Theorem 6626.4 (Valuation domain local-field handoff)**.** *Every* $\mathsf{LocalField}^{\uparrow}$ *consumer of an accepted* $\mathsf{ValuationDomain}^{\uparrow}$ *packet reads the local valuation-facing boundary only after the source ring, fraction-field boundary, and ideal-chain comparability rows have been displayed. The handoff route is*

$$\mathsf{ValuationDomain}^{\uparrow} \longmapsto \mathsf{Ring}^{\uparrow} \longmapsto \mathsf{Field}^{\uparrow} \longmapsto \mathsf{Ideal}^{\uparrow} \longmapsto \mathsf{LocalField}^{\uparrow}.$$

It exports no complete local field, residue-field construction, chosen uniformizer, discrete valuation, or completion theorem beyond the displayed L row.

Proof. Read L as a downstream row of the accepted carrier. The carrier places L after the ring row R, the fraction-field boundary F, and the ideal-comparability row I.

A local-field consumer therefore receives only the displayed valuation-facing handoff. The packet does not contain a residue-field construction, selected uniformizer, discrete valuation, completion theorem, or host local-field equality, so those data cannot be exported by the $\mathsf{ValuationDomain}^{\uparrow}$ NameCert. □

Theorem 6626.5 (Valuation domain fraction-field boundary)**.** *Every fraction-field read of an accepted* $\mathsf{ValuationDomain}^{\uparrow}$ *carrier remains bounded by the displayed route*

$$R, F, I, L, Q.$$

In particular, inverse comparison and divisibility information are visible only through the source $\mathsf{Ring}^{\uparrow}$ *row, the* $\mathsf{Field}^{\uparrow}$ *boundary, the* $\mathsf{Ideal}^{\uparrow}$ *comparability ledger, the* $\mathsf{LocalField}^{\uparrow}$ *handoff, and the nonescape row* Q*.*

Proof. Project the fraction-field boundary row F and the nonescape row Q. The row F names the field in which fractions are read, while Q records that later consumers may use only the comparisons already routed through R, F, I, L.

Thus inverse comparison and divisibility information remain inside the displayed NameCert packet. There is no row for an ambient field quotient beyond F, a selected valuation map, a chosen value group, or algebraic closure, so the local classifier cannot export such data. □

Closure status for $\mathsf{NameCert}_{\mathsf{ValuationDomain}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ValuationDomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6626.1, Definition 6626.2, Definition 6626.3, Definition 6626.4, and Definition 6626.5 seed the valuation-domain route through Ring, Field, Ideal, LocalField, fraction-boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ValuationDomain}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.ValuationDomainUp`

Bridge status: none

Not claimed: This chapter does not close selected valuation maps, chosen value groups, discrete valuation data, Noetherianity, principal generation, residue-field construction, completion, algebraic closure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fraction-field boundary exposure, ideal-chain comparability, local-field handoff, fraction-field nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ValuationDomain

Constructive story: A $\mathsf{ValuationDomain}^{\uparrow}$ packet is generated from a RingUp source, a FieldUp fraction-field boundary, an IdealUp comparability row, a LocalFieldUp handoff row, a fraction-field nonescape row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6627

A Concrete Naming Certificate for $\mathsf{FastCauchyAccelerationSelector}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FastCauchyAccelerationSelector}^{\uparrow}$ packet records the finite selector surface that accelerates an ordinary regular Cauchy tail ledger into a fast Cauchy budget schedule. It sits between the selected-tail packet of chapter 458, the fast-subsequence route of chapter 1518, the dyadic rational core of chapter 291, the stream-name surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name row of chapter 38.

The selector is finite: it names requested precision budgets, inspected tail windows, dyadic tolerances, regular-rational reads, and a fast-subsequence handoff. It does not add countable choice, quotient stream equality, a host real equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6627.1 (Fast Cauchy acceleration selector carrier)**.** *A* $\mathsf{FastCauchyAccelerationSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, F, D, S, R, E, B, H, C, P, N)$$

with the following visible rows:

1. *T is an accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet that supplies the ordinary selected-tail witness for the inspected source;*
2. *F is the* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *handoff row that records the accelerated tail schedule consumed by fast Cauchy readers;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger translating each fast budget into the dyadic comparison checked on the selected tail;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose inspected windows are shared by the ordinary selector and the accelerated schedule;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the selected tail and dyadic budget rows are displayed;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only through T, F, D, S, R;*
7. *B is the finite acceleration-budget schedule, listing the displayed precision request, selected tail index, and fast-budget target for each inspected row;*

8. *H stores componentwise* hsame *transports for the selector, fast-subsequence, dyadic, stream, readback, seal, budget, provenance, and local naming rows;*
9. *C stores the displayed* Cont *routes by which completion-facing consumers may read the packet;*
10. *P is the* Pkg *provenance over* $\mathsf{FastCauchyAccelerationSelector}^{\uparrow}$, $\mathsf{RegularCauchyTailSelector}^{\uparrow}$, FastCauchySubsequen $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FastCauchyAccelerationSelector}^{\uparrow}}$ *row.*

No coordinate of A is a quotient of streams, a choice function on all precisions, a host-level real equality, a selected limit value, or a real-completeness theorem.

Theorem 6627.2 (Fast Cauchy acceleration selector NameCert obligations)**.** *The carrier of Definition 6627.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{FastCauchyAccelerationSelector}^{\uparrow}}$ *obligation surface. Its obligations are exactly:*

1. *carrier admission for $A = (T, F, D, S, R, E, B, H, C, P, N)$;*
2. *ordinary-tail admission, requiring T to be read as an accepted* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *packet before any fast schedule is consumed;*
3. *fast-schedule admission, requiring F and B to expose the accelerated tail budget through* FastCauchySubsequence$^{\uparrow}$
4. *dyadic budget exactness, requiring each budget entry in B to be checked through D against the same finite* $\mathsf{StreamName}^{\uparrow}$ *windows in S;*
5. *regular-readback exactness, requiring R to be reached only after T, F, D, S, B have been displayed;*
6. *real-seal non-escape, requiring E to expose only the finite acceleration route and no quotient stream, chosen limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is the displayed finite BHist tuple. Each coordinate is either a named sibling packet, a finite budget row, transport data, a displayed continuation route, package provenance, or the local naming row.

The ordinary-tail and fast-schedule obligations are read in sequence. First T supplies the selected-tail witness from $\mathsf{RegularCauchyTailSelector}^{\uparrow}$; then F and B record the accelerated schedule consumed by FastCauchySubsequence$^{\uparrow}$.

Dyadic budget exactness follows by inspecting D and S together. Each budget in B is attached to a visible dyadic tolerance and to the same finite stream window that the ordinary selector inspected.

For regular readback, R is downstream of T, F, D, S, B. Since the carrier has no alternate readback coordinate, every $\mathsf{RegSeqRat}^{\uparrow}$ consumer of the accelerated schedule must pass through those rows.

Finally E is reached only through the displayed route. The carrier lists no quotient stream, host equality, chosen limit, countable-choice selector, or ambient completeness coordinate, so the local NameCert surface is exhausted by the finite acceleration packet. □

Theorem 6627.3 (Fast Cauchy acceleration selector window readback)**.** *Every accepted* FastCauchyAccelerationSele *packet exposes the finite completion-facing route*

$$\mathsf{RegularCauchyTailSelector}^{\uparrow} \longmapsto \mathsf{FastCauchySubsequence}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{R}$$

In the carrier notation $A = (T, F, D, S, R, E, B, H, C, P, N)$, a completion consumer may read only the selected-tail row T, the accelerated schedule F, B, the dyadic tolerance ledger D, the shared

stream window S, the regular-rational readback R, the real seal E, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data.*

Proof. Start from the NameCert obligations of Definition 6627.2. They force the ordinary selected tail T to be displayed before the accelerated schedule F, B is read.

