite-intersection discipline, refinement witnesses, and event rows.*
2. *Nb is the neighbourhood-eventuality row inherited from the* $\mathsf{ConvergenceFilter}^{\uparrow}$ *surface, recording which displayed neighbourhood tokens are eventually met by the base.*
3. *Cy is the* $\mathsf{CauchyFilter}^{\uparrow}$ *criterion row, recording the finite pairwise closeness checks and Cauchy-facing event refinements on the same base.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row read by completion-facing consumers when the filter criterion is sampled.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those displayed windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the filter-base, neighbourhood, Cauchy, window, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for the filter-base row, neighbourhood-eventuality row, Cauchy row, StreamName windows, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from finite filter events through neighbourhood eventuality, Cauchy closeness, windows, readback, and Real sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{FilterLimitCriterion}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{ConvergenceFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FilterLimitCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, Nb, Cy, W, R, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, host equality of filters or neighbourhood systems, countable-choice schedules, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6580.2 (Filter limit criterion NameCert obligations)**.** *For every accepted* $\mathsf{FilterLimitCriterion}^{\uparrow}$ *carrier $K = (F, Nb, Cy, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FilterLimitCriterion}^{\uparrow}}$ *surface consists exactly of filter-base exposure through F, neighbourhood-eventuality exposure through Nb, Cauchy-filter criterion exposure through Cy, StreamName window exposure through W, RegSeqRat readback through R, Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6580.1. The accepted packet exposes exactly the rows $F, Nb, Cy, W, R, E, H, C, P, N$.

The filter-facing rows come first. Row F supplies finite base data, Nb records neighbourhood eventuality for the displayed convergence route, and Cy records the Cauchy-facing closeness checks on that same base.

The completion-facing rows are downstream. Consumers read finite windows through W, regular rational readback through R, and the terminal Real seal through E only after the filter-base, neighbourhood, and Cauchy rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since quotient filters, selected limits, host filter equality, host neighbourhood equality, countable choice, host real equality, and ambient Real completeness are absent from the classifier, the listed rows exhaust the local NameCert surface. □

Lean4 (statement) `BEDC.Derived.FilterLimitCriterionUp`

Theorem 6580.3 (Filter limit criterion Cauchy-filter handoff)**.** *Every completion-facing read exported by an accepted* $\mathsf{FilterLimitCriterion}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{FilterBase}^{\uparrow}$ *row F, the neighbourhood-eventuality row Nb, the* $\mathsf{CauchyFilter}^{\uparrow}$ *criterion row Cy, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E in that order. The handoff remains a finite criterion route from Cauchy-filter data to convergence-filter data and not a quotient-filter, selected-limit, countable-choice, or ambient-completeness construction.*

Proof. Start with the NameCert obligations of Definition 6580.2. They force every accepted consumer to expose F, Nb, Cy, W, R, E before any structural row can name a completion-facing read.

The shared base row is the only source for event data. Its finite refinement and intersection witnesses are read before Nb may certify eventual membership of displayed neighbourhood tokens and before Cy may certify the Cauchy-facing closeness checks.

The completion route is then fixed by the L10 readback rows. StreamName windows are exposed through W, regular rational readback through R, and the Real-facing endpoint is sealed through E.

Rows H, C, P, N keep the Cauchy-filter and convergence-filter readings on the same finite packet. Thus the criterion handoff is stable for completion consumers while excluding quotient filters, selected limits, choice schedules, host equality, and ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{FilterLimitCriterion}^{\uparrow}$ completion-facing read exposes a FilterBaseUp row, a neighbourhood-eventuality row, a CauchyFilterUp criterion row, StreamNameUp windows, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before it can serve a Real or Completion consumer.

Independence witness: filterbase, cauchyfilter, convergencefilter, streamname, regseqrat, real: none is bijective with $\mathsf{FilterLimitCriterion}^{\uparrow}$ because this packet jointly carries the finite filter-base route, neighbourhood-eventuality checks, Cauchy-filter criterion rows, finite windows, readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FilterLimitCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{FilterLimitCriterion}^{\uparrow}$ packet is generated from a FilterBase row, a neighbourhood-eventuality row, a CauchyFilter criterion row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FilterLimitCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6580.1, Definition 6580.2, and Definition 6580.3 seed the finite filter-limit criterion route over $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{ConvergenceFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FilterLimitCriterion}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.FilterLimitCriterionUp`

Bridge status: none

Not claimed: This chapter does not close quotient filter equality, selected limits, countable choice, host equality of filters or neighbourhood systems, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-base exposure, neighbourhood eventuality, Cauchy-filter criterion exposure, StreamNameUp window exposure, RegSeqRatUp readback, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FilterLimitCriterionUp.

Chapter 6581

RegularCauchyInterleavingStability NameCert Construction

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyInterleavingStability}^{\uparrow}$ packet isolates the finite stability surface for interleaved regular Cauchy names. It reads the regular rational rows of chapter 301, the finite stream schedules of chapter 126, the dyadic tolerance core of chapter 291, the interleaving carrier of chapter 414, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a named stability certificate between selected even–odd windows and the shared modulus ledger; it does not identify quotient reals, choose host limits, or invoke ambient completeness.

Definition 6581.1 (Regular Cauchy interleaving stability carrier)**.** *A* $\mathsf{RegularCauchyInterleavingStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, S_A, S_B, \sigma, M, W, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose finite regular Cauchy windows are interleaved.*
2. *S_A and S_B are the selected* $\mathsf{StreamName}^{\uparrow}$ *schedules for the even and odd sides.*
3. *σ is the alternating selector row inherited from the* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *carrier.*
4. *M is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *modulus ledger, carrying the matched dyadic budgets for selected even and odd requests.*
5. *W records the selected even and odd* $\mathsf{RegSeqRat}^{\uparrow}$ *windows after the schedules and shared modulus have been displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after $A, B, S_A, S_B, \sigma, M, W$ have been read.*
7. *H records componentwise* hsame *transport for the source rows, schedules, selector, shared modulus ledger, selected windows, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the same finite route.*
9. *P records the* Pkg *provenance over* $\mathsf{RegularCauchyInterleavingStability}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, S_A, S_B, \sigma, M, W, E, H, C, P, N$. It has no coordinate for quotient-real equality, selected host limits, ambient completeness, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingStabilityUp.RegularCauchyInterleavingStabilityTasteGate single carrier alignment`

Theorem 6581.2 (Regular Cauchy interleaving stability obligations)**.** *For every accepted* RegularCauchyInterleaving *carrier*

$$T = (A, B, S_A, S_B, \sigma, M, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingStability}^{\uparrow}}$ *surface is exhausted by five obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet $A, B, S_A, S_B, \sigma, M, W, E, H, C, P, N$;*
2. *selected-window stability: the even and odd rows in W are read from A and B through S_A, S_B, σ without changing the selected finite regular Cauchy windows;*
3. *shared-modulus exactness: every selected even or odd request uses the corresponding component of the single dyadic ledger M;*
4. *componentwise transport: H carries* hsame *transport for each displayed row and C replays the same finite route through* Cont*;*
5. *Real seal nonescape: E exports no quotient real, selected host limit, ambient completeness principle, or bridge-checked schema beyond the displayed rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingStabilityUp.RegularCauchyInterleavingStabilityCarrier obligations`

Theorem 6581.3 (Regular Cauchy interleaving stability classifier)**.** *Accepted* $\mathsf{RegularCauchyInterleavingStability}^{\uparrow}$ *packets classify together exactly when the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *windows and shared modulus rows transport componentwise through the displayed* hsame *and* Cont *routes. Equivalently, the classifier sees the same two source rows A, B, the same schedules S_A, S_B, the same alternating selector σ, the same shared dyadic ledger M, the same selected-window row W, and the same Real seal boundary E up to the displayed transport, replay, provenance, and local naming rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.RegularCauchyInterleavingStabilityUp.RegularCauchyInterleavingStabilityClassifier`

Falsifiable prediction: An accepted $\mathsf{RegularCauchyInterleavingStability}^{\uparrow}$ packet is refuted if a Real or Completion consumer reaches the seal row E without first displaying the even and odd $\mathsf{RegSeqRat}^{\uparrow}$ source rows, the two $\mathsf{StreamName}^{\uparrow}$ schedules, the alternating selector, the shared $\mathsf{DyadicRatCore}^{\uparrow}$ modulus ledger, the selected-window row, transport, replay, provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, regularcauchyinterleaving, real: none alone is bijective with $\mathsf{RegularCauchyInterleavingStability}^{\uparrow}$ because the packet jointly binds two regular rational sources, two selected schedules, one alternating selector, one shared dyadic modulus ledger, selected even and odd windows, one Real seal, componentwise transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingStability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyInterleavingStability}^{\uparrow}$ packet is generated from two RegSeqRat source rows, two StreamName schedules, an alternating selector, a shared DyadicRatCore modulus ledger, selected even and odd windows, a Real seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingStability}^{\uparrow}}$, seed)

Scope closed: Definition 6581.1, Definition 6581.2, and Definition 6581.3 seed the finite stability certificate for interleaved regular Cauchy names.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyInterleavingStability}\uparrow}$, unformalized)

Lean target: `BEDC.Derived.RegularCauchyInterleavingStabilityUp`

Bridge status: none

Not claimed: This chapter does not close quotient reals, selected host limits, ambient completeness, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, selected-window stability, shared-modulus exactness, componentwise transport, Real seal nonescape, and classifier transport for BEDC.Derived.RegularCauchyInterleavingStabilityUp.

Chapter 6582

A Concrete Naming Certificate for $\mathsf{LowerUpperRealSeparator}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LowerUpperRealSeparator}^{\uparrow}$ packet records the finite BEDC surface by which a lower-real ledger and an upper-real ledger are held apart by an explicit separator row. It reads the one-sided real carriers of chapter 1446 and chapter 1447, the cut interface of chapter 404, the located-real handoff of **??**, the stream window of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names only the constructive separator boundary; it does not assert trichotomy, quotient equality, selected suprema, countable choice, or host completeness.

Definition 6582.1 (LowerUpperRealSeparator carrier)**.** *A* $\mathsf{LowerUpperRealSeparator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (L, U, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LowerReal}^{\uparrow}$ *ledger, including the lower-set classifier, rational read rows, and displayed lower approximation evidence.*
2. *U is the* $\mathsf{UpperReal}^{\uparrow}$ *ledger, including the upper-set classifier, rational read rows, and displayed upper approximation evidence.*
3. *S is the separator row, recording the finite apartness or located-cut boundary that keeps accepted lower and upper reads in their declared order.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window through which consumers request finite readback precision.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the windowed request into regular rational comparison data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal naming the terminal real-facing route when the lower and upper evidence is exported together.*
7. *H records componentwise* hsame *transport for L, U, S, W, R, E and the structural rows.*
8. *C records displayed* Cont *replay of the route*
$$L, U, S \longmapsto W, R \longmapsto E.$$
9. *P is the* Pkg *provenance over* $\mathsf{LowerUpperRealSeparator}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerUpperRealSeparator}^{\uparrow}}$ *row.*

The classifier of the carrier compares accepted packets only through the displayed lower ledger, upper ledger, separator row, stream window, regular rational readback, Real seal, componentwise transport, continuation replay, provenance, and local naming row.

Theorem 6582.2 (LowerUpperRealSeparator NameCert obligations)**.** *For every accepted* LowerUpperRealSeparato *carrier*

$$G = (L, U, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LowerUpperRealSeparator}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the lower ledger, upper ledger, separator row, stream window, regular rational readback, Real seal, transport row, replay row, provenance row, and local naming row;*
2. *componentwise classifier compatibility, requiring accepted comparison to be read row by row from $L, U, S, W, R, E, H, C, P, N$;*
3. *lower/upper compatibility, requiring the separator row S to display the boundary by which lower and upper reads remain ordered under the same windowed request;*
4. *Real-route stability, requiring the terminal read through E to preserve the preceding* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows;*
5. *separator-ledger nonescape, requiring the provenance and local NameCert rows to source no trichotomy, quotient equality, selected supremum, countable-choice, or host-completeness coordinate.*

No separator obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 6582.1. The visible one-sided real coordinates are exactly the lower ledger L, the upper ledger U, the separator row S, the stream window W, the regular rational readback R, and the Real seal E.

Classifier compatibility is componentwise. A transported packet keeps each ledger on the same displayed field, and replay through C can only revisit the rows already named by L, U, S, W, R, E.

Lower/upper compatibility is supplied by the separator row. It is read after the one-sided ledgers and before the readback window, so a consumer cannot replace it by a host trichotomy decision or by an unlisted supremum selector.

Finally inspect P and N. Their source list contains only the displayed packet dependencies and local naming data. Since no coordinate stores quotient real equality, choice, selected suprema, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6582.3 (LowerUpperRealSeparator Real route)**.** *Every consumer route from an accepted* $\mathsf{LowerUpperRealSeparator}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

after reading the displayed lower ledger, upper ledger, and separator row. The route may export finite one-sided-real boundary data to $\mathsf{Real}^{\uparrow}$*, but it cannot expose trichotomy, quotient equality, selected suprema, countable choice, or host completeness.*

Proof. Begin with an accepted carrier $G = (L, U, S, W, R, E, H, C, P, N)$. The only route out of the one-sided ledgers first reads L and U, then the separator row S.

The consumer request is then windowed by W and read back by R. These rows give finite regular rational comparison data before any terminal Real-facing seal is available.

The Real export is the row E, transported by H and replayed by C. Because P and N name only this finite route, a consumer receives no trichotomy, quotient equality, selected supremum, countable-choice principle, or host-completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowerUpperRealSeparator}^{\uparrow}}$.

Constructive story: A $\mathsf{LowerUpperRealSeparator}^{\uparrow}$ packet is generated from lower and upper real ledgers, a separator row, finite StreamName windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerUpperRealSeparator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6582.1, Definition 6582.2, and Definition 6582.3 seed the one-sided-real separator boundary over displayed lower, upper, stream, readback, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerUpperRealSeparator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Cauchy completion, trichotomy, quotient equality, selected suprema, countable choice, host completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, componentwise classifier compatibility, lower/upper compatibility, Real-route stability, separator-ledger nonescape, and a Lean carrier surface for BEDC.Derived.LowerUpperRealSeparatorUp.

Chapter 6583

A Concrete Naming Certificate for KolmogorovRieszFiniteTranslation$^{\uparrow}$

Following Kolmogorov and Riesz, the KolmogorovRieszFiniteTranslation$^{\uparrow}$ packet records the finite translation-tightness surface used by compactness consumers before any ambient function-space compactness theorem is available. It sits between the Frechet–Kolmogorov compactness route of chapter 3846, the totally bounded metric surface of TotallyBoundedMetric$^{\uparrow}$, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite translation windows, finite norm-readback rows, and the handoff into Frechet compactness; it is not an unrestricted compact embedding theorem, a quotient function-space object, countable choice, selected subsequence data, or ambient Real$^{\uparrow}$ completeness.

Definition 6583.1 (Kolmogorov-Riesz finite translation carrier)**.** *A* KolmogorovRieszFiniteTranslation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, T, D, R, Q, B, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the function-family row read through the Frechet–Kolmogorov compactness sibling.*
2. *T is the finite translation-window row, listing the finitely many shifts and tolerances exposed to the present compactness request.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used to compare translation budgets, radius bounds, and finite-window refinements.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row for all rational norm estimates and translation differences.*
5. *Q is the* Real$^{\uparrow}$ *seal row reached by the displayed norm and distance reads.*
6. *B is the* TotallyBoundedMetric$^{\uparrow}$ *support row recording the finite metric net seen by the request.*
7. *E is the Frechet compactness handoff row; it packages F, T, D, R, Q, B as finite translation-tightness data.*
8. *H records componentwise* hsame *transport for the family, translation, tolerance, readback, Real seal, totally bounded, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a compactness-facing request through the same rows.*

10. *P is the* Pkg *provenance over* KolmogorovRieszFiniteTranslation$^{\uparrow}$, FrechetKolmogorovCompactness$^{\uparrow}$, TotallyBoundedMetric$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{KolmogorovRieszFiniteTranslation}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted function-space compactness, quotient equality of functions, countable choice, selected subsequences, selected cluster points, ambient measure theory, Lean verification, or bridge checking.

Lean4 (statement) `BEDC.Derived.KolmogorovRieszFiniteTranslationUp`

Theorem 6583.2 (Kolmogorov-Riesz finite translation NameCert obligations)**.** *For every accepted carrier $K = (F, T, D, R, Q, B, E, H, C, P, N)$ of Definition 6583.1, the local* NameCert$_{\text{KolmogorovRieszFiniteTranslation}^{\uparrow}}$ *surface is exhausted by the following finite obligation rows:*

1. *function-family admission through F, read beside the Frechet–Kolmogorov compactness sibling rather than through a host function space;*
2. *finite translation-window admission through T, requiring every shift and tolerance inspected by the consumer to be named in the displayed window;*
3. *dyadic tolerance and regular-rational readback exactness through D and R;*
4. *Real seal admission through Q for all displayed norm and distance values;*
5. *totally bounded metric support through B, exposing only finite net rows and their metric comparisons;*
6. *Frechet compactness handoff exactness through E;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No local obligation is stored outside these rows.

Proof. Project the carrier rows. The projection exposes the function-family row, finite translation-window row, dyadic tolerance ledger, regular rational readback, Real seal, totally bounded metric support, Frechet handoff, and structural tail.

Read the local NameCert row N against those projections. Translation tightness is checked only by the displayed finite shifts and tolerances in T, and all numerical comparisons pass through the dyadic, regular-rational, and Real rows D, R, Q.

Inspect the compactness-facing endpoint. The request can reach the totally bounded metric support B and then the handoff row E, but the carrier contains no unrestricted function-space compactness coordinate, quotient-function equality, countable-choice schedule, selected subsequence, or selected cluster point. Thus the listed rows exhaust the finite translation-tightness obligation surface. □

Theorem 6583.3 (Kolmogorov-Riesz handoff to Frechet compactness)**.** *Every compactness-facing read of an accepted* KolmogorovRieszFiniteTranslation$^{\uparrow}$ *carrier factors through the displayed route*

$$F, T, D, R, Q, B \longmapsto E, H, C, P, N.$$

The consumer receives a finite translation-tightness subcertificate and the corresponding Frechet compactness handoff, but receives no unrestricted compact embedding theorem, no quotient function-space object, no selected subsequence, no selected cluster point, and no ambient Real$^{\uparrow}$ *completeness claim.*

Proof. Begin with a compactness-facing request. It first reads the family row F and the finite translation-window row T, so the only shifts and tolerances available to the request are already displayed.

The numerical tests then pass through D, R, Q. These rows expose dyadic budgets, regular-rational readbacks, and Real seal values, while preserving the finite-window source of each comparison.

The request next reaches the totally bounded metric support B and the handoff row E. These rows present the finite translation-tightness packet to Frechet compactness consumers without adding an unrestricted compactness theorem or a chosen limiting object.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since no carrier coordinate stores quotient function-space equality, countable choice, a selected subsequence, or a selected cluster point, the exported handoff is exactly the finite subcertificate named above. □

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovRieszFiniteTranslation}^{\uparrow}}$.

Constructive story: A $\mathsf{KolmogorovRieszFiniteTranslation}^{\uparrow}$ packet is generated from a function-family row, finite translation windows, DyadicRatCore tolerance ledgers, RegSeqRat readbacks, Real seal rows, totally bounded metric support, Frechet compactness handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovRieszFiniteTranslation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6583.1, Definition 6583.2, and Definition 6583.3 seed the finite translation-tightness subcertificate consumed by Frechet compactness and Real-completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovRieszFiniteTranslation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted compact embedding, quotient function-space equality, countable choice, selected subsequences, selected cluster points, ambient measure theory, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite translation-window exactness, dyadic and regular-rational readback exactness, Real seal admission, totally bounded metric support, Frechet compactness handoff, transport, replay, provenance, and local naming for BEDC.Derived.KolmogorovRieszFiniteTranslationUp.

Chapter 6584

A Concrete Naming Certificate for $\mathsf{CauchyRegularExtraction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRegularExtraction}^{\uparrow}$ packet records the finite route by which ordinary Cauchy evidence is read as a regular rational sequence before a $\mathsf{Real}^{\uparrow}$ consumer sees a terminal seal. It sits over the Cauchy evidence surface of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite-window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet makes the extraction route explicit without quotient equality of Cauchy streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6584.1 (Cauchy regular extraction carrier)**.** *A* $\mathsf{CauchyRegularExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (C, D, W, R, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the ordinary* $\mathsf{Cauchy}^{\uparrow}$ *evidence row, carrying the displayed Cauchy comparisons and the source history being regularized.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic radii, comparison cells, slack rows, and endpoint observations used by the extraction.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the source Cauchy evidence and by each downstream precision request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerance data.*
5. *E is the extraction witness row, recording that the Cauchy comparisons, dyadic tolerances, and finite windows determine the displayed regular rational readback.*
6. *H records componentwise* hsame *transport for the Cauchy evidence, dyadic ledger, windows, regular readback, extraction witness, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay of the extraction route*

$$C, D, W \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchyRegularExtraction}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRegularExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, D, W, R, E, H, T, P, N$. It has no coordinate for quotient equality of Cauchy streams, a selected limit, countable-choice schedules, host real equality, a hidden completion operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyRegularExtractionUp`

Theorem 6584.2 (Cauchy regular extraction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRegularExtraction}^{\uparrow}$ *carrier*

$$X = (C, D, W, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRegularExtraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Cauchy evidence row, DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, extraction witness, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *Cauchy-to-window exactness, requiring every read of ordinary Cauchy evidence to pass through the displayed finite windows W and dyadic tolerance data D;*
3. *regular readback exactness, requiring R to read only the displayed C, D, W data and not an unbounded stream representative or quotient class;*
4. *extraction-witness stability, requiring E to bind the same Cauchy evidence, tolerance ledger, windows, and regular readback under the displayed transports;*
5. *downstream nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer to receive only $C, D, W, R, E, H, T, P, N$ and no selected limit, quotient equality, countable choice, host real equality, hidden completion operator, or ambient completeness claim.*

No $\mathsf{CauchyRegularExtraction}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 6584.1. The accepted packet displays exactly the ordinary Cauchy evidence, dyadic tolerance ledger, finite windows, regular readback, extraction witness, transport, replay, provenance, and local naming rows.

Cauchy-to-window exactness is read from C, D, W. The Cauchy evidence is visible only through the finite comparisons and tolerance cells recorded in the packet, so no consumer can inspect a hidden stream representative.

Regular readback exactness is the role of R. Since R is downstream of the displayed windows and dyadic ledger, it records the regular rational sequence as certificate data rather than as a quotient or selected limit.

The extraction witness E binds the same rows under the componentwise transport H and replay T. Thus the NameCert surface is stable under the displayed hsame and Cont data.

Finally, P and N source and name the same finite route. The excluded objects are absent from every accepted packet, so the listed rows exhaust the local NameCert obligations. □

Theorem 6584.3 (Cauchy regular extraction RegSeqRat readback)**.** *Let*

$$X = (C, D, W, R, E, H, T, P, N)$$

be an accepted $\mathsf{CauchyRegularExtraction}^{\uparrow}$ *carrier. Every regular rational read exported by X factors through the finite route*

$$C, D, W \longmapsto R \longmapsto E \longmapsto H, T, P, N.$$

Consequently a downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing consumer receives a displayed Cauchy evidence row, DyadicRatCore tolerance ledger, StreamName window row, RegSeqRat readback, extraction witness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data, and receives no quotient stream equality, selected limit, countable choice, host real equality, hidden completion operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness credential.*

Proof. Begin with a regular rational read of an accepted packet. Projection exposes the ordered carrier rows $C, D, W, R, E, H, T, P, N$.

The read starts at the ordinary Cauchy evidence row C. The dyadic tolerance ledger D and finite windows W are the only displayed observations available to the extraction route.

The regular rational sequence is then read from R. Because R is downstream of C, D, W, it cannot be replaced by quotient equality of streams, countable choice, or a selected limit.

The witness row E records that the same displayed observations determine the readback. The structural rows H, T, P, N transport, replay, source, and name that route.

Therefore every downstream read factors through the displayed packet and exports only the listed finite data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRegularExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRegularExtraction}^{\uparrow}$ packet is generated from ordinary Cauchy evidence, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, an extraction witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRegularExtraction}^{\uparrow}}$, seed)

Scope closed: Definition 6584.1, Definition 6584.2, and Definition 6584.3 seed the finite route from ordinary Cauchy evidence through dyadic tolerances and StreamName windows to RegSeqRat readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRegularExtraction}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.CauchyRegularExtractionUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality of Cauchy streams, selected limits, countable choice, host real equality, hidden completion operators, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-to-window exactness, regular readback exactness, extraction-witness stability, and downstream nonescape for BEDC.Derived.CauchyRegularExtractionUp.

Chapter 6585

A Concrete Naming Certificate for $\mathsf{ConvexCompactInterval}^{\uparrow}$

Following Bishop and Bridges' constructive analysis of intervals, and the Bourbaki treatment of convex compact subsets of the real line, the $\mathsf{ConvexCompactInterval}^{\uparrow}$ packet records the finite NameCert surface by which a closed bounded interval is read as a convex compact interval through located finite nets. It sits beside the closed interval carrier of chapter 1591, the located finite-net route of chapter 1808, the finite ϵ-net packet of chapter 1767, the compact metric carrier of chapter 129, the terminal real seal of chapter 38, the regular rational handoff of chapter 301, and the stream-window interface of chapter 126. The packet names the constructive compact-interval route only: it does not assert an open-cover Heine–Borel theorem, ambient completeness of $\mathsf{Real}^{\uparrow}$, quotient equality of interval names, selected suprema, or countable choice.

Definition 6585.1 (Convex compact interval carrier)**.** *A* $\mathsf{ConvexCompactInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, L, F, M, R, E, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source interval, including its endpoint ledger and closed containment classifier.*
2. *L is the* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *row that records located interval reads as finite observation windows.*
3. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *net row obtained from those located windows and the displayed tolerance ledger.*
4. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *consumer row, read as compact-metric finite-net data rather than as open-cover compactness.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that repacks the finite interval observations as regular rational data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the closed interval, located net, finite net, compact-metric row, and regular handoff have been displayed.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *request window through which endpoint, net, and tolerance reads are inspected.*
8. *H records componentwise* hsame *transport for I, L, F, M, R, E, W and the structural rows.*

9. *C records displayed* Cont *replay of the route*

$$I, W \longmapsto L, F \longmapsto M, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* ConvexCompactInterval$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, LocatedClosedIntervalFiniteNet$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, CompactMetric$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{ConvexCompactInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. No coordinate stores an open-cover compactness proof, ambient real completeness, quotient equality of interval names, a selected supremum, or a choice-selected point.

Lean4 (statement) BEDC.Derived.ConvexCompactIntervalUp

Theorem 6585.2 (Convex compact interval NameCert obligations)**.** *For every accepted* ConvexCompactInterval$^{\uparrow}$ *carrier $K = (I, L, F, M, R, E, W, H, C, P, N)$, the local* NameCert$_{\text{ConvexCompactInterval}^{\uparrow}}$ *surface is exhausted by the following finite rows:*

1. *carrier admission for the closed bounded interval, located finite-net row, finite ϵ-net row, compact-metric row, regular rational handoff, Real seal, stream window, transport, replay, provenance, and local naming;*
2. *convex interval source compatibility, requiring all convexity and endpoint reads to be inherited from the displayed* ClosedBoundedInterval$^{\uparrow}$ *row I;*
3. *located-net visibility, requiring every compactness-facing request to pass through W, L, F before the compact-metric row M is available;*
4. *Real-seal stability, requiring R and E to be downstream from the same finite interval and net rows;*
5. *ledger non-escape, requiring H, C, P, N to export no open-cover Heine–Borel principle, ambient* Real$^{\uparrow}$ *completeness, quotient equality of interval names, selected supremum, or countable-choice schedule.*

No local NameCert obligation is stored outside $I, L, F, M, R, E, W, H, C, P, N$.

Proof. Project the carrier of Definition 6585.1. The only analytic rows available are the closed bounded interval source, the located finite-net row, the finite net row, the compact-metric consumer row, the regular rational handoff, the Real seal, and the stream request window.

Convexity and endpoint discipline are inherited from I. The carrier has no second ambient real line or host interval equality, so a consumer cannot replace the closed interval source by an untracked convex set.

Located compactness is read through the finite route W, L, F, M. The request window exposes only finite endpoint, tolerance, and net observations before the compact-metric row is visible, so the route is finite-net compactness rather than open-cover compactness.

Finally, R, E, H, C, P, N preserve and name that same route. Since the carrier has no coordinate for ambient Real completeness, quotient equality, selected suprema, or countable choice, the displayed rows exhaust the local NameCert obligations. □

Theorem 6585.3 (Convex compact interval located-net route)**.** *Every* CompactMetric$^{\uparrow}$ *or* Real$^{\uparrow}$ *consumer of an accepted* ConvexCompactInterval$^{\uparrow}$ *packet receives the finite dependency route*

ClosedBoundedInterval$^{\uparrow}$, LocatedClosedIntervalFiniteNet$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, CompactMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, S

The route reads the closed interval source through located finite windows, repacks those windows as finite ϵ-net and regular rational data, and reaches the terminal Real seal only after the compact-metric row is displayed. It exports no open-cover Heine–Borel theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient interval equality, selected supremum, or countable-choice data.*

Proof. Begin with the carrier projection. The interval row I supplies the closed bounded source, while W gives the finite request window through which endpoints and tolerances are inspected.

Apply the located-net rows L and F. These rows convert the displayed window into located finite-net data and then into the finite ϵ-net surface consumed by M.

The regular and Real-facing rows are downstream. The handoff R repacks the same finite observations as regular rational data, and the seal E is available only after the preceding closed-interval, located-net, finite-net, and compact-metric rows have been read.

Transport, replay, provenance, and local naming preserve the same finite route. Since no excluded compactness, completeness, quotient, supremum, or choice coordinate occurs in K, the located-net route is exactly the dependency surface stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConvexCompactInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{ConvexCompactInterval}^{\uparrow}$ packet is generated from a closed bounded interval, located closed-interval finite-net rows, finite epsilon-net data, a compact-metric consumer row, RegSeqRat handoff, Real seal, StreamName window, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvexCompactInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6585.1, Definition 6585.2, and Definition 6585.3 seed the constructive convex compact interval route over closed interval, located finite-net, compact metric, regular rational, stream, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvexCompactInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover Heine–Borel compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient interval equality, selected suprema, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convex interval source compatibility, located-net visibility, Real-seal stability, ledger nonescape, and a Lean carrier surface for BEDC.Derived.ConvexCompactIntervalUp.

Chapter 6586

A Concrete Naming Certificate for $\mathsf{EffectiveSeparableMetric}^{\uparrow}$

Following Bishop-Bridges/Weihrauch-style computable-analysis practice, the $\mathsf{EffectiveSeparableMetric}^{\uparrow}$ packet records the finite BEDC surface by which a metric space is read with an explicit dense schedule and computable distance readback. It sits after the metric observation carrier of chapter 57, the Real separability route of chapter 1809, the finite window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet gives Real and Completion consumers a displayed dense witness without countable choice, quotient stream equality, selected representatives, host completeness, or an ambient separability theorem.

Definition 6586.1 (EffectiveSeparableMetric carrier)**.** *An* $\mathsf{EffectiveSeparableMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, D, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *distance-read ledger, carrying the displayed point rows and finite distance observations.*
2. *D is the dense schedule row, listing the finite approximation requests by which a consumer reads a named dense family.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which finite precision requests are made.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the metric comparisons attached to those windows.*
5. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, D, W, R have been exposed.*
6. *H records componentwise* hsame *transport for M, D, W, R, Q and the structural rows.*
7. *C records displayed* Cont *replay of the route*

$$M, D \longmapsto W, R \longmapsto Q.$$

8. *P is the* Pkg *provenance over* $\mathsf{EffectiveSeparableMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveSeparableMetric}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, D, W, R, Q, H, C, P, N$. It has no coordinate for host separability, choice-selected dense sequences, quotient stream equality, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6586.2 (EffectiveSeparableMetric NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveSeparableMetric}^{\uparrow}$ *carrier*

$$E = (M, D, W, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveSeparableMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric ledger M, dense schedule D, StreamName window W, RegSeqRat readback R, Real seal Q, transport row H, replay row C, provenance row P, and local naming row N; componentwise classifier compatibility for those rows; dense-schedule exposure through D before any separability read; metric readback through M, W, R, Q; and non-escape from host separability, choice-selected enumeration, quotient stream equality, selected representatives, and ambient completeness.*

Proof. Project the carrier of Definition 6586.1. The accepted packet exposes exactly the rows $M, D, W, R, Q, H, C, P, N$.