Next read the dyadic and stream rows. The budget exactness clause attaches each accelerated request to D and S, so the fast schedule cannot bypass the inspected source window or replace the dyadic tolerance ledger.

Then consume the regular-rational and real-seal rows. The regular-readback obligation places R after T, F, D, S, B, and the real-seal non-escape obligation places E after the same finite route.

The structural rows H, C, P, N transport, replay, source, and name only this packet. Therefore the readback route exports the displayed finite acceleration selector and no quotient stream equality, hidden limit selector, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchyAccelerationSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{FastCauchyAccelerationSelector}^{\uparrow}$ packet is generated from an accepted regular Cauchy tail selector, a fast-subsequence handoff, dyadic budget rows, shared stream windows, regular-rational readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FastCauchyAccelerationSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed chapter names the finite carrier, ordinary tail-selector dependency, fast-subsequence schedule, dyadic budget, stream-window, regular-readback, and real-seal rows for a Bishop-style Cauchy acceleration selector.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FastCauchyAccelerationSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, quotient stream equality, countable choice, host real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Formalization should encode the finite carrier and prove the local NameCert obligation surface from the displayed selector rows.

Chapter 6628

A Concrete Naming Certificate for $\mathsf{LikelihoodRatioTest}^{\uparrow}$

Following Neyman and Pearson, the $\mathsf{LikelihoodRatioTest}^{\uparrow}$ packet records a finite decision ledger for comparing a displayed null hypothesis against a displayed alternative through likelihood-score rows. It sits after the hypothesis surface of chapter 231, the estimator ledger of chapter 230, the Fisher-information score route of chapter 228, the Bayesian likelihood row of chapter 232, and the probability source of chapter 184. The packet names only a finite test decision surface, not asymptotic optimality, host probability measure theory, selected critical regions, posterior odds, or measure-theoretic choice.

Definition 6628.1 (Likelihood-ratio test carrier)**.** *A* $\mathsf{LikelihoodRatioTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (H_0, H_1, L, \tau, D, H, C, P, N)$$

with the following displayed rows:

1. H_0 *is the null-hypothesis row, read through the* $\mathsf{Hypothesis}^{\uparrow}$ *carrier and attached to the displayed* $\mathsf{ProbSpace}^{\uparrow}$ *source.*
2. H_1 *is the alternative-hypothesis row, read through the same hypothesis and probability-source surface.*
3. L *is the finite likelihood-score ledger, carrying the inspected observation windows, likelihood comparisons, estimator readbacks, Fisher-information score rows when present, and Bayesian likelihood row when present.*
4. τ *is the threshold row, displaying the finite critical comparison requested by the test.*
5. D *is the decision row, recording the accepted local decision after* H_0, H_1, L, τ *have been displayed.*
6. H *records componentwise* hsame *transport for the null hypothesis, alternative hypothesis, likelihood ledger, threshold, decision, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from the probability source and hypothesis rows through the likelihood ledger and threshold to the decision row.*
8. P *is the* Pkg *provenance over* $\mathsf{LikelihoodRatioTest}^{\uparrow}$, $\mathsf{Hypothesis}^{\uparrow}$, $\mathsf{Estimator}^{\uparrow}$, $\mathsf{FisherInfo}^{\uparrow}$, $\mathsf{Bayesian}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{LikelihoodRatioTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $H_0, H_1, L, \tau, D, H, C, P, N$. It has no coordinate for asymptotic power, uniformly most powerful optimality, posterior odds, selected rejection regions, ambient measure completion, or host probability choice.

Theorem 6628.2 (Likelihood-ratio test NameCert obligations)**.** *For every accepted* $\mathsf{LikelihoodRatioTest}^{\uparrow}$ *carrier $T = (H_0, H_1, L, \tau, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LikelihoodRatioTest}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the null hypothesis, alternative hypothesis, likelihood-score ledger, threshold, decision, transport, replay, provenance, and local naming rows;*
2. *hypothesis-source stability, requiring H_0 and H_1 to remain attached to the same* $\mathsf{ProbSpace}^{\uparrow}$ *source and to the hypothesis carrier of chapter 231;*
3. *likelihood-ledger stability, requiring every score comparison in L to be read through the displayed estimator, Fisher-information, Bayesian likelihood, or probability-source row named by chapter 230, chapter 228, chapter 232, and chapter 184;*
4. *threshold stability, requiring τ to be displayed before the decision row D is consumed;*
5. *decision nonescape, requiring D to export only the finite likelihood-ratio decision and not asymptotic optimality, posterior odds, selected critical regions, host measure completion, or measure-theoretic choice;*
6. *componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N.*

These obligations certify only the finite statistical decision ledger.

Proof. Project the carrier of Definition 6628.1. Its visible rows are exactly the two hypothesis rows, likelihood-score ledger, threshold, decision, and structural rows.

Hypothesis-source stability is read from H_0 and H_1. Both rows point back to the displayed hypothesis carrier and probability source, so the test does not compare hypotheses from unrelated sources.

Likelihood-ledger stability is read from L. Each score comparison is attached to displayed observation, estimator, Fisher-information, Bayesian likelihood, or probability-source rows before the threshold can be applied.

The threshold and decision rows are downstream. The row τ supplies the finite comparison boundary, and D records the resulting local decision only after the ledger has been displayed.

Rows H, C, P, N transport, replay, source, and name the same packet. Since no additional coordinate stores asymptotic optimality, posterior odds, selected critical regions, host measure completion, or choice, the listed obligations exhaust the NameCert surface. □

Theorem 6628.3 (Likelihood-ratio test finite-ledger threshold stability)**.** *Let $T = (H_0, H_1, L, \tau, D, H, C, P, N)$ and $T' = (H_0', H_1', L', \tau', D', H', C', P', N')$ be accepted* $\mathsf{LikelihoodRatioTest}^{\uparrow}$ *carriers. If componentwise* hsame *transport identifies the null rows, alternative rows, likelihood ledgers, threshold rows, decision rows, replay rows, provenance rows, and local naming rows, then the threshold decision exposed by T is the same finite decision exposed by T'. The comparison is made only through the displayed hypothesis, estimator, Fisher-information, Bayesian likelihood, probability-source, transport, replay, provenance, and local NameCert rows.*

Proof. Start with the two accepted carriers. The classifier has no readable coordinates beyond $H_0, H_1, L, \tau, D, H, C, P, N$ and their primed counterparts.

Use componentwise hsame transport. The null and alternative hypotheses are compared through the displayed hypothesis and probability-source rows, the likelihood ledgers are compared

through their finite score entries, and the threshold rows are compared before either decision row is read.

The replay and provenance rows preserve the same route to the local decision. Because neither carrier contains an asymptotic optimality theorem, posterior-odds row, selected critical region, host measure completion, or choice principle, the transported threshold decision is the same finite ledger decision. □

Falsifiable prediction: Every $\mathsf{LikelihoodRatioTest}^{\uparrow}$ decision read factors through a null hypothesis row, an alternative hypothesis row, a finite likelihood-score ledger, a displayed threshold, a decision row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: hypothesis, estimator, fisherinfo, bayesian, probspace: $\mathsf{LikelihoodRatioTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two hypothesis rows, likelihood-score entries, a threshold row, a decision row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LikelihoodRatioTest}^{\uparrow}}$.