The dense witness is read through D before any Real-facing observation is available. The metric ledger M supplies only displayed point and distance observations, and the finite window row W fixes the precision at which those observations are sampled.

The numerical readback is then forced through R and the terminal Real seal Q. These rows provide regular rational comparisons and Real-facing sealing, but no quotient stream equality or selected representative.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since host separability, countable choice, selected dense sequences, quotient equality, selected representatives, and ambient completeness have no coordinate in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 6586.3 (EffectiveSeparableMetric L10 source handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{EffectiveSeparableMetric}^{\uparrow}$ *carrier factors through*

$$\mathsf{Met}^{\uparrow}, \mathsf{RealSeparability}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

in the displayed order. The handoff may export metric distance observations, an explicit dense schedule, finite StreamName windows, regular rational readback, and a Real seal, but it cannot export a host separability theorem, selected dense sequence, quotient stream equality, countable choice, or ambient completeness.

Proof. Start with the NameCert obligations of Definition 6586.2. They require the dense schedule and metric ledger to be visible before a consumer reads any windowed numerical data.

The L10 read then consumes StreamName windows through W and RegSeqRat readback through R. The Real seal Q is downstream of those finite rows, so a Real or Completion route receives scheduled metric data rather than an unstructured separability assertion.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Because the carrier lacks choice, quotient, representative-selection, and ambient-completeness coordinates, the handoff remains the finite source route stated above. □

Falsifiable prediction: Every accepted $\mathsf{EffectiveSeparableMetric}^{\uparrow}$ L10 read exposes a MetricUp ledger, an explicit dense schedule, StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before it can serve a Real or Completion consumer.

Independence witness: metric, real-separability, streamname, regseqrat, real: none is bijective with $\mathsf{EffectiveSeparableMetric}^{\uparrow}$ because this packet jointly carries the metric ledger, dense schedule, finite windows, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveSeparableMetric}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveSeparableMetric}^{\uparrow}$ packet is generated from a MetricUp ledger, an explicit dense schedule, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveSeparableMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6586.1, Definition 6586.2, and Definition 6586.3 seed the effective separable metric source route over $\mathsf{Met}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveSeparableMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full separability, countable choice, quotient stream equality, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-schedule exposure, metric readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveSeparableMetricUp.

Chapter 6587

A Concrete Naming Certificate for $\mathsf{BochnerIntegral}^{\uparrow}$

Following Bochner and Dunford–Schwartz, the $\mathsf{BochnerIntegral}^{\uparrow}$ packet records vector-valued integration as finite BEDC NameCert data over displayed measurable simple-function approximants and Banach norm Cauchy tails. It sits after the measure carrier of chapter 92, the simple-function approximation surface of chapter 5884, the measurable-function rows of chapter 3461, the public integral row of chapter 123, and the Banach endpoint carrier of chapter 90. The packet names the finite route by which a vector-valued integral readback is accepted; it does not import a host almost-everywhere quotient, a completed measure algebra, a selected representative, countable choice, or a global completeness theorem beyond the displayed Banach row.

Definition 6587.1 (Bochner integral carrier)**.** *A* $\mathsf{BochnerIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, X, Y, F, A, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row, including the measurable-event carrier, finite value ledger, null-boundary rows, and measure-facing classifier.*
2. *X is the measurable source-domain row recording the displayed domain carrier, measurable preimage tests, and source classifier rows consumed from* $\mathsf{MeasurableFunction}^{\uparrow}$*.*
3. *Y is the target* $\mathsf{Banach}^{\uparrow}$ *row, including the carried vector endpoints, norm metric, addition and scalar rows, and visible completion ledger.*
4. *F is the displayed vector-valued measurable-function row over X and Y.*
5. *A is the* $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ *row recording simple vector-valued approximants, measurable fibres, finite range data, and pointwise approximation windows.*
6. *R is the simple-integral readback row, reducing each approximant to finitely many scalar measure values and Banach vector sums before any limit is read.*
7. *Q is the Banach norm Cauchy-tail ledger for the simple-integral sequence, including the precision requests, tail bounds, and norm comparisons used by consumers.*
8. *H records componentwise* hsame *transport for M, X, Y, F, A, R, Q and the structural rows.*

9. *C records displayed* Cont *replay of the route*

$$M, X, Y, F \longmapsto A \longmapsto R \longmapsto Q.$$

10. *P is the* Pkg *provenance over* $\mathsf{BochnerIntegral}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{MeasurableFunction}^{\uparrow}$, $\mathsf{SimpleFunctionApproximation}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BochnerIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed measure row, measurable source row, Banach target row, measurable-function row, simple-function approximants, finite simple-integral readbacks, Banach Cauchy-tail ledger, transport, replay, provenance, and local naming row.

Theorem 6587.2 (Bochner integral NameCert obligations)**.** *For every accepted* $\mathsf{BochnerIntegral}^{\uparrow}$ *carrier*

$$J = (M, X, Y, F, A, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BochnerIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission, measurable source preservation, Banach target preservation, simple-function approximation stability, simple-integral readback exactness, Banach norm Cauchy-tail visibility, componentwise classifier transport, displayed continuation replay, provenance, and local naming through N.*

Proof. Project the carrier of Definition 6587.1. The analytic rows visible to the certificate are the measure row M, measurable source row X, Banach target row Y, measurable-function row F, approximation row A, simple-integral row R, and Cauchy-tail ledger Q.

Measurable source preservation follows through M, X, F. Every preimage or fibre read is tied to the displayed measurable source rows and the measure carrier; no host sigma-algebra completion or almost-everywhere quotient is introduced.

Approximation and readback preservation follow through A and R. The simple-function approximants have finite range and measurable fibre rows, and each simple integral is read as finitely many measure values and Banach vector sums before the tail ledger is consulted.

The limit-facing obligation is only the Banach norm Cauchy-tail row Q. It records the precision requests and norm comparisons needed for consumers to read the integral endpoint through Y, while H, C, P, N transport, replay, source, and name exactly those displayed rows. □

Theorem 6587.3 (Bochner integral simple-function limit route)**.** *Every* $\mathsf{BochnerIntegral}^{\uparrow}$ *consumer reads the vector-valued integral through the finite route*

$$\mathsf{Measure}^{\uparrow}, \mathsf{MeasurableFunction}^{\uparrow}, \mathsf{Banach}^{\uparrow} \longmapsto \mathsf{SimpleFunctionApproximation}^{\uparrow} \longmapsto \mathsf{Integral}^{\uparrow} \longmapsto \mathsf{BochnerIntegral}^{\uparrow}.$$

For a carrier $J = (M, X, Y, F, A, R, Q, H, C, P, N)$, the consumer must inspect the simple approximants in A, the finite simple-integral readbacks in R, and the Banach norm Cauchy-tail ledger Q before any integral endpoint is named. The route is a NameCert-level limit readback, not a quotient class of functions, a selected representative, or a choice-based convergence theorem.

Proof. Start with the measurable-function row F over the measure and source rows M, X and the target Banach row Y. These rows place the integrand inside the displayed measurable and normed carrier data already available to downstream consumers.

Use the simple-function approximation row A. It supplies finite-range approximants with measurable fibre rows, so each approximant can be reduced by R to finitely many scalar measure values and Banach vector sums.

The passage from approximants to the integral endpoint is then read only through Q. Its norm Cauchy-tail entries bind precision requests to Banach norm comparisons in Y, and the structural rows H, C, P, N preserve that same finite route under transport, replay, provenance, and local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{BochnerIntegral}\uparrow}$.

Constructive story: A $\mathsf{BochnerIntegral}^{\uparrow}$ packet is generated from displayed measure, measurable-function, Banach, simple-function approximation, simple-integral readback, Banach norm tail, transport, continuation, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BochnerIntegral}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6587.1, Definition 6587.2, and Definition 6587.3 seed the vector-valued integration NameCert surface through simple approximants and Banach norm Cauchy tails.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BochnerIntegral}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host almost-everywhere quotient equality, measure completion, selected representatives, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked simple-approximant, simple-integral, and Banach-tail obligations for BEDC.Derived.BochnerIntegralUp.

Chapter 6588

A Concrete Naming Certificate for $\mathsf{PettisMeasurability}^{\uparrow}$

Following Pettis and Dunford–Schwartz on weak and strong measurability for vector-valued functions, the $\mathsf{PettisMeasurability}^{\uparrow}$ packet records the finite BEDC route by which weak scalar measurability, separable-range inspection, and simple-function approximation windows are named before a strong-measurability consumer is admitted. It sits between the weak scalar integration surface of chapter 6638, the norm-approximant route of chapter 6587, the weak-integration boundary of chapter 8555, the measurable source rows of chapter 92, and the Banach endpoint carrier of chapter 90. The packet names a finite measurability bridge; it is not a measure-completion theorem, a quotient almost-everywhere equality, a selected representative, a countable-choice principle, or an ambient separability theorem.

Definition 6588.1 (Pettis measurability carrier)**.** *A* $\mathsf{PettisMeasurability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, X, W, S, A, B, D, R, H, C, Q, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row naming the finite measurable sets, null-window comparisons, and measurable-event family visible to the packet.*
2. *X is the* $\mathsf{Banach}^{\uparrow}$ *target row naming the displayed Banach carrier, norm windows, and finite vector observations.*
3. *W is the weak scalar measurability row, recording that each displayed bounded linear probe reads a scalar measurable shadow through M and X.*
4. *S is the separable-range inspection row, recording the finite dense-code windows and range-localization tests visible to the packet.*
5. *A is the simple-function approximation row, recording finite simple approximants, measurable fibres, and norm-error windows.*
6. *B is the* $\mathsf{BochnerIntegral}^{\uparrow}$ *handoff row, available only after A and the Banach norm windows have been displayed.*
7. *D is the* $\mathsf{DunfordIntegral}^{\uparrow}$ *handoff row, available only through the same weak scalar rows and finite probe windows.*

8. *R is the refusal row excluding host almost-everywhere representatives, quotient function equality, measure completion, countable choice, and ambient separability extraction.*
9. *H records componentwise* hsame *transport for M, X, W, S, A, B, D, R and the local structural rows.*
10. *C records displayed* Cont *replay from weak scalar measurability through separable-range inspection, simple approximation, integration handoffs, refusal, provenance, and naming.*
11. *Q is the* Pkg *provenance over* $\mathsf{PettisMeasurability}^{\uparrow}$, $\mathsf{PettisIntegral}^{\uparrow}$, $\mathsf{BochnerIntegral}^{\uparrow}$, $\mathsf{DunfordIntegral}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PettisMeasurability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for a completed measure algebra, quotient almost-everywhere equality, selected vector representative, countable-choice schedule, or ambient separability theorem.

Theorem 6588.2 (Pettis measurability NameCert obligations)**.** *For every accepted* $\mathsf{PettisMeasurability}^{\uparrow}$ *carrier*

$$P = (M, X, W, S, A, B, D, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PettisMeasurability}^{\uparrow}}$ *surface consists exactly of measure-source exposure through M, Banach endpoint exposure through X, weak scalar measurability through W, separable-range inspection through S, simple-function approximation through A, Bochner and Dunford handoff rows through B and D, refusal through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through Q, and local naming through N.*

Proof. Project the carrier of Definition 6588.1. Its displayed rows are precisely $M, X, W, S, A, B, D, R, H, C, Q, N$.

The analytic rows M, X, W, S, A fix the measurable source, Banach endpoint, weak scalar shadows, separable-range inspection, and simple-function approximation windows. Thus a strong-measurability-facing consumer sees the finite Pettis route before it can ask for a Bochner or Dunford handoff.

The handoff and structural rows preserve that route. The rows B, D are available only after the weak and approximation data are displayed, while R, H, C, Q, N refuse excluded endpoints, transport the same packet, replay the same route, record provenance, and name the local certificate. Since no further coordinate occurs in the carrier, these rows exhaust the NameCert surface. □

Theorem 6588.3 (Pettis measurability strong-window handoff)**.** *Every accepted* $\mathsf{BochnerIntegral}^{\uparrow}$ *or* $\mathsf{DunfordIntegral}^{\uparrow}$ *consumer that cites* $\mathsf{PettisMeasurability}^{\uparrow}$ *for a finite strong-measurability window must first read the route*

$$M, X, W, S, A \longmapsto B, D \longmapsto R, H, C, Q, N.$$

The route supplies weak scalar measurability, separable-range inspection, and simple-function approximation windows before any vector-valued integration handoff is public, and supplies no completed measure algebra, quotient almost-everywhere equality, selected representative, countable-choice schedule, or ambient separability theorem.

Proof. Begin with the NameCert obligations of Definition 6588.2. They place the measure row M, Banach row X, weak scalar row W, separable-range row S, and simple-approximation row A before either integration handoff can be consumed.

For a Bochner-facing read, use B. It is downstream from A and the displayed Banach norm windows, so it receives a finite strong-measurability window rather than a selected almost-everywhere representative.

For a Dunford-facing read, use D. It remains tied to the same weak scalar rows and finite probe windows, so it cannot manufacture a measure completion, quotient equality, countable-choice schedule, or ambient separability theorem.

Finally replay R, H, C, Q, N. These rows refuse the excluded endpoints and preserve the same packet under transport, continuation, provenance, and local naming. Hence the handoff is exactly the displayed finite route. □

Lean4 (statement) `BEDC.Derived.PettisMeasurabilityUp`

Falsifiable prediction: A vector-valued integration read that claims a finite strong-measurability window while bypassing the displayed $\mathsf{Measure}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, weak scalar measurability, separable-range inspection, simple-function approximation, $\mathsf{BochnerIntegral}^{\uparrow}$, $\mathsf{DunfordIntegral}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 6588.1.

Independence witness: pettis-integral, bochner-integral, dunford-integral, measure, banach: $\mathsf{PettisMeasurability}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries weak scalar measurability, separable-range inspection, simple-function approximation, integration handoffs, refusal, transport, replay, provenance, and local naming while refusing completed measure, quotient, representative-selection, countable-choice, and ambient separability endpoints.

Closure status for $\mathsf{NameCert}_{\mathsf{PettisMeasurability}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PettisMeasurability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6588.1, Definition 6588.2, and Definition 6588.3 seed the finite strong-measurability route over weak scalar rows, separable-range inspection, simple approximants, Bochner and Dunford handoffs, refusal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PettisMeasurability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed measure algebras, quotient almost-everywhere equality, selected vector representatives, countable choice, ambient separability theorems, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak scalar measurability exposure, separable-range inspection, simple-function approximation stability, integration handoff nonescape, refusal, transport, replay, provenance, and local naming for BEDC.Derived.PettisMeasurabilityUp.

Constructive story: A $\mathsf{PettisMeasurability}^{\uparrow}$ packet is generated from Measure, Banach, weak scalar measurability, separable-range inspection, simple-function approximation, Bochner and Dunford integration handoffs, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6589

A Concrete Naming Certificate for $\mathsf{SmithVolterraCantor}^{\uparrow}$

Following Smith and Volterra, the $\mathsf{SmithVolterraCantor}^{\uparrow}$ packet names the finite-prefix interval-removal presentation of a closed nowhere-dense set with positive remaining length. It is routed through the Cantor-style classifier of chapter 1895, the located closed interval rows of chapter 1709, and the dyadic schedule discipline of chapter 1812. The packet records only the finite stage data needed by constructive consumers: no Lebesgue measure completion, arbitrary open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is present.

Definition 6589.1 (Smith-Volterra-Cantor carrier)**.** *A* $\mathsf{SmithVolterraCantor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, R, D, L, C, G, T, H, P, N)$$

with the following displayed rows:

1. *I is the initial located interval row, naming the ambient closed interval as a* $\mathsf{LocatedRealInterval}^{\uparrow}$ *packet.*
2. *R is the finite removal ledger, listing a bounded family of middle intervals already removed at the inspected stage.*
3. *D is the dyadic schedule row, requiring every listed endpoint and every inspected gap width to be read through the same* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *schedule.*
4. *L is the located closed-set row, recording finite separation evidence for points outside the surviving interval family.*
5. *C is the Cantor classifier row, distinguishing survivor, removed-gap, and boundary reads without changing the dyadic schedule.*
6. *G is the finite gap-order row, recording disjointness and endpoint order for the removed intervals visible at the stage.*
7. *T records componentwise* hsame *transport for the interval, schedule, classifier, located-set, and gap rows.*
8. *H records displayed* Cont *replay from a consumer read to the same finite interval-removal route.*
9. *P is the* Pkg *provenance over* BHist*, located interval rows, dyadic schedule rows, classifier rows, transport, replay, and local naming.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SmithVolterraCantor}^{\uparrow}}$ *row.*
The carrier contains no coordinate for completed Lebesgue measure, countable complement enumeration, arbitrary open-cover compactness, or an ambient completeness proof for $\mathsf{Real}^{\uparrow}$.

Theorem 6589.2 (Smith-Volterra-Cantor NameCert obligations)**.** *For an accepted* $\mathsf{SmithVolterraCantor}^{\uparrow}$ *carrier*

$$S = (I, R, D, L, C, G, T, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SmithVolterraCantor}^{\uparrow}}$ *surface consists exactly of carrier admission for the initial located interval, finite removal ledger, dyadic schedule, located closed-set row, survivor classifier, gap-order ledger, componentwise transport, displayed replay, package provenance, and local naming. Any consumer of the packet must read those rows on the same finite route before using the Smith-Volterra-Cantor name.*

Proof. Project the accepted carrier. Rows I, R, D, L, C, G are the only mathematical data rows, so carrier admission exposes the located interval, removed intervals, dyadic schedule, located closed-set evidence, classifier, and finite gap order before the local name is read.

Transport and replay are row-local. The hsame row T preserves the interval-removal ledger componentwise, while H replays a consumer read to the same displayed route rather than to a completed complement or measure object.

Finally P and N provide provenance and local naming. Since the carrier has no measure-completion, arbitrary compactness, countable-choice, or ambient completeness coordinate, the NameCert obligations are exhausted by the displayed finite rows. □

Theorem 6589.3 (Smith-Volterra-Cantor located interval nonescape)**.** *Every accepted* $\mathsf{SmithVolterraCantor}^{\uparrow}$ *consumer that reads survivor membership, removed-gap membership, boundary membership, or local closed-set separation must keep the initial* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, the* $\mathsf{DyadicIntervalNesting}^{\uparrow}$ *schedule row, the finite removal ledger, and the classifier row on the same route*

$$S = (I, R, D, L, C, G, T, H, P, N).$$

The read cannot replace finite located interval evidence by Lebesgue measure completion, arbitrary open-cover compactness, selected complement enumeration, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the located interval row I and the dyadic schedule row D. They determine the inspected endpoints and finite stage widths before any survivor or gap classifier can be read.

Next attach the finite removal ledger R and the gap-order row G. These rows record exactly the removed middle intervals visible at the stage and keep disjointness and boundary order inside the same dyadic route.

The classifier row C and located closed-set row L then expose only survivor, removed-gap, boundary, and finite separation reads. Transport through T and replay through H preserve those rows, while P, N name the local packet. A consumer seeking measure completion, arbitrary compactness, selected complement enumeration, or Real completeness would need a coordinate absent from S. □

Falsifiable prediction: Every accepted $\mathsf{SmithVolterraCantor}^{\uparrow}$ read reaches a finite removal ledger row and a dyadic schedule row before it exports survivor, removed-gap, boundary, or located closed-set data.

Independence witness: cantorfunction, locatedrealinterval, dyadicintervalnesting: none is bijective to $\mathsf{SmithVolterraCantor}^{\uparrow}$ because this packet jointly carries a positive-length interval-removal

schedule, finite gap ledger, survivor classifier, located closed-set row, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{SmithVolterraCantor}\uparrow}$.

Constructive story: A $\mathsf{SmithVolterraCantor}^{\uparrow}$ packet is generated from a located initial interval, finite interval-removal ledger, dyadic endpoint schedule, located closed-set evidence, survivor classifier, finite gap-order ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SmithVolterraCantor}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6589.1, Definition 6589.2, and Definition 6589.3 seed the finite interval-removal NameCert packet for the Smith-Volterra-Cantor construction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SmithVolterraCantor}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lebesgue measure completion, arbitrary open-cover compactness, selected complement enumeration, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite removal-ledger exposure, located closed-set separation, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.SmithVolterraCantorUp.

Chapter 6590

A Concrete Naming Certificate for $\mathsf{MuckenhouptWeight}^{\uparrow}$

Following Muckenhoupt, Stein, and Grafakos, the $\mathsf{MuckenhouptWeight}^{\uparrow}$ packet records the finite A_p weight surface used by weighted maximal-function arguments. It sits after the maximal-function carrier of chapter 3581, the finite covering ledger of chapter 2166, the measure and regular-measure rows of chapter 92 and chapter 2263, and the real and dyadic readback surfaces of chapter 38 and chapter 291. The packet names the displayed local-average rows required to inspect an A_p window without importing a general weighted norm theorem, Lebesgue differentiation, choice-selected covers, or ambient measure completion.

Definition 6590.1 (Muckenhoupt weight carrier)**.** *A* $\mathsf{MuckenhouptWeight}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (X, M, R, Q, B, A, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric-source row, recording the carried points and the finite ball names read by the weight request.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *row, refined when needed through* $\mathsf{RadonMeasure}^{\uparrow}$ *regular finite-measure windows.*
3. *R is the positive-radius and dyadic-scale row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparisons for the inspected balls.*
4. *Q is the exponent row. It records the displayed p and conjugate-budget comparisons used by the A_p ledger.*
5. *B is the finite ball-window row, listing the balls on which weight and reciprocal-power averages are read.*
6. *A is the weight-average row. For every displayed ball it records the finite* $\mathsf{Real}^{\uparrow}$ *readback of the weight average.*
7. *D is the reciprocal-power average row, recording the finite readback needed for the conjugate side of the A_p test.*
8. *L is the A_p ledger row. It stores the finite comparison budget showing that the product of the displayed averages stays below the named local constant on each inspected ball.*

9. *E is the maximal-consumer boundary row, recording which* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *request may read the weight packet and which rows remain hidden from that consumer.*
10. *H records componentwise* hsame *transport for $X, M, R, Q, B, A, D, L, E, C, P, N$.*
11. *C records displayed* Cont *replay of the route*

$$\mathsf{Measure}^{\uparrow}, \mathsf{RadonMeasure}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto A, D, L \longmapsto \mathsf{MuckenhouptWeight}^{\uparrow}.$$

12. *P is the* Pkg *provenance over* $\mathsf{MuckenhouptWeight}^{\uparrow}$, $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$, $\mathsf{FiniteVitaliCover}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MuckenhouptWeight}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, R, Q, B, A, D, L, E, H, C, P, N$. It has no coordinate for a global weighted norm theorem, a Lebesgue differentiation theorem, a choice-selected cover, quotient function equality, or an ambient measure-completion object.

Theorem 6590.2 (Muckenhoupt weight NameCert obligations)**.** *For every accepted* $\mathsf{MuckenhouptWeight}^{\uparrow}$ *carrier*

$$W = (X, M, R, Q, B, A, D, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MuckenhouptWeight}^{\uparrow}}$ *surface consists exactly of carrier admission, measure and Radon-window visibility, dyadic radius comparison, exponent-budget visibility, ball-window coverage, weight-average readback, reciprocal-power average readback, A_p ledger comparison, maximal-consumer boundary exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6590.1. The source, measure, dyadic-radius, exponent, ball-window, average, reciprocal-average, ledger, and consumer-boundary rows are the only analytic rows visible to the local certificate.

Measure visibility is read through M and, for regular finite windows, through the $\mathsf{RadonMeasure}^{\uparrow}$ provenance in P. Radius and scale comparisons are read through R, so the local averages in A and D are attached to displayed finite ball windows rather than to a host family of balls.

The A_p obligation is exactly the ledger row L. It compares the displayed weight average and reciprocal-power average against the local bound named for the same ball window and exponent budget.

Finally E, H, C, P, N expose the maximal-consumer boundary, transport, replay, source, and local name for the same finite route. Since no coordinate stores a global weighted norm theorem, Lebesgue differentiation, a choice-selected cover, quotient function equality, or measure completion, the listed rows exhaust the NameCert surface. □

Theorem 6590.3 (Muckenhoupt weight maximal consumer boundary)**.** *Every* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *consumer of an accepted* $\mathsf{MuckenhouptWeight}^{\uparrow}$ *packet reads only the displayed finite rows $M, R, Q, B, A, D, L, E, H, C$. The consumer may inspect finite weighted averages, reciprocal-power averages, and the A_p comparison ledger on named ball windows, but it does not receive a general weighted norm theorem, a Lebesgue differentiation theorem, a choice-selected cover, quotient function equality, or ambient measure completion.*

Proof. Start with the boundary row E. It records the exact maximal-function request allowed to inspect the weight packet and points that request back to the same ball windows B, dyadic-radius row R, and measure row M.

The numerical data available to the consumer are the finite readbacks A and D together with the ledger L. These rows certify only the displayed A_p comparison on inspected balls, and the replay row C keeps the route inside $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readbacks.

The structural rows H, P, N transport, source, and name the same packet. Because the carrier lacks coordinates for norm inequalities, differentiation, selected covers, quotient equality, and measure completion, the maximal consumer boundary exports exactly the finite rows stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{MuckenhouptWeight}^{\uparrow}}$.

Constructive story: A $\mathsf{MuckenhouptWeight}^{\uparrow}$ packet is generated from metric source, measure, RadonMeasure, dyadic radius, exponent, ball-window, weight-average, reciprocal-average, Ap ledger, maximal-consumer boundary, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MuckenhouptWeight}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6590.1, Definition 6590.2, and Definition 6590.3 seed the finite A_p weight NameCert surface for maximal-function consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MuckenhouptWeight}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a general weighted norm theorem, Lebesgue differentiation, choice-selected covers, quotient function equality, ambient measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average readbacks, Ap ledger comparison, and maximal-consumer boundary for BEDC.Derived.MuckenhouptWeightUp.

Chapter 6591

A Concrete Naming Certificate for $\mathsf{KuratowskiConvergence}^{\uparrow}$

Following Kuratowski and Painleve–Kuratowski hyperspace convergence, the $\mathsf{KuratowskiConvergence}^{\uparrow}$ packet records finite BEDC convergence data for displayed closed-set sequences in a metric hyperspace. It sits over the metric source of chapter 57, the located-set source of chapter 1541, the projection boundary of chapter 2356, the compact metric hyperspace surface of chapter 5184, the Kuratowski hyperspace carrier of chapter 5944, and the hit–miss convergence route of chapter 3880. The packet names only displayed lower-hit, upper-miss, projection, and Real-seal rows; it does not quotient closed sets, select hyperspace representatives, invoke choice, or import ambient completeness.

Definition 6591.1 (Kuratowski convergence carrier)**.** *A* $\mathsf{KuratowskiConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, A, Q, H, R, L, U, W, E, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the finite distance observations used by all hit, miss, and projection reads.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *closed-set source row, naming each inspected set by located-radius observations rather than by a host powerset.*
3. *Q is the* $\mathsf{MetricProjection}^{\uparrow}$ *boundary row that supplies point-to-set distance and nearest-boundary evidence only through displayed projection data.*
4. *H is the* $\mathsf{CompactMetricHyperspace}^{\uparrow}$ *row carrying finite Hausdorff and Vietoris windows for compact hyperspace reads.*
5. *R is the* $\mathsf{KuratowskiHyperspace}^{\uparrow}$ *row that compares hyperspace and Kuratowski-profile classifiers through finite metric data.*
6. *L is the lower-hit ledger: each entry names a displayed source point, a finite stage window, and a tolerance row witnessing that the inspected closed-set sequence meets the requested neighborhood.*
7. *U is the upper-miss ledger: each entry names a finite cover or finite complement test witnessing that, beyond the displayed stage window, no inspected set escapes the requested metric neighborhood.*

8. *W is the* $\mathsf{PainleveKuratowskiConvergence}^{\uparrow}$ *hit–miss window row tying L and U to the sibling convergence classifier.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal row used by Real and completion consumers to read tolerances without quotienting closed sets.*
10. *T, C, P, N are respectively componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{KuratowskiConvergence}^{\uparrow}}$ *naming row.*

The carrier has no coordinate for an ambient powerset of closed subsets, quotient equality of closed sets, a selected limit set, countable choice, or an untracked hyperspace completion.

Theorem 6591.2 (Kuratowski convergence NameCert obligations)**.** *For every accepted* $\mathsf{KuratowskiConvergence}^{\uparrow}$ *carrier*

$$K = (M, A, Q, H, R, L, U, W, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KuratowskiConvergence}^{\uparrow}}$ *surface consists exactly of metric source admission, located-set admission, metric-projection boundary admission, compact metric hyperspace admission, Kuratowski hyperspace profile comparison, lower-hit ledger admission, upper-miss ledger admission, Painleve–Kuratowski hit–miss synchronization, Real and regular-rational tolerance sealing, componentwise transport, displayed replay, provenance, and local naming. Every convergence-facing consumer must read through these rows before it may inspect a limit claim.*

Proof. Project the carrier of Definition 6591.1. The metric source, located-set source, projection row, compact hyperspace row, Kuratowski profile row, lower ledger, upper ledger, hit–miss window, and Real seal are the only mathematical coordinates.

The lower-hit and upper-miss obligations are separate rows. A lower request reads a point, stage window, and tolerance from L; an upper request reads a finite cover or complement test from U. The synchronization row W is the only place where those two ledgers are compared.

The structural rows T, C, P, N preserve and name that same route. Since the carrier has no powerset, quotient, selected-limit, or choice coordinate, no local NameCert obligation can be stored outside the listed finite rows. □

Theorem 6591.3 (Kuratowski convergence metric hyperspace handoff)**.** *Every compact-hyperspace or projection-facing read exported by an accepted* $\mathsf{KuratowskiConvergence}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{LocatedSet}^{\uparrow}, \mathsf{MetricProjection}^{\uparrow}, \mathsf{CompactMetricHyperspace}^{\uparrow}, \mathsf{KuratowskiHyperspace}^{\uparrow}, \mathsf{PainleveKuratowskiConver}$$

The handoff exposes finite Hausdorff windows, Kuratowski-profile comparisons, and projection-distance rows before any Real or completion consumer reads the convergence packet. It exports no quotient closed-set equality, selected hyperspace representative, selected limit set, or ambient compactness theorem.

Proof. Begin with a compact-hyperspace read. The carrier forces the consumer to inspect the metric source M, located-set row A, projection boundary Q, compact hyperspace row H, and Kuratowski profile row R before the convergence windows L, U, W are available.

The lower-hit ledger and upper-miss ledger then provide the finite convergence evidence. Their comparison is read only through W, which is already tied to the sibling Painleve–Kuratowski hit–miss surface.

Finally the tolerance readback is sealed by E and replayed through T, C, P, N. Thus the handoff is a finite BEDC route through the named sibling anchors, not a route through quotient closed sets or host hyperspace objects. □

Theorem 6591.4 (Kuratowski convergence Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance read of an accepted* $\mathsf{KuratowskiConvergence}^{\uparrow}$ *carrier is downstream of the lower-hit ledger* L*, the upper-miss ledger* U*, and the hit–miss synchronization row* W*. The Real seal records only the displayed tolerance values used by those finite windows; it cannot be used to recover a host limit set, quotient equality of closed sets, countable-choice schedule, or ambient hyperspace completion.*

Proof. Read the Real-facing coordinate E. By Definition 6591.1, it is attached to the convergence packet only after the lower-hit and upper-miss ledgers have been displayed and synchronized.

Apply Definition 6591.2. The local naming surface sends every tolerance read through $M, A, Q, H, R, L, U, W, E$, so the Real row cannot be detached from the finite convergence evidence.

The nonescape claim follows from absence of carrier coordinates. There is no field for a selected closed-set limit, quotient equality, choice schedule, or ambient hyperspace completion, hence the Real seal can certify only the displayed tolerance route. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{KuratowskiConvergence}^{\uparrow}$ packet is generated from MetricUp source rows, LocatedSetUp closed-set rows, MetricProjectionUp distance-boundary rows, CompactMetricHyperspaceUp finite Hausdorff and Vietoris windows, KuratowskiHyperspaceUp profile comparison, PainleveKuratowskiConvergenceUp hit–miss synchronization, Real and RegSeqRat tolerance seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6591.1, Definition 6591.2, Definition 6591.3, and Definition 6591.4 seed the finite metric hyperspace convergence surface over displayed closed-set data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiConvergence}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of closed sets, host powersets, selected limit sets, countable choice, ambient hyperspace completion, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-hit coverage, upper-miss coverage, metric hyperspace handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KuratowskiConvergenceUp.

Lean4 (statement) `BEDC.Derived.KuratowskiConvergenceUp`

Chapter 6592

A Concrete Naming Certificate for $\mathsf{ChebyshevInequality}^{\uparrow}$

Following Chebyshev and Kolmogorov, the $\mathsf{ChebyshevInequality}^{\uparrow}$ packet records the finite probability tail-bound surface used before weak-law consumers read a variance-controlled estimate. It sits after the normalized event rows of chapter 184, the measurable random-variable surface of chapter 185, the finite measure ledger of chapter 6127, and the terminal real-name seal of chapter 38. It is the standalone tail-bound carrier consumed by chapter 4373, not a limit theorem, countable-choice selector, almost-sure convergence result, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6592.1 (Chebyshev inequality carrier)**.** *A* $\mathsf{ChebyshevInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (P, M, X, \mu, V, \epsilon, T, R, H, K, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row carrying the event classifier and total-mass normalization.*
2. *M is the* $\mathsf{FiniteMeasure}^{\uparrow}$ *measure row for the exceptional event and its complement inside the displayed probability source.*
3. *X is the* $\mathsf{RandomVar}^{\uparrow}$ *row whose finite observation windows are inspected over P.*
4. *μ is the displayed center row for the same random-variable surface.*
5. *V is the finite variance or second-moment bound row consumed by the tail estimate.*
6. *ϵ is the positive* $\mathsf{Real}^{\uparrow}$ *tolerance seal naming the requested separation from the center.*
7. *T is the displayed tail-event row, recording the event where the random-variable observation differs from μ by more than ϵ.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *probability-bound row reached only after $P, M, X, \mu, V, \epsilon, T$ have been displayed.*
9. *H stores componentwise* hsame *transport for the source, measure, random-variable, center, variance, tolerance, tail-event, probability-bound, replay, provenance, and local naming rows.*
10. *K records displayed* Cont *replay of the finite tail-bound route.*
11. *Q is the* Pkg *provenance over* $\mathsf{ChebyshevInequality}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{FiniteMeasure}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ChebyshevInequality}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $P, M, X, \mu, V, \epsilon, T, R, H, K, Q, N$. It has no coordinate for an infinite sequence of variables, almost-sure convergence, selected subsequence, central-limit normalization, host measure algebra, or ambient real completeness.

Theorem 6592.2 (Chebyshev inequality NameCert obligations)**.** *For every accepted* $\mathsf{ChebyshevInequality}^{\uparrow}$ *carrier* $C = (P, M, X, \mu, V, \epsilon, T, R, H, K, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ChebyshevInequality}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed probability source, finite-measure row, random-variable row, center row, variance-bound row, positive tolerance seal, tail-event row, probability-bound row, transport, replay, provenance, and local naming;*
2. *source and event stability, requiring M and T to remain attached to the event classifier displayed by P;*
3. *random-variable stability, requiring every tail-event read to consume the same* $\mathsf{RandomVar}^{\uparrow}$ *row X and center row μ;*
4. *variance-budget stability, requiring V to be displayed before the tail probability bound is read;*
5. *tolerance seal stability, requiring ϵ to be a displayed* $\mathsf{Real}^{\uparrow}$ *positive tolerance before T and R are consumed;*
6. *probability-bound nonescape, requiring R to seal only the displayed Chebyshev tail estimate and not an infinite-limit, selected-subsequence, host-measure, or ambient-completeness claim;*
7. *componentwise transport, displayed replay, package provenance, and local naming through H, K, Q, N.*

These obligations certify only the finite probability tail-bound route. They do not close a weak law, almost-sure convergence, a central limit theorem, countable choice, host probability limits, or Lean verification.

Proof. Project the carrier of Definition 6592.1. The accepted rows are exactly the probability source, finite-measure row, random-variable row, center row, variance-bound row, tolerance seal, tail-event row, probability-bound row, and the structural rows.

Source and event stability are read from P, M, T. The event classifier comes from P, the finite measure row M attaches measure data to that source, and T names only the displayed exceptional event.

Random-variable and variance-budget stability are read from X, μ, V. A tail estimate can be consumed only after the variable, center, and variance-bound rows have been displayed.

The endpoint R is downstream from the positive tolerance seal ϵ and from the tail-event row. Since the carrier has no coordinate for infinite limits, selected subsequences, host measure algebra, or ambient completeness, R cannot export any of those objects.

The rows H, K, Q, N preserve, replay, source, and name the same finite route. Hence the listed obligations exhaust the local NameCert surface. □

Theorem 6592.3 (Chebyshev tail-bound nonescape)**.** *Every accepted* $\mathsf{ChebyshevInequality}^{\uparrow}$ *tail-bound read factors through*

$$P \longmapsto M \longmapsto X \longmapsto \mu \longmapsto V \longmapsto \epsilon \longmapsto T \longmapsto R \longmapsto H, K, Q, N$$

before any downstream probability consumer receives the estimate. The route exposes a finite probability source, finite-measure event row, random-variable row, center, variance budget, positive tolerance, tail event, real probability bound, transport, replay, provenance, and local naming. It

cannot be replaced by a host law of large numbers, almost-sure convergence, central-limit normalization, countable-choice subsequence selection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a tail-bound request from an accepted carrier. Projection gives the source rows P, M and no independent host probability-space coordinate.

The request next reads X, μ, V, ϵ. These rows display the random variable, center, variance budget, and positive real tolerance before the exceptional event can be measured.

Only after those rows are visible can T and R be consumed as the finite Chebyshev tail estimate. The structural rows H, K, Q, N then transport, replay, package, and name the same route for downstream consumers.

Since every readable coordinate has already been listed, the route has no path to almost-sure convergence, a central-limit theorem, selected subsequences, host probability limits, or ambient real completeness. □

Falsifiable prediction: Every $\mathsf{ChebyshevInequality}^{\uparrow}$ tail-bound read factors through a ProbSpace source row, a FiniteMeasure event row, a RandomVar observation row, a displayed center, a variance-bound row, a positive Real tolerance, a tail-event row, a Real probability-bound row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: probspace, finite-measure, randomvar, real, weak-law-large-numbers: $\mathsf{ChebyshevInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a probability source, finite-measure event row, random-variable observation, center, variance budget, positive tolerance, tail event, probability-bound seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ChebyshevInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{ChebyshevInequality}^{\uparrow}$ packet is generated from a probability source row, a finite-measure event row, a random-variable row, a displayed center, a variance or second-moment bound row, a positive RealUp tolerance, a tail-event row, a RealUp probability-bound row, componentwise hsame transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChebyshevInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6592.1, Definition 6592.2, and Definition 6592.3 seed the finite probability tail-bound route through ProbSpace, FiniteMeasure, RandomVar, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChebyshevInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close weak laws, almost-sure convergence, central-limit normalization, countable-choice subsequence selection, host probability limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and event stability, random-variable stability, variance-budget stability, tolerance seal stability, probability-bound nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ChebyshevInequalityUp.

Chapter 6593

A Concrete Naming Certificate for $\mathsf{CauchyStabilityModulus}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy moduli, the $\mathsf{CauchyStabilityModulus}^{\uparrow}$ packet records the finite tolerance-window object that lets Real and completion consumers reuse one displayed Cauchy stability route. It sits over the Cauchy evidence surface of chapter 3413, the finite observation spine of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite stability modulus; it is not quotient equality of Cauchy streams, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6593.1 (Cauchy stability modulus carrier)**.** *A* $\mathsf{CauchyStabilityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (C, D, R, W, H, T, P, N)$$

with the following displayed rows:

1. *C is the Cauchy source row, carrying the finite comparison data and the source history whose stability is being read.*
2. *D is the dyadic tolerance row, recording the displayed tolerance request and any smaller tolerance admitted by the same packet.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window row that turns the Cauchy comparison into regular rational readback at the requested tolerance.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row naming the finite stream windows inspected by R.*
5. *H records componentwise* hsame *transport for the Cauchy source, dyadic tolerance, regular window, stream observation, replay, provenance, and local naming rows.*
6. *T records displayed* Cont *replay from the tolerance request through Cauchy comparison, finite stream windows, and regular rational readback.*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyStabilityModulus}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyStabilityModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through C, D, R, W, H, T, P, N. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, hidden completion operators, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyStabilityModulusUp`

Theorem 6593.2 (Cauchy stability modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyStabilityModulus}^{\uparrow}$ *carrier*

$$S = (C, D, R, W, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyStabilityModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy source exposure, dyadic tolerance admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window readback,* $\mathsf{StreamName}^{\uparrow}$ *observation replay, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for quotient stream equality, selected limits, countable choice, host real equality, hidden completion operators, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6593.1. The accepted packet exposes exactly the Cauchy source row, dyadic tolerance row, regular rational finite-window row, stream observation row, transport, replay, provenance, and local naming.

The classifier reads tolerance data only through D. The Cauchy source row C supplies the comparison evidence, while R and W record the finite regular-rational and stream-window observations made at that tolerance.

The rows H and T preserve the same route under transport and replay. Provenance and local naming are then supplied by P and N.

Since the carrier has no additional coordinate, no accepted read can import quotient stream equality, selected limits, countable choice, host real equality, hidden completion operators, or ambient completeness. □

Theorem 6593.3 (Cauchy stability modulus finite-window stability)**.** *Let* $S = (C, D, R, W, H, T, P, N)$ *be an accepted* $\mathsf{CauchyStabilityModulus}^{\uparrow}$ *carrier. If* D' *is a displayed dyadic tolerance row obtained by shrinking the tolerance named by* D*, and the same Cauchy source row* C *supplies the comparison witnesses needed for* D' *through the transported finite windows* R, W, H*, then the packet accepts the corresponding finite-window Cauchy stability read. The accepted read remains inside* C, D', R, W, H, T, P, N *and exports no quotient stream equality, selected limit, countable choice, host real equality, hidden completion operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with the accepted carrier and replace only the dyadic tolerance row by the displayed smaller row D'. The source Cauchy row C is unchanged, so the comparison witnesses still come from the same finite packet.

The rows R and W are read at the transported finite windows. Componentwise hsame transport in H keeps the regular rational readback and stream observations attached to the same Cauchy source while the tolerance is refined.

The replay row T then repeats the tolerance-to-window route for D'. Provenance and local naming through P, N identify this as the same $\mathsf{CauchyStabilityModulus}^{\uparrow}$ certificate surface.

Thus shrinking a displayed dyadic tolerance preserves accepted finite-window stability, and all excluded completion or quotient data remain outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyStabilityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyStabilityModulus}^{\uparrow}$ packet is generated from Cauchy source rows, dyadic tolerance rows, RegSeqRat finite-window rows, StreamName observation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyStabilityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6593.1, Definition 6593.2, and Definition 6593.3 seed the finite tolerance-window stability route for Cauchy, RegSeqRat, StreamName, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyStabilityModulus}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.CauchyStabilityModulusUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality of Cauchy streams, selected limits, countable choice, host real equality, hidden completion operators, ambient $\mathrm{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, tolerance-shrink stability, replay exactness, provenance, and ledger nonescape for BEDC.Derived.CauchyStabilityModulusUp.

Chapter 6594

A Concrete Naming Certificate for $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, a regular Cauchy name carries its own visible rate of stability rather than asking the ambient real line to choose a limit. The $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$ packet specializes the finite tolerance-window route of chapter 6593 to regular rational names. It reads the $\mathsf{StreamName}^{\uparrow}$ finite windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance-shrink ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seal as displayed rows of one local NameCert object.

Definition 6594.1 (Regular Cauchy stability modulus carrier)**.** *A* $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (C, S, R, D, E, H, T, P, N)$$

with the following rows:

1. *C is the* $\mathsf{CauchyStabilityModulus}^{\uparrow}$ *source row, naming the finite stability-modulus data being reused.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row of finite observation windows inspected by the stability read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that interprets those windows as a regular rational Cauchy name.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-shrink row, recording the displayed move from a requested tolerance to a smaller admitted tolerance.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular Cauchy window has been read.*
6. *H records componentwise* hsame *transport for the source modulus, stream windows, regular rational readback, dyadic tolerance, real seal, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay from the source modulus through the finite windows, regular rational readback, dyadic shrink, and terminal seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$, $\mathsf{CauchyStabilityModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyStabilityModulus}^{\uparrow}}$ *row.*

The classifier compares packets only through $C, S, R, D, E, H, T, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6594.2 (Regular Cauchy stability modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$ *carrier*

$$M = (C, S, R, D, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyStabilityModulus}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{CauchyStabilityModulus}^{\uparrow}$ *source exposure,* $\mathsf{StreamName}^{\uparrow}$ *finite-window coverage,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-shrink compatibility, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every refused endpoint remains outside the carrier: quotient streams, selected limits, countable choice, trichotomy, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6594.1. The accepted packet exposes the source stability modulus C, the finite windows S, the regular rational readback R, the dyadic shrink row D, and the terminal real seal E before any structural rows are read.

The source row is the already named $\mathsf{CauchyStabilityModulus}^{\uparrow}$ route of Definition 6593.2. The specialization to regular Cauchy data is exactly the requirement that S and R are displayed before D shrinks the tolerance and before E seals the real-facing read.

The transport row H and replay row T preserve the same finite path under componentwise equality and continuity replay. The provenance row P and local name row N then package the displayed route as a local NameCert surface.

Since no carrier coordinate records a quotient stream, selected limit, countable choice schedule, trichotomy test, host real equality, or ambient completeness principle, no accepted read can export any of those endpoints. □

Theorem 6594.3 (Regular Cauchy stability modulus Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$ *packet must first read the source* $\mathsf{CauchyStabilityModulus}^{\uparrow}$ *row, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-shrink row before the terminal seal E is available. The handoff to* $\mathsf{Real}^{\uparrow}$ *is therefore the finite route*

$$\mathsf{CauchyStabilityModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

transported by hsame*, replayed by* Cont*, and named by P, N.*

Proof. Start with the accepted carrier $M = (C, S, R, D, E, H, T, P, N)$. A consumer that reads E must have already projected the preceding rows, because the seal row is part of the same displayed finite packet and has no independent entry point.

The rows S and R make the regular Cauchy read finite-windowed. The row D records the dyadic tolerance shrink needed before the regular rational read can be sealed as a real-facing stability read.

Componentwise transport and displayed replay are supplied by H and T. Provenance and local naming through P, N identify the route as a $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$ handoff rather than a host real equality or ambient completeness argument. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyStabilityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyStabilityModulus}^{\uparrow}$ packet is generated from a CauchyStabilityModulus source, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance shrink, Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyStabilityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6594.1, Definition 6594.2, and Definition 6594.3 seed the regular-Cauchy stability-modulus route from finite windows to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyStabilityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, axiom audit, or bridge checking.

Upgrade path: Obligation closure requires a Lean carrier and checked NameCert obligations for source exposure, finite-window readback, dyadic tolerance shrink, seal handoff, transport, replay, provenance, and ledger refusal.

Chapter 6595

A Concrete Naming Certificate for $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$

Following the Poincare disk model and the Denjoy–Wolff boundary principle, the $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ packet records boundary-fixed disk transport as finite NameCert data. It realizes the boundary-fixed disk transport schema of Definition 9463.10 through the isometry rows of chapter 5159, the boundary refusal rows of chapter 6142, and the ray-boundary rows of chapter 6470. The packet names a finite disk-map and boundary-transport carrier; it is not a completed hyperbolic plane, a selected ideal endpoint, quotient boundary equality, or a global dynamical theorem.

Definition 6595.1 (Hyperbolic boundary transport carrier)**.** *A* $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, F, R, P, H, T, M, N)$$

with the following displayed rows:

1. *D is the finite disk-map row, recording the displayed source and target disk observations and the map applied between them.*
2. *F is the boundary far-end row, recording the boundary commitment preserved by the transport.*
3. *R is the reversible transport row, recording the displayed inverse route and the finite two-sided replay checks.*
4. *P is the provenance row over the Poincare disk, Denjoy–Wolff boundary reading,* $\mathsf{HyperbolicIsometryGroup}^{\uparrow}$, $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
5. *H records componentwise* hsame *transport for disk maps, boundary far-end rows, reversible transport, provenance, metric noncollapse, replay, and local naming.*
6. *T records displayed* Cont *replay from disk-map inspection through boundary preservation, reversible transport, metric noncollapse, provenance, and local naming.*
7. *M is the metric noncollapse row, refusing any read that turns boundary-fixed transport into an interior-center fixed point or a collapsed zero-distance transport.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryTransport}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, F, R, P, H, T, M, N. It has no coordinate for a completed disk, selected ideal endpoint, quotient boundary equality, hidden global hyperbolic metric, or physical observer law.

Lean4 (definition) `BEDC.Derived.HyperbolicBoundaryTransportUp`

Theorem 6595.2 (Hyperbolic boundary transport NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ *carrier*

$$B = (D, F, R, P, H, T, M, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryTransport}^{\uparrow}}$ *surface consists exactly of finite disk-map admission, boundary far-end preservation, reversible transport replay, provenance, componentwise* hsame *transport, displayed* Cont *replay, metric noncollapse, local naming, and refusal of completed hyperbolic planes, selected ideal endpoints, quotient boundary equality, hidden global metrics, and physical observer laws.*

Lean4 ✓ `BEDC.Derived.HyperbolicBoundaryTransportUp.HyperbolicBoundaryTransportTasteGate single carrier alignment`

Proof. Project the carrier of Definition 6595.1. The disk-map row D, boundary row F, reversible transport row R, provenance row P, transport row H, replay row T, metric noncollapse row M, and naming row N are the whole accepted packet.

Boundary preservation is read from F after the disk-map row D has been displayed. Reversibility is read from R and replayed through T, so the consumer sees finite two-sided route data rather than a host global transformation.

Metric noncollapse is the row M. It keeps the boundary-fixed route from becoming an interior-center fixed point or a collapsed metric read.

Finally, P, H, T, N source, transport, replay, and name the same finite surface. Since the excluded objects are absent from every carrier coordinate, they cannot enter the local NameCert obligations. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ read is refuted if it exports boundary-fixed transport without the disk-map row, boundary far-end row, reversible transport row, metric noncollapse row, hsame transport, Cont replay, provenance, and local NameCert row.

Independence witness: hyperbolic_isometry_group, boundary_far_end_noncenter, gromov_boundary: the isometry sibling carries group and metric-preservation rows, the noncenter sibling carries boundary refusal rows, and the Gromov-boundary sibling carries ray-boundary rows, but only $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ binds disk map, fixed boundary far end, reversible transport, provenance, noncollapse, replay, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryTransport}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ packet is generated from disk-map rows, boundary far-end rows, reversible transport rows, provenance, componentwise hsame transport, displayed Cont replay, metric noncollapse rows, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryTransport}^{\uparrow}}$, seed)

Scope closed: Definition 6595.1, Definition 6595.2, the falsifiable prediction, and the independence witness seed the finite boundary-fixed disk transport route over disk-map, boundary, reversible transport, provenance, noncollapse, replay, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryTransport}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.HyperbolicBoundaryTransportUp.HyperbolicBoundaryTransportTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic planes, selected ideal endpoints, quotient boundary equality, hidden global hyperbolic metrics, physical observer laws, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-map admission, boundary preservation, reversible transport replay, provenance, metric noncollapse, transport, replay, and local naming for BEDC.Derived.HyperbolicBoundaryTransportUp.

Chapter 6596

A Concrete Naming Certificate for $\mathsf{EffectiveCompactness}^{\uparrow}$

Following Bishop and Bridges on constructive compactness, the $\mathsf{EffectiveCompactness}^{\uparrow}$ packet records compactness by displayed finite ε-nets and located metric coverage rather than by an ambient open-cover principle. It sits over the compact metric source of chapter 129, the total-bounded schedule of chapter 127, the metric carrier of chapter 57, and the rational tolerance rows of chapter 37. The packet isolates the finite-net compactness object used by the compact-uniform-continuity route of chapter 9237: a consumer receives located finite nets, rational tolerance bookkeeping, and a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff, not a selected open subcover, quotient point equality, countable choice, or ambient completeness theorem.

Definition 6596.1 (Effective compactness carrier)**.** *An* $\mathsf{EffectiveCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, T, F, L, R, Q, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing only the distance comparisons and located balls admitted by the named metric carrier.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *schedule row, assigning a finite-net request to each positive rational tolerance.*
3. *F is the finite center bundle returned by the schedule for the current tolerance request.*
4. *L is the located coverage row, recording for each inspected point the displayed center and metric comparison witnessing membership in the requested ball.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *tolerance ledger, carrying positivity, halving, slack, and comparison rows used by the finite-net read.*
6. *Q is the compact metric provenance row tying M, T, F, L, R to the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source.*
7. *U is the tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row consumed by compact-uniform-continuity arguments after the finite-net coverage has been displayed.*
8. *H records componentwise* hsame *transport for M, T, F, L, R, Q, U.*
9. *C records displayed* Cont *replay from a tolerance request through the finite-net schedule, located coverage row, rational comparison ledger, and uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{EffectiveCompactness}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCompactness}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open-cover compactness, selected subcovers outside F, quotient equality of points, countable choice, host completeness, or an external modulus selector.

Theorem 6596.2 (Effective compactness NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveCompactness}^{\uparrow}$ *carrier*

$$E = (M, T, F, L, R, Q, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCompactness}^{\uparrow}}$ *surface consists exactly of metric-source exposure, total-bounded schedule exposure, finite center-bundle admission, located coverage readback, rational tolerance comparison, compact-metric provenance, tolerance-only uniform-modulus handoff, componentwise transport, displayed replay, package provenance, and local naming. Every compactness-facing read must pass through the displayed finite-net rows T, F, L, R before it may consume the handoff row U.*

Proof. Project the carrier of Definition 6596.1. Its visible rows are exactly the metric source, total-bounded schedule, finite center bundle, located coverage row, rational tolerance ledger, compact-metric provenance, uniform-modulus handoff, and structural rows.

Finite-net exposure is supplied by T, F, L, R. The schedule row T receives the rational tolerance, the finite bundle F lists the centers, the located row L records coverage, and the rational ledger R records the positive slack and comparisons used by that read.

The compact source and downstream handoff are confined to Q and U. The row Q ties the read to the compact metric source, and U exposes only the tolerance-only modulus output available after the finite-net rows have been displayed.

Transport, replay, provenance, and naming are supplied by H, C, P, N. Since none of the excluded open-cover, choice, quotient, completeness, or external-selector objects occurs in the packet, the displayed rows exhaust the local certificate surface. □

Theorem 6596.3 (Effective compactness finite-net modulus)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{EffectiveCompactness}^{\uparrow}$ *carrier obtains its tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *row through the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{TotallyBounded}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

Concretely, the consumer first reads the metric source row M, the finite-net schedule T, the center bundle F, the located coverage row L, the rational tolerance ledger R, and the compact-metric provenance row Q before it may use the modulus handoff U. The route exports no open-cover compactness, selected subcover outside the bundle, quotient point equality, countable choice, host completeness, or external modulus selector.

Proof. Start with an accepted carrier $E = (M, T, F, L, R, Q, U, H, C, P, N)$. The only metric-facing source is M, and the only finite-net schedule is T.

Read the finite-net data. The center bundle F is produced for the requested tolerance, the located coverage row L records the displayed metric comparisons, and R carries the rational slack needed to compare the requested tolerance with the finite coverage radius.

The compact-metric provenance row Q ties those rows to the compact metric source used in the route of chapter 9237. Only after that finite coverage read is displayed does the handoff row U expose the tolerance-only uniform-modulus datum.

The structural rows H, C, P, N preserve, replay, source, and name the same packet. Because the carrier contains no open-cover, selected-subcover, quotient, countable-choice, completeness, or external-selector coordinate, the finite-net route is the whole modulus-facing export. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCompactness}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveCompactness}^{\uparrow}$ packet is generated from a MetricUp source row, a TotallyBoundedUp finite-net schedule, a finite center bundle, located coverage rows, RatUp tolerance comparisons, CompactMetricUp provenance, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6596.1, Definition 6596.2, and Definition 6596.3 seed the explicit finite-net compactness object consumed by compact-uniform-continuity routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, selected subcovers outside the displayed finite bundle, quotient point equality, countable choice, host completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net schedule exposure, located coverage readback, rational tolerance comparison, compact-metric provenance, uniform-modulus handoff, and ledger non-escape for BEDC.Derived.EffectiveCompactnessUp.

Chapter 6597

A Concrete Naming Certificate for CompactlySupportedRealFunction$^{\uparrow}$

Following Bourbaki and Rudin, a compactly supported real function is a real-valued function whose nonzero behavior is confined to a compact portion of the real line. The CompactlySupportedRealFunction$^{\uparrow}$ packet records this classical object as finite NameCert data over the constructive real and completion frontier. It consumes the real terminal surface of chapter 38, the stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic source core of chapter 291, the continuous-map carrier of chapter 130, and the closed bounded interval route of chapter 1591. The packet names finite support, readback, and continuity obligations only; it does not assert full function-space completeness, host extensional equality of functions, a global Heine–Borel theorem, or choice-selected support endpoints.

Definition 6597.1 (Compactly supported real function carrier)**.** *A* CompactlySupportedRealFunction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, R, S, K, H, T, C, P, N)$$

with the following displayed rows:

1. *G is the function graph window row. It records finite stream observations of input and output names and exposes graph data only through the same* StreamName$^{\uparrow}$ *requests.*
2. *R is the* Real$^{\uparrow}$ *readback row. It seals output observations as real names only after the stream, regular rational, and dyadic source rows have been displayed.*
3. *S is the support-bound certificate. It records a closed bounded interval outside which every accepted graph-window read is certified as the zero real output.*
4. *K is the compact and closed-bounded support handoff row. It reads S through the* ClosedBoundedInterval$^{\uparrow}$ *route and exposes compact-support data as a finite interval handoff rather than as open-cover compactness.*
5. *H stores componentwise* hsame *transport for graph windows, Real readback, support bounds, compact interval handoff, continuity replay, provenance, and the local naming row.*
6. *T stores* Cont *replay for the route from stream observations to regular rational and dyadic reads, from those reads to the Real seal, and from the support-bound row to continuous-map consumers.*
7. *C is the* ContinuousMap$^{\uparrow}$ *compatibility row. It records that a consumer may read continuity only through the displayed graph-window, Real readback, support-bound, and support-handoff rows.*

8. *P is the* Pkg *provenance over* $\mathsf{CompactlySupportedRealFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactlySupportedRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, R, S, K, H, T, C, P, N$. It has no coordinate for host function equality, total function-space completeness, open-cover Heine–Borel compactness, selected support endpoints, or ambient quotient equality of Real names.

Lean4 (definition) `BEDC.Derived.CompactlySupportedRealFunctionUp`

Theorem 6597.2 (Compactly supported real function NameCert obligations)**.** *For every accepted* $\mathsf{CompactlySupportedRealFunction}^{\uparrow}$ *carrier $F = (G, R, S, K, H, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactlySupportedRealFunc}}$ *surface is exhausted by carrier admission, graph-window coherence, Real readback, support-bound stability, compact and closed-bounded support handoff, componentwise transport, continuity replay, provenance, and local naming. Every consumer must read the finite route*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, BHist, hsame, Cont

through the displayed rows $G, R, S, K, H, T, C, P, N$.

Proof. Project Definition 6597.1. The graph-window row, Real readback row, support-bound row, compact support handoff, transport, replay, continuity, provenance, and local name are the only rows in the carrier.

Graph-window coherence is read through G. The row exposes input and output observations as finite stream requests, so a consumer cannot replace the graph by host function equality or by an untracked total map.

The Real readback and support obligations are downstream from the same finite observations. The rows R, S, K seal regular rational and dyadic data as Real outputs, record the closed bounded support interval, and hand that interval to compact-support consumers without importing open-cover compactness.

Finally H, T, C, P, N transport, replay, source, and name this same route. Since no excluded equality, endpoint-selection, completeness, or open-cover row occurs in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 6597.3 (Compactly supported real function support bound)**.** *Let $F = (G, R, S, K, H, T, C, P, N)$ be an accepted* $\mathsf{CompactlySupportedRealFunction}^{\uparrow}$ *packet. Any consumer that cites compact support for F must read the support-bound certificate S and the closed-bounded handoff K before it reads the* $\mathsf{ContinuousMap}^{\uparrow}$ *compatibility row C or the* $\mathsf{Real}^{\uparrow}$ *output seal R as compact-support data. Thus support is witnessed by the displayed closed bounded interval route, not by a selected endpoint pair outside the packet or by a host-level compactness theorem.*

Proof. Start with the carrier projection. The only support data are the certificate row S and the compact closed-bounded handoff row K.

Read S through the graph-window row G. The certificate states that accepted observations outside the displayed interval are zero-output observations, so support is tied to the same stream, regular rational, dyadic, and Real readback route.

Now use K and C. The handoff exposes support through $\mathsf{ClosedBoundedInterval}^{\uparrow}$, while the continuity row allows continuous-map consumers to replay the same graph-window and Real-readback data. No row supplies open-cover compactness, selected endpoints, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{CompactlySupportedRealFunction}^{\uparrow}$ read from an accepted packet factors through graph windows, Real readback, a displayed support-bound certificate, closed-bounded support handoff, componentwise transport, Cont replay, continuous-map compatibility, provenance, and local NameCert before compact-support consumers inspect the route.

Independence witness: real, streamname, regseqrat, dyadicratcore, continuousmap, closed-boundedinterval: $\mathsf{CompactlySupportedRealFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries graph-window data, Real output readback, support-bound evidence, closed-bounded compact-support handoff, continuity replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactlySupportedRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactlySupportedRealFunction}^{\uparrow}$ packet starts from finite graph windows, reads Real outputs through StreamName, RegSeqRat, and DyadicRatCore rows, records a closed bounded support certificate, hands support to compact and continuous-map consumers, and preserves the route by hsame transport, Cont replay, Pkg provenance, and local NameCert.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactlySupportedRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6597.1, Definition 6597.2, and Definition 6597.3 seed the finite compact-support route over Real, stream, regular rational, dyadic, continuous-map, and closed bounded interval rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactlySupportedRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, function-space completeness, open-cover Heine–Borel compactness, selected support endpoints, quotient equality of Real names, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked graph-window coherence, Real readback, support-bound stability, closed-bounded support handoff, continuity replay, ledger nonescape, and a Lean carrier surface for BEDC.Derived.CompactlySupportedRealFun

Chapter 6598

A Concrete Naming Certificate for CompactMetricUniformContinuity$^{\uparrow}$

Following Bishop–Bridges and the Heine–Cantor finite-net proof, the CompactMetricUniformContinuity$^{\uparrow}$ packet records the uniform-continuity theorem for a continuous map on a compact metric source as finite NameCert data. It sits over the compact finite-net source of chapter 129, the pointwise map rows of chapter 130, the downstream modulus interface of chapter 369, the metric carrier of chapter 57, and the rational real seal of chapter 38. The packet names the finite route from local continuity radii and compact nets to a tolerance-only modulus; it does not import open-cover compactness, sequential compactness, host function equality, or a choice-selected center family.

Definition 6598.1 (Compact metric uniform continuity carrier)**.** *A* CompactMetricUniformContinuity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, F, M, Q, D, R, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-net row, including the displayed center bundle, cover radii, and located membership witnesses for the source metric space.*
2. *F is the* ContinuousMap$^{\uparrow}$ *row, carrying the graph read and the pointwise continuity modulus rows attached to the centers named by K.*
3. *M is the* Met$^{\uparrow}$ *triangle-estimate ledger used to compare a point, a selected displayed center, and their images under the map row.*
4. *Q is the finite* Rat$^{\uparrow}$ *lower-bound fold over the centerwise source radii supplied by F.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for halving, positivity, lower-bound comparison, and final source-tolerance transport.*
6. *R is the* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *seal boundary used only to read the rational and real comparison rows already displayed by Q, D, M.*
7. *T is the resulting tolerance-only* UniformModulus$^{\uparrow}$ *handoff row.*
8. *H records componentwise* hsame *transport for the compact source, continuous-map rows, metric estimates, rational fold, dyadic ledger, real seal, handoff, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a target tolerance through $K, F, M, Q, D, R, H, P, N$ to the handoff row T.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactMetricUniformContinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricUniformContinuity}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open-cover compactness, sequential compactness, choice-selected centers, quotient equality of functions, ambient Real completeness, or host equality of maps.