Constructive story: A $\mathsf{LikelihoodRatioTest}^{\uparrow}$ packet is generated from a null hypothesis row, an alternative hypothesis row, a finite likelihood-score ledger, a displayed threshold row, a decision row, componentwise hsame transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LikelihoodRatioTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6628.1, Definition 6628.2, and Definition 6628.3 seed the finite likelihood-ratio decision route through Hypothesis, Estimator, FisherInfo, Bayesian, ProbSpace, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LikelihoodRatioTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close asymptotic optimality, uniformly most powerful tests, posterior odds, selected critical regions, host probability measure theory, ambient measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, hypothesis-source stability, likelihood-ledger stability, threshold stability, decision nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LikelihoodRatioTestUp.

Chapter 6629

A Concrete Naming Certificate for $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$

Following Wald's sequential analysis, the $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$ packet records a finite stopping-and-decision ledger for a likelihood-ratio test whose observations are inspected one window at a time. It sits after the hypothesis-test surface $\mathsf{HypothesisTest}^{\uparrow}$, the likelihood-ratio packet of chapter 6628, the probability source of chapter 184, and the distribution readback of chapter 186. The packet names the finite route by which stopping, continuation, and Type I/II error-budget rows are displayed; it does not claim asymptotic optimality, optional-stopping theorems, selected sample paths, ambient measure completion, or host probability choice.

Definition 6629.1 (Sequential probability ratio test carrier)**.** *A* $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (H_0, H_1, L, A, B, W, \sigma, D, E, H, C, P, N)$$

with the following displayed rows:

1. *H_0 is the displayed null-hypothesis row, read through the* $\mathsf{HypothesisTest}^{\uparrow}$ *and* $\mathsf{ProbSpace}^{\uparrow}$ *source surfaces.*
2. *H_1 is the displayed alternative-hypothesis row, read through the same hypothesis-test and probability-source surfaces.*
3. *L is the sequential likelihood-ratio ledger, whose finite prefixes are read through* $\mathsf{LikelihoodRatioTest}^{\uparrow}$ *and* $\mathsf{Distribution}^{\uparrow}$ *rows.*
4. *A is the lower stopping boundary row and B is the upper stopping boundary row.*
5. *W is the finite observation-window ledger inspected before the stopping row is exposed.*
6. *σ is the stopping row, recording whether the displayed finite prefix continues, accepts the null row, or accepts the alternative row.*
7. *D is the terminal decision row, available only when σ displays a terminal stopping outcome.*
8. *E is the Type I/II error-budget route, naming the finite budget rows attached to A, B, L, W, σ, D.*
9. *H records componentwise* hsame *transport for the hypotheses, likelihood ledger, boundaries, observation windows, stopping row, decision row, budget route, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from the probability source and distribution rows through the sequential likelihood ledger to stopping and decision.*

11. *P is the* Pkg *provenance over* $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$, $\mathsf{HypothesisTest}^{\uparrow}$, $\mathsf{LikelihoodRatioTest}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialProbabilityRatioTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for asymptotic optimality, optional-stopping principles, selected infinite sample paths, external likelihood calibration, host measure completion, or probability-space choice.

Theorem 6629.2 (Sequential probability ratio test NameCert obligations)**.** *For every accepted* $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$ *carrier* $S = (H_0, H_1, L, A, B, W, \sigma, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialProba}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the null hypothesis, alternative hypothesis, sequential likelihood ledger, lower boundary, upper boundary, observation windows, stopping row, decision row, error-budget route, transport, replay, provenance, and local naming;*

2. *hypothesis-source stability, requiring H_0 and H_1 to stay attached to the same* $\mathsf{HypothesisTest}^{\uparrow}$ *and* $\mathsf{ProbSpace}^{\uparrow}$ *source rows;*

3. *likelihood-prefix stability, requiring every prefix in L and W to be read through the displayed* $\mathsf{LikelihoodRatioTest}^{\uparrow}$ *and* $\mathsf{Distribution}^{\uparrow}$ *rows before a stopping comparison is consumed;*

4. *boundary stability, requiring the lower and upper rows A, B to be displayed before σ can classify a prefix as continuing or terminal;*

5. *stopping and decision nonescape, requiring σ, D to export only the displayed sequential decision route and not an optional-stopping theorem, selected infinite path, host probability computation, or ambient measure-completion object;*

6. *error-budget routing, requiring E to name only the Type I and Type II budget rows carried by the displayed hypotheses, likelihood prefixes, boundaries, stopping row, and decision row.*

These obligations certify only the finite sequential decision packet.

Proof. Project the carrier of Definition 6629.1. Its analytic rows are the two hypothesis rows, sequential likelihood ledger, two boundary rows, finite observation windows, stopping row, terminal decision, and error-budget route.

The source obligations come first. Rows H_0 and H_1 keep the null and alternative hypotheses on the same $\mathsf{HypothesisTest}^{\uparrow}$ and $\mathsf{ProbSpace}^{\uparrow}$ source, while L and W expose only finite likelihood prefixes read through $\mathsf{LikelihoodRatioTest}^{\uparrow}$ and $\mathsf{Distribution}^{\uparrow}$.

The stopping obligations are downstream of those rows. The boundaries A and B are displayed before the row σ can decide whether the finite prefix continues or terminates, and the terminal decision row D is visible only after a terminal stopping outcome has been displayed.

The budget and structural rows exhaust the packet. Row E records the Type I/II budget route attached to the same finite data, while H, C, P, N transport, replay, source, and name the carrier. Since no other coordinate is present, the listed obligations exclude optional-stopping principles, selected sample paths, ambient probability computation, and measure-completion data. □

Theorem 6629.3 (Sequential probability ratio test stopping-ledger stability)**.** *Let* $S = (H_0, H_1, L, A, B, W, \sigma, D, E$ *and* $S' = (H_0', H_1', L', A', B', W', \sigma', D', E', H', C', P', N')$ *be accepted* $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$ *carriers. If componentwise* hsame *transport identifies the hypothesis rows, likelihood-prefix ledgers,*

boundary rows, observation windows, stopping rows, decision rows, error-budget routes, replay rows, provenance rows, and local naming rows, then the stopping outcome and terminal decision exposed by S are the same finite sequential read exposed by S'. The comparison is made only through the displayed hypothesis-test, likelihood-ratio, probability-space, distribution, transport, replay, provenance, and local NameCert rows.

Proof. Start with the two accepted carriers. Their classifiers have no readable coordinates beyond the rows listed in Definition 6629.1.

Use componentwise hsame transport. The hypothesis rows remain on the same source surface, the likelihood prefixes and observation windows transport through the displayed $\mathsf{LikelihoodRatioTest}^{\uparrow}$ and $\mathsf{Distribution}^{\uparrow}$ rows, and the boundary rows transport before either stopping row is inspected.

The stopping and decision rows are therefore compared along the same finite route. The replay, provenance, and local naming rows keep that route attached to the same packet, so the transported carrier exposes the same continuation or terminal decision and cannot import an excluded optional-stopping or infinite-path principle. □

Theorem 6629.4 (Sequential probability ratio test error-budget route)**.** *Every Type I or Type II error-budget read exported by a* $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{HypothesisTest}^{\uparrow},\quad \mathsf{LikelihoodRatioTest}^{\uparrow},\quad \mathsf{ProbSpace}^{\uparrow},\quad \mathsf{Distribution}^{\uparrow},\quad L,\quad A,\quad B,\quad W,\quad \sigma,\quad D.$$

Thus a downstream decision consumer receives only displayed hypothesis rows, likelihood-prefix rows, probability and distribution source rows, boundary rows, finite observation windows, stopping and decision rows, componentwise transport, replay, provenance, and local naming before the budget route is visible.