Theorem 6598.2 (Compact metric uniform continuity NameCert obligations)**.** *For every accepted* $\mathsf{CompactMetricUniformContinuity}^{\uparrow}$ *carrier*

$$U = (K, F, M, Q, D, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactMetricUniformContinuity}^{\uparrow}}$ *surface consists exactly of compact finite-net exposure, continuous-map pointwise-modulus exposure, metric triangle-estimate replay, rational lower-bound fold exactness, dyadic tolerance transport, RegSeqRat and Real seal discipline, tolerance-only UniformModulus handoff, componentwise transport, displayed continuation replay, package provenance, and local naming. Every theorem-facing read must display K, F, M, Q, D, R before it may consume the handoff row T.*

Proof. Project the carrier of Definition 6598.1. Its visible rows are precisely the compact finite-net source, continuous-map pointwise rows, metric comparison ledger, rational fold, dyadic tolerance ledger, Real-facing seal, uniform-modulus handoff, and structural rows.

The finite-net and pointwise-modulus obligations are supplied by K and F. The row K displays the centers and coverage witnesses, while F attaches a pointwise continuity radius to each displayed center.

The theorem-facing estimate is routed through M, Q, D, R. The metric ledger M records the triangle comparisons, the rational fold Q selects the displayed lower bound, the dyadic ledger D transports positivity and halving data, and the seal row R permits only the rational and Real reads already displayed by those rows.

Finally T, H, C, P, N hand the result to the public certificate. Since no excluded compactness, choice, function-equality, or ambient-completeness coordinate occurs in the carrier, the stated rows exhaust the NameCert obligation surface. □

Theorem 6598.3 (Finite-net modulus route)**.** *Every accepted* $\mathsf{CompactMetricUniformContinuity}^{\uparrow}$ *packet sends a compact-metric continuous map to a tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *row through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Unifor}$$

Concretely, the consumer reads the compact finite-net row K, the pointwise modulus row F, the metric triangle-estimate ledger M, the rational lower-bound fold Q, the dyadic tolerance ledger D, and the RegSeqRat and Real seal row R before it may use the modulus handoff T. The route exports no open-cover compactness, sequential compactness, choice-selected centers, host function equality, or external equality principle for maps.

Proof. Start with an accepted packet $U = (K, F, M, Q, D, R, T, H, C, P, N)$. The compact source row K provides the displayed centers and coverage witnesses, while the continuous-map row F provides the pointwise radius rows over those same centers.

Use the metric triangle ledger M to compare an arbitrary inspected point with its displayed center and then compare the corresponding image values. The rational fold Q reads the finite family of source radii and records the lower bound used by the uniform tolerance.

The dyadic ledger D transports the requested target tolerance through halving, positivity, and lower-bound comparisons. The RegSeqRat and Real seal row R is then read only as a boundary for those already displayed numerical comparisons.

The handoff row T is therefore a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ output. The structural rows H, C, P, N preserve, replay, source, and name the same finite route, so no excluded compactness, choice, function-equality, or external map-equality object can enter the export. □

Theorem 6598.4 (Compact metric uniform-continuity explicit modulus scope)**.** *An accepted* $\mathsf{CompactMetricUniformContinuity}^{\uparrow}$ *packet may export a uniform-continuity claim only through the displayed compact witness K, metric distance witness M, finite-net radius budget Q, D, modulus handoff row T, componentwise* hsame *transport H, and displayed* Cont *replay C. Pointwise continuity data in F alone do not determine an exported* $\mathsf{UniformModulus}^{\uparrow}$ *row; the packet must also expose the compact finite-net coverage and the metric comparison route that make the modulus tolerance-only.*

Proof. Start with the carrier of Definition 6598.1. The compact row K displays the finite centers and coverage witnesses, while the continuous-map row F supplies only centerwise or pointwise continuity data. Without the finite-net row, those pointwise rows have no tolerance-only export surface.

Compose the compact, metric, and continuous-map rows. The point under inspection is first related to a displayed center by K and the metric comparison ledger M; the row F is then read at that displayed center. The rational lower-bound fold Q and dyadic ledger D turn the finite family of centerwise source radii into the radius budget used by the modulus handoff T.

The structural rows keep the export constructive. Componentwise hsame transport H preserves the compact witness, metric distance witness, radius budget, and handoff, while displayed Cont replay C records the same route for each requested tolerance. Hence the exported uniform-continuity claim is the finite-net route $K, F, M, Q, D, R, T, H, C, P, N$, not open-cover compactness, a choice-selected subcover, or pointwise continuity detached from a displayed modulus. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricUniformContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactMetricUniformContinuity}^{\uparrow}$ packet is generated from compact finite-net rows, ContinuousMapUp pointwise-modulus rows, MetricUp triangle ledgers, RatUp lower-bound folds, DyadicRatCoreUp tolerance transport, RegSeqRatUp and RealUp seal boundaries, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactMetricUniformContinuity}^{\uparrow}}$, seed)

Scope closed: Definition 6598.1, Definition 6598.2, and Definition 6598.3 seed the finite-net Heine–Cantor certificate over compact metric sources and pointwise continuous maps.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactMetricUniformContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, sequential compactness, choice-selected centers, host function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, pointwise-modulus coverage, metric triangle-estimate replay, lower-bound fold exactness, dyadic tolerance transport, Real seal discipline, UniformModulus handoff, and non-escape for BEDC.Derived.CompactMetricUniformContinuityUp.

Chapter 6599

A Concrete Naming Certificate for $\mathsf{BishopContractionIteration}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopContractionIteration}^{\uparrow}$ packet records the finite iteration-budget surface for a displayed contraction before any fixed-point endpoint or host limit is claimed. It sits after the complete-metric carrier of chapter 128, the one-step Picard contraction surface of chapter 395, the Cauchy-modulus schedule of chapter 292, the finite stream route of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the visible budget by which contraction iterates become completion-facing data; it does not select a fixed point, quotient an orbit, or import countable choice.

Definition 6599.1 (BishopContractionIteration carrier)**.** *A* $\mathsf{BishopContractionIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, T, x_0, W, I, A, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row carrying only the displayed distance reads needed by the contraction route.*
2. *T is the* $\mathsf{PicardContraction}^{\uparrow}$ *one-step row, exposing the accepted contraction graph and its adjacent-iterate comparison surface.*
3. *x_0 is the initial-point row from which the displayed orbit windows are generated.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule requested by a downstream completion or fixed-point consumer.*
5. *I is the finite iterate ledger, listing the visible orbit rows $x_0, x_1, \ldots, x_n$ and the replayed applications of T used to obtain them.*
6. *A is the adjacent-distance ledger, storing the contraction-bound comparisons and tail estimates read from I inside the metric row X.*
7. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *budget row extracted from A for the requested windows W.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite orbit budget and its regular rational tail presentation.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, I, A, M, R have been displayed.*

10. *H records componentwise* hsame *transport for the metric source, contraction row, initial point, window schedule, iterate ledger, adjacent-distance ledger, modulus row, readback row, seal row, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from complete-metric and Picard-contraction admission through finite iteration, tail-budget extraction, regular readback, and real-seal separation.*
12. *P is the* Pkg *provenance over* $\mathsf{BishopContractionIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopContractionIteration}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, T, x_0, W, I, A, M, R, E, H, C, P, N$. It has no coordinate for a selected limit, a Banach fixed point, host function extensionality, quotient orbit equality, countable choice, or ambient completeness beyond the displayed $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Theorem 6599.2 (BishopContractionIteration NameCert obligations)**.** *For every accepted* BishopContractionIterat *carrier $B = (X, T, x_0, W, I, A, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopContractionIteration}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed complete-metric, Picard-contraction, initial-point, stream-window, iterate-ledger, adjacent-distance, Cauchy-modulus, regular-readback, Real-seal, transport, replay, provenance, and local naming rows; iteration visibility through I; tail-budget visibility through A and M; readback visibility through R; Real seal non-escape through E; and componentwise preservation through H, C, P, N.*

Proof. Project the carrier of Definition 6599.1. Carrier admission is exactly the displayed finite inventory $X, T, x_0, W, I, A, M, R, E, H, C, P, N$.

The iterate ledger I is generated from the initial row x_0 by replaying the Picard-contraction row T inside the complete-metric source X. The adjacent-distance ledger A reads only those displayed orbit rows and the contraction comparisons attached to them.

The modulus row M is therefore a budget extracted from visible finite comparisons for the requested windows W. The regular readback R and terminal seal E are downstream rows, so they cannot add a selected endpoint or a fixed-point theorem.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since every readable coordinate has been listed, the certificate exports the contraction-iteration budget and not host function equality, quotient orbit equality, countable choice, or ambient completion. □

Theorem 6599.3 (BishopContractionIteration budget extraction)**.** *For every accepted* $\mathsf{BishopContractionIteration}^{\uparrow}$ *carrier $B = (X, T, x_0, W, I, A, M, R, E, H, C, P, N)$, every requested finite window in W receives its contraction budget only through the route*

$$\mathsf{PicardContraction}^{\uparrow} \longmapsto I \longmapsto A \longmapsto \mathsf{CauchyModulus}^{\uparrow}.$$

The row M is read after the finite orbit ledger and adjacent-distance comparisons have been displayed, and no budget is read from a selected fixed point, completed orbit endpoint, or host metric completion.

Proof. Start with the rows T, x_0, W, I. The only source of successive iterates is the displayed Picard-contraction row T replayed from the initial point x_0 for the finite windows requested in W.

The row A then records the adjacent-distance comparisons over those visible iterates. Because A is tied to I and the metric row X, it cannot read a completed endpoint or an external fixed-point equation.

The Cauchy-modulus row M is extracted from A for the same finite windows. Thus the budget route passes through $\mathsf{PicardContraction}^{\uparrow}$, the finite iterate ledger, the adjacent-distance ledger, and $\mathsf{CauchyModulus}^{\uparrow}$ before any regular readback or Real seal is available. □

Theorem 6599.4 (BishopContractionIteration completion boundary)**.** *Every completion-facing or fixed-point-facing consumer of an accepted* $\mathsf{BishopContractionIteration}^{\uparrow}$ *carrier must first read the displayed rows*

$$X,\ T,\ x_0,\ W,\ I,\ A,\ M,\ R,\ E,\ H,\ C,\ P,\ N.$$

The consumer receives a finite $\mathsf{StreamName}^{\uparrow}$ *window schedule, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and a* $\mathsf{Real}^{\uparrow}$ *seal boundary for the contraction orbit, but it receives no Banach fixed point, selected limit, quotient orbit equality, host function extensionality, countable choice, or ambient completeness beyond the named complete-metric row.*

Proof. Read the carrier inventory from Definition 6599.1. The complete-metric row X, Picard-contraction row T, initial row x_0, requested windows W, iterate ledger I, and adjacent-distance row A are all visible before the Cauchy-modulus row can be consumed.

Apply Definition 6599.3. It places the modulus row M downstream of the finite orbit and contraction comparisons rather than downstream of a selected endpoint.

The readback and seal rows R, E are therefore boundary rows for the displayed budget. Transport, replay, provenance, and local naming preserve that same route through H, C, P, N, so a downstream endpoint theorem must supply its own fixed-point and uniqueness obligations. □

Theorem 6599.5 (BishopContractionIteration Real seal nonescape)**.** *For every accepted* $\mathsf{BishopContractionIteration}^{\uparrow}$ *carrier* $B = (X, T, x_0, W, I, A, M, R, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *seals only the finite contraction-iteration readback built from* W, I, A, M, R*. It excludes Banach fixed points, selected limits, host function equality, quotient orbit equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier. The seal row E is downstream of the stream windows, finite iterate ledger, adjacent-distance comparisons, modulus row, and regular readback.

Use Definition 6599.4. Any completion-facing consumer must read the same finite rows before it can inspect E.

Since the classifier has no coordinate for fixed points, selected limits, quotient orbit equality, host function equality, countable choice, or ambient real completeness, none of those objects can escape through the terminal seal. □

Falsifiable prediction: Every accepted $\mathsf{BishopContractionIteration}^{\uparrow}$ read factors through one CompleteMetric row, one PicardContraction row, one initial-point row, one StreamName window schedule, one finite iterate ledger, one adjacent-distance ledger, one CauchyModulus budget, one RegSeqRat readback, one RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming before any endpoint theorem consumes it.

Independence witness: completemetric, picardcontraction, cauchymodulus, streamname, regseqrat, real: $\mathsf{BishopContractionIteration}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the initial point, finite orbit windows, contraction-distance budget, modulus extraction, regular readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopContractionIteration}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopContractionIteration}^{\uparrow}$ packet is generated from a CompleteMetric source row, a PicardContraction row, an initial point, StreamName windows, a finite iterate ledger, adjacent-distance comparisons, a

CauchyModulus budget, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopContractionIteration}\uparrow}$, seed)

Scope closed: Definition 6599.1, Definition 6599.2, Definition 6599.3, and Definition 6599.4 seed the finite contraction-iteration budget consumed by later completion and fixed-point routes.

Formal verification: FormalStatus(NameCert$_{\text{BishopContractionIteration}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Banach fixed points, selected limits, quotient orbit equality, host function extensionality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iteration visibility, tail-budget visibility, Cauchy-modulus extraction, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BishopContractionIterationUp.

Chapter 6600

A Concrete Naming Certificate for $\mathsf{RealOscillationMajorant}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealOscillationMajorant}^{\uparrow}$ packet records a finite oscillation-bound ledger for Real-facing estimates without appealing to host suprema or ambient completeness. It sits over the real-name seal of chapter 38, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance arithmetic of chapter 291, and the convergence-rate packet of chapter 2074. The carrier is meant for later Cauchy, continuity, and compact-interval estimates that need a displayed oscillation majorant before they read a terminal $\mathsf{Real}^{\uparrow}$ seal.

Definition 6600.1 (Real oscillation majorant carrier)**.** *A* $\mathsf{RealOscillationMajorant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (E, Q, S, D, M, A, W, H, C, P, N)$$

with the following displayed rows:

1. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row whose accepted real-name boundary is being estimated.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplying regular rational approximants to the sealed real name.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the stream observations used by Q.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying dyadic radii, comparisons, and halving slack.*
5. *M is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *schedule row that bounds which windows must be inspected at the displayed tolerance.*
6. *A is the finite oscillation-majorant ledger, recording a dyadic bound above all displayed pairwise oscillations seen through Q, S, D, M.*
7. *W is the finite witness-window family naming the inspected indices and comparisons that justify the ledger row A.*
8. *H records componentwise* hsame *transport for E, Q, S, D, M, A, W.*
9. *C records displayed* Cont *replay from a tolerance request through the modulus row and finite witness windows to the majorant ledger.*
10. *P is the* Pkg *provenance over* $\mathsf{RealOscillationMajorant}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{RealOscillationMajorant}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host supremum, a completed metric-space bound, a selected limit, quotient equality of streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6600.2 (Real oscillation majorant NameCert obligations)**.** *For every accepted* $\mathsf{RealOscillationMajorant}^{\uparrow}$ *carrier*

$$O = (E, Q, S, D, M, A, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealOscillationMajorant}^{\uparrow}}$ *surface consists exactly of Real seal admission, regular rational readback, finite stream-window exposure, dyadic tolerance arithmetic, convergence-modulus scheduling, oscillation-majorant ledger exactness, witness-window coverage, componentwise transport, displayed replay, package provenance, local naming, and non-escape for host suprema, selected limits, quotient stream equality, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 6600.1. Its visible rows are precisely the Real seal, RegSeqRat readback, StreamName window, DyadicRatCore tolerance, RealModulusOfConvergence schedule, majorant ledger, witness windows, and structural rows.

The analytic obligations are finite. Row D fixes the dyadic tolerance arithmetic, row M fixes the inspected tail window, rows Q, S expose the regular rational observations, and row W lists the finite comparisons whose dyadic upper bound is recorded by A.

The structural obligations then bind the read. Componentwise transport through H, replay through C, provenance through P, and local naming through N keep every oscillation-majorant consumer on the same displayed packet. Since the excluded supremum, selected-limit, quotient, choice, and completeness objects have no coordinate, the listed rows exhaust the certificate surface. □

Theorem 6600.3 (Real oscillation majorant L10 readback)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{RealOscillationMajorant}^{\uparrow}$ *packet reads an oscillation bound only through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealModulusOfConvergence}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads the dyadic tolerance row D, the finite stream-window row S, the regular rational readback row Q, the convergence-modulus row M, and the terminal Real seal row E before it may use the majorant ledger A and witness family W. The route exports no host supremum, selected Cauchy limit, quotient stream equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Begin with an accepted carrier $O = (E, Q, S, D, M, A, W, H, C, P, N)$. The only tolerance source is D, and the only finite observation source is S.

Read the Real-facing schedule. The modulus row M bounds which stream windows are inspected, the regular rational row Q supplies the displayed approximants on those windows, and the Real seal row E is reached only after that finite route has been exposed.

The majorant ledger is then read from A together with the witness family W. Rows H, C, P, N transport, replay, source, and name the same packet, so the L10 consumer cannot replace the displayed route by a host supremum, selected limit, quotient equality, choice schedule, or completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealOscillationMajorant}^{\uparrow}}$.

Constructive story: A $\mathsf{RealOscillationMajorant}^{\uparrow}$ packet is generated from a RealUp seal row, RegSeqRat readback, StreamName finite windows, DyadicRatCore tolerance arithmetic, a RealModulusOfConvergence schedule, a finite

oscillation-majorant ledger, witness windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealOscillationMajorant}^{\uparrow}}$, seed)

Scope closed: Definition 6600.1, Definition 6600.2, and Definition 6600.3 seed the finite oscillation-majorant route for Real, RegSeqRat, StreamName, DyadicRatCore, and convergence-modulus consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealOscillationMajorant}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host suprema, selected Cauchy limits, quotient stream equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance arithmetic, finite-window readback, convergence-modulus scheduling, majorant-ledger exactness, witness-window coverage, structural replay, and non-escape for BEDC.Derived.RealOscillationMajorantUp.

Chapter 6601

A Concrete Naming Certificate for $\mathsf{MarkovInequality}^{\uparrow}$

Following Feller, Markov's inequality is read as a finite first-moment tail-bound route. It sits beside the second-moment packet of chapter 6592 and consumes the probability source of chapter 184, the random-variable surface of chapter 185, the distribution readback of chapter 186, and the terminal real-name seal of chapter 38. The packet names a nonnegative tail-bound certificate; it is not a weak-law theorem, a variance estimate, a selected exceptional event, a host measure-algebra quotient, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6601.1 (Markov inequality carrier)**.** *A* $\mathsf{MarkovInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (P, X, a, E, T, B, S, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row carrying the normalized event classifier.*
2. *X is the nonnegative* $\mathsf{RandomVar}^{\uparrow}$ *row whose finite observation windows are inspected over P.*
3. *a is the positive threshold row, displayed as a* $\mathsf{Real}^{\uparrow}$ *comparison seal before any tail event is read.*
4. *E is the expectation/readback row for X, with any rational approximation window displayed through the same probability source.*
5. *T is the tail-event row naming the event where the observation of X lies above the threshold a.*
6. *B is the probability-bound comparison row, displaying the Markov estimate between the probability of T and the first-moment ratio read from E and a.*
7. *S stores the paired* $\mathsf{Real}^{\uparrow}$ *and rational seals used to compare the threshold, expectation, tail probability, and ratio rows.*
8. *H stores componentwise* hsame *transport for the probability source, random variable, threshold, expectation/readback, tail event, probability comparison, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the finite first-moment tail-bound route.*
10. *Q is the* Pkg *provenance over* $\mathsf{MarkovInequality}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovInequality}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $P, X, a, E, T, B, S, H, C, Q, N$. It has no coordinate for a variance budget, almost-sure convergence, selected subevent, host integration theorem, quotient real equality, countable choice, or ambient real completeness.

Theorem 6601.2 (Markov inequality NameCert obligations)**.** *For every accepted* $\mathsf{MarkovInequality}^{\uparrow}$ *carrier $M = (P, X, a, E, T, B, S, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MarkovInequality}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the probability source, nonnegative random-variable row, positive threshold, expectation/readback row, tail event, probability-bound comparison, Real/Rat seals, transport, replay, provenance, and local naming;*
2. *source stability, requiring X, T, E to remain attached to the event classifier displayed by P;*
3. *nonnegativity stability, requiring the random-variable read in X to be exposed as nonnegative before the threshold comparison is consumed;*
4. *threshold stability, requiring a to be displayed as a positive* $\mathsf{Real}^{\uparrow}$ *row before T and B are read;*
5. *first-moment stability, requiring E to be displayed before the probability-bound comparison consumes the first-moment ratio;*
6. *seal nonescape, requiring S to bind the Real and rational comparison rows without exporting quotient real equality, a host integral theorem, or ambient completeness;*
7. *componentwise transport, displayed replay, package provenance, and local naming through H, C, Q, N.*

These obligations certify only the finite first-moment tail-bound route. They do not close Chebyshev's inequality, a weak law, almost-sure convergence, host probability limits, selected exceptional events, Lean verification, or bridge checking.

Proof. Project the carrier of Definition 6601.1. The displayed rows are exactly the probability source, nonnegative random-variable row, threshold, expectation/readback, tail event, probability-bound comparison, seals, and structural rows.

Source, nonnegativity, threshold, and first-moment stability are read from P, X, a, E, T, B. The probability-bound comparison cannot be consumed until the event classifier, nonnegative observation row, positive threshold, and expectation/readback row have all been displayed.

The seal row S records only the Real and rational endpoints used by that comparison. Since the carrier has no coordinate for quotient real equality, a host integral theorem, selected exceptional event, countable choice, or ambient completeness, the seal cannot export those objects.

The rows H, C, Q, N transport, replay, source, and name the same finite route. Hence the listed obligations exhaust the local NameCert surface. □

Theorem 6601.3 (Markov–Chebyshev handoff)**.** *Every* $\mathsf{ChebyshevInequality}^{\uparrow}$ *consumer that requests a first-moment tail-bound precursor can read a* $\mathsf{MarkovInequality}^{\uparrow}$ *packet only through*

$$P \longmapsto X \longmapsto a \longmapsto E \longmapsto T \longmapsto B \longmapsto S \longmapsto H, C, Q, N.$$

The handoff supplies a probability source, nonnegative random-variable row, positive threshold, expectation/readback row, tail event, probability-bound comparison, Real/Rat seals, transport, replay, provenance, and local naming. It does not supply a variance budget, centered second-moment estimate, weak-law limit, almost-sure convergence claim, selected subsequence, or ambient real-completeness principle.

Proof. Begin with a Chebyshev-facing request for a first-moment precursor. Projection of Definition 6601.1 displays the probability source P and the nonnegative random-variable row X before any tail estimate can be consumed.

The request next reads the positive threshold a, the expectation/readback row E, and the tail-event row T. Only then can the probability-bound comparison B and seal row S be handed to the consumer.

The structural rows H, C, Q, N preserve the same route. Because the Markov carrier has no variance-budget or centered second-moment coordinate, the consumer cannot treat this handoff as a Chebyshev proof, weak-law limit, selected subsequence, or ambient completeness claim. □

Theorem 6601.4 (Markov Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or rational seal read from an accepted* $\mathsf{MarkovInequality}^{\uparrow}$ *carrier is downstream from the displayed probability source, nonnegative random-variable row, threshold, expectation/readback row, tail event, and probability-bound comparison. The seal exposes only the finite first-moment comparison route and cannot escape to quotient real equality, host expectation theory, selected events, countable choice, distributional convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the seal row S through the carrier coordinates P, X, a, E, T, B. Each endpoint used by the comparison is attached to either the threshold, expectation/readback, tail probability, or first-moment ratio row.

The rational windows in S are displayed only as comparison seals, and the $\mathsf{Real}^{\uparrow}$ endpoints remain downstream from the same probability source and random-variable surface. No carrier coordinate stores a quotient real equality, host expectation theorem, selected event, countable-choice selector, or convergence principle.

Therefore every seal read remains inside the finite first-moment tail-bound route named by $\mathsf{MarkovInequality}^{\uparrow}$. □

Falsifiable prediction: Every $\mathsf{MarkovInequality}^{\uparrow}$ tail-bound read factors through a ProbSpace source row, a nonnegative RandomVar row, a positive threshold, an expectation/readback row, a tail-event row, a probability-bound comparison, Real/Rat seals, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: probspace, randomvar, distribution, real, chebyshev-inequality: $\mathsf{MarkovInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a probability source, nonnegative random variable, threshold, expectation/readback, tail event, probability-bound comparison, Real/Rat seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovInequality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovInequality}^{\uparrow}$ packet is generated from a probability source row, a nonnegative random-variable row, a positive threshold row, an expectation/readback row, a tail-event row, a probability-bound comparison row, Real and rational seals, componentwise hsame transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6601.1, Definition 6601.2, Definition 6601.3, and Definition 6601.4 seed the finite first-moment tail-bound route through ProbSpace, RandomVar, Distribution, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Chebyshev's inequality, weak laws, almost-sure convergence, host probability limits, selected exceptional events, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source stability, nonnegativity stability, threshold stability, first-moment stability, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MarkovInequalityUp.

Chapter 6602

A Concrete Naming Certificate for $\mathsf{PolarDecomposition}^{\uparrow}$

Following Conway and Reed–Simon, the polar-decomposition interface records the finite operator-factorization surface by which a bounded operator is read as a positive part followed by a partial-isometry or unitary handoff. The $\mathsf{PolarDecomposition}^{\uparrow}$ packet consumes the bounded-operator route of chapter 1644, the Hilbert and inner-product rows of chapter 91 and chapter 86, the matrix and singular-value ledgers of chapter 49 and chapter 6037, the unitary-group boundary of chapter 219, and the spectral-radius estimates of chapter 2352. It names only a displayed finite factorization packet; it does not assert a global spectral theorem, selected bases, quotient operator equality, or ambient Hilbert completeness.

Definition 6602.1 (Polar decomposition carrier)**.** *A* $\mathsf{PolarDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, A, U, S, R, H, C, G, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row whose source and target Hilbert endpoints are the operator being factored.*
2. *A is the positive-part row. It records the displayed nonnegative self-adjoint endpoint read as the finite positive component of the factorization, not as an unbounded spectral-calculus object.*
3. *U is the partial-isometry or unitary handoff row. It is read through* $\mathsf{UnitaryGroup}^{\uparrow}$ *when the inspected finite window supports a unitary restriction and otherwise records the partial-isometry boundary over the same Hilbert endpoint rows.*
4. *S is the* $\mathsf{SingularValueDecomposition}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *ledger. It records finite matrix windows, singular values, and frame data used by finite-dimensional consumers of the same factorization route.*
5. *R is the* $\mathsf{SpectralRadius}^{\uparrow}$ *estimate row. It supplies only the norm-growth and radius bounds displayed by the sibling packet.*
6. *H stores componentwise* hsame *transport for the operator row, positive part, handoff row, SVD and matrix ledger, spectral estimate, replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay from a factorization request through T, A, U, S, R, H.*

8. *G is the* Pkg *provenance over* $\mathsf{PolarDecomposition}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{SingularValueDecomposition}^{\uparrow}$, $\mathsf{UnitaryGroup}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{PolarDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host spectral theorem, a selected basis outside the packet, quotient equality of operators, or a completeness theorem for the ambient Hilbert carrier.

Theorem 6602.2 (Polar decomposition NameCert obligations)**.** *For every accepted* $\mathsf{PolarDecomposition}^{\uparrow}$ *carrier*

$$P = (T, A, U, S, R, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PolarDecomposition}^{\uparrow}}$ *surface consists exactly of bounded-operator admission, positive-part exposure, partial-isometry or unitary handoff, SVD and matrix ledger routing, spectral-radius estimate routing, componentwise transport, displayed replay, provenance, local naming, and nonescape for global spectral theorems, selected bases, quotient operator equality, and ambient Hilbert completeness.*

Proof. Project Definition 6602.1. The only analytic rows are the bounded operator T, the positive part A, the handoff row U, the finite SVD and matrix ledger S, and the spectral estimate R.

The factorization obligation is therefore finite. A consumer first reads T through $\mathsf{BoundedLinearOperator}^{\uparrow}$, then reads A as the positive component attached to the same Hilbert and inner-product rows, and then reads U as the displayed partial-isometry or unitary handoff.

The matrix and spectral consumers are downstream from that same route. Row S exposes only finite matrix and singular-value windows, while R exposes only the sibling spectral-radius estimate. Rows H, C, G, N transport, replay, source, and name the packet, so no excluded global theorem or quotient object can be read from the carrier. □

Theorem 6602.3 (Polar decomposition partial-isometry handoff)**.** *Every accepted* $\mathsf{PolarDecomposition}^{\uparrow}$ *packet reads a factorization handoff only through the route*

$$\mathsf{BoundedLinearOperator}^{\uparrow} \longrightarrow \mathsf{Hilbert}^{\uparrow} \longrightarrow \mathsf{InnerProduct}^{\uparrow} \longrightarrow \mathsf{UnitaryGroup}^{\uparrow} \longrightarrow \mathsf{SingularValueDecomposition}^{\uparrow} \longrightarrow \mathsf{S}$$

The row U is admissible only as the displayed partial-isometry or unitary boundary attached to the same bounded operator row T and positive part A. It exports no selected polar factor outside the packet, no host quotient equality of operators, and no ambient Hilbert completeness claim.

Proof. Begin with an accepted carrier $P = (T, A, U, S, R, H, C, G, N)$. The operator endpoint is T, so every factorization read starts from the displayed $\mathsf{BoundedLinearOperator}^{\uparrow}$ row over Hilbert and inner-product data.

Read the positive part A and the handoff row U together. The handoff is accepted only when it is tied to the same source and target rows as T and to the same positive component A; the unitary case is read through the sibling $\mathsf{UnitaryGroup}^{\uparrow}$ route.

Finally read S and R. The SVD and matrix ledger supplies finite inspected windows, and the spectral-radius row supplies only displayed estimate data. Since the carrier contains no selected external polar factor, quotient operator equality, or Hilbert-completeness row, the handoff remains the finite packet described in the statement. □

Falsifiable prediction: Every $\mathsf{PolarDecomposition}^{\uparrow}$ consumer that reaches a factorization handoff must first read the bounded-operator row, positive-part row, partial-isometry or unitary row, SVD

and matrix ledger, spectral-radius estimate, transport, replay, provenance, and local NameCert rows.

Independence witness: boundedlinearoperator, hilbert, innerproduct, matrix, singularvaluedecomposition, unitarygroup, spectralradius: $\mathsf{PolarDecomposition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded operator, positive part, partial-isometry or unitary handoff, finite SVD and matrix ledger, spectral-radius estimate, structural replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PolarDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{PolarDecomposition}^{\uparrow}$ packet is generated from a BoundedLinearOperatorUp row over Hilbert and inner-product data, a positive-part row, a partial-isometry or unitary handoff, finite SVD and matrix ledgers, a SpectralRadiusUp estimate, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolarDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6602.1, Definition 6602.2, and Definition 6602.3 seed the finite polar-factorization packet over bounded operators, Hilbert rows, positive parts, unitary handoffs, SVD ledgers, and spectral-radius estimates.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolarDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a global spectral theorem, selected bases, quotient operator equality, ambient Hilbert completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-part exactness, partial-isometry handoff, SVD and spectral ledger routing, structural replay, provenance, and nonescape for BEDC.Derived.PolarDecompositionUp.

Chapter 6603

A Concrete Naming Certificate for $\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}$

Following Bishop and Bridges on compact intervals and located reals, the $\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}$ packet records the finite subsequence-extraction surface available for bounded located $\mathsf{Real}^{\uparrow}$ sequences. It sits over located membership data from chapter 1541, the sequential completeness route of chapter 1515, the regular rational readback of chapter 301, the finite window schedule of chapter 126, and the terminal Real seal of chapter 38. The packet names located finite windows and extracted regular subsequence reads; it does not claim open-cover compactness, choice-selected infinite subsequences, quotient stream equality, excluded-middle trichotomy, or ambient classical compactness.

Definition 6603.1 (Located Bolzano-Weierstrass carrier)**.** *A* $\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, L, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded source sequence row, presenting the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of a located* $\mathsf{Real}^{\uparrow}$ *sequence together with its displayed lower and upper bounds.*
2. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *row, recording the located interval or located subset surface in which the sequence terms are read.*
3. *M is the* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *row, exposing only the sequential metric-completeness interface needed by the extracted regular reads.*
4. *W is the finite window row of candidate indices and rational brackets inspected before the subsequence read is named.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from the accepted windows and bounds.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the extracted finite-window read.*
7. *H records componentwise* hsame *transport across source sequence, located-set, completeness, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the extraction route*

$$S, L, M, W \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, L, M, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected infinite subsequences, quotient equality of streams, countable choice, host real equality, or ambient classical compactness.

Theorem 6603.2 (Located Bolzano-Weierstrass carrier obligations)**.** *For every accepted* LocatedBolzanoWeierstrass *carrier*

$$B = (S, L, M, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded source sequence,* $\mathsf{LocatedSet}^{\uparrow}$ *row,* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *row, finite candidate windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every bounded located sequence consumer must pass through these rows before using the packet as a finite subsequence-extraction certificate.*

Proof. Project the carrier of Definition 6603.1. The accepted packet exposes exactly the bounded sequence, located-set, sequential-completeness, finite-window, readback, seal, transport, replay, provenance, and local naming rows.

The located-set row supplies the finite located membership and distance surface. The sequential-completeness row supplies only the metric route needed for regular readbacks, while W records the inspected candidate windows.

The readback row R and Real seal E are downstream of those finite observations. Transport through H and replay through C preserve the same displayed route, and P, N source and name it.

Since the carrier has no coordinate for the excluded compactness, selection, quotient, choice, or host equality data, the listed rows exhaust the local NameCert obligations. □

Theorem 6603.3 (Located Bolzano-Weierstrass finite-window subsequence)**.** *Let $B = (S, L, M, W, R, E, H, C, P, N$ be an accepted* $\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}$ *carrier. Every finite-window subsequence read exported by B factors through*

$$S, L, M, W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently downstream compactness, completion, or limit consumers receive a bounded located source row, a $\mathsf{LocatedSet}^{\uparrow}$ *route, a* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *route, finite candidate windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a terminal* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data, but no open-cover compactness proof, choice-selected infinite subsequence, quotient stream equality, or ambient classical compactness principle.*

Proof. Begin with an exported finite-window subsequence read. Projection exposes the ordered carrier rows $S, L, M, W, R, E, H, C, P, N$.

The read starts from the bounded source sequence row S and located-set row L. The sequential-completeness row M is read only as a metric route, not as a global compactness assertion.

The finite candidate window W determines the regular rational readback R, and the terminal Real seal E is visible only after that readback. The structural rows H, C, P, N then transport, replay, source, and name the same route.

Thus every downstream consumer receives the displayed finite subsequence-extraction surface and none of the excluded selection, quotient, choice, compactness, or host-equality data. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}$ packet is generated from bounded located Real sequence windows, LocatedSet membership data, SequentiallyCompleteMetric route data, finite candidate windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6603.1, Definition 6603.2, and Definition 6603.3 seed the finite located subsequence-extraction surface for bounded located Real sequences.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedBolzanoWeierstrass}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected infinite subsequences, quotient stream equality, countable choice, host real equality, ambient classical compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window stability, sequential-completeness route stability, regular readback exactness, Real seal handoff, and downstream nonescape for BEDC.Derived.LocatedBolzanoWeierstrassUp.

Chapter 6604

A Concrete Naming Certificate for $\mathsf{RegularCauchyLiftedLimit}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real construction, the $\mathsf{RegularCauchyLiftedLimit}^{\uparrow}$ packet records the diagonal-limit handoff anticipated by section 9238.2 and Definition 9238.5. It sits over the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the finite rows by which a regular Cauchy diagonal read is lifted to a Real-facing limit seal without selected representatives, quotient stream equality, countable choice, or ambient Real-completeness as a hidden coordinate.

Definition 6604.1 (Regular Cauchy lifted-limit carrier)**.** *A* $\mathsf{RegularCauchyLiftedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, W, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diagonal tolerance ledger, carrying the finite precision budgets and comparison cells used by the lift.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, naming the finite windows inspected at each displayed diagonal budget.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row produced from the scheduled windows and dyadic budgets.*
4. *W is the lifted-limit witness row, recording that the same finite diagonal observations determine the displayed limit read.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available after D, S, R, W have been exposed.*
6. *H records componentwise* hsame *transport across dyadic budget, stream schedule, regular readback, lifted witness, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the diagonal handoff route*

$$D, S \longmapsto R \longmapsto W \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLiftedLimit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLiftedLimit}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, R, W, E, H, C, P, N$. It has no coordinate for quotient equality of regular streams, selected representatives, countable choice, host real equality, a detached completion operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6604.2 (Regular Cauchy lifted-limit NameCert obligations)**.** *For every accepted* RegularCauchyLiftedLim *carrier*

$$L = (D, S, R, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLiftedLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diagonal tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, lifted-limit witness, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the Real-completeness limit theorem's diagonal handoff must pass through these rows and cannot replace them by quotient stream equality, selected representatives, countable choice, host real equality, a detached completion operator, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLiftedLimitUp.TasteGate.RegularCauchyLiftedLimitNamecertObligations`

Proof. Project the carrier of Definition 6604.1. The accepted packet exposes exactly the dyadic budget, finite stream schedule, regular rational readback, lifted-limit witness, Real seal, transport, replay, provenance, and local naming rows.

The diagonal handoff begins at the $\mathsf{DyadicRatCore}^{\uparrow}$ row D and the $\mathsf{StreamName}^{\uparrow}$ row S. These rows supply the finite precision and window data cited by the originating limit theorem.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is downstream of those observations, and the witness row W binds the same observations to the terminal $\mathsf{Real}^{\uparrow}$ seal E. Transport through H and replay through C preserve the route.

Finally P and N source and name the same finite packet. Since no excluded quotient, selector, choice, host equality, detached completion, or ambient-completeness row is present, the displayed rows exhaust the NameCert obligations. □

Theorem 6604.3 (Regular Cauchy lifted-limit diagonal handoff)**.** *Let $L = (D, S, R, W, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyLiftedLimit}^{\uparrow}$ *carrier. Every diagonal-limit read exported toward a* $\mathsf{Real}^{\uparrow}$ *consumer factors through*

$$D, S \longmapsto R \longmapsto W \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a $\mathsf{DyadicRatCore}^{\uparrow}$ *budget ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, lifted-limit witness, terminal* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data, and receives no quotient stream equality, selected representative, countable choice schedule, detached completion operator, or ambient Real-completeness credential.*

Proof. Start with a diagonal-limit read from the accepted packet. Projection exposes the ordered rows $D, S, R, W, E, H, C, P, N$.

The dyadic budget ledger D and finite schedule S are the only data available before the regular rational readback. Thus R is determined by displayed finite observations rather than by a quotient stream.

The witness row W records the lift from that regular readback to the terminal Real seal E. The rows H, C, P, N then transport, replay, source, and name the same finite handoff.

Therefore every Real-facing consumer receives exactly the displayed diagonal route and none of the excluded quotient, selection, choice, completion, or ambient-completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLiftedLimit}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyLiftedLimit}^{\uparrow}$ packet is generated from a DyadicRatCore diagonal tolerance ledger, StreamName finite-window schedule, RegSeqRat readback, lifted-limit witness, terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLiftedLimit}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6604.1, Definition 6604.2, and Definition 6604.3 seed the finite diagonal-limit handoff surface for Real-completeness consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLiftedLimit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of regular streams, selected representatives, countable choice, host real equality, detached completion operators, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal-budget stability, finite-window readback exactness, lifted-limit witness stability, Real seal handoff, and downstream nonescape for BEDC.Derived.RegularCauchyLiftedLimitUp.

Chapter 6605

A Concrete Naming Certificate for $\mathsf{LocatedSetDistance}^{\uparrow}$

Following Bishop and Bridges on located subsets of metric spaces, the $\mathsf{LocatedSetDistance}^{\uparrow}$ packet records the finite distance-to-a-located-set surface as displayed metric and real-valued ledger data. It sits over the located-subset carrier of chapter 1541, the distance-to-set surface of chapter 4364, the proximinal boundary of chapter 3498, the metric source of chapter 57, and the terminal real-name seal of chapter 38. The packet names the finite route from an admitted ambient point and located subset to a $\mathsf{Real}^{\uparrow}$ distance read; it does not select a nearest point, quotient subset presentations, assert ambient compactness, or import full real completeness.

Definition 6605.1 (Located set distance carrier)**.** *A* $\mathsf{LocatedSetDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, A, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *source row, including the admitted point classifier and distance observations.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *row for the displayed subset, including its admission and locatedness comparisons.*
3. *D is the* $\mathsf{DistanceToSet}^{\uparrow}$ *ledger row assigning each admitted ambient point and tolerance request a finite distance-to-subset comparison.*
4. *R is the rational-window row through which the distance ledger is read before the terminal value is sealed.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed distance value.*
6. *H records componentwise* hsame *transport for the metric source, located subset, distance ledger, rational windows, real seal, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from point admission and located-subset reads to distance ledger, rational-window readback, real seal, and proximinal-facing requests.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{DistanceToSet}^{\uparrow}$, $\mathsf{ProximinalSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSetDistance}^{\uparrow}}$ *row.*

The carrier has no coordinate for a chosen nearest point, quotient equality of subset presentations, host infimum, ambient compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6605.2 (Located set distance NameCert obligations)**.** *For an accepted* $\mathsf{LocatedSetDistance}^{\uparrow}$ *carrier* $L = (X, A, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedSetDistance}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, located subset, distance ledger, rational-window row, real seal, transport, replay, provenance, and local naming; classifier stability under componentwise* hsame *transport; exact routing through the* $\mathsf{DistanceToSet}^{\uparrow}$ *ledger before the* $\mathsf{Real}^{\uparrow}$ *seal; compatibility with the* $\mathsf{LocatedSet}^{\uparrow}$ *locatedness rows; and non-escape from nearest-point selection, subset quotients, host infima, ambient compactness, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier. The rows $X, A, D, R, E, H, C, P, N$ are the complete visible inventory, with the metric source and located-subset rows read before any distance value is available.

Use the sibling located-set and distance-to-set surfaces. The row A supplies located-subset admission and comparison data, while D supplies the distance-to-subset ledger over the same metric source X.

The rational-window and real-seal rows preserve that order. A consumer reaches E only after R has displayed the finite readback of D, and the support rows H, C, P, N transport, replay, source, and name exactly this route.

Since no row stores a nearest-point choice, quotient subset equality, host infimum, compactness witness, or full real-completeness theorem, the local NameCert obligations are exhausted by the displayed carrier rows. □

Theorem 6605.3 (Located set distance Real-metric handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-valued distance read exposed by an accepted* $\mathsf{LocatedSetDistance}^{\uparrow}$ *carrier factors through the finite route*

$$X \longmapsto A \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the handoff from $\mathsf{Met}^{\uparrow}$ *to* $\mathsf{Real}^{\uparrow}$ *is a displayed distance ledger over a located subset, not a host infimum, quotient subset value, selected nearest point, ambient completion, or full real-completeness claim.*

Proof. Start with the metric row X. It supplies the admitted ambient points and metric-distance observations used by the distance request.

Read the located subset row A next. Locatedness makes the distance request a subset-facing comparison before any real-valued read is sealed.

Now project D, R, E. The ledger D records the distance-to-set comparison, the rational-window row R exposes its finite readback, and the terminal row E seals that read as $\mathsf{Real}^{\uparrow}$ data.

The support rows H, C, P, N add transport, replay, provenance, and local naming only for the same route. Hence the Real-metric handoff cannot bypass the finite ledger through a host infimum, nearest-point choice, quotient subset value, ambient completion, or real-completeness theorem. □

Theorem 6605.4 (Located set distance proximinal nonescape)**.** *Any* $\mathsf{ProximinalSet}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedSetDistance}^{\uparrow}$ *carrier receives only the displayed* $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{DistanceToSet}^{\uparrow}$*, rational-window,* $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg*, and local* $\mathsf{NameCert}$ *rows. A proximinal request may reuse the distance ledger, but it cannot extract a nearest point, a choice function selecting minimizers, quotient subset equality, compactness of the subset, or completeness of the ambient real line.*

Proof. Project the proximinal-facing request through P and C. The provenance names $\mathsf{ProximinalSet}^{\uparrow}$ only as a consumer boundary, and the continuation row exposes the same route X, A, D, R, E before any proximinal read can inspect the packet.

Apply the NameCert obligations above. They force every distance value to pass through the located subset, distance ledger, rational-window readback, and real seal.

There is no carrier coordinate for a selected minimizer, a choice function, quotient subset equality, compactness of the subset, or ambient real completeness. Therefore proximinal consumers can reuse the finite distance surface but cannot escape to nearest-point data. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSetDistance}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedSetDistance}^{\uparrow}$ packet is generated from a displayed metric source, located-subset admission, distance-to-set ledger, rational-window readback, real seal, componentwise transport, continuation replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSetDistance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6605.1, Definition 6605.2, Definition 6605.3, and Definition 6605.4 seed the finite Real-valued distance ledger for located subsets over a displayed metric source.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSetDistance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected nearest points, subset quotient equality, host infima, ambient compactness, $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, distance-ledger exactness, Real-metric handoff, proximinal non-escape, transport, replay, provenance, and local naming for the same finite packet.

Chapter 6606

A Concrete Naming Certificate for $\mathsf{CauchyProductTailBudget}^{\uparrow}$

Following Cauchy and Hardy on finite estimates for products of convergent series, the $\mathsf{CauchyProductTailBudget}^{\uparrow}$ packet records the tail-budget surface used before a Cauchy product read may reach a Real-facing endpoint. It sits after the Cauchy-product convergence route of chapter 3608, the product metric route of chapter 3551, the real-series source of chapter 1581, the dyadic rational arithmetic core of chapter 291, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite tail budgets for product estimates; it does not claim selected infinite sums, quotient series equality, choice, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6606.1 (Cauchy product tail-budget carrier)**.** *A* $\mathsf{CauchyProductTailBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, C, M, S, D, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *A and C are the two* $\mathsf{RealSeries}^{\uparrow}$ *source rows whose finite partial-sum windows are inspected.*
2. *M is the* $\mathsf{CauchyProduct}^{\uparrow}$ *convergence and product-metric row, read through the sibling routes of chapter 3608 and chapter 3551.*
3. *S is the finite tail schedule, naming the left tail, right tail, and mixed finite convolution windows allowed for a requested precision.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the product estimate, including the dyadic radii assigned to the two source tails and to the mixed product window.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed source windows and the tail schedule.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after A, C, M, S, D, Q are visible.*
7. *H records componentwise* hsame *transport for the source series, product row, tail schedule, dyadic ledger, readback, Real seal, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay of the same tail-budget route.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyProductTailBudget}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductTailBudget}^{\uparrow}}$ *row.*

The classifier reads only these rows. It has no coordinate for a selected infinite sum, quotient equality of series, a choice-selected tail, trichotomy, host multiplication on completed reals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6606.2 (Cauchy product tail-budget NameCert obligations)**.** *For every accepted* CauchyProductTailBudg *carrier* $B = (A, C, M, S, D, Q, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductTailBudget}^{\uparrow}}$ *surface consists exactly of carrier admission, two* $\mathsf{RealSeries}^{\uparrow}$ *source exposures, Cauchy-product convergence and metric routing, finite tail-schedule exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6606.1. The two source rows A, C, the product row M, the tail schedule S, and the dyadic ledger D are the only numerical rows available before readback.

The readback row Q is downstream of those finite rows. It repacks displayed source windows and product-tail budgets as regular rational data rather than as quotient series equality or a chosen infinite sum.

Finally inspect E, H, T, P, N. The Real seal E is reached only after the source, product, schedule, dyadic, and readback rows have been displayed, while the structural rows preserve the same packet. Hence the listed rows exhaust the local NameCert obligation surface. □

Theorem 6606.3 (Cauchy product tail-budget Real-seal nonescape)**.** *Every Real-facing read of an accepted* $\mathsf{CauchyProductTailBudget}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{RealSeries}^{\uparrow},\ \mathsf{CauchyProduct}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the displayed tail schedule, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows still attached. The route exports no selected infinite sum, quotient series equality, choice-selected tail, trichotomy row, host completed multiplication, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with Definition 6606.2. It makes the two real-series sources, product convergence and metric row, finite tail schedule, dyadic tolerance ledger, and regular readback mandatory before the Real seal can be consumed.

The finite route through S, D, Q controls the tail request. A consumer may inspect only the displayed left, right, and mixed product windows assigned to the requested precision; no coordinate supplies an external tail selector or a host infinite-sum object.

The structural rows H, T, P, N preserve this same route under transport, replay, provenance, and naming. Therefore any Real-facing read reaches E only through the displayed BEDC rows and cannot escape to quotient series equality, choice, trichotomy, host multiplication, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyProductTailBudget}^{\uparrow}$ endpoint read exposes two RealSeries source rows, one CauchyProduct convergence and metric row, a finite tail schedule, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence before any product-tail estimate is public.

Independence witness: cauchy-product-convergence, cauchy-product-metric, realseries, dyadicratcore, regseqrat: $\mathsf{CauchyProductTailBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two source series, the product convergence and metric route, finite left-right-mixed

tail schedules, dyadic product tolerances, regular readback, terminal Real sealing, transport, replay, provenance, and local naming in one tail-budget packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductTailBudget}\uparrow}$.

Constructive story: A $\mathsf{CauchyProductTailBudget}^{\uparrow}$ packet is generated from two RealSeries source rows, a CauchyProduct convergence and metric row, a finite tail schedule, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductTailBudget}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6606.1, Definition 6606.2, and Definition 6606.3 seed the finite Cauchy-product tail-budget route over displayed series, product, dyadic, readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductTailBudget}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected infinite sums, quotient series equality, choice, trichotomy, host completed multiplication, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, product-convergence and metric routing, finite tail-schedule exposure, dyadic tolerance accounting, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductTailBudgetUp.

Chapter 6607

A Concrete Naming Certificate for $\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}$ packet records the finite cover-refinement surface available for a displayed closed bounded interval once the cover has already been reduced to dyadic mesh rows and finite comparison rows. It sits after the closed bounded interval source of chapter 1591, the finite positive-radius route of chapter 452, the finite comparison packet of chapter 3430, and the terminal real-name seal of chapter 38. The packet names the finite interval cover route only; it is not open-cover compactness, a selected subcover theorem, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6607.1 (Compact interval finite cover-refinement carrier)**.** *A* $\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, C, M, L, R, O, S, D, E, H, T, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, carrying endpoint order, rational containment, dyadic containment, finite windows, regular readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary;*
2. *C is the finite interval-cover row, listing displayed interval cover members and their local containment witnesses over I;*
3. *M is the dyadic mesh row, recording the finite subdivision cells inspected by the cover comparison;*
4. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius row attached to the displayed cover and mesh route;*
5. *R is the* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *comparison row, pairing each retained mesh cell or refined cover member with its displayed parent cover row;*
6. *O is the finite refinement-order row, recording the inspection order for retained cells, parent cover members, and overlap checks;*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect endpoint names, mesh cells, cover witnesses, and retained members;*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row for mesh endpoints, radius comparisons, and containment inequalities;*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, C, M, L, R, O, S, D have been displayed;*
10. *H records componentwise* hsame *transport for the interval, cover, mesh, radius, refinement, order, window, dyadic, and seal rows;*
11. *T records displayed* Cont *replay for interval containment, mesh inspection, finite radius reads, refinement comparison, and Real-facing seal reads;*
12. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, host finite-subcover choice, quotient real equality, countable choice, selected Lebesgue numbers outside the displayed finite row, or ambient Real completeness.

Theorem 6607.2 (Compact interval finite cover-refinement obligations)**.** *For the carrier of Definition 6607.1, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (I, C, M, L, R, O, S, D, E, H, T, P, N)$, closed-interval source admission through I, finite cover admission through C, dyadic mesh admission through M, finite Lebesgue-number admission through L, finite refinement comparison through R, refinement-order admission through O, stream-window and dyadic readback through S, D, Real seal non-escape through E, componentwise* hsame *transport through H, displayed* Cont *replay through T, provenance through P, and local naming through N.*

Proof. Project the accepted carrier row by row. The interval source is I, the cover data is C, the mesh is M, the radius row is L, and the refinement comparison is R with order ledger O.

The finite interval cover is inspected only after the closed bounded interval row has displayed its endpoint and containment data. The mesh row M refines that same source interval, so every retained cover member is checked inside the interval packet rather than inside a host set of reals.

The radius and refinement rows are then read together. The finite Lebesgue-number row L supplies the visible positive-radius ledger, while R and O record how the retained mesh cells refine the displayed cover rows.

Finally S, D, E, H, T, P, N provide window inspection, dyadic arithmetic, the terminal Real seal, transport, replay, provenance, and local naming. Since no excluded compactness, selection, quotient, choice, or completeness coordinate occurs in the carrier, the listed rows exhaust the NameCert obligation surface. □

Theorem 6607.3 (Compact interval finite cover-refinement route)**.** *Every Real-facing or compact-interval consumer of an accepted* $\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto C, M \longmapsto \mathsf{FiniteLebesgueNumber}^{\uparrow}, \mathsf{FiniteCoverRefinement}^{\uparrow} \longmapsto S, D, E \longmapsto H, T, P, N.$$

Thus the consumer receives finite interval cover rows, dyadic mesh rows, finite refinement order, and the $\mathsf{Real}^{\uparrow}$ *seal boundary before it may use the packet as compact-interval cover-refinement data. The route exports no open-cover compactness theorem, choice-selected subcover, quotient equality, countable choice, selected external Lebesgue number, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the closed interval source. The consumer first reads I, so endpoint order, rational containment, dyadic containment, finite windows, regular readback, and the terminal Real boundary are already visible before cover data is opened.

Next inspect the cover and mesh rows C, M. Induction over the finite mesh rows checks each displayed cell against the finite cover row and records the retained member before any order count is consumed.

The positive-radius and refinement rows are then composed. The row L supplies the finite radius ledger, and R, O project each retained mesh or refined cover member back to its displayed parent cover row in finite order.

The terminal rows S, D, E, H, T, P, N keep the same route visible to Real-facing consumers. They seal the displayed finite route without adding arbitrary open covers, selected subcovers, quotient real equality, countable choice, external radius selection, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, finite interval-cover rows, dyadic mesh rows, a FiniteLebesgueNumberUp radius row, a FiniteCoverRefinementUp comparison row, a finite refinement-order ledger, StreamName windows, DyadicRatCore observations, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6607.1, Definition 6607.2, and Definition 6607.3 seed the finite compact-interval cover-refinement route over displayed interval, mesh, radius, refinement, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteCoverRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient real equality, countable choice, external Lebesgue-number selection, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite interval-cover admission, dyadic mesh stability, finite radius/refinement compatibility, refinement-order transport, and Real seal non-escape.

Chapter 6608

A Concrete Naming Certificate for $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$

Following Pontryagin, Boltyanskii, Gamkrelidze, and Mishchenko, and the optimal-control textbook route through Hamiltonian stationarity, the $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$ packet records only the finite certificate surface by which a control problem exposes state dynamics, endpoint cost, adjoint rows, a Hamiltonian comparison, and transversality data before any global existence theorem or selected optimizer is read. It sits after the differential-equation route of chapter 193, the dynamic-system rows of chapter 195, the derivative and variational rows of chapter 3632, the convex control rows of chapter 208, the scalar seal of chapter 38, and the finite vector-space rows of chapter 47. The packet names a displayed maximum-principle handoff; it does not assert existence of optimal controls, measurable-selection closure, smoothness beyond the displayed rows, host Euler–Lagrange completeness, or a global phase-space theorem.

Definition 6608.1 (Pontryagin maximum-principle carrier)**.** *A* $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, U, F, J, A, H, T, R, V, Q, C, G, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Ode}^{\uparrow}$ *state-equation row, recording the finite state window, endpoint rows, and local flow witnesses under inspection.*
2. *U is the admissible-control row, read through* $\mathsf{ConvexSet}^{\uparrow}$ *when the inspected control window carries convex constraints and otherwise only as the displayed finite admissibility ledger.*
3. *F is the* $\mathsf{DynSystem}^{\uparrow}$ *rollout row tying the state and control windows to the same finite transition route.*
4. *J is the* $\mathsf{Real}^{\uparrow}$ *cost row, storing the displayed objective, endpoint contribution, and finite comparison budget.*
5. *A is the adjoint row. It records the covector or multiplier window in the same* $\mathsf{VecSpace}^{\uparrow}$ *coordinates as the state and control rows.*
6. *H is the Hamiltonian row, storing the finite expression obtained from the state, control, cost, and adjoint rows.*
7. *T is the transversality row, containing only the displayed endpoint boundary relation attached to X, J, A.*

8. *R is the Real-seal row for the Hamiltonian comparison and endpoint cost comparison.*
9. *V stores componentwise* hsame *transport for state, control, rollout, cost, adjoint, Hamiltonian, transversality, Real-seal, replay, provenance, and local naming rows.*
10. *Q stores displayed* Cont *replay from an optimal-control query through $X, U, F, J, A, H, T, R, V$.*
11. *C is the convexity and local-variation ledger, recording only the finite variation rows needed to compare admissible controls in the displayed window.*
12. *G is the* Pkg *provenance over* $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PontryaginMaximumPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected optimal control, a host measurable-selection theorem, ambient smooth manifold completeness, quotient trajectory equality, or a global existence theorem.

Theorem 6608.2 (Pontryagin maximum-principle NameCert obligations)**.** *For every accepted* $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$ *carrier*

$$P = (X, U, F, J, A, H, T, R, V, Q, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PontryaginMaximumPrinciple}^{\uparrow}}$ *surface consists exactly of state-equation admission, admissible-control exposure, dynamic rollout, Real-valued cost readback, adjoint-row exposure, Hamiltonian construction, transversality exposure, finite variation comparison, Real-seal ordering, componentwise transport, displayed replay, provenance, local naming, and nonescape for selected optimizers, host measurable selection, quotient trajectory equality, ambient smoothness, and global existence.*

Proof. Project Definition 6608.1. The accepted inventory is $X, U, F, J, A, H, T, R, V, Q, C, G, N$, so every readable optimal-control datum is one of those displayed rows.

The analytic route is finite. The state and rollout rows X, F are read before the control and cost rows U, J can be compared, and the adjoint row A is attached to the same vector-space and calculus windows. The Hamiltonian row H is then computed only from those already displayed rows.

The endpoint and stationarity boundaries are also local. Row T records the transversality relation, row C records the finite variation ledger, and R seals only the displayed Real comparisons. The structural rows V, Q, G, N transport, replay, source, and name that route without adding selected optimizers, measurable selection, quotient trajectories, ambient smoothness, or global existence. □

Theorem 6608.3 (Pontryagin maximum-principle Hamiltonian handoff)**.** *Every accepted* PontryaginMaximumPrinc *packet reads a Hamiltonian stationarity surface only through the finite route*

$$\mathsf{Ode}^{\uparrow} \longrightarrow \mathsf{DynSystem}^{\uparrow} \longrightarrow \mathsf{Calculus}^{\uparrow} \longrightarrow \mathsf{ConvexSet}^{\uparrow} \longrightarrow \mathsf{VecSpace}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

In carrier notation, the Hamiltonian row H is admissible only after the state-equation row X, admissible-control row U, rollout row F, cost row J, adjoint row A, variation ledger C, and terminal Real-seal row R have been displayed. The handoff exports no selected optimizer, no host maximum theorem, no measurable-selection closure, and no global phase-space completion.

Proof. Start from an accepted carrier $P = (X, U, F, J, A, H, T, R, V, Q, C, G, N)$. The state endpoint is X, and the finite dynamic rollout is F, so a stationarity read cannot begin from an unrecorded phase-space object.

Read the control, cost, and adjoint data next. The admissible-control row U is constrained by the displayed convex or finite admissibility ledger, J stores the Real-valued objective window, and A stores the adjoint data in the same vector-space coordinates used by the state rows.

The Hamiltonian handoff is then the displayed row H together with the variation ledger C, transversality row T, and Real seal R. Since the carrier contains no selected optimizer, measurable-selection theorem, host maximum theorem, or global completion row, the exported stationarity surface is exactly the finite route stated above. □

Falsifiable prediction: Every $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$ consumer that reaches Hamiltonian stationarity must first display state-equation, admissible-control, dynamic-rollout, Real-cost, adjoint, Hamiltonian, transversality, variation-ledger, Real-seal, transport, replay, provenance, and local NameCert rows.

Independence witness: ode, dynsystem, calculus, convexset, real, vecspace: $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a state equation, control constraint, dynamic rollout, Real cost, adjoint row, Hamiltonian row, transversality boundary, variation ledger, structural replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PontryaginMaximumPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{PontryaginMaximumPrinciple}^{\uparrow}$ packet is generated from an OdeUp state row, a DynSystemUp rollout row, a displayed admissible-control row, a RealUp cost row, a CalculusUp variation row, a VecSpaceUp adjoint row, a Hamiltonian row, transversality data, Real-seal ordering, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PontryaginMaximumPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6608.1, Definition 6608.2, and Definition 6608.3 seed the traditional optimal-control maximum-principle packet over state dynamics, controls, adjoints, Hamiltonian comparison, endpoint data, and finite variation rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PontryaginMaximumPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close existence of optimal controls, measurable-selection closure, global smooth phase-space theorems, host maximum principles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, state-equation exposure, admissible-control exposure, rollout exactness, cost readback, adjoint exposure, Hamiltonian handoff, transversality exposure, variation-ledger exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PontryaginMaximumPrincipleUp.

Chapter 6609

A Concrete Naming Certificate for $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$

The $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ packet realizes the joint visual-metric, geodesic-flow, boundary-shadow, observer-expansion, and Real-seal route of chapter 9463 as finite NameCert data. It sits after the visual-metric packet of chapter 3866, the geodesic-flow packet of chapter 3856, the boundary-shadow route of chapter 3813, the observer-expansion packet of chapter 4167, and the terminal scalar seal of chapter 38. The packet names a finite visual-flow shadow surface; it is not a quotient boundary, a chosen geodesic ray, a global hyperbolic model, a physical observer, or an ambient Real-completeness claim.

Definition 6609.1 (Hyperbolic visual-flow shadow carrier)**.** *A* $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, B, O, R, T, Q, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row, recording the visible metric comparison and basepoint window under inspection.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, storing the finite flow segment and its endpoint ledger.*
3. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, exposing only the displayed boundary-shadow witness attached to the same metric and flow window.*
4. *O is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row, recording the observer-expansion readout that consumes the visual metric, flow, and boundary-shadow data.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for the visual-flow comparison and the expansion budget.*
6. *T stores componentwise* hsame *transport for visual metric, geodesic-flow, boundary-shadow, observer-expansion, Real-seal, replay, provenance, and local naming rows.*
7. *Q stores displayed* Cont *replay from a visual-flow request through M, F, B, O, R, T.*
8. *P is the* Pkg *provenance over* $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a quotient ideal boundary, selected global ray, completed hyperbolic model, physical observer, or ambient Real completion theorem.

Theorem 6609.2 (Hyperbolic visual-flow shadow obligation)**.** *For every accepted* $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ *carrier* $S = (M, F, B, O, R, T, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}}$ *surface consists exactly of visual-metric admission, geodesic-flow exposure, boundary-shadow exposure, observer-expansion exposure, Real-seal ordering, componentwise transport, displayed replay, provenance, local naming, and nonescape for quotient boundaries, selected rays, global hyperbolic models, physical observers, and ambient Real completeness.*

Proof. Project Definition 6609.1. The metric, flow, boundary, observer, and Real rows are the only analytic coordinates in the carrier.

The visual route starts with M and F. The boundary-shadow row B is accepted only as the displayed shadow attached to that same visual metric and finite geodesic-flow segment, so it cannot introduce an independent quotient boundary or selected ray.