Proof. Project the budget row E from the carrier. By definition it is attached to the hypotheses, likelihood prefixes, boundaries, finite observation windows, stopping row, and terminal decision row.

The upstream rows are displayed before E is consumed. Hypothesis and probability rows provide the source, likelihood-ratio and distribution rows provide the finite prefix readback, and A, B, W, σ, D provide the stopping and decision ledger.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since E has no coordinate for asymptotic optimality, selected paths, host probability computation, optional-stopping theorems, or ambient measure completion, the error-budget read factors only through the finite rows stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialProbabilityRatioTest}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialProbabilityRatioTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6629.1, Definition 6629.2, Definition 6629.3, and Definition 6629.4 seed the finite stopping, decision, and Type I/II budget route through hypothesis-test, likelihood-ratio, probability-space, distribution, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialProbabilityRatioTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close asymptotic optimality, optional-stopping theorems, selected infinite sample paths, ambient measure completion, host probability choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, hypothesis-source stability, likelihood-prefix stability, boundary stability, stopping-ledger stability, error-budget routing, transport, replay, provenance, and local naming for BEDC.Derived.SequentialProbabilityRatioTestUp.

Constructive story: A $\mathsf{SequentialProbabilityRatioTest}^{\uparrow}$ packet is generated from displayed null and alternative hypothesis rows, a sequential likelihood-prefix ledger, lower and upper boundary rows, finite observation windows, a stopping

row, a terminal decision row, a Type I/II error-budget route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6630

Compact Completion Dense Image Name Certificate

Following Bishop and Bridges, the $\mathsf{CompactCompletionDenseImage}^{\uparrow}$ packet records the finite route by which compact metric source data enters a completion-facing dense-image certificate. It sits between the compact metric source of chapter 129, the Cauchy-thread and limit-service surface of chapter 128, and the terminal real-name seal of chapter 38. The packet gives completion consumers one displayed NameCert route for compactness, density, regular readback, and real sealing; it does not choose completion representatives, identify quotient classes, prove open-cover compactness, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6630.1 (Compact completion dense image carrier)**.** *A* $\mathsf{CompactCompletionDenseImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, M, E, T, S, R, F, H, C, P, N)$$

with the following displayed rows:

1. *K is a* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the finite metric and compactness-facing certificate data available before completion is read.*
2. *M is a* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row for the completion-facing metric service consumed by the dense-image route.*
3. *E is the dense embedding row from the compact source into the completion surface; it records only displayed image membership and dense-window access.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by finite density requests.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation-window row attached to the dense-image request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row consumed before any real-facing seal is inspected.*
7. *F is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for completion-facing distance and limit-name requests.*
8. *H records componentwise* hsame *transport for the compact source, completion handoff, dense embedding, tolerance ledger, finite windows, regular readback, real seal, replay, provenance, and local naming row.*
9. *C records displayed* Cont *replay from a compact-source request through $K, M, E, T, S, R, F, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactCompletionDenseImage}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCompletionDenseImage}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. No coordinate stores an open-cover compactness proof, a selected completion representative, quotient equality of completion names, a host dense-image equality theorem, countable choice, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6630.2 (CompactCompletionDenseImage NameCert obligations)**.** *For every accepted* $\mathsf{CompactCompletionDenseImage}^{\uparrow}$ *carrier*

$$D = (K, M, E, T, S, R, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactCompletionDenseImage}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact-source admission: the source row K is the only compact metric data made visible to the dense-image certificate;*
2. *completion handoff: the row M is the only completion-facing metric service read before the dense image can be consumed;*
3. *dense-image exposure: the row E exposes image membership and finite density windows without selecting representatives in the completion;*
4. *tolerance-window readback: the rows T, S, R force every density request to pass through the dyadic tolerance ledger, finite stream window, and regular rational readback before the real seal F;*
5. *provenance and name exhaustion: the rows H, C, P, N transport, replay, package, and name the same route and introduce no open-cover compactness proof, selected completion representative, quotient equality, host equality, countable choice, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6630.1. The visible completion route begins at the compact metric row K, reaches the completion handoff M, and exposes density only through the displayed embedding row E.

The finite readback rows are then forced in order. A density request first reads the dyadic tolerance ledger T, then the finite observation window S, then the regular rational readback row R, and only after those rows may it inspect the terminal real seal F.

Finally use the structural rows. Componentwise hsame transport in H and replay in C preserve the same compact source, completion handoff, dense embedding, tolerance, window, readback, and real-seal rows, while P and N record provenance and local naming.

Since the carrier has no coordinate for open-cover compactness, selected completion representatives, quotient equality, host equality, countable choice, or full $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCompletionDenseImage}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactCompletionDenseImage}^{\uparrow}$ packet is generated from a CompactMetricUp source, a CompleteMetricUp completion handoff, a dense embedding row, a DyadicRatCoreUp tolerance ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactCompletionDenseImage}^{\uparrow}}$, seed)

Scope closed: Definition 6630.1 and Definition 6630.2 seed the finite carrier and local NameCert obligation rows for compact completion dense-image packets.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactCompletionDenseImage}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected completion representatives, quotient equality, full Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, completion handoff routing, dense-image exposure, dyadic tolerance discipline, StreamName window locality, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactCompletionDenseImageUp.

Chapter 6631

A Concrete Naming Certificate for $\mathsf{ClassEquation}^{\uparrow}$

Following Artin, the class equation records the conjugacy-orbit decomposition of a finite group as the sum of the center and the noncentral conjugacy classes. The $\mathsf{ClassEquation}^{\uparrow}$ packet consumes the finite group rows of chapter 41, the orbit-stabilizer handoff of chapter 6559, the orbit-counting ledger of chapter 3578, and the Sylow-facing subgroup route of chapter 3728. It names only the displayed conjugation action, center row, noncentral orbit ledger, stabilizer-index accounting, and finite counting read; it does not import a host quotient by conjugacy, selected representatives, a full subgroup lattice, or a character table.

Definition 6631.1 (ClassEquation carrier)**.** *A* $\mathsf{ClassEquation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (G, Z, A, O, S, L, H, C, P, N)$$

with the following rows:

1. *G is the consumed finite* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row, including multiplication, unit, inverse, finite support, and componentwise group transport.*
2. *Z is the displayed center row, read as the finite list of group endpoints whose conjugation action is fixed by every visible group row.*
3. *A is the conjugation-action row of G on its displayed finite support.*
4. *O is the finite noncentral conjugacy-orbit ledger, with each retained orbit read through the action row A.*
5. *S is the stabilizer-index ledger supplied by the orbit-stabilizer route; it records the centralizer-style stabilizer row and the finite orbit-size read for each noncentral orbit.*
6. *L is the class-equation counting row, displaying the center-orbit split*

$$\mathsf{groupSize}(G) = \mathsf{centerSize}(Z) + \mathsf{noncentralOrbitSum}(O, S).$$

7. *H records componentwise* hsame *transport for G, Z, A, O, S, L.*
8. *C records displayed* Cont *replay from group rows through conjugation, center exposure, orbit-stabilizer accounting, and the final counting row.*

9. *P is the* Pkg *provenance over* $\mathsf{ClassEquation}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{OrbitStabilizer}^{\uparrow}$, $\mathsf{BurnsideOrbitCount}^{\uparrow}$, $\mathsf{Sylow}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassEquation}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host conjugacy quotient, selected class representatives, quotient subgroup equality, character-theoretic class functions, or an ambient finite-group structure theorem.