The observer-expansion and Real-facing rows are downstream. Row O reads the joint visual metric, flow, and shadow surface, while R seals only the displayed comparison. The rows T, Q, P, N transport, replay, source, and name the same finite packet, so no global hyperbolic model, physical observer, or ambient Real-completeness theorem can be exported. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ consumer must display visual-metric, geodesic-flow, boundary-shadow, observer-expansion, Real-seal, transport, replay, provenance, and local naming rows before reading a visual-flow shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-geodesic-flow, hyperbolic-boundary-shadow, hyperbolic-observer-expansion: $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries visual metric, geodesic flow, boundary shadow, observer expansion, Real sealing, structural replay, provenance, and local naming.

The later Lean TasteGate route for `BEDC.Derived.HyperbolicVisualFlowShadowUp.TasteGate` must include Nontrivial $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ instances preserving $M, F, B, O, R, T, Q, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$ packet is generated from a HyperbolicVisualMetricUp row, a HyperbolicGeodesicFlowUp row, a HyperbolicBoundaryShadowUp row, a HyperbolicObserverExpansionUp row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}}$, seed)

Scope closed: Definition 6609.1 and Definition 6609.2 seed the finite visual-flow shadow packet over visual metric, geodesic-flow, boundary-shadow, observer-expansion, and Real-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient ideal boundaries, selected global rays, physical observer semantics, global hyperbolic models, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visual-metric exposure, geodesic-flow exposure, boundary-shadow exposure, observer-expansion exposure, Real-seal ordering, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicVisualFlowShadowUp.

Chapter 6610

A Concrete Naming Certificate for $\mathsf{KripkeSpread}^{\uparrow}$

Following Kripke on intuitionistic models and Brouwer on spreads, the $\mathsf{KripkeSpread}^{\uparrow}$ packet records finite spread inspection along the L10 countable-name route. It sits beside the binary prefix surface of chapter 1475, the finite-bar discipline of chapter 400, the finite branching carrier of chapter 6488, and the countable-name consumers of chapter 126 and chapter 301. The packet exposes only finite nodes, finite successor ledgers, prefix persistence, and readback windows; it is not weak Koenig path selection, countable choice, quotient stream equality, or completed Real data.

Definition 6610.1 (Kripke spread carrier)**.** *A* $\mathsf{KripkeSpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, N, B, A, S, Q, O, H, C, P, L)$$

with the following displayed rows:

1. *W is the finite world-prefix ledger, listing the inspected nodes and their prefix order.*
2. *N is the decidable node-admission row, recording which displayed prefixes belong to the spread.*
3. *B is the finite branching row, recording the displayed successor family for each inspected node.*
4. *A is the persistence row, requiring every displayed successor to retain the admitted prefix data of its predecessors.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which countable-name reads inspect the spread.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available only after the finite StreamName windows have been displayed.*
7. *O is the refusal row excluding weak Koenig path selection, countable choice, quotient stream equality, unbounded branch search, and completed* $\mathsf{Real}^{\uparrow}$ *closure.*
8. *H records componentwise* hsame *transport for worlds, node admission, finite branching, persistence, StreamName windows, RegSeqRat readback, refusal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a finite spread-inspection request through $W, N, B, A, S, Q, O, H, P, L$.*
10. *P is the* Pkg *provenance over* $\mathsf{KripkeSpread}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{FinitelyBranchingTree}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *L is the local* $\mathsf{NameCert}_{\mathsf{KripkeSpread}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these finite rows form one spread-inspection packet. It has no coordinate for a selected infinite branch, a total path functional, countable choice, quotient stream equality, ambient compactness, or completed real closure.

Theorem 6610.2 (Kripke spread NameCert obligations)**.** *For every accepted* $\mathsf{KripkeSpread}^{\uparrow}$ *carrier* $K = (W, N, B, A, S, Q, O, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{KripkeSpread}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite world-prefix ledger, node-admission row, finite branching row, persistence row, StreamName window schedule, RegSeqRat readback row, refusal row, componentwise transport, displayed replay, provenance, and local naming. Every L10 countable-name consumer must read the finite route*

$$W, N, B, A, S, Q, O, H, C, P, L$$

before extracting StreamName or RegSeqRat data, and no obligation is stored outside those rows.

Proof. Project the carrier of Definition 6610.1. The displayed finite coordinates are precisely $W, N, B, A, S, Q, O, H, C, P, L$.

The world, admission, branching, and persistence rows give the spread-inspection content. They record inspected prefixes, admitted nodes, displayed successors, and predecessor retention without creating an infinite path.

The StreamName and RegSeqRat rows are downstream. A countable-name consumer first opens the finite window schedule S, then reads the regular-rational row Q attached to that window.

Finally O, H, C, P, L keep the refusal boundary, transport, replay, provenance, and local name attached to the same packet. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6610.3 (Kripke spread prefix non-escape)**.** *Every accepted* $\mathsf{KripkeSpread}^{\uparrow}$ *consumer that inspects StreamName or RegSeqRat data must remain inside the finite route*

$$W, N, B, A, S, Q, O, H, C, P, L.$$

The consumer may reuse finite Cantor-space prefix observations, finite FanTheorem bar data, finite branching-tree rows, StreamName windows, and RegSeqRat readback data, but it receives no weak Koenig path selector, no countable-choice functional, no quotient stream equality, no unbounded branch search, and no completed $\mathsf{Real}^{\uparrow}$ *closure.*

Proof. Begin with a StreamName or RegSeqRat read of an accepted carrier. The carrier exposes countable-name data only through the finite window row S and the readback row Q.

The prefix rows W, N, B, A remain visible before that read. They supply admitted nodes and displayed successors as finite inspection data, not as a completed branch through the spread.

The refusal row O is part of the same packet. It blocks any reinterpretation of the finite route as weak Koenig path selection, countable choice, quotient stream equality, unbounded branch search, or completed real closure.

Transport, replay, provenance, and local naming through H, C, P, L preserve that boundary. Thus every consumer stays inside the finite prefix route and none of the excluded principles is exported. □

Falsifiable prediction: A $\mathsf{KripkeSpread}^{\uparrow}$ consumer that extracts a weak Koenig path selector, countable-choice functional, quotient stream equality, unbounded branch search, or completed $\mathsf{Real}^{\uparrow}$ closure without first reading $W, N, B, A, S, Q, O, H, C, P, L$ refutes the carrier surface.

Independence witness: cantorspace, fantheorem, finitely-branching-tree, streamname, regseqrat: $\mathsf{KripkeSpread}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite world-prefix inspection, node admission, finite branching, persistence, StreamName windows, RegSeqRat readback, refusal, transport, replay, provenance, and local naming while refusing selected branches and completed real data.

Closure status for $\mathsf{NameCert}_{\mathsf{KripkeSpread}^{\uparrow}}$.

Constructive story: A $\mathsf{KripkeSpread}^{\uparrow}$ packet is generated from finite world-prefix rows, node admission, finite branching, persistence, StreamName windows, RegSeqRat readback, an explicit refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KripkeSpread}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6610.1, Definition 6610.2, and Definition 6610.3 seed the finite spread-inspection boundary for L10 StreamName and RegSeqRat consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KripkeSpread}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close weak Koenig path selection, selected infinite branches, countable choice, quotient stream equality, unbounded branch search, completed $\mathsf{Real}^{\uparrow}$ closure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, node-admission exactness, finite branching coverage, prefix persistence, StreamName window handoff, RegSeqRat readback, transport, replay, provenance, and non-escape for BEDC.Derived.KripkeSpreadUp.

Chapter 6611

A Concrete Naming Certificate for $\mathsf{ChoquetSimplex}^{\uparrow}$

Following Choquet on compact convex sets and the Bishop–Bridges constructive reading of probability measures, the $\mathsf{ChoquetSimplex}^{\uparrow}$ packet records the boundary-facing finite NameCert surface for compact convex probability carriers. It sits after the compact source of chapter 60, the convex carrier of chapter 208, the Radon-measure route of chapter 2263, and the locally convex source of chapter 3386. The chapter names only the carrier rows needed by a compact-convex probability-boundary consumer; it does not assert representing-measure uniqueness, full Krein–Milman strength, selected extreme points, countable choice, quotient measure equality, or ambient locally convex completeness.

Definition 6611.1 (Choquet simplex carrier surface)**.** *A* $\mathsf{ChoquetSimplex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, V, P, B, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *K is the compact source row, read through the compact carrier and compact-metric observation surfaces.*
2. *V is the convex carrier row, including the displayed affine-combination and convex-subcarrier data visible to the packet.*
3. *P is the probability row, recording finite probability-window requests over the compact convex source.*
4. *B is the boundary-window row, naming the inspected extreme-boundary candidates only as finite observations.*
5. *R is the* $\mathsf{RadonMeasure}^{\uparrow}$ *readback row available after the compact, convex, probability, and boundary-window rows have been displayed.*
6. *E is the locally convex exposure row, read through* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *seminorm and neighbourhood observations needed by affine consumers.*
7. *H records componentwise* hsame *transport for compact, convex, probability, boundary, Radon, locally convex, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-convex probability-boundary request through the same rows.*

9. *Q is the* Pkg *provenance over* $\mathsf{ChoquetSimplex}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoquetSimplex}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, V, P, B, R, E, H, C, Q, N$. It has no coordinate for a host simplex object, selected barycentric measure, representing-measure uniqueness, full extreme-point generation, quotient measure equality, countable choice, or ambient locally convex completeness.

Lean4 ✓ `BEDC.Derived.ChoquetSimplexUp.ChoquetSimplexTasteGate single carrier alignment`

Theorem 6611.2 (Choquet simplex certificate surface)**.** *For every accepted* $\mathsf{ChoquetSimplex}^{\uparrow}$ *carrier $S = (K, V, P, B, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChoquetSimplex}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, convex-carrier admission through V, probability-window admission through P, boundary-window exposure through B, Radon readback through R, locally convex exposure through E, componentwise transport through H, displayed replay through C, provenance through Q, and local naming through N. Any probability-boundary consumer must read those rows before using the simplex packet.*

Proof. Project the accepted carrier of Definition 6611.1. The compact and convex rows are the only source rows, so a consumer first reads compact observations through K and affine convex data through V.

The probability and boundary rows are displayed next. The row P records finite probability-window requests, while B records the inspected boundary candidates as finite observations rather than selected extreme points.

The Radon and locally convex rows are downstream. The readback row R is available only after the compact, convex, probability, and boundary rows are visible, and E exposes the locally convex observation surface used by affine consumers.

Finally the structural rows H, C, Q, N transport, replay, source, and name exactly this route. Since no row stores representing-measure uniqueness, a selected barycentric measure, full extreme-point generation, quotient measure equality, countable choice, or ambient locally convex completeness, the listed rows exhaust the certificate surface. □

Falsifiable prediction: Every $\mathsf{ChoquetSimplex}^{\uparrow}$ probability-boundary consumer reads compact rows, convex rows, finite probability windows, boundary observations, Radon readback, locally convex exposure, transport, replay, provenance, and local naming before it exports a simplex-facing certificate.

Independence witness: compact, convexset, radon-measure, locally-convex-space: $\mathsf{ChoquetSimplex}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact source rows, convex affine rows, probability windows, boundary observations, Radon readback, locally convex exposure, transport, replay, provenance, and local NameCert naming while refusing selected representation data.

Closure status for $\mathsf{NameCert}_{\mathsf{ChoquetSimplex}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoquetSimplex}^{\uparrow}$ packet is generated from compact source rows, convex affine rows, finite probability-window rows, boundary observations, Radon readback, locally convex exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChoquetSimplex}^{\uparrow}}$, seed)

Scope closed: Definition 6611.1 and Definition 6611.2 seed the compact-convex probability-boundary certificate over compact, convex, Radon, locally convex, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChoquetSimplex}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close representing-measure uniqueness, full Krein–Milman generation, selected extreme points, quotient measure equality, countable choice, ambient locally convex completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, convex affine exposure, probability-window exactness, boundary-window readback, Radon handoff, locally convex exposure, transport, replay, provenance, and local naming for BEDC.Derived.ChoquetSimplexUp.

Chapter 6612

A Concrete Naming Certificate for $\mathsf{DyadicOrderTopology}^{\uparrow}$

Following Bishop and Bridges, the order topology of the dyadic rationals is read through located rational intervals and common dyadic refinements. The $\mathsf{DyadicOrderTopology}^{\uparrow}$ packet sits over the dyadic arithmetic source of chapter 291, the rational comparison source of chapter 37, and the order interface of chapter 1378; it presents its interval-window and basis-refinement rows to the metric route of chapter 57 and the real-name seal of chapter 38. The packet names only the finite order-topology surface needed before $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers read the first licensed infinite real name.

Definition 6612.1 (DyadicOrderTopology carrier)**.** *A* $\mathsf{DyadicOrderTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, O, I, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, including dyadic endpoints, common denominators, comparison budgets, and refinement witnesses.*
2. *O is the order row over the same dyadic source, recording the rational comparison and endpoint-order data inherited from* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Order}^{\uparrow}$*.*
3. *I is a finite interval-window row, listing located rational intervals with dyadic endpoints and the membership comparisons used by the topology basis.*
4. *B is the basis-refinement row, recording finite common dyadic refinements of overlapping interval windows.*
5. *H records componentwise* hsame *transport for D, O, I, B, C, P, N.*
6. *C records the displayed* Cont *replay from dyadic endpoints through order comparison, interval-window inspection, basis refinement, and consumer handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicOrderTopology}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only by these displayed rows. It has no coordinate for trichotomy beyond the displayed order row, arbitrary Dedekind cuts, quotient stream equality, selected limits, ambient real completeness, or host topological equality.

Lean4 (statement) `BEDC.Derived.DyadicOrderTopologyUp`

Theorem 6612.2 (DyadicOrderTopology basis stability)**.** *For an accepted* $\mathsf{DyadicOrderTopology}^{\uparrow}$ *carrier* $T = (D, O, I, B, H, C, P, N)$*, every pair of interval-window reads that overlap through the displayed order row admits a common dyadic refinement read through* B*. The refinement preserves the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row* D*, the same* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Order}^{\uparrow}$ *comparison data in* O*, and the same transport, replay, provenance, and local NameCert rows* H, C, P, N*.*

Proof. Project the accepted carrier onto D, O, I, B, H, C, P, N. The interval-window row I contains only finite dyadic endpoint data, and the order row O supplies the displayed comparisons used to test overlap.

Use common dyadic refinement. Given two displayed interval windows over the same source row, refine their endpoints to a common dyadic denominator and read the resulting subwindow through B. The comparison data remain those of O, because the refinement is a dyadic re-expression of the same rational interval order.

Finally transport and replay the refined row through H and C. Provenance and local naming are unchanged, so the common refinement remains inside the same $\mathsf{DyadicOrderTopology}^{\uparrow}$ packet and exports no selected real point, quotient stream equality, or ambient completeness principle. □

Theorem 6612.3 (DyadicOrderTopology located interval window)**.** *Every* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicOrderTopology}^{\uparrow}$ *carrier must read a located interval window through*

$$D \longrightarrow O \longrightarrow I \longrightarrow B \longrightarrow H, C, P, N.$$

The consumer may use the finite dyadic basis refinement as a topology source surface, but it receives no arbitrary open-set enumeration, no quotient equality of real names, no selected limit, no trichotomy outside O*, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the carrier rows. The dyadic source D and order row O are upstream of every interval-window row, so a consumer cannot inspect I without first displaying the dyadic endpoint and rational comparison data.

Apply basis stability. Any overlap or shrinking request is handled by a common dyadic refinement in B, still over the same D and O rows.

The structural rows H, C, P, N then carry the finite route to metric, regular-sequence, and real-name consumers. Since the carrier contains no row for arbitrary open-set enumeration, quotient real-name equality, selected limits, external trichotomy, or ambient real completeness, those objects cannot be exported by the located interval window. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicOrderTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicOrderTopology}^{\uparrow}$ packet is generated from DyadicRatCore endpoint data, rational order comparisons, located interval windows, common dyadic basis refinements, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicOrderTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6612.1, Definition 6612.2, and Definition 6612.3 seed the finite dyadic order-topology interface over displayed dyadic endpoint, rational order, interval-window, and basis-refinement rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicOrderTopology}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.DyadicOrderTopologyUp`

Bridge status: none

Not claimed: This chapter does not claim checked carrier obligations, arbitrary open-set enumeration, quotient equality of real names, selected limits, trichotomy outside the displayed order row, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, order-row stability, interval-window readback, common dyadic basis refinement, metric consumer handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicOrderTopologyUp.

Chapter 6613

A Concrete Naming Certificate for $\mathsf{RealBorelCode}^{\uparrow}$

Following Bishop and Bridges and descriptive-set-theoretic Borel-code practice, the $\mathsf{RealBorelCode}^{\uparrow}$ packet records constructive Borel codes over the existing $\mathsf{Real}^{\uparrow}$ naming surface as finite certificate data. It sits beside the regular-real carrier of chapter 38, the finite window route of chapter 126, the regular rational readback of chapter 301, and the dyadic endpoint arithmetic of chapter 291. The packet names code rows and their displayed interpretation schedules; it does not import host set equality, quotient equality of real names, impredicative sigma algebras, or a completed external powerset of $\mathsf{Real}^{\uparrow}$.

Definition 6613.1 (RealBorelCode carrier)**.** *A* $\mathsf{RealBorelCode}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, S, R, D, T, U, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite code-index ledger, listing exactly the inspected code rows and their immediate predecessor references.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule through which real-name consumers inspect only finite prefixes of the real input.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used to compare inspected windows with rational endpoint data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, carrying displayed lower and upper dyadic rational bounds for basic real cylinders.*
5. *T is the constructor-tag row. Its admitted tags are basic-cylinder, complement, and countable-coded union; the union tag stores only a displayed schedule of requested child rows, not an external subset family.*
6. *U is the finite interpretation schedule saying how a basic cylinder reads S, R, D, how complement flips an already displayed child decision row, and how a countable-coded union exposes the finite child windows demanded by the current query.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary: every interpretation row reaches the real-name seal only through the displayed StreamName, RegSeqRat, and DyadicRatCore rows.*

8. *H records componentwise* hsame *transport for code indices, StreamName windows, regular rational readback, dyadic endpoints, constructor tags, interpretation schedules, Real-seal rows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a finite code-inspection request through $I, S, R, D, T, U, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RealBorelCode}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealBorelCode}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive Borel-code packet. It has no coordinate for host membership in an external set of reals, quotient equality of real names, countable choice over code branches, or an ambient Boolean algebra of subsets.

Theorem 6613.2 (RealBorelCode NameCert obligations)**.** *For every accepted* $\mathsf{RealBorelCode}^{\uparrow}$ *carrier $B = (I, S, R, D, T, U, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealBorelCode}^{\uparrow}}$ *surface consists exactly of carrier admission for finite code indices, StreamName window exposure, RegSeqRat readback, DyadicRatCore endpoint comparison, constructor-tag admission, displayed interpretation schedules, Real-seal discipline, componentwise transport, displayed continuation replay, provenance, and local naming. Every code consumer must display*

$$I, S, R, D, T, U, E, H, C, P, N$$

before it may read the interpretation of a code row on a $\mathsf{Real}^{\uparrow}$ *name.*

Proof. Project the carrier of Definition 6613.1. The rows $I, S, R, D, T, U, E, H, C, P, N$ are the only accepted coordinates, so the NameCert obligations are read from those coordinates.

The basic-cylinder obligation is routed through S, R, D: a finite real-name window is compared with displayed dyadic endpoints by regular rational readback. Complement and countable-coded union use T and U to replay already displayed child rows or the finite child windows requested by the present query.

The Real-facing row E is reached only after the StreamName, RegSeqRat, and DyadicRatCore rows have been displayed. The structural rows H, C, P, N transport, replay, source, and locally name the same packet, leaving no further obligation outside the listed rows. □

Theorem 6613.3 (RealBorelCode cylinder stability)**.** *Every basic-cylinder row of an accepted* $\mathsf{RealBorelCode}^{\uparrow}$ *packet is stable under* hsame *transport of the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints. If two inspected real-name windows are transported componentwise through the packet support, the same basic-cylinder decision schedule is replayed by* Cont *and the same constructor tag remains accepted.*

Proof. Read the basic-cylinder branch of the constructor row T. Its interpretation schedule U names only the inspected StreamName window, the regular rational readback row, and the dyadic endpoint comparison.

Apply the componentwise transport row H to those three pieces. The transported window, readback, and endpoint rows remain attached to the same code index in I, and the local name row N keeps the carrier coordinate fixed.

The replay row C then re-executes the basic-cylinder schedule with the transported data. Since the packet contains no host real equality or external set membership coordinate, the stable output is exactly the displayed cylinder decision row. □

Theorem 6613.4 (RealBorelCode Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{RealBorelCode}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The complement and countable-coded union tags can replay only displayed child schedules and finite query windows before the terminal seal row E is consumed. They export no quotient equality of real names, host set equality, countable-choice branch selector, external sigma algebra, or ambient powerset object.

Proof. Start from an accepted packet $B = (I, S, R, D, T, U, E, H, C, P, N)$. The only Real-facing row is E, and it is named after S, R, D, T, U in the carrier.

For a basic-cylinder read, the route reaches E through the inspected window, regular rational comparison, and dyadic endpoints. For a complement read, U replays the displayed child schedule and flips only that local decision row.

For a countable-coded union read, the schedule exposes the finite child windows demanded by the current query. The row records no external infinite branch selector and no host subset family.

Thus every Real-facing consumer remains inside the displayed finite route. The refused quotient, host equality, choice, sigma-algebra, and powerset objects have no coordinate in the carrier. □

Falsifiable prediction: A $\mathsf{RealBorelCode}^{\uparrow}$ consumer that evaluates a code row on a $\mathsf{Real}^{\uparrow}$ name without first displaying $I, S, R, D, T, U, E, H, C, P, N$ refutes the carrier surface.

Independence witness: real, streamname, regseqrat, dyadicratcore: $\mathsf{RealBorelCode}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite code indices, constructor tags, interpretation schedules, StreamName windows, RegSeqRat readback, DyadicRatCore endpoints, Real-seal discipline, transport, replay, provenance, and local naming while refusing host set equality and quotient real equality.

Closure status for $\mathsf{NameCert}_{\mathsf{RealBorelCode}^{\uparrow}}$.

Constructive story: A $\mathsf{RealBorelCode}^{\uparrow}$ packet is generated from finite code-index rows, StreamName windows, RegSeqRat readback, DyadicRatCore endpoints, constructor tags for basic cylinders, complement, and countable-coded union, displayed interpretation schedules, Real-seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealBorelCode}^{\uparrow}}$, seed)

Scope closed: Definition 6613.1, Definition 6613.2, Definition 6613.3, and Definition 6613.4 seed the constructive Borel-code boundary over RealUp names.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealBorelCode}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host set equality, quotient equality of real names, countable-choice branch selection, external sigma-algebra completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, constructor-tag exactness, basic-cylinder stability, complement replay, countable-coded-union window coverage, Real-seal non-escape, transport, provenance, and local naming for BEDC.Derived.RealBorelCodeUp.

Chapter 6614

A Concrete Naming Certificate for $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$

Following Bishop–Bridges and the finite-net proof of uniform continuity on compact metric spaces, the $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ packet realizes the route of chapter 9237 as finite NameCert data for families of maps. It sits over the compact source packet of chapter 129, the map surface of chapter 130, the tolerance-only handoff of chapter 369, the family stability surface of chapter 4076, and the rational fold carrier of chapter 37. The packet records a finite router from compact nets and local family moduli to a public uniform-modulus row; it does not import open-cover compactness, sequential compactness, host function equality, or a choice-selected center family.

Definition 6614.1 (Compact family modulus router carrier)**.** *A* $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, E, L, Q, D, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including displayed centers, cover radii, and located source membership witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, listing the inspected map names and their pointwise modulus rows over the centers named by K.*
3. *E is the* $\mathsf{Equicontinuity}^{\uparrow}$ *compatibility row, requiring the family pointwise moduli to share the same tolerance request and source metric comparison.*
4. *L is the local finite-net lookup row sending a tolerance history to the displayed center-radius rows relevant to the family request.*
5. *Q is the finite* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over the displayed centerwise radii.*
6. *D is the dyadic tolerance ledger used for halving, positivity, lower-bound transport, and metric-triangle budget checks.*
7. *T is the public* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, depending only on the tolerance history and the displayed router packet.*
8. *H records componentwise* hsame *transport for compact nets, family map rows, equicontinuity rows, local lookups, rational folds, dyadic budgets, uniform-modulus handoffs, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a tolerance request through $K, F, E, L, Q, D, H, P, N$ to the handoff row T.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactFamilyModulusRouter}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, selected centers, external function equality, countable choice over a map family, or an ambient completeness principle.

Theorem 6614.2 (Compact family modulus router NameCert obligations)**.** *For every accepted* $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ *carrier $R = (K, F, E, L, Q, D, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactFamilyModulusR}}$ *surface consists exactly of compact finite-net exposure, family ContinuousMap pointwise-modulus exposure, Equicontinuity compatibility, finite lookup exactness, RatUp lower-bound fold exactness, dyadic tolerance transport, UniformModulus handoff, componentwise transport, displayed continuation replay, package provenance, and local naming. Every theorem-facing read must display*

$$K, F, E, L, Q, D, H, C, P, N$$

before it may consume T.

Proof. Project the carrier of Definition 6614.1. Its accepted rows are exactly the compact finite-net, family pointwise-modulus, equicontinuity, lookup, rational fold, dyadic budget, uniform handoff, and support rows.

The source of the router is K, F, E, L. These rows display the compact centers, the inspected family map names, the pointwise radii attached to those centers, and the compatibility data that lets all maps in the displayed family consume the same tolerance request.

The numerical route is Q, D. The finite $\mathsf{Rat}^{\uparrow}$ fold records a lower-bound history for the displayed radii, while the dyadic ledger transports positivity, halving, and metric-triangle budget checks.

Finally T, H, C, P, N export the tolerance-only handoff and preserve the packet under transport and replay. No open-cover, choice-selected, host-function, or completeness coordinate exists outside those rows. □

Theorem 6614.3 (Compact family finite-net routing)**.** *Every accepted* $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ *packet turns the compact-uniform-continuity route of chapter 9237 into a finite router*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Equicontinuity}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The output $\mathsf{UniformModulus}^{\uparrow}$ *row is a tolerance-only read from the displayed compact finite-net, family pointwise-modulus rows, equicontinuity compatibility, rational lower-bound fold, and dyadic tolerance ledger. It exports no open-cover compactness, selected center family, host equality of maps, countable choice, or ambient completeness.*

Proof. Begin with an accepted router $R = (K, F, E, L, Q, D, T, H, C, P, N)$. The compact row K supplies displayed centers and finite coverage data, and the family row F attaches pointwise modulus rows to those centers.

Use E to synchronize those pointwise rows across the inspected family. The lookup row L then selects only displayed center-radius data for the current tolerance request.

Fold the displayed radii through Q and transport the tolerance budget through D. This produces a lower-bound history depending on the tolerance and the finite router packet, not on an external center selector.

The handoff row T is therefore a public $\mathsf{UniformModulus}^{\uparrow}$ row. The support rows preserve the same finite route, so the excluded compactness, choice, host-equality, and completeness objects are not exported. □

Theorem 6614.4 (Compact family tolerance nonescape)**.** *Every tolerance read exported by an accepted* $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ *packet reaches* $\mathsf{UniformModulus}^{\uparrow}$ *only through the displayed compact finite-net, ContinuousMap family, Equicontinuity compatibility, RatUp fold, dyadic budget,* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. A downstream consumer cannot replace the router by a host choice of centers, a pointwise family selector, quotient equality of maps, sequential compactness, or ambient Real completeness.*

Proof. Read the requested tolerance through the replay row C. The replay exposes K, F, E, L, Q, D before the handoff row T is visible.

The compact and family rows display only finite center and pointwise-modulus data. The equicontinuity row synchronizes that data for the inspected family, while the rational and dyadic rows compute the lower-bound budget inside the packet.

Transport and provenance through H, P, N keep the same finite route attached to the local name. Since the carrier has no coordinate for host choices, quotient equality of maps, sequential compactness, or ambient completeness, a UniformModulus consumer cannot escape the displayed router. □

Falsifiable prediction: A $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ consumer that reads a $\mathsf{UniformModulus}^{\uparrow}$ row without first displaying $K, F, E, L, Q, D, H, C, P, N$ refutes the router surface.

Independence witness: compactmetric, continuousmap, uniformmodulus, equicontinuity, rat: $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite-net rows, family pointwise-modulus rows, equicontinuity compatibility, finite lookup, RatUp fold, dyadic tolerance budget, UniformModulus handoff, transport, replay, provenance, and local naming while refusing host choice of centers and map equality.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFamilyModulusRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactFamilyModulusRouter}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap family pointwise-modulus rows, Equicontinuity compatibility, finite lookup rows, RatUp lower-bound folds, dyadic tolerance budgets, UniformModulus handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactFamilyModulusRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6614.1, Definition 6614.2, Definition 6614.3, and Definition 6614.4 seed the finite family-router boundary for compact-uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactFamilyModulusRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, sequential compactness, host function equality, selected center families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, family pointwise-modulus coverage, equicontinuity compatibility, lookup exactness, RatUp fold exactness, dyadic budget transport, UniformModulus handoff, and non-escape for BEDC.Derived.CompactFamilyModulusRouterUp.

Chapter 6615

A Concrete Naming Certificate for $\mathsf{DynkinPiLambda}^{\uparrow}$

Following Dynkin and Halmos, the $\mathsf{DynkinPiLambda}^{\uparrow}$ packet records the finite BEDC surface of the pi-lambda theorem as a handoff from displayed pi-system generators to a Dynkin-system closure route. It sits after the monotone-class carrier of chapter 4194, the measurable-event rows of chapter 92, the generated-set boundary of chapter 3384, and the displayed membership discipline of chapter 3668. The packet names generator admission, finite intersection closure, complement closure, disjoint-union closure, monotone-class handoff, measure-facing seal, transport, replay, provenance, and local naming; it does not import a host sigma-algebra completion, measure-extension theorem, quotient subset equality, or selected countable family.

Definition 6615.1 (Dynkin pi-lambda carrier)**.** *A* $\mathsf{DynkinPiLambda}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (G, I, C, U, M, S, H, R, P, N)$$

with the following displayed rows:

1. *G is the displayed pi-system generator family, read through* $\mathsf{SetLike}^{\uparrow}$ *rows and through the* $\mathsf{BorelSet}^{\uparrow}$ *generated-set boundary whenever the source is Borel-facing.*
2. *I records finite intersection closure for generator rows that are jointly visible in G.*
3. *C records complement closure relative to the named universe row exposed by the same displayed family.*
4. *U records disjoint countable-union requests only through finite observed stages and their named continuation rows.*
5. *M is the* $\mathsf{MonotoneClass}^{\uparrow}$ *handoff row that turns the displayed Dynkin closure route into the monotone-class closure surface already named by chapter 4194.*
6. *S is the* $\mathsf{Measure}^{\uparrow}$ *seal row reached only after the generator, finite-intersection, complement, disjoint-union, and monotone-class rows have been exposed.*
7. *H stores componentwise* hsame *transport for G, I, C, U, M, S and the structural rows.*
8. *R stores displayed* Cont *replay of the finite route*

$$G, I \longmapsto C, U \longmapsto M \longmapsto S, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{DynkinPiLambda}^{\uparrow}$, $\mathsf{MonotoneClass}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DynkinPiLambda}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, I, C, U, M, S, H, R, P, N$. It has no coordinate for an ambient sigma-algebra, host pi-lambda theorem, selected countable family, measure extension, quotient equality of subsets, or external equality of events.

Theorem 6615.2 (Dynkin pi-lambda NameCert obligations)**.** *For the carrier of Definition 6615.1, the local* $\mathsf{NameCert}_{\mathsf{DynkinPiLambda}^{\uparrow}}$ *surface consists exactly of generator admission through G, finite-intersection closure through I, complement closure through C, disjoint-union continuation through U, monotone-class handoff through M, measure-facing seal through S, componentwise* hsame *transport through H, displayed* Cont *replay through R, package provenance through P, and local naming through N. Every accepted* $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, *or* $\mathsf{SetLike}^{\uparrow}$ *consumer that reads a pi-lambda conclusion must expose those rows before it treats the generated family as measure-visible.*

Proof. Project the carrier $D = (G, I, C, U, M, S, H, R, P, N)$. The generator row G is the only entry point for displayed subset requests, and the finite-intersection row I is the only pi-system closure coordinate.

Read the Dynkin closure rows next. Complement requests pass through C, while disjoint-union requests pass through the finite observed stages and continuation rows stored in U. These rows stay attached to the same displayed generator family.

The handoff and seal rows then determine every downstream consumer. The monotone-class row M is the only route to the already named $\mathsf{MonotoneClass}^{\uparrow}$ surface, and the measure-facing row S is reached only after that route has been exposed.

Finally replay H, R, P, N. Transport, continuation replay, provenance, and local naming preserve exactly the same finite packet, so no host sigma-algebra completion, selected countable family, measure-extension theorem, quotient subset equality, or external event equality can enter the certificate. □

Theorem 6615.3 (Dynkin pi-lambda MonotoneClass handoff)**.** *Every accepted* $\mathsf{DynkinPiLambda}^{\uparrow}$ *packet exports the handoff route*

$$G, I, C, U \longmapsto M \longmapsto H, R, P, N$$

to $\mathsf{MonotoneClass}^{\uparrow}$. *A downstream consumer may cite monotone closure of the displayed generator family only after the pi-system intersection row, Dynkin complement row, disjoint-union continuation row, monotone-class handoff row, transport row, replay row, provenance row, and local name row have all been exposed.*

Proof. Start with the displayed generator row G. The pi-system condition is not a host family assertion; in the packet it is the finite-intersection row I over the visible subset rows.

Pass through the Dynkin-system rows. Complement closure is read through C, and disjoint-union closure is read through the finite observed stages stored in U. Both rows keep the same displayed generator family and do not choose an external countable family.

Apply the monotone-class handoff row M. It is the only coordinate that lets a consumer enter the $\mathsf{MonotoneClass}^{\uparrow}$ surface, so the consumer receives the existing monotone closure route rather than an ambient pi-lambda theorem.

The structural rows H, R, P, N transport, replay, source, and name the same handoff. Therefore the route exports no sigma-algebra completion, measure extension, quotient subset equality, or selected countable chain. □

Theorem 6615.4 (Dynkin pi-lambda measure seal nonescape)**.** *For every accepted* $\mathsf{DynkinPiLambda}^{\uparrow}$ *carrier*

$$D = (G, I, C, U, M, S, H, R, P, N),$$

the $\mathsf{Measure}^{\uparrow}$ *seal row* S *may be consumed only through the finite route*

$$G, I, C, U, M, H, R, P, N.$$

In particular, the seal cannot be used as a proof of host sigma-algebra completion, measure extension, quotient equality of subsets, selected countable families, external event equality, or an ambient pi-lambda theorem.

Proof. Project the measure-facing row S from the carrier. Its source rows are the displayed generator, finite-intersection, complement, disjoint-union, monotone-class handoff, transport, replay, provenance, and local naming rows.

Use the NameCert obligations of Definition 6615.2. They force every measure-facing consumer to expose $G, I, C, U, M, H, R, P, N$ before S can be read.

The excluded principles have no carrier coordinate in that route. The seal is therefore a terminal measure-facing consumer of the finite Dynkin pi-lambda handoff, not an ambient sigma-algebra or measure-extension principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DynkinPiLambda}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DynkinPiLambda}^{\uparrow}$ packet is generated from displayed pi-system generators, finite-intersection closure, complement closure, disjoint-union continuation, a MonotoneClass handoff, a Measure seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DynkinPiLambda}^{\uparrow}}$, seed)

Scope closed: Definition 6615.1, Definition 6615.2, Definition 6615.3, and Definition 6615.4 seed the finite pi-lambda handoff surface over displayed set generators, Dynkin closure rows, monotone-class handoff, measure seal, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DynkinPiLambda}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host sigma-algebra completion, measure extension, selected countable families, quotient subset equality, external event equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pi-system closure, Dynkin closure, monotone-class handoff, measure-seal nonescape, transport, provenance, and replay for BEDC.Derived.DynkinPiLambdaUp.

Chapter 6616

A Concrete Naming Certificate for BishopLocatedUniformConvergence$^{\uparrow}$

Following Bishop and Bridges, located uniform convergence is the constructive interface where a family of displayed functions approaches a displayed limit by a finite modulus that can be read at every source observation and positive tolerance. The BishopLocatedUniformConvergence$^{\uparrow}$ packet sits over the uniform-limit handoff of chapter 463, the continuous-map rows of chapter 130, the metric source of chapter 57, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, and the finite schedule surface of chapter 126. It names finite located-modulus data for uniform convergence without importing host functions, choice, quotient equality of maps, selected pointwise limits, or ambient Real$^{\uparrow}$ completeness.

Definition 6616.1 (Bishop located uniform convergence carrier)**.** *A* BishopLocatedUniformConvergence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, F, L, M, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *X is the source* Met$^{\uparrow}$ *row, including the point classifier, distance observations, and finite source histories.*
2. *F is the* ContinuousMap$^{\uparrow}$ *family row, recording the displayed functions and their local modulus-bearing readback data.*
3. *L is the displayed limit-map row consumed through the* UniformLimit$^{\uparrow}$ *route.*
4. *M is the located uniform modulus row. Given a positive tolerance request, it records a finite stage bound that works uniformly over the displayed source observations.*
5. *W is the* StreamName$^{\uparrow}$ *schedule row for finite source windows, function-stage windows, limit-value windows, and tolerance requests.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the rational comparison windows generated by M and W.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row for the comparison values and the accepted limit read.*
8. *H stores componentwise* hsame *transport for the metric source, continuous-map family, limit row, located modulus, schedules, rational readbacks, Real seals, replay, provenance, and local name.*

9. *C stores displayed* Cont *replay from a uniform-convergence request through* X, F, L, M, W, R, E, H.
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedUniformConvergence}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedUniformConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, L, M, W, R, E, H, C, P, N$. It has no coordinate for a host function space, choice-selected convergence stage, quotient equality of maps, selected pointwise limit, open-cover compactness, or ambient real completeness.

Theorem 6616.2 (Bishop located uniform convergence NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedUniformConvergence}^{\uparrow}$ *carrier*

$$U = (X, F, L, M, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedUniformConvergence}^{\uparrow}}$ *obligations are exactly carrier admission, source-metric compatibility, continuous-map family exposure, uniform-limit handoff, located finite-modulus stability, stream-window scheduling, regular-rational comparison readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6616.1. The accepted packet displays exactly the metric source, continuous-map family, limit row, located modulus, stream schedules, rational readbacks, Real seals, transport, replay, provenance, and local naming rows.

The uniform part is M. A tolerance request can become public only as a finite stage bound that is read together with the source row X, the function family F, the limit row L, and the finite schedule row W.

The located comparison part is R, E. The regular rational windows record the finite comparisons produced by the modulus and schedule rows, and the terminal Real seal is read only after those windows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for host functions, choice-selected stages, quotient map equality, selected pointwise limits, open-cover compactness, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6616.3 (Bishop located uniform convergence nonescape)**.** *Every* $\mathsf{BishopLocatedUniformConvergence}^{\uparrow}$ *consumer that reads a located uniform convergence claim must pass through*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{UniformLimit}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows retained. The packet exports finite located-modulus uniform convergence only; it does not export host functions, choice-selected stages, quotient equality of maps, selected pointwise limits, open-cover compactness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier admission theorem. The only rows available to a consumer are $X, F, L, M, W, R, E, H, C, P, N$.

Apply the NameCert obligations theorem. It makes source-metric compatibility, continuous-map exposure, uniform-limit handoff, located finite-modulus stability, stream scheduling, regular-rational readback, and Real-seal nonescape the public route for the packet.

The consumer therefore receives a finite route through $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with transport and replay preserved by H, C, P, N. None of the excluded host, choice, quotient, pointwise-selection, compactness, or completeness principles is a row of the carrier, so none can be exported by the local name. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedUniformConvergence}^{\uparrow}$ read exposes a source $\mathsf{Met}^{\uparrow}$ row, continuous-map family, displayed uniform-limit row, located finite-modulus row, $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{RegSeqRat}^{\uparrow}$ comparison windows, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any consumer reads uniform convergence.

Independence witness: uniformlimit, continuousmap, metric, real, regseqrat, streamname: no listed sibling is bijective with $\mathsf{BishopLocatedUniformConvergence}^{\uparrow}$ because this packet jointly binds source metric data, continuous-map family rows, a displayed limit row, a located finite modulus, finite schedules, rational comparison windows, Real seals, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedUniformConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedUniformConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6616.1, Definition 6616.2, and Definition 6616.3 seed the finite located-modulus route for constructive uniform convergence over metric, continuous-map, uniform-limit, stream, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedUniformConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function spaces, choice-selected stages, quotient equality of maps, selected pointwise limits, open-cover compactness, ambient Real completeness, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-metric compatibility, continuous-map exposure, uniform-limit handoff, located finite-modulus stability, stream scheduling, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedUniformConvergenceUp.

Constructive story: A $\mathsf{BishopLocatedUniformConvergence}^{\uparrow}$ packet is generated from a source Metric row, continuous-map family, displayed limit row, located finite modulus, stream schedules, regular-rational comparison windows, terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Chapter 6617

A Concrete Naming Certificate for MetaCICTypedNormalFormScheduler$^{\uparrow}$

The MetaCICTypedNormalFormScheduler$^{\uparrow}$ packet realizes the normalization remaining question of section 9386.4 as finite scheduler-state data for closed typed terms with candidate gates and endpoint seals. It sits beside the frontier carrier of chapter 892, the bounded normal equality checker of chapter 752, the closed type checker seal of chapter 2182, the candidate normalization router of chapter 5210, and the candidate normalization witness of chapter 6577. The packet names scheduler-budget, candidate-gate, endpoint-seal, obstruction, transport, replay, provenance, and local naming rows; it is not an evidence-free strong-normalization theorem, unrestricted evaluator, quotient syntax equality, host reduction oracle, or closed consistency principle.

Definition 6617.1 (MetaCIC typed normal-form scheduler carrier)**.** *A* MetaCICTypedNormalFormScheduler$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, G, B, N, E, O, R, H, C, P, L)$$

with the following displayed rows:

1. *T is the sealed closed typed term row, read through the closed type checker surface.*
2. *G is the candidate-gate row, recording which candidate interface admits the term for scheduler inspection.*
3. *B is the scheduler-budget row, storing finite fuel, phase, residual, and replay-window accounting for the normalization attempt.*
4. *N is the typed normal-form row, recording the endpoint syntax together with the type seal under which it is read.*
5. *E is the endpoint-seal row consumed by bounded normal equality and normal-endpoint budget consumers.*
6. *O is the obstruction row, retaining missing candidate gates, budget exhaustion, blocked residuals, failed endpoint seals, and failed typed replay as visible scheduler boundaries.*
7. *R is the router handoff row, tying the scheduler to the candidate normalization router and candidate normalization witness surfaces.*
8. *H records componentwise* hsame *transport for the closed typed term, candidate gate, scheduler budget, typed endpoint, endpoint seal, obstruction, router handoff, replay, provenance, and local name.*

9. *C records displayed* Cont *replay from a normalization request through T, G, B, N, E, O, R, H.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$, $\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}$, $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}}$ *row.*

The classifier compares accepted scheduler packets only through $T, G, B, N, E, O, R, H, C, P, L$. It has no coordinate for global strong normalization, unrestricted subject reduction, quotient syntax equality, hidden evaluator state, host reduction oracles, or completed closed consistency.

Theorem 6617.2 (MetaCIC typed normal-form scheduler obligations)**.** *For every accepted* MetaCICTypedNormalFo *carrier*

$$S = (T, G, B, N, E, O, R, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}}$ *obligations are exactly carrier admission, closed typed-term seal exposure, candidate-gate visibility, scheduler-budget totality for accepted requests, typed normal endpoint sealing, obstruction exactness, candidate-router handoff, candidate-witness compatibility, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6617.1. The accepted packet displays exactly the closed typed term, candidate gate, scheduler budget, typed endpoint, endpoint seal, obstruction, router handoff, transport, replay, provenance, and local naming rows.

The gate and budget rows G, B are consumed before any endpoint is public. Thus a scheduler read cannot reach N or E without exposing the candidate interface that admits the term and the finite scheduler accounting that bounds the attempt.

The obstruction row O remains visible for missing gates, exhausted budget, blocked residuals, failed endpoint seals, and failed typed replay. The router row R then hands only the displayed finite endpoint or obstruction data to the candidate router and candidate witness surfaces.

Finally H, C, P, L transport, replay, source, and name the same route. Since no carrier coordinate supplies global strong normalization, unrestricted subject reduction, quotient syntax equality, hidden evaluator state, host reduction oracles, or closed consistency, the listed obligations exhaust the local NameCert surface. □

Theorem 6617.3 (MetaCIC typed normal-form scheduler nonescape)**.** *Every public normalization-frontier consumer of an accepted* $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$ *packet factors through*

$$\mathsf{ClosedTypeCheckerSeal}^{\uparrow} \longmapsto G, B \longmapsto N, E \longmapsto O, R \longmapsto H, C, P, L.$$

The consumer receives a sealed closed typed term, candidate-gate verdict, finite scheduler budget, typed normal endpoint or visible obstruction, router handoff, transport, replay, provenance, and local naming. It receives no hidden scheduler state, evaluator oracle, quotient syntax equality, evidence-free normalization theorem, unrestricted subject reduction, or completed closed consistency.

Proof. Start with the closed typed term row T. The only scheduler route from this row to endpoint data passes through the candidate gate G and finite budget row B.

Apply Definition 6617.2. It makes typed endpoint sealing, obstruction exactness, candidate-router handoff, and candidate-witness compatibility obligations of the same finite packet.

The structural rows H, C, P, L preserve the displayed route when the scheduler packet is consumed by the normalization frontier, bounded equality checker, router, or candidate witness. Because hidden scheduler state, evaluator oracles, quotient syntax equality, evidence-free normalization, unrestricted subject reduction, and closed consistency are not carrier coordinates, none can be exported by the local name. □

Falsifiable prediction: Any accepted $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$ read that exposes typed endpoint data without first displaying the sealed closed typed term, candidate gate, finite scheduler budget, obstruction row, router handoff, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: metacicnormalizationfrontier, boundednormalequalitychecker, closed-type-checker-seal, metacic-candidate-normalization-router, metacic-candidate-normalization-witness: no listed sibling is bijective with $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$ because this packet jointly carries sealed closed typed terms, candidate gates, scheduler budgets, typed endpoint seals, obstruction rows, router handoff, transport, replay, provenance, and local NameCert rows.

Lean TasteGate work for $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$ must include Nontrivial and FieldFaithful instances so the candidate gate, scheduler budget, endpoint seal, obstruction, router handoff, replay, provenance, and local naming rows remain distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6617.1, Definition 6617.2, and Definition 6617.3 seed the finite typed normal-form scheduler route through closed typed terms, candidate gates, scheduler budgets, typed endpoints, obstruction, router handoff, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global strong normalization, unrestricted subject reduction, quotient syntax equality, hidden evaluator state, host reduction oracles, completed closed consistency, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed type seal exposure, candidate-gate visibility, scheduler-budget totality, typed endpoint sealing, obstruction exactness, router handoff, candidate-witness compatibility, Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICTypedNormalFormSched

Constructive story: A $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$ packet is generated from a sealed closed typed term, candidate-gate row, finite scheduler budget, typed normal endpoint, endpoint seal, obstruction row, router handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Chapter 6618

A Concrete Naming Certificate for $\mathsf{SearchableCompact}^{\uparrow}$

Following Escardo searchable compactness and Bishop constructive compactness, the $\mathsf{SearchableCompact}^{\uparrow}$ packet records a finite-search compactness interface as BEDC NameCert data. It sits beside the finite bar and modulus routes of chapter 1525, the Boolean-prefix source of chapter 1475, the finite-net compact metric surface of chapter 129, the modulus handoff of chapter 369, and the finite observation schedules of chapter 126. The packet exports searchable finite selectors for displayed predicates and modulus consumers; it does not export open-cover compactness, choice-selected witnesses, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6618.1 (SearchableCompact carrier)**.** *A* $\mathsf{SearchableCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, B, Q, F, M, W, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, read through either* $\mathsf{CompactMetric}^{\uparrow}$ *finite nets or* $\mathsf{CantorSpace}^{\uparrow}$ *prefix windows;*
2. *B is the finite branch or net boundary row supplied by* $\mathsf{FanFunctional}^{\uparrow}$ *when the source is a fan-like searchable domain;*
3. *Q is the inspected decidable predicate row, opened only on the finite windows named by the carrier;*
4. *F is the finite-selector row, recording the retained candidate list and the first accepted candidate when the inspected predicate is witnessed;*
5. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row used when a downstream continuous predicate asks for a bounded search depth;*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for predicate, prefix, and finite-net reads;*
7. *R is the replay ledger from compact source and predicate windows to selector admission and modulus handoff;*
8. *H records componentwise* hsame *transport for K, B, Q, F, M, W, R;*
9. *C records displayed* Cont *replay of the same finite-search route;*

10. *P is the* Pkg *provenance over* $\mathsf{SearchableCompact}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SearchableCompact}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through these displayed rows. It has no coordinate for an arbitrary open cover, a choice-selected witness outside the retained finite window, a host compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6618.2 (SearchableCompact NameCert obligations)**.** *For an accepted* $\mathsf{SearchableCompact}^{\uparrow}$ *carrier $S = (K, B, Q, F, M, W, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SearchableCompact}^{\uparrow}}$ *surface consists exactly of compact source admission through K, finite boundary admission through B, decidable predicate exposure through Q, finite selector admission through F, modulus handoff through M, finite observation scheduling through W, replay through R, C, componentwise transport through H, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6618.1. Its source-facing rows are K and B: they expose compact metric finite nets, Cantor prefix windows, or fan-functional finite bar data before any selector is read.

The predicate and selector rows are read next. The row Q opens only the displayed finite predicate windows, and F records the finite retained candidates and accepted candidate boundary when such a boundary is displayed.

Finally M, W, R, H, C, P, N route the selector to downstream modulus and observation consumers. Because the carrier has no coordinate for an arbitrary open cover, selected global witness, host compactness theorem, or ambient real completeness, those objects cannot be exported by the local NameCert. □

Theorem 6618.3 (SearchableCompact finite-selection soundness)**.** *Every finite-selection read exported by an accepted* $\mathsf{SearchableCompact}^{\uparrow}$ *carrier factors through*

$$K, B, Q, F, M, W, R, H, C, P, N.$$

The consumer first reads the compact source and finite boundary rows, then the displayed decidable predicate windows, then the retained selector row, and only then the modulus and replay rows. Thus the exported search result is a constructive finite selector over the displayed packet, not an open-cover compactness proof, a choice-selected witness outside the packet, or a $\mathsf{Real}^{\uparrow}$ *completeness argument.*

Proof. Begin with the compact source rows. The row K supplies the finite compact metric or Cantor prefix source, and B supplies the fan-functional or finite boundary data when the search route requires a bounded branch depth.

The predicate row Q is inspected only through W. The selector row F is therefore tied to the finite observation schedule and cannot name a candidate outside the displayed predicate windows.

Apply the replay rows R and C, then transport and provenance through H, P, N. The modulus consumer M can read only the same finite route. Hence the finite selector is sound for the packet that was displayed, while open-cover compactness, choice-selected witnesses, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the carrier. □

Falsifiable prediction: Every $\mathsf{SearchableCompact}^{\uparrow}$ finite-selector consumer must read the compact source row, finite boundary row, decidable predicate windows, retained selector row, modulus

handoff, observation schedule, replay, transport, provenance, and local naming before consuming the selected candidate.

Independence witness: fanfunctional, cantorspace, compactmetric, uniformmodulus, streamname: $\mathsf{SearchableCompact}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact-source admission, finite boundary exposure, decidable predicate windows, retained selector rows, modulus handoff, observation schedules, replay, transport, provenance, and local naming in one finite-search packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SearchableCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{SearchableCompact}^{\uparrow}$ packet is generated from compact source rows, finite boundary rows, decidable predicate windows, finite selector rows, modulus handoff, StreamName schedules, replay ledgers, componentwise transport, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SearchableCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6618.1, Definition 6618.2, and Definition 6618.3 seed the finite-search compactness interface over displayed FanFunctionalUp, CantorSpaceUp, CompactMetricUp, UniformModulusUp, StreamNameUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SearchableCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, choice-selected witnesses, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires classifier stability, finite-selector replay, modulus-handoff nonescape, and downstream compact-uniform-continuity consumption for the same displayed packet.

Chapter 6619

A Concrete Naming Certificate for GalerkinErrorEstimate$^{\uparrow}$

Following Cea and standard Galerkin finite-element error analysis, the GalerkinErrorEstimate$^{\uparrow}$ packet records the constructive best-approximation surface exposed after a coercive variational problem has been projected onto a displayed finite trial space. It sits over the residual certificate of chapter 5169, the variational solution row of chapter 3419, the Hilbert comparison surface of chapter 91, the bounded-operator action row of chapter 1644, the norm ledger of chapter 89, and the scalar seal of chapter 38. The packet gives downstream finite-element and PDE consumers a finite error-estimate route without importing quotient function spaces, selected minimizers, host projection theorems, or choice.

Definition 6619.1 (Galerkin error estimate carrier)**.** *A* GalerkinErrorEstimate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (V, a, l, u, u_h, e, c, C, H, R, T, P, N)$$

with the following displayed rows:

1. *V is the finite trial-space row, naming the accepted trial basis, finite coefficient windows, and admissible comparison tests.*
2. *a is the coercive bilinear-form row, read through the bounded operator and Hilbert surfaces with displayed continuity and coercivity evidence.*
3. *l is the load row, naming the bounded functional data consumed by the variational problem.*
4. *u is the exact variational row supplied through the* LaxMilgram$^{\uparrow}$ *handoff and exposed only by its displayed equation against admitted tests.*
5. *u_h is the Galerkin row supplied through the* GalerkinProjection$^{\uparrow}$ *residual-orthogonality surface on the displayed trial space.*
6. *e is the error row recording the comparison between u and u_h in the displayed norm ledger.*
7. *c and C are the coercivity and continuity constants as finite scalar rows, with no selected optimizer or ambient real-number oracle.*
8. *H is the best-approximation comparison row. It records that each displayed trial competitor is compared through the same norm and bilinear-form rows before the scalar estimate is read.*
9. *R is the* Real$^{\uparrow}$ *bound row, reached only after the residual orthogonality, variational equation, coercivity, continuity, and comparison rows have been displayed.*

10. *T records componentwise* hsame *transport for trial-space, bilinear-form, load, exact-solution, Galerkin, error, constant, comparison, scalar-bound, replay, provenance, and local naming rows.*
11. *P is the* Pkg *provenance over* $\mathsf{GalerkinErrorEstimate}^{\uparrow}$, $\mathsf{GalerkinProjection}^{\uparrow}$, $\mathsf{LaxMilgram}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{GalerkinErrorEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, a, l, u, u_h, e, c, C, H, R, T, P, N$. It has no coordinate for a quotient function space, selected minimizer, host Hilbert projection theorem, ambient best-approximation theorem, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 6619.2 (Galerkin error estimate NameCert obligations)**.** *For every accepted* $\mathsf{GalerkinErrorEstimate}^{\uparrow}$ *carrier*

$$G = (V, a, l, u, u_h, e, c, C, H, R, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GalerkinErrorEstimate}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier locality over the displayed rows, residual orthogonality through u_h, coercivity and continuity through c, C, best-approximation comparison through H, scalar-bound readback through R, componentwise transport through T, replay through the displayed finite route, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6619.1. The trial space, bilinear form, load, exact variational row, Galerkin row, error row, constants, comparison row, scalar bound, transport, provenance, and local name are the visible inventory.

The residual-orthogonality obligation is read from the Galerkin row u_h and the finite trial row V. The exact variational obligation is read from u through the Lax-Milgram handoff, so the two analytic inputs remain separate before the error row is formed.

Coercivity and continuity are then read from c, C as displayed scalar rows. The comparison row H uses those constants to compare the error with each displayed trial competitor, and R records the resulting $\mathsf{Real}^{\uparrow}$ bound only after that route is visible.

Finally T, P, N transport, source, and name the same finite surface. Since no carrier coordinate stores a quotient space, selected minimizer, host projection theorem, choice schedule, or ambient real-completeness datum, the listed rows exhaust the NameCert obligations. □

Theorem 6619.3 (Galerkin best-approximation route)**.** *Every public* $\mathsf{GalerkinErrorEstimate}^{\uparrow}$ *error-estimate read factors through the* $\mathsf{GalerkinProjection}^{\uparrow}$ *residual row and the* $\mathsf{LaxMilgram}^{\uparrow}$ *variational row before it reads the* $\mathsf{Real}^{\uparrow}$ *scalar bound. In carrier terms, the public route is*

$$V, a, l, u, u_h, e, c, C, H \longmapsto R \longmapsto T, P, N.$$

The route exposes residual orthogonality, the exact variational equation, coercivity, continuity, and finite best-approximation comparison before any scalar estimate is consumed, with no quotient function space, selected minimizer, host Hilbert projection theorem, or choice principle.

Proof. Start with a public error-estimate consumer. The consumer cannot inspect the scalar bound row R directly, because the carrier places the trial-space, bilinear-form, load, exact variational, Galerkin, error, constant, and comparison rows before it.

Use the Galerkin projection sibling for the discrete side. The row u_h is available only together with the finite trial space V and the residual-orthogonality surface supplied by chapter 5169.

Use the Lax-Milgram sibling for the exact side. The row u is read through the variational equation and bounded functional route of chapter 3419, while a, l, c, C keep the bilinear, load, coercivity, and continuity data visible.

The comparison row H then forms the best-approximation route against displayed trial competitors, and the scalar row R seals that route as a $\mathsf{Real}^{\uparrow}$ bound. Transport, provenance, and naming through T, P, N preserve the same finite path, so the refused quotient, minimizer, host projection, and choice objects are not exported. □

Falsifiable prediction: Every accepted $\mathsf{GalerkinErrorEstimate}^{\uparrow}$ read displays the finite trial space, bilinear-form row, load row, LaxMilgram exact variational row, GalerkinProjection residual row, error row, coercivity and continuity constants, best-approximation comparison, RealUp scalar bound, componentwise transport, provenance, and local NameCert row before an error-estimate consumer reads the bound.

Independence witness: galerkin-projection, lax-milgram, hilbert, boundedlinearoperator, norm, real: $\mathsf{GalerkinErrorEstimate}^{\uparrow}$ is not bijective to any listed sibling because it binds residual orthogonality, variational exactness, coercivity, continuity, best-approximation comparison, and scalar error bound into one finite certificate surface.

Lean4 (statement) `BEDC.Derived.GalerkinErrorEstimateUp`

Closure status for $\mathsf{NameCert}_{\mathsf{GalerkinErrorEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{GalerkinErrorEstimate}^{\uparrow}$ packet is generated from finite trial-space rows, bilinear-form rows, load rows, exact variational rows, Galerkin residual rows, error rows, coercivity and continuity constants, best-approximation comparison rows, RealUp scalar bounds, componentwise transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GalerkinErrorEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6619.1, Definition 6619.2, and Definition 6619.3 seed the constructive Galerkin best-approximation error route over projection, variational, Hilbert, bounded-operator, norm, and real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GalerkinErrorEstimate}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.GalerkinErrorEstimateUp`

Bridge status: none

Not claimed: This chapter does not close quotient function spaces, selected minimizers, host Hilbert projection theorems, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual orthogonality, coercivity and continuity rows, best-approximation comparison, scalar-bound readback, transport, replay, provenance, and local naming for BEDC.Derived.GalerkinErrorEstimateUp.

Chapter 6620

A Concrete Naming Certificate for $\mathsf{TotallyBoundedLocatedSet}^{\uparrow}$

Bishop and Bridges use located subsets and finite nets as separate constructive interfaces before compactness arguments are allowed to read them together. The $\mathsf{TotallyBoundedLocatedSet}^{\uparrow}$ packet records that joint L10 metric-frontier surface over the located-subset carrier of chapter 1541, the finite-net carrier of chapter 127, the ambient metric source of chapter 57, the rational-window readback of chapter 301, and the terminal distance seal of chapter 38. It supplies later compactness, projection, completion, and uniformity consumers with displayed finite-net plus located-distance data, while making no claim of open-cover compactness, nearest-point choice, quotient subset equality, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6620.1 (Totally bounded located set carrier)**.** *A* $\mathsf{TotallyBoundedLocatedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, A, B, Q, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *source row, including admitted points and metric-distance observations.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *row for the displayed subset, including admission and located-distance comparisons from chapter 1541.*
3. *B is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, including for each accepted tolerance request a finite bundle of centers and coverage witnesses.*
4. *Q is the located-distance window ledger tying each admitted ambient point, subset read, and net-center request to a displayed rational comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational windows used by both the located-distance and finite-net routes.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed distance value attached to the located-set read.*
7. *T is the handoff row saying that finite-net coverage and located-distance readback are consumed in the same ambient metric route.*
8. *H records componentwise* hsame *transport for the ambient metric, located subset, finite nets, rational windows, real seal, handoff, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from tolerance and point requests through $X, A, B, Q, R, E, T, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{TotallyBoundedLocatedSet}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedLocatedSet}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected nearest point, quotient equality of subset presentations, an ambient completion, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TotallyBoundedLocatedSetUp.TotallyBoundedLocatedSetTasteGate single carrier alignment`

Theorem 6620.2 (Totally bounded located set NameCert obligations)**.** *For an accepted* TotallyBoundedLocatedSet *carrier $K = (X, A, B, Q, R, E, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedLocatedSet}^{\uparrow}}$ *surface consists exactly of carrier admission for the ambient metric row, located subset row, finite-net row, located-distance windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, joint handoff, componentwise transport, continuation replay, package provenance, and local naming. Every compactness, projection, completion, or uniformity consumer must display $X, A, B, Q, R, E, T, H, C, P, N$ before it may read any finite-net or located-distance conclusion.*

Proof. Project the carrier of Definition 6620.1. Its visible rows are exactly the ambient metric source, located subset, finite nets, distance windows, rational readback, Real seal, joint handoff, and structural rows.

The located-set obligations are read from A, Q, R, E. These rows provide the finite distance comparison and real-valued seal while keeping every read downstream of the same ambient metric row X.

The total-boundedness obligations are read from B over the same source. The finite bundle and its coverage witnesses are therefore available only as displayed packet data, not as an open-cover compactness theorem or hidden choice of centers outside the carrier.

The rows T, H, C, P, N preserve, replay, source, and name the same joint route. Since no excluded compactness, nearest-point, quotient, completion, or real-completeness coordinate appears in the carrier, the stated rows exhaust the NameCert obligation surface. □

Theorem 6620.3 (Finite-net located-distance handoff)**.** *Every accepted* $\mathsf{TotallyBoundedLocatedSet}^{\uparrow}$ *packet exposes a finite-net plus located-distance consumer route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{LocatedSet}^{\uparrow} \longmapsto \mathsf{TotallyBounded}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, a consumer reads the ambient metric row X, located-subset row A, finite-net row B, located-distance windows Q, rational readback R, and real seal E before it may use the handoff row T. The route exports no open-cover compactness, nearest-point choice, quotient subset equality, ambient completion, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with $K = (X, A, B, Q, R, E, T, H, C, P, N)$. The metric row X fixes the admitted ambient point and distance observations used by both the located-distance and finite-net reads.

Read A and B next. The located-set row supplies the subset-facing distance interface, while the totally-bounded row supplies finite bundles and coverage witnesses at accepted tolerance requests over the same metric source.

The numerical readback passes through Q, R, E. The window ledger Q records the finite comparison, R exposes the rational readback, and E seals the displayed distance as $\mathsf{Real}^{\uparrow}$ data.

The handoff and structural rows T, H, C, P, N only package that same route for downstream consumers. Thus the packet can feed later compactness and completion arguments with finite-net and located-distance data, but it cannot export any of the excluded principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedLocatedSet}^{\uparrow}}$.

Constructive story: A $\mathsf{TotallyBoundedLocatedSet}^{\uparrow}$ packet is generated from a displayed Metric row, a LocatedSet row, a TotallyBounded finite-net row, located-distance rational windows, RegSeqRat readback, a RealUp distance seal, a joint handoff, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyBoundedLocatedSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6620.1, Definition 6620.2, and Definition 6620.3 seed the finite-net plus located-distance carrier over the L10 constructive metric frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedLocatedSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, nearest-point choice, quotient subset equality, ambient completion, full $\mathsf{Real}^{\uparrow}$ completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, located-distance exactness, finite-net coverage compatibility, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for future BEDC.Derived.TotallyBoundedLocatedSetUp.