Theorem 6631.2 (ClassEquation NameCert obligations)**.** *For every accepted* $\mathsf{ClassEquation}^{\uparrow}$ *carrier* $E = (G, Z, A, O, S, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClassEquation}^{\uparrow}}$ *surface consists of five finite rows: carrier admission for the displayed group, center, conjugation-action, orbit, stabilizer-index, counting, transport, replay, provenance, and naming data; classifier stability under componentwise* hsame *for those same rows; center-orbit split exactness for the fixed conjugation rows and the noncentral orbit ledger; orbit-stabilizer ledger replay through chapter 6559; and nonescape, requiring every class-equation consumer to factor through* $G, Z, A, O, S, L, H, C, P, N$ *without receiving a host conjugacy quotient, selected representative, subgroup lattice, character table, or ambient finite-group classification.*

Proof. Carrier admission is projection of Definition 6631.1. The group row G, center row Z, conjugation action A, noncentral orbit ledger O, stabilizer-index ledger S, and counting row L are all finite BHist data.

Classifier stability is componentwise. The group coordinate is compared by the finite $\mathsf{Group}^{\uparrow}$ classifier, the center and action rows are transported by the same hsame ledger, and the orbit, stabilizer, and counting rows are replayed through H and C.

The center-orbit split is read before the final counting row. Fixed conjugation rows enter through Z, while noncentral rows enter through O and then through the orbit-stabilizer ledger S; the resulting finite sum is exactly the displayed row L.

The orbit-stabilizer dependency is the sibling route of chapter 6559, and the finite orbit accounting is compatible with the orbit-counting surface of chapter 3578. Thus Sylow-style consumers may cite the class-equation row only through the displayed group and subgroup-facing ledgers.

Nonescape follows from the packet inventory. Since no coordinate contains a host conjugacy quotient, selected representative, subgroup lattice, character table, or ambient classification theorem, no accepted consumer read can extract one from $\mathsf{ClassEquation}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClassEquation}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassEquation}^{\uparrow}$ packet is generated from a finite GroupUp row, a displayed center row, a conjugation-action row, a noncentral orbit ledger, an orbit-stabilizer index ledger, a class-equation counting row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClassEquation}^{\uparrow}}$, seed)

Scope closed: Definition 6631.1 and Definition 6631.2 seed the finite class-equation packet over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{OrbitStabilizer}^{\uparrow}$, $\mathsf{BurnsideOrbitCount}^{\uparrow}$, and $\mathsf{Sylow}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClassEquation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a host conjugacy quotient, selected class representatives, subgroup-lattice classification, character-table computation, or ambient finite-group classification.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, center-orbit split exactness, orbit-stabilizer ledger replay, and nonescape for BEDC.Derived.ClassEquationUp.

Chapter 6632

A Concrete Naming Certificate for $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$ packet records the finite filter data that constructive analysis can inspect before an ultrafilter or unrestricted selector would be needed. It sits beside the finite refusal surfaces of chapter 1872, chapter 1739, chapter 1173, and chapter 677, while its scheduled observations use the finite windows of chapter 126. The packet names the boundary between finite-intersection filter witnesses and nonconstructive ultrafilter selection; it does not supply a maximal filter, a quotient-selected extension, a host Boolean-prime-ideal theorem, countable choice, or ambient completion data.

Definition 6632.1 (Constructive ultrafilter boundary carrier)**.** *A* $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, I, E, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite filter-base row, listing the inspected base members, declared ambient meet operation, inhabited witness rows, and monotonicity data visible to the packet.*
2. *I is the finite-intersection ledger, recording each displayed finite meet request and the witness that the resulting row remains inside the generated filter base.*
3. *E is the extension-request row, naming the requested ultrafilter or maximal-filter extension and the finite data the request is allowed to inspect.*
4. *R is the ultrafilter and choice-refusal row. It records that the packet answers E only by finite witness replay and by refusal accounting, not by producing a maximal filter or selector.*
5. *H records componentwise* hsame *transport for the filter base, finite-intersection ledger, extension request, refusal row, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from finite base and intersection data to the refusal boundary.*
7. *P is the* Pkg *provenance over* $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$, $\mathsf{CountableChoiceBoundary}^{\uparrow}$, $\mathsf{UniqueChoicePrinciple}$ $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{ChoiceRecipeLedger}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through F, I, E, R, H, C, P, N. It has no coordinate for hidden maximality, quotient Boolean-algebra equality, global ultrafilter selection, countable-choice enumeration, or host-side excluded middle.

Theorem 6632.2 (Finite filter witness row)**.** *For every accepted* $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$ *carrier $U = (F, I, E, R, H, C, P, N)$, every filter witness available to a consumer is read through the finite base row F and finite-intersection ledger I, then transported and replayed through H, C, P, N. The consumer cannot read a maximal filter, an ultrafilter extension, or a selected extension family from those rows.*

Proof. Project the carrier of Definition 6632.1. The only rows carrying positive filter data are the finite base row F and the finite-intersection ledger I.

The structural rows do not add new filter members. They transport the displayed rows through H, replay the same finite route through C, record source data in P, and name the local packet through N.

The extension request E is therefore a demand boundary, not a witness source. Since maximality, ultrafilter selection, quotient equality, countable choice, and excluded middle have no carrier coordinate, every available filter witness is exhausted by the displayed finite rows. □

Theorem 6632.3 (No ultrafilter selector nonescape)**.** *An accepted* $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$ *packet may record an ultrafilter-extension request, but every answer to that request factors through the refusal row R and the finite witness route F, I, H, C, P, N. Thus the packet exports no ultrafilter selector, no maximal-filter extension, no Boolean-prime-ideal principle, no countable-choice schedule, and no hidden host predicate deciding all subsets.*

Proof. Start from the extension-request row E. By the carrier definition, E is paired with the refusal row R before any consumer can interpret the request.

The refusal row is downstream of the finite data. It can cite the inspected base row F and intersection ledger I, but it has no field that returns a maximal filter or a selector.

Use the sibling boundaries named in the provenance row. chapter 1872, chapter 1739, chapter 1173, and chapter 677 keep selector demand, unique-choice demand, Cauchy choice demand, and finite recipe demand separate from a produced choice output.

Finally the $\mathsf{StreamName}^{\uparrow}$ dependency supplies only finite inspection windows. Transport, replay, provenance, and local naming preserve the same refusal route, so the extension request cannot escape into an ultrafilter selector or host maximality theorem. □

Falsifiable prediction: If an accepted packet displays only F, I, H, C, P, N, an ultrafilter-extension request can be recorded only as the refusal row R; it cannot be read as a selected maximal filter.

Independence witness: countable-choice-boundary, unique-choice-principle, cauchy-choice-boundary, choice-recipe-ledger, streamname: $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$ is not bijective to any listed sibling because it binds finite filter bases, finite-intersection ledgers, extension requests, ultrafilter refusal, transport, replay, provenance, and local NameCert rows in one boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$ packet is generated from finite filter-base rows, finite-intersection ledgers, extension-request rows, ultrafilter and choice-refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6632.1, Definition 6632.2, and Definition 6632.3 seed the finite filter-witness boundary against ultrafilter selection.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ultrafilter existence, maximal-filter selection, Boolean-prime-ideal transfer, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-intersection ledger stability, extension-request refusal, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveUltrafilterBoundaryUp.

Chapter 6633

A Concrete Naming Certificate for CompactLebesgueNumberLedger$^{\uparrow}$

Following Bishop–Bridges and the constructive Heine–Cantor finite-cover proof, the CompactLebesgueNumberLedge packet records the finite radius fold behind the compact-uniform-continuity vision of chapter 9237. It sits over the compact finite-net source of chapter 129, the pointwise continuity rows of chapter 130, the tolerance-only output of chapter 369, the metric comparison carrier of chapter 57, and the rational and real seal rows of chapter 291, chapter 301, and chapter 38. The packet names the finite cover/radius/minimum fold; it does not import arbitrary open-cover compactness, a selected subcover theorem, host function equality, or ambient Real completeness.

Definition 6633.1 (Compact Lebesgue-number ledger carrier)**.** *A* CompactLebesgueNumberLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, F, M, C, R, D, Q, U, H, T, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-cover row, listing the displayed centers, cover members, membership witnesses, and finite inspection order.*
2. *F is the* ContinuousMap$^{\uparrow}$ *pointwise-radius row attached to the centers and cover members named by K.*
3. *M is the* Met$^{\uparrow}$ *comparison ledger used to read source distances, target distances, and triangle estimates for the same finite cover route.*
4. *C is the finite cover-refinement row, pairing each inspected compact witness with the cover member and local radius that protects it.*
5. *R is the finite positive-radius family row, recording the candidate Lebesgue radii generated from the displayed cover and pointwise-modulus data.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *radius ledger for positivity, halving, minimum comparison, and strict lower-bound transport.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *seal row used only to read numerical comparisons already displayed by R, D, M.*
8. *U is the* UniformModulus$^{\uparrow}$ *handoff row produced by the finite minimum fold.*

9. *H records componentwise* hsame *transport for the compact cover, continuous-map radius rows, metric comparisons, cover refinement, radius family, dyadic ledger, real seal, uniform-modulus handoff, replay, provenance, and local naming rows.*
10. *T records displayed* Cont *replay from a requested tolerance through $K, F, M, C, R, D, Q, H, P, N$ to the handoff row U.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactLebesgueNumberLedger}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactLebesgueNumberLedger}^{\uparrow}}$ *row.*

The classifier compares accepted ledgers only through $K, F, M, C, R, D, Q, U, H, T, P, N$. It has no coordinate for arbitrary open-cover compactness, selected subcovers, quotient equality of real names, hidden radius choice, or host equality of maps.

Lean4 ✓ `BEDC.Derived.CompactLebesgueNumberLedgerUp.CompactLebesgueNumberLedgerTasteGate single carrier alignment`

Theorem 6633.2 (Compact finite-cover radius fold)**.** *Every accepted* $\mathsf{CompactLebesgueNumberLedger}^{\uparrow}$ *packet turns compact finite-cover data into a tolerance-facing* $\mathsf{UniformModulus}^{\uparrow}$ *row by reading the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The finite minimum fold uses only the displayed cover row K, pointwise radius row F, metric ledger M, cover-refinement row C, radius family R, dyadic ledger D, and numerical seal row Q before exporting the handoff U.

Proof. Project an accepted carrier $L = (K, F, M, C, R, D, Q, U, H, T, P, N)$. The compact source and finite cover data are exactly K, while pointwise local radii are supplied by F.

The cover-refinement and metric rows bind those local radii to the same compact source. The row C records which displayed cover member protects each inspected witness, and M records the triangle and distance comparisons consumed by the fold.

The positive-radius family and dyadic ledger then perform the finite minimum step. The rows R, D expose positivity, halving, and lower-bound comparisons, and Q seals only the numerical reads already present in those rows.

Finally U, H, T, P, N export, transport, replay, source, and name the tolerance-only uniform-modulus handoff. No excluded compactness, selected subcover, hidden radius choice, quotient real equality, or host map equality has a carrier coordinate. □

This finite-radius fold is the predecessor consumed by the compact-uniform modulus route of chapter 388; locally it is the radius-source sibling of chapter 452, because the compact-uniform consumer reads the displayed K, F, M, C, R, D, Q ledger before any $\mathsf{UniformModulus}^{\uparrow}$ handoff is available.

Theorem 6633.3 (Compact Lebesgue-number nonescape)**.** *A consumer of an accepted* CompactLebesgueNumberLe *packet cannot read a Lebesgue number, compact cover bound, or uniform-modulus handoff without displaying the compact cover row K, pointwise-radius row F, metric comparison row M, refinement row C, radius family R, dyadic ledger D, RegSeqRat and Real seal row Q, transport row H, replay row T, provenance row P, and local* NameCert *row N.*

Proof. Use Definition 6633.1. The rows listed in the statement are the entire accepted packet and the only route to the handoff U.

The finite fold theorem above identifies the order in which those rows are consumed. Cover data and pointwise radii precede metric comparison, metric comparison precedes the positive-radius family, and the dyadic and real seal rows precede the uniform-modulus handoff.

Transport and replay preserve that route rather than adding another source of compactness or radius choice. Therefore a consumer asking for an arbitrary open-cover proof, selected subcover, hidden radius, quotient real equality, host map equality, or ambient Real completeness has left the accepted packet. □

Falsifiable prediction: If R, D, Q are absent, an accepted compact finite-cover read cannot be consumed as a $\mathsf{UniformModulus}^{\uparrow}$ handoff through $\mathsf{CompactLebesgueNumberLedger}^{\uparrow}$.

Independence witness: compactmetric, continuousmap, uniformmodulus, metric, dyadicratcore, regseqrat, real: $\mathsf{CompactLebesgueNumberLedger}^{\uparrow}$ is not bijective to any listed sibling because it binds compact cover rows, pointwise radius rows, metric comparisons, finite refinement, radius-family folds, dyadic comparisons, real seals, uniform-modulus handoff, transport, replay, provenance, and local NameCert rows in one finite ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactLebesgueNumberLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactLebesgueNumberLedger}^{\uparrow}$ packet is generated from compact finite-cover rows, ContinuousMap pointwise-radius rows, Metric comparison ledgers, finite cover-refinement rows, positive-radius families, DyadicRatCore folds, RegSeqRat and Real seal rows, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactLebesgueNumberLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6633.1, Definition 6633.2, and Definition 6633.3 seed the compact finite-cover radius fold used by uniform-modulus extraction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactLebesgueNumberLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, quotient real equality, hidden radius choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cover exposure, pointwise-radius compatibility, metric comparison replay, finite radius-fold exactness, dyadic and Real seal discipline, UniformModulus handoff, and non-escape for BEDC.Derived.CompactLebesgueNumberLedgerUp.

Chapter 6634

A Concrete Naming Certificate for $\mathsf{HankelOperator}^{\uparrow}$

Following Hankel's moment-matrix tradition and the operator-theoretic reading of anti-diagonal kernels, the $\mathsf{HankelOperator}^{\uparrow}$ packet records the finite BEDC surface that a moment or kernel consumer may inspect before any infinite Hankel operator is named. It sits between the moment-window rows of chapter 6193 and chapter 6454, the finite matrix carrier of chapter 49, the inner-product readback of chapter 86, the scalar seal of chapter 38, and the collision-kernel shadow boundary of chapter 444. The certificate names only displayed moment rows, finite index windows, anti-diagonal matrix rows, shift rows, boundedness ledgers, transport, replay, provenance, and local naming.