Chapter 6621

A Concrete Naming Certificate for $\mathsf{MazurTheorem}^{\uparrow}$

Following Mazur and Bourbaki, the $\mathsf{MazurTheorem}^{\uparrow}$ packet records the finite convex weak-closure certificate by which a norm-closed convex claim is read from displayed weak-topology windows without importing a host dual quotient, a selected separating functional, countable choice, or ambient functional-analysis completeness. It sits over the Banach carrier of chapter 90, the weak-topology observation surface of chapter 3597, the locally convex seminorm rows of chapter 3386, the convex carrier of chapter 208, and the terminal scalar readback of chapter 38.

Definition 6621.1 (Mazur theorem carrier)**.** *A* $\mathsf{MazurTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, L, W, V, K, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{Banach}^{\uparrow}$ *row, including the normed vector carrier, addition and scalar rows, norm metric, and visible completeness ledger used by norm-facing consumers.*
2. *L is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *observation row, exposing only the finite seminorm and neighbourhood tests needed to read weak windows.*
3. *W is the* $\mathsf{WeakTopology}^{\uparrow}$ *finite-window row over B and L, naming the inspected weak neighbourhoods and their admissible observation coordinates.*
4. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row, carrying the displayed convex subcarrier and the affine-combination operations admitted by the packet.*
5. *K is the convex-combination ledger. It records the finite barycentric coefficients, the inspected points, and the convexity witnesses used to move from weak-window data back to the convex row.*
6. *Q is the norm-closure handoff row, stating which norm-radius request is being read after the finite convex-combination ledger has been displayed.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for coefficients, seminorm values, norm radii, and comparison bounds.*
8. *H records componentwise* hsame *transport for Banach, locally convex, weak-window, convex, convex-combination, norm-closure, scalar, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$B, L, W, V \longmapsto K \longmapsto Q \longmapsto R.$$

10. *P is the* Pkg *provenance over* $\mathsf{MazurTheorem}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MazurTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, W, V, K, Q, R, H, C, P, N$. It has no coordinate for the whole dual space, quotient weak convergence, a selected separating functional, countable choice, a host closed convex hull, or ambient Banach-space theorem export.

Theorem 6621.2 (Mazur theorem NameCert obligations)**.** *For every accepted* $\mathsf{MazurTheorem}^{\uparrow}$ *carrier $M = (B, L, W, V, K, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MazurTheorem}^{\uparrow}}$ *surface consists exactly of Banach-source admission, locally convex observation admission, weak-topology finite-window exposure, convex-carrier admission, convex-combination ledger exactness, norm-closure handoff visibility, Real scalar readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer that reads a weak closure claim as norm-closure data must pass through those rows before the norm-facing claim is visible.*

Proof. Project the carrier of Definition 6621.1. The source rows B, L, W, V display the Banach carrier, locally convex observation surface, weak-window ledger, and convex carrier before any closure read is available.

The finite convex step is the ledger K. It exposes the barycentric coefficients, inspected points, and convexity witnesses, with scalar comparisons read only through the $\mathsf{Real}^{\uparrow}$ row R.

The norm-facing conclusion is read through Q after the weak-window and convex-combination rows have been displayed. Thus a consumer receives a finite norm-closure handoff from the convex ledger, not a quotient weak limit or selected functional.

Finally H, C, P, N transport, replay, source, and name exactly the same rows. Since the carrier has no coordinate for the whole dual, countable choice, selected separating functionals, or an ambient closed-convex-hull theorem, none of those objects can be exported by the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{MazurTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MazurTheorem}^{\uparrow}$ packet is generated from Banach source data, locally convex seminorm observations, weak-topology finite windows, convex-set rows, a finite convex-combination ledger, norm-closure handoff data, Real scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MazurTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 6621.1 and Definition 6621.2 seed the finite weak-to-norm convex closure certificate over Banach, WeakTopology, LocallyConvexSpace, ConvexSet, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MazurTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a full host Mazur theorem, dual-space quotient semantics, selected separating functionals, countable choice, host equality of closed convex hulls, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak-window exposure, convex-combination ledger exactness, norm-closure handoff visibility, Real scalar readback, transport, replay, provenance, and non-escape for BEDC.Derived.MazurTheoremUp.

Chapter 6622

A Concrete Naming Certificate for $\mathsf{PolishCompletionCriterion}^{\uparrow}$

Following Alexandrov–Urysohn and Bishop–Bridges, the $\mathsf{PolishCompletionCriterion}^{\uparrow}$ packet records the traditional separable complete-metric criterion as finite naming data before any Real-facing completion read is sealed. It sits after the complete-metric witness surface of chapter 128, the metric-completion carrier of chapter 1506, the separability schedule of chapter 1809, the finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names the Polish completion criterion through displayed dense Cauchy threads; it is not a quotient completion, selected representative principle, countable-choice construction, host equality test, or ambient completeness theorem for all $\mathsf{Real}^{\uparrow}$ names.

Definition 6622.1 (Polish completion criterion carrier)**.** *A* $\mathsf{PolishCompletionCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, D, S, Q, L, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric source row whose distance classifier supplies the separated boundary used by the criterion.*
2. *D is the countable dense schedule row, recording the finite dense points and requested approximation indices exposed to the consumer.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened along the dense schedule.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from those stream windows and their tolerance requests.*
5. *L is the displayed limit row supplied by the completion criterion for the Cauchy thread read through D, S, Q.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dense thread, readback, and displayed limit are visible.*
7. *H records componentwise* hsame *transport for the metric source, dense schedule, stream windows, regular readback, displayed limit, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through X, D, S, Q, L, E.*
9. *P is the* Pkg *provenance over* $\mathsf{PolishCompletionCriterion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PolishCompletionCriterion}^{\uparrow}}$ *row naming the criterion packet and its admitted consumer reads.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for quotient completion equality, selected representatives, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6622.2 (Polish completion criterion NameCert obligations)**.** *For every accepted* PolishCompletionCriterio *carrier $K = (X, D, S, Q, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PolishCompletionCriterion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric source, dense schedule, stream windows, regular rational readback, displayed limit, Real seal, transport, replay, provenance, and local naming rows;*
2. *dense schedule stability, requiring every completion-facing observation to preserve the same displayed dense row D under componentwise* hsame *transport;*
3. *Cauchy-thread handoff, requiring the route from D through S and Q to be displayed before L or E is consumed;*
4. *separated-limit boundary, requiring limit comparison to use the source metric classifier of X together with the displayed limit row L;*
5. *Real-seal nonescape, requiring the Real-facing row E to remain downstream of D, S, Q, L and upstream only of structural rows;*
6. *ledger refusal for quotient completion equality, selected representatives, countable choice, host real equality, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside $X, D, S, Q, L, E, H, C, P, N$.

Proof. Project the carrier of Definition 6622.1. The accepted packet displays exactly the metric source, dense schedule, finite windows, regular readback, displayed limit, Real seal, transport, replay, provenance, and naming rows.

The dense schedule stability and Cauchy-thread handoff are read in that order. A completion-facing consumer first opens D, then the finite $\mathsf{StreamName}^{\uparrow}$ windows S, and then the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q before the displayed limit L is available.

The separated-limit boundary is supplied by the same metric source X and displayed limit L. The Real seal E is downstream of this boundary, so it cannot be used as an ambient completeness source.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no row for quotient completion equality, selected representatives, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the ledger refuses those reads. □

Theorem 6622.3 (Polish completion criterion Cauchy-thread handoff)**.** *Every completion-criterion read exported by an accepted* $\mathsf{PolishCompletionCriterion}^{\uparrow}$ *carrier $K = (X, D, S, Q, L, E, H, C, P, N)$ factors through the dense Cauchy thread*

$$D \longmapsto S \longmapsto Q \longmapsto L$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal E is consumed. The read exposes the metric source X, the dense schedule D, finite* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the displayed limit row L, componentwise transport H, displayed replay C, provenance P, and local naming N; it does not export quotient completion equality, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier and project a completion-criterion consumer read. By Definition 6622.2, every such read must display carrier admission, dense schedule stability, and Cauchy-thread handoff before the Real seal is available.

The only dense-source route in the carrier is D, S, Q, L. The row D supplies the displayed dense schedule, S supplies finite windows along that schedule, Q supplies the regular rational readback, and L records the displayed limit reached by the thread.

The Real seal row E is therefore downstream of the displayed Cauchy thread. The structural rows H, C, P, N can transport, replay, source, and name this route, but they do not add quotient completion equality, selected representatives, choice, host real equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolishCompletionCriterion}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolishCompletionCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6622.1, Definition 6622.2, and Definition 6622.3 seed the finite Polish completion criterion route through dense schedules, stream windows, regular rational readback, displayed limits, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolishCompletionCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense schedule stability, Cauchy-thread handoff, separated-limit boundary, Real-seal nonescape, and ledger refusal for BEDC.Derived.PolishCompletionCriterionUp.

Constructive story: A $\mathsf{PolishCompletionCriterion}^{\uparrow}$ packet is generated from a metric source, a countable dense schedule, StreamName finite windows, RegSeqRat readback, a displayed limit row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6623

A Concrete Naming Certificate for $\mathsf{ChebyshevCenter}^{\uparrow}$

Following classical Chebyshev-center and minimal-enclosing-ball theory, the $\mathsf{ChebyshevCenter}^{\uparrow}$ packet records only compact metric data, convex-set data, located-radius comparisons, and center-candidate rows. It sits over the metric carrier of chapter 57, the projection-facing metric row of chapter 2356, the convex carrier of chapter 208, the located-set surface of chapter 1541, and the scalar readback of chapter 38. The certificate does not import a host minimizer theorem, selected center, quotient compactness, ambient convex duality, countable choice, `Classical.choice`, or `Quot.sound`.

Definition 6623.1 (Chebyshev center carrier)**.** *A* $\mathsf{ChebyshevCenter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (M, K, V, L, R, S, C, A, H, T, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, naming the admitted points, distance comparisons, triangle ledger, and closed-ball tests used by the packet.*
2. *K is the compact metric row, recording the finite cover and total-boundedness observations consumed by radius comparisons.*
3. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row, exposing the displayed convex subcarrier and the admitted affine-combination operations.*
4. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *row, recording located membership and distance-to-set comparisons for the candidate set.*
5. *R is the located-radius row, listing the finite radius requests, comparison tolerances, and scalar bounds read through* $\mathsf{Real}^{\uparrow}$*.*
6. *S is the center-candidate row, naming the inspected candidates and the ball-containment observations certified for each candidate.*
7. *C is the compact-radius ledger. It records that every displayed finite cover and center-candidate comparison is evaluated through M, K, L, R, S before a radius bound is read.*
8. *A is the admissible-center row, exposing the local witness that a candidate is read as an accepted center only after the displayed radius ledger has been inspected.*
9. *H records componentwise* hsame *transport for metric, compact, convex, located, radius, center-candidate, radius-ledger, admissible-center, replay, provenance, and local naming rows.*

10. *T records displayed* Cont *replay of the route*

$$M, K, V, L \longmapsto R, S \longmapsto C, A.$$

11. *P is the* Pkg *provenance over* $\mathsf{ChebyshevCenter}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ChebyshevCenter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, V, L, R, S, C, A, H, T, P, N$. It has no coordinate for a host minimizer, selected center outside the displayed candidates, quotient compactness, ambient Hilbert projection theorem, separating functional, choice schedule, or global uniqueness claim.

Lean4 ✓ `BEDC.Derived.ChebyshevCenterUp.ChebyshevCenterTasteGate single carrier alignment`

Theorem 6623.2 (Chebyshev center NameCert obligations)**.** *For every accepted* $\mathsf{ChebyshevCenter}^{\uparrow}$ *carrier*

$$Z = (M, K, V, L, R, S, C, A, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ChebyshevCenter}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source admission, compact finite-cover exposure, convex-carrier admission, located-set readback, located-radius comparison, center-candidate visibility, compact-radius ledger exactness, admissible-center exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6623.1. The rows $M, K, V, L, R, S, C, A, H, T, P, N$ are the visible inventory, so any local consumer first sees the metric, compact, convex, located, radius, candidate, ledger, admissible-center, transport, replay, provenance, and naming rows.

Metric and compact admission are read from M, K. The packet can inspect distance comparisons and finite-cover data, but it cannot replace them with a host compactness theorem or a selected minimizing sequence.

Convex and located data are read from V, L. These rows expose the set in which candidates are tested and the located comparisons used to read distances to the displayed set.

The radius and center obligations are then read from R, S, C, A. A center is accepted only through the displayed compact-radius ledger, so the certificate records a finite radius comparison surface rather than an ambient minimizer.

Finally H, T, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for quotient compactness, a selected center outside S, ambient convex duality, choice, `Classical.choice`, or `Quot.sound`, none of those objects can be exported by the local certificate. □

Theorem 6623.3 (Chebyshev compact-radius ledger)**.** *Every* $\mathsf{ChebyshevCenter}^{\uparrow}$ *radius read factors through the displayed compact metric, located-set, and center-candidate rows before it reaches a scalar bound:*

$$M, K, V, L \longmapsto R, S \longmapsto C, A \longmapsto H, T, P, N.$$

Thus a public consumer receives finite compact-cover comparisons, located-radius requests, and admissible-center evidence before any center or radius datum is visible. The route does not assert uniqueness of centers, existence of a host minimizer, selected projection, quotient compactness, or ambient convex duality.

Proof. Start with a radius-facing consumer of Z. The consumer cannot read a scalar radius directly, because the carrier places the metric row M, compact row K, convex row V, and located row L before any radius or candidate row.

The located-radius row R and center-candidate row S are then inspected together. Radius comparisons are meaningful only for the displayed candidate and set data, so the route remains local to the packet.

The compact-radius ledger C and admissible-center row A bind those comparisons to finite cover observations and ball-containment tests. This is the finite NameCert surface corresponding to the minimal-enclosing-ball question.

Transport, replay, provenance, and naming through H, T, P, N preserve the same route. Since no further coordinate exists, the packet exports neither a selected minimizer nor a host compact convex optimization theorem. □

Falsifiable prediction: Every accepted $\mathsf{ChebyshevCenter}^{\uparrow}$ read displays the metric source, compact metric row, convex set row, located set row, located radius row, center-candidate row, compact-radius ledger, admissible-center row, componentwise transport, replay, provenance, and local NameCert row before a center or radius consumer reads the bound.

Independence witness: metric, compact-metric, metric-projection, convexset, locatedset, real: $\mathsf{ChebyshevCenter}^{\uparrow}$ is not bijective to any listed sibling because it binds compact-radius comparisons, located-radius rows, center-candidate evidence, and admissible-center readback into one finite certificate surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ChebyshevCenter}^{\uparrow}}$.

Constructive story: A $\mathsf{ChebyshevCenter}^{\uparrow}$ packet is generated from metric rows, compact metric rows, convex-set rows, located-set rows, located-radius comparisons, center-candidate rows, compact-radius ledgers, admissible-center rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChebyshevCenter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6623.1, Definition 6623.2, and Definition 6623.3 seed the compact-metric Chebyshev center certificate over metric, compact, convex, located, scalar, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChebyshevCenter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close uniqueness of centers, host minimizer existence, selected projections, quotient compactness, ambient convex duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-cover exposure, located-radius comparison, center-candidate visibility, compact-radius ledger exactness, admissible-center exposure, transport, replay, provenance, and non-escape for BEDC.Derived.ChebyshevCenterUp.

Chapter 6624

A Concrete Naming Certificate for $\mathsf{LocatedSequentialCompleteness}^{\uparrow}$

Following Bishop and Bridges, located sequential completeness is read from regular sequence data with a displayed modulus, not from a quotient stream or a selected ambient limit. The $\mathsf{LocatedSequentialCompleteness}^{\uparrow}$ packet records the standard constructive route by which a modulus-controlled sequence supplies finite windows, regular-rational readback, and a Real-facing seal. It sits over the regular sequence surface of chapter 301, the stream naming discipline of chapter 126, the Real certificate of chapter 38, and the completion criterion of chapter 3404.

Definition 6624.1 (Located sequential completeness carrier)**.** *A* $\mathsf{LocatedSequentialCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, M, W, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *A is the sequence source row. It names the admitted sequence observations and exposes no host stream equality.*
2. *M is the located Cauchy modulus row, recording the finite tolerance requests and the index bounds that answer them.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing the inspected sequence windows and their observation schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, packaging the rational regularity comparisons obtained from M and W.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, opened only after the regular-rational readback has been displayed.*
6. *U is the uniqueness ledger. It records that two accepted reads with the same modulus, finite windows, regular readback, and Real seal compare through the same displayed rows.*
7. *H stores componentwise* hsame *transport for the source, modulus, StreamName windows, RegSeqRat readback, Real seal, uniqueness ledger, replay, provenance, and local naming rows.*
8. *C stores* Cont *replay from source observations to modulus requests, from modulus requests to finite windows, from windows to regular-rational readback, and from readback to the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedSequentialCompleteness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedSequentialCompleteness}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, M, W, R, E, U, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host equality of Real names, ambient completeness, or an unbounded choice schedule.

Theorem 6624.2 (Located sequential completeness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSequentialCompleteness}^{\uparrow}$ *carrier $S = (A, M, W, R, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedSequentialComplete}}$ *surface consists exactly of sequence-source admission, located Cauchy modulus visibility, StreamName finite-window coverage, RegSeqRat readback, Real seal handoff, uniqueness-ledger stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A completion or Real-facing consumer must read those rows before it consumes the sequential-completeness output.*

Proof. Project the carrier of Definition 6624.1. The source, modulus, finite-window, regular-rational, Real-seal, uniqueness, transport, replay, provenance, and naming rows are the visible inventory.

The modulus and window obligations are read together. The located Cauchy modulus supplies finite bounds for positive tolerance requests, while the StreamName row records exactly which finite observations are inspected under those bounds.

The RegSeqRat and Real-facing obligations are downstream. The row R packages the regular rational comparisons produced by the modulus and windows, and E seals the compatible readback as a $\mathsf{Real}^{\uparrow}$ name only after R has appeared.

Finally U, H, C, P, N stabilize, transport, replay, source, and name the same route. Since the carrier has no coordinate for quotient stream equality, selected limits, host equality, ambient completeness, or choice schedules, the listed obligations exhaust the NameCert surface. □

Theorem 6624.3 (Located sequential completeness RegSeqRat handoff)**.** *Every accepted* $\mathsf{LocatedSequentialComple}$ *packet hands a modulus-controlled sequence to Real-facing consumers through the route*

$$A \longmapsto M \longmapsto W \longmapsto R \longmapsto E.$$

Thus the consumer reads the sequence source, located Cauchy modulus, StreamName finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal before any completion criterion or Real seal is public.*

Proof. Start from the source row A. It provides only the admitted sequence observations, so no consumer can begin with a host stream or quotient class.

Use the modulus row M and finite-window row W. A positive tolerance request is answered by a displayed index bound and by the finite StreamName observations inspected under that bound.

Read the regular-rational row R next. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff packages the rational comparison windows supplied by M and W, and the Real seal E is downstream of that readback.

The structural rows H, C, P, N preserve this route for completion and Real-facing consumers. Therefore the handoff exports the displayed finite route rather than a selected limit, quotient stream equality, host equality, or ambient completeness principle. □

Theorem 6624.4 (Located sequential completeness uniqueness ledger)**.** *If two accepted* $\mathsf{LocatedSequentialComplete}$ *packets display the same sequence source, located Cauchy modulus, StreamName finite windows, RegSeqRat readback, and Real seal rows, then their public completion read is compared only through the uniqueness ledger U and the structural rows H, C, P, N. The comparison does not use host equality of streams or selected limit witnesses.*

Proof. Read the equality premise row by row. Agreement of A, M, W, R, E fixes the admitted observations, the tolerance-to-index bounds, the finite observation windows, the regular-rational comparisons, and the Real-facing seal.

The uniqueness ledger U records that no further coordinate is available for public comparison. Componentwise hsame transport in H and displayed replay in C keep the same rows attached to both packets.

Provenance and local naming through P, N then identify the comparison as a NameCert read over the displayed route. Since neither packet contains a host stream equality row, selected limit row, or ambient completeness row, the uniqueness comparison cannot appeal to those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSequentialCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedSequentialCompleteness}^{\uparrow}$ packet is generated from sequence-source observations, a located Cauchy modulus, StreamName finite windows, RegSeqRat readback, a Real seal, a uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSequentialCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6624.1, Definition 6624.2, Definition 6624.3, and Definition 6624.4 seed the finite located sequential-completeness route from modulus-controlled sequence reads to RegSeqRat and Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSequentialCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host equality of Real names, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located modulus visibility, StreamName finite-window coverage, RegSeqRat readback, Real seal handoff, uniqueness stability, transport, replay, provenance, and local naming for BEDC.Derived.LocatedSequentialCompletenessUp.

Chapter 6625

A Concrete Naming Certificate for $\mathsf{CertifiedModelQualityLedger}^{\uparrow}$

The $\mathsf{CertifiedModelQualityLedger}^{\uparrow}$ packet realizes the model-quality branch of section 9462.15 as finite NameCert data. It turns a narrative quality comparison into a displayed ledger over behavior coverage, public weights, cost, debt, stability, transfer, safety, semantic, and verification rows. The packet is AI-origin because its carrier is a BEDC-native accounting object for classifier quality rather than a reconstruction of a classical analytic theorem.

The ledger consumes the physical model-audit row of chapter 1129 and the certified model-quality carrier of chapter 6117 before it scores benefit, cost, debt, safety, verification, and semantic rows. This dependency places the quality ledger after model audit and model-quality certification data, without changing the chapter's closure grade.

Definition 6625.1 (Certified model quality ledger carrier)**.** *A* $\mathsf{CertifiedModelQualityLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, B, W, C, D, T, A, V, G, H, R, P, N)$$

with the following displayed rows:

1. *S is the declared model-quality scope row, naming the evaluation domain, model state, admitted intervention family, critical behavior family, and public protocol.*
2. *B is the behavior-coverage row, separating certified critical behaviors from uncovered or partially certified behaviors.*
3. *W is the public weight-profile row used to compare benefit, cost, and debt.*
4. *C is the cost row, recording model, data, training, certificate, ledger, intervention, and verification costs.*
5. *D is the debt row, recording black-box, ledger, stability, generalization, safety, shortcut, semantic, and verification debts.*
6. *T is the stability and transfer row for the certified behavior classifiers.*
7. *A is the safety and shortcut-boundary row, recording failure cases and not-claimed scope.*
8. *V is the verification row, separating checked, target, and unverified certificate obligations.*
9. *G is the quality-score gate row. It reads benefit, cost, and debt only through B, W, C, D, T, A, V.*

10. *H records componentwise* hsame *transport for the scope, coverage, weights, costs, debts, stability, safety, verification, score, replay, provenance, and local naming rows.*
11. *R records displayed* Cont *replay from scope and behavior coverage to score comparison, gate acceptance, and refusal boundaries.*
12. *P is the* Pkg *provenance over* $\mathsf{CertifiedModelQualityLedger}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CertifiedModelQualityLedger}^{\uparrow}}$ *row.*

The classifier compares accepted ledgers only through $S, B, W, C, D, T, A, V, G, H, R, P, N$. It has no coordinate for private benchmark preference, hidden weight selection, unledgered classifier gain, performance-only quality, or verification laundering.

Theorem 6625.2 (Certified model quality ledger NameCert obligations)**.** *For every accepted* $\mathsf{CertifiedModelQualityLedger}^{\uparrow}$ *carrier $Q = (S, B, W, C, D, T, A, V, G, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CertifiedModelQuality}}$ *surface consists exactly of scope admission, behavior-coverage visibility, public weight-profile display, cost accounting, debt accounting, stability and transfer accounting, safety and shortcut-boundary display, verification status display, quality-score gate replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6625.1. The scope, coverage, weight, cost, debt, stability, safety, verification, score, transport, replay, provenance, and naming rows are the entire displayed inventory.

The accounting rows are read before any score comparison. Behavior coverage supplies certified and uncovered critical behavior families, the public weight profile states how benefit, cost, and debt are compared, and the cost and debt rows record the negative terms.

The stability, safety, and verification rows restrict what may count as certified benefit. A classifier gain without those rows remains a debt-bearing or target-only entry rather than a closed quality gain.

Finally G, H, R, P, N replay, transport, source, and name the same finite ledger. Since the carrier has no coordinate for hidden weights, private benchmark preference, performance-only quality, unledgered classifier gain, or verification laundering, the listed rows exhaust the local certificate obligations. □

Theorem 6625.3 (Certified model quality score nonescape)**.** *Every accepted quality-score comparison in a* $\mathsf{CertifiedModelQualityLedger}^{\uparrow}$ *packet must display the behavior-coverage row B, public weight-profile row W, cost row C, debt row D, stability and transfer row T, safety row A, verification row V, and score gate row G before the comparison is read. Two accepted ledgers with identical behavior-coverage rows but different public weight profiles cannot be compared without displaying the weight-profile row.*

Proof. Start from the score gate row G. By Definition 6625.1, G reads benefit, cost, and debt only through B, W, C, D, T, A, V.

If two ledgers agree on behavior coverage but differ in public weights, the row B alone does not determine the score comparison. The row W specifies how certified benefit, cost, and debt are weighed, so it must be displayed before the comparison is public.

The remaining rows keep the score inside the ledger. Costs and debts are read from C, D, stability and safety qualifications from T, A, verification status from V, and transport and replay from H, R, P, N.

Thus score comparison cannot escape to a private benchmark, hidden weight protocol, performance-only metric, unledgered classifier gain, or verification laundering artifact. □

Theorem 6625.4 (Certified model quality TasteGate follow-up boundary)**.** *The finite* CertifiedModelQualityLedger$^{\uparrow}$ *carrier supplies the displayed ledger rows needed by later TasteGate checks, while the Nontrivial and FieldFaithful instances are supplied by the Lean follow-up in* `lean4/BEDC/Derived/CertifiedModelQualityLedge` *The paper packet records the classifier, ledger, and score-gate obligations; it does not claim those Lean instances inside this chapter.*

Proof. Use the carrier and NameCert obligation theorems. They display the scope, coverage, weight, cost, debt, stability, safety, verification, score, transport, replay, provenance, and naming rows required by a finite ledger.

The TasteGate follow-up consumes those rows as an implementation-facing obligation. This chapter records the public finite surface and the boundary of the future instance check without adding a Lean marker or claiming an existing declaration.

Since no Nontrivial or FieldFaithful instance row is part of Q, the chapter remains a paper-side certificate landing. The Lean file named in the statement is the place where those instances are to be supplied. □

Falsifiable prediction: If two accepted ledgers have identical behavior-coverage rows but different public weight profiles, their quality-score comparison cannot be read without displaying the weight-profile row.

Independence witness: modelselectionboundary, open_fit_packet, reality_constrained_model_audit, reality_constrained_signature_fit, physical_truth_certificate: CertifiedModelQualityLedger$^{\uparrow}$ is not bijective to any listed sibling because it binds behavior coverage, public weights, cost, debt, stability, safety, verification, score replay, transport, provenance, and local NameCert rows into one finite quality-accounting surface.

Closure status for NameCert$_{\text{CertifiedModelQualityLedger}^{\uparrow}}$**.**

Constructive story: A CertifiedModelQualityLedger$^{\uparrow}$ packet is generated from model-quality scope rows, behavior-coverage rows, public weight profiles, cost rows, debt rows, stability and transfer rows, safety and shortcut-boundary rows, verification rows, score-gate replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CertifiedModelQualityLedger}^{\uparrow}}$, seed)

Scope closed: Definition 6625.1, Definition 6625.2, Definition 6625.3, and Definition 6625.4 seed the finite certified model-quality ledger and score-gate surface.

Formal verification: FormalStatus(NameCert$_{\text{CertifiedModelQualityLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close hidden weight selection, private benchmark preference, performance-only quality, unledgered classifier gain, Lean verification, TasteGate instances, or bridge checking.

Upgrade path: Obligation closure requires checked scope admission, behavior-coverage visibility, weight-profile display, cost and debt accounting, stability and transfer accounting, safety and verification rows, score-gate nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CertifiedModelQualityLedgerUp.

Chapter 6626

A Concrete Naming Certificate for $\mathsf{ValuationDomain}^{\uparrow}$

Following Bourbaki and Zariski–Samuel, the $\mathsf{ValuationDomain}^{\uparrow}$ packet records the traditional valuation-domain surface as finite naming data over a ring whose fraction-field comparisons are routed through displayed ideal comparability and local-field boundary rows. It sits after the ring carrier of chapter 43, the field boundary of chapter 45, the ideal lattice of chapter 81, and the local-field handoff of chapter 173. The packet names the valuation-domain read; it does not export a selected valuation map, total host order on a fraction field, Krull dimension theorem, Noetherianity, principal-ideal generation, or ambient algebraic closure.

Definition 6626.1 (Valuation domain carrier)**.** *A* $\mathsf{ValuationDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (R, F, I, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{Ring}^{\uparrow}$ *row, including the multiplication, addition, zero, one, and ring classifier rows used by ideal-facing consumers.*
2. *F is the* $\mathsf{Field}^{\uparrow}$ *fraction-field boundary row naming which field read receives the embedded ring data.*
3. *I is the* $\mathsf{Ideal}^{\uparrow}$ *comparability row. It records the displayed principal-fraction ideal tests by which any two nonzero fraction reads are compared through containment before the valuation-domain claim is visible.*
4. *L is the* $\mathsf{LocalField}^{\uparrow}$ *handoff row, recording the local valuation-facing boundary available to downstream local-field and completion consumers.*
5. *Q is the fraction-field nonescape row. It states that a consumer may read divisibility or inverse comparison only through R, F, I, L and not through an ambient selected valuation function.*
6. *H records componentwise* hsame *transport for the ring, fraction-field, ideal-comparability, local-field, fraction-boundary, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$R, F, I \longmapsto L \longmapsto Q.$$

8. *P is the* Pkg *provenance over* $\mathsf{ValuationDomain}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, $\mathsf{LocalField}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ValuationDomain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, F, I, L, Q, H, C, P, N$. It has no coordinate for a chosen value group, a selected valuation map, quotient fraction equality outside the displayed field boundary, Noetherianity, principal generation, or ambient algebraic closure.

Theorem 6626.2 (Valuation domain NameCert obligations)**.** *For every accepted* $\mathsf{ValuationDomain}^{\uparrow}$ *carrier $V = (R, F, I, L, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ValuationDomain}^{\uparrow}}$ *surface consists exactly of ring-source admission, fraction-field boundary exposure, ideal-chain comparability, local-field handoff visibility, fraction-field nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer that reads a valuation-domain claim must pass through those rows before it may compare fraction-field representatives or ideal containment data.*

Proof. Project the carrier of Definition 6626.1. The source rows R, F, I, L, Q display the ring carrier, fraction-field boundary, ideal-comparability ledger, local-field handoff, and fraction-field nonescape row before any valuation-domain read is available.

The structural rows H, C, P, N transport, replay, source, and name exactly the same finite route. Since the carrier has no coordinate for a chosen value group, selected valuation map, Noetherianity, principal generation, or ambient algebraic closure, none of those objects can be exported by the local certificate. □

Theorem 6626.3 (Valuation domain ideal-chain route)**.** *Every ideal-facing read exported by an accepted* $\mathsf{ValuationDomain}^{\uparrow}$ *carrier $V = (R, F, I, L, Q, H, C, P, N)$ factors through the displayed comparability route*

$$\mathsf{Ring}^{\uparrow} \longmapsto \mathsf{Field}^{\uparrow} \longmapsto \mathsf{Ideal}^{\uparrow}$$

before a fraction-field comparison is visible. The route records containment comparison for the principal-fraction ideal rows named by I and refuses any detached host-order, value-group, or selected-valuation read.

Proof. Start with the ring row R and the fraction-field boundary F. These rows fix the source multiplication and the field read in which fraction representatives are inspected.

The ideal-chain row I is the only comparability surface in the carrier. Thus a consumer compares fraction reads by opening the displayed $\mathsf{Ideal}^{\uparrow}$ containment data after R and F, not by appealing to a host value group or an unnamed total order.

The nonescape row Q and the structural rows H, C, P, N preserve that route under transport and replay. Therefore the ideal-facing read remains a finite NameCert route through Ring, Field, Ideal, local handoff, and local naming rows. □