Definition 6634.1 (Hankel operator carrier)**.** *A* $\mathsf{HankelOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, I, A, S, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite moment-row ledger, read from a displayed* $\mathsf{MomentProblem}^{\uparrow}$ *or* $\mathsf{HausdorffMomentProblem}^{\uparrow}$ *window and sealed through* $\mathsf{Real}^{\uparrow}$ *scalar rows;*
2. *I is the finite index-window row, listing exactly which source and target indices are visible to the packet;*
3. *A is the anti-diagonal* $\mathsf{Mat}^{\uparrow}$ *row whose entry at the displayed pair (i, j) is read from the moment row indexed by $i + j$ when that index is present in I;*
4. *S is the finite shift row, recording the visible source-window and target-window shift by which a Hankel-shadow consumer reuses A;*
5. *B is the boundedness ledger, containing only displayed finite norm, inner-product, or tolerance rows from* $\mathsf{InnerProduct}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*;*
6. *H records componentwise* hsame *transport for moment rows, index windows, anti-diagonal matrix rows, shift rows, boundedness rows, replay, provenance, and the local naming row;*
7. *C records displayed* Cont *replay from a moment-window request through I, A, S, B, H before any downstream read sees the packet;*
8. *P is the* Pkg *provenance over* $\mathsf{HankelOperator}^{\uparrow}$*,* $\mathsf{MomentProblem}^{\uparrow}$*,* $\mathsf{HausdorffMomentProblem}^{\uparrow}$*,* $\mathsf{CollisionKernel}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{HankelOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, I, A, S, B, H, C, P, N$. It has no coordinate for an infinite matrix, ambient bounded operator, representing measure, spectral theorem, selected domain completion, or host Hilbert-space equality.

Theorem 6634.2 (Hankel operator NameCert obligations)**.** *For every accepted* $\mathsf{HankelOperator}^{\uparrow}$ *carrier $K = (M, I, A, S, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HankelOperator}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for the moment rows, finite index window, anti-diagonal matrix row, shift row, boundedness ledger, transport, replay, provenance, and local name;*
2. *moment-window exactness, requiring every entry of A to be read from M using an index named by I;*
3. *anti-diagonal exactness, requiring the displayed* $\mathsf{Mat}^{\uparrow}$ *row to depend only on the visible sum index $i + j$;*
4. *shift-moment stability, requiring the row S to transport moment-window reads without adding an unlisted source or target index;*
5. *boundedness nonescape, requiring B to expose only finite inner-product, norm, or tolerance rows and no ambient bounded-operator theorem;*
6. *componentwise transport, displayed replay, package provenance, and local naming through H, C, P, N.*

No Hankel obligation is stored outside this finite packet.

Proof. Project the carrier of Definition 6634.1. The visible rows are exactly $M, I, A, S, B, H, C, P, N$.

Moment-window exactness and anti-diagonal exactness read M, I, A together. The matrix row is admitted only when each displayed entry uses a visible moment row at the displayed sum index.

Shift-moment stability is the row S. It reuses the same finite index and moment data under the displayed source-target shift, while H and C transport and replay only those rows.

The boundedness and nonescape clauses follow from B, P, N. The provenance row names the moment, collision-kernel, matrix, inner-product, and real scalar sources, and the local naming row contains no coordinate for an infinite operator, spectral object, representing measure, selected completion, or host Hilbert-space equality. □

Theorem 6634.3 (Hankel operator shift-moment route)**.** *Every shift-moment read of an accepted* $\mathsf{HankelOperator}^{\uparrow}$ *packet factors through the finite moment ledger M, the index-window row I, the anti-diagonal matrix row A, the shift row S, the boundedness ledger B, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{HankelOperator}^{\uparrow}}$ *row. Thus the read is a positive finite carrier for the Hankel-shadow routes used by* $\mathsf{MomentProblem}^{\uparrow}$*,* $\mathsf{HausdorffMomentProblem}^{\uparrow}$*, and* $\mathsf{CollisionKernel}^{\uparrow}$*, not an infinite Hankel operator.*

Proof. Start from the NameCert obligations of Definition 6634.2. They force a shift-moment consumer to expose M, I, A, S before any Hankel-shadow read is exported.

Use the moment-window exactness and anti-diagonal exactness clauses. A requested shifted entry is read from the same finite moment ledger by the visible sum-index rule, and no unlisted index can be manufactured by the carrier.

Next consume the boundedness ledger and structural rows. The row B supplies only displayed finite inner-product, norm, or tolerance evidence, while H, C, P, N transport, replay, source, and name the same finite packet.

Consequently the route supplies the positive finite carrier requested by the moment and collision-kernel chapters. Since the carrier lacks an infinite matrix, ambient bounded-operator theorem, spectral row, representing measure, selected completion, or host equality, the shift-moment read stops at the displayed finite Hankel surface. □

Lean4 (statement) `BEDC.Derived.HankelOperatorUp`

Falsifiable prediction: An accepted $\mathsf{HankelOperator}^{\uparrow}$ read is refuted if a Hankel-shadow consumer reaches an anti-diagonal or shift-moment conclusion without first displaying the moment ledger, finite index window, anti-diagonal matrix row, shift row, boundedness ledger, transport row, replay row, provenance row, and local naming row.

Independence witness: moment-problem, Hausdorff moment problem, collision kernel, matrix, inner product, real scalar: $\mathsf{HankelOperator}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries moment rows, finite index windows, anti-diagonal matrix data, shift-moment rows, boundedness ledgers, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{HankelOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{HankelOperator}^{\uparrow}$ packet is generated from finite moment rows, finite index windows, anti-diagonal matrix rows, shift rows, boundedness ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HankelOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6634.1, Definition 6634.2, and Definition 6634.3 seed the finite Hankel carrier consumed by moment-window, collision-kernel, matrix, inner-product, and real scalar rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HankelOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, infinite Hankel operators, ambient bounded-operator theory, spectral data, representing measures, selected domain completions, or host Hilbert-space equality.

Upgrade path: Obligation closure requires checked carrier admission, moment-window exactness, anti-diagonal exactness, shift-moment stability, boundedness nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HankelOperatorUp.

Chapter 6635

A Concrete Naming Certificate for $\mathsf{BaireFunctionRank}^{\uparrow}$

Following Hausdorff, Kuratowski, and Kechris in classical descriptive set theory, the $\mathsf{BaireFunctionRank}^{\uparrow}$ packet records the finite BEDC route by which a real-valued function on a Polish source exposes a displayed Baire-class rank to downstream consumers. It sits over the complete separable source of chapter 1490, the displayed rank schedule of chapter 4020, the Borel-function row of chapter 3479, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the real seal of chapter 38. The packet names a rank-read route only; it does not assert Baire hierarchy completeness, selected codes, quotient equality of functions, countable choice, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6635.1 (Baire-function rank carrier)**.** *A* $\mathsf{BaireFunctionRank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (P, B, F, S, Q, E, H, C, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *source row for the domain of the real-valued function.*
2. *B is the* $\mathsf{BorelHierarchy}^{\uparrow}$ *rank schedule row, including the visible predecessor, successor, and limit-stage windows used by the current rank read.*
3. *F is the* $\mathsf{BorelFunction}^{\uparrow}$ *row that hands the source-side function query to the displayed Borel schedule.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row for finite observation of source names, rank positions, and real-facing output windows.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used before the rank read reaches the real seal.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the real-valued output readback.*
7. *H records componentwise* hsame *transport for the Polish source, rank schedule, Borel-function row, stream windows, regular-rational readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a source query through the rank schedule, Borel-function handoff, readback, and real seal.*
9. *G is the* Pkg *provenance over the sibling surfaces named above.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireFunctionRank}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, B, F, S, Q, E, H, C, G, N$. It has no coordinate for a host-space function, a chosen Baire code, quotient equality of functions, countable-choice selection, completed measure structure, or ambient real-completion principle.

Theorem 6635.2 (Baire-function rank NameCert obligations)**.** *For every accepted* $\mathsf{BaireFunctionRank}^{\uparrow}$ *carrier*

$$R = (P, B, F, S, Q, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{BaireFunctionRank}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. *Polish source exposure, requiring the domain read to pass through P before any rank-facing row is consumed;*
3. *Borel rank schedule exposure, requiring every inspected predecessor, successor, or limit-stage window to be displayed in B;*
4. *Borel-function handoff, requiring the function row F to connect the source query to the rank schedule before the real readback is used;*
5. *Real readback nonescape, requiring the route through S, Q, E before any real-facing consumer receives a rank value;*
6. *transport, requiring H to preserve $P, B, F, S, Q, E, C, G, N$ componentwise;*
7. *continuation replay, requiring C to replay the same ordered route for each accepted consumer;*
8. *provenance, requiring G to cite only the displayed PolishSpace, BorelHierarchy, BorelFunction, StreamName, RegSeqRat, and Real sibling surfaces;*
9. *local naming, requiring N to certify exactly the rows $P, B, F, S, Q, E, H, C, G$.*

No $\mathsf{BaireFunctionRank}^{\uparrow}$ *obligation stores a selected code, host function quotient, countable-choice selector, measure-completion datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 6635.1. The tuple displays the Polish source, Borel rank schedule, Borel-function handoff, stream windows, regular rational readback, real seal, transport, replay, provenance, and local naming rows.

The rank-facing read starts at P, B, F. The Polish source is exposed first, the Borel hierarchy row supplies only visible rank windows, and the Borel-function row is the single handoff from the source query to that schedule.

The real-facing part is downstream of S, Q, E. Stream windows and regular rational readback are consumed before the real seal, so no consumer can replace the route by host equality, selected limits, or ambient real completeness.

Finally H, C, G, N transport, replay, source, and name the same finite packet. Since no row contains a selected Baire code, quotient function equality, countable-choice selector, or measure-completion object, the enumerated obligations exhaust the local certificate surface. □

Theorem 6635.3 (Baire-function rank Borel handoff)**.** *Every rank read of an accepted* $\mathsf{BaireFunctionRank}^{\uparrow}$ *carrier*

$$R = (P, B, F, S, Q, E, H, C, G, N)$$

passes through

$$P \longmapsto B \longmapsto F \longmapsto S \longmapsto Q \longmapsto E$$

before any real-facing consumer may use it. The structural rows H, C, G, N only transport, replay, source, and name that route; they do not add a selected Baire code, quotient equality of functions, countable-choice schedule, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 6635.2. The Polish source exposure, Borel rank schedule exposure, and Borel-function handoff obligations force the route through P, B, F before a rank value is read.

Apply the Real readback nonescape obligation. It places every real-facing rank use behind the finite stream window S, regular rational readback Q, and real seal E.

The rows H, C, G, N cannot create a second path. They preserve, replay, cite, and name the displayed packet, so the handoff remains the ordered route through the six source and readback rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireFunctionRank}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireFunctionRank}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6635.1, Definition 6635.2, and Definition 6635.3 seed the rank-read route over Polish source, Borel schedule, Borel-function handoff, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireFunctionRank}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Baire hierarchy completeness, selected Baire codes, quotient equality of functions, countable choice, measure completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Polish source exposure, Borel rank schedule exposure, Borel-function handoff, Real readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BaireFunctionRankUp.

Constructive story: A $\mathsf{BaireFunctionRank}^{\uparrow}$ packet is generated from a PolishSpace row, BorelHierarchy rank schedule, BorelFunction handoff, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6636

A Concrete Naming Certificate for BanachContractionRealCompletion$^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive completion, the BanachContractionRealC
packet records the finite route by which contraction iterates become a completion-facing real seal. It sits after the fixed-point endpoint discipline of chapter 396, the complete-metric service of chapter 128, the Cauchy-modulus surface of chapter 292, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names contraction iteration as displayed RegSeqRat and Real completion data; it does not select a host fixed point, quotient completion representative, or ambient completeness principle.

Definition 6636.1 (Banach contraction real-completion carrier)**.** *A* BanachContractionRealCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, F, x_0, I, D, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* CompleteMetric$^{\uparrow}$ *source row, carrying only the displayed metric and completion-facing Cauchy service available to the contraction route.*
2. *F is the contraction self-map row, including the graph read and contraction-ratio ledger used to compare successive iterates.*
3. *x_0 is the initial-point row.*
4. *I is the finite iterate ledger naming the inspected Picard stages $x_0, x_1, \ldots, x_n$.*
5. *D is the adjacent-distance ledger, recording the contraction-controlled distance comparisons extracted from I and F.*
6. *M is the* CauchyModulus$^{\uparrow}$ *row generated from D.*
7. *W is the finite observation-window row used when a completion or real consumer asks for a displayed precision read.*
8. *R is the* RegSeqRat$^{\uparrow}$ *handoff row built from M and W.*
9. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after the contraction, modulus, window, and regular-rational rows have been displayed.*
10. *H records componentwise* hsame *transport for $X, F, x_0, I, D, M, W, R, E, C, P, N$.*

11. *C records displayed* Cont *replay from a contraction-iteration request through the metric, modulus, regular-rational, and real-seal rows.*
12. *P is the* Pkg *provenance over* $\mathsf{BanachContractionRealCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachContractionRealCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a selected fixed point, quotient real equality, host function extensionality, countable choice over iterates, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6636.2 (Banach contraction real-completion obligations)**.** *For every accepted* BanachContractionRealCom *carrier $B = (X, F, x_0, I, D, M, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachContractionRealCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, complete-metric source exposure, contraction self-map stability, initial-point visibility, finite iterate-ledger visibility, adjacent-distance exactness, Cauchy-modulus extraction, observation-window locality,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6636.1. The rows X, F, x_0, I, D expose the complete metric source, the contraction graph, the initial point, the inspected iterates, and the adjacent-distance comparisons before any completion-facing row is read.

The Cauchy data are downstream. The row M is generated from the displayed distance ledger, and the row W names the finite windows used by each requested precision read.

The real-completion boundary is terminal. The row R is the only regular rational handoff, and E is the only Real seal. The structural rows H, C, P, N preserve and package the same route, so the certificate cannot export a selected fixed point, quotient representative, countable-choice schedule, or host completeness theorem. □

Theorem 6636.3 (Banach contraction iteration Cauchy route)**.** *Every completion-facing consumer of an accepted* $\mathsf{BanachContractionRealCompletion}^{\uparrow}$ *carrier must read the contraction iteration through*

$$X, F, x_0, I, D, M, W, R, E, H, C, P, N.$$

The adjacent-distance ledger D produces the $\mathsf{CauchyModulus}^{\uparrow}$ *row M, the finite windows W expose the requested precision reads, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R gives the regular rational handoff, and the* $\mathsf{Real}^{\uparrow}$ *row E seals the completion-facing real datum. No public read bypasses this order through host completeness or a chosen fixed-point object.*

Proof. Start with a completion-facing read. The carrier admits the candidate iteration only through the complete metric row X, contraction row F, initial point x_0, and finite iterate ledger I.

The Cauchy route is forced by the distance ledger. The row D records the contraction-controlled adjacent distances, and M is the only Cauchy-modulus row available to the consumer.

The regular and real rows are then read in order. The window row W fixes the inspected precision budget, R translates that budget into regular rational data, and E seals the resulting real-facing read. Transport, replay, provenance, and local naming preserve the same route, leaving no coordinate for a host fixed point, selected limit, quotient equality, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{BanachContractionRealCompletion}^{\uparrow}$ real-completion read factors through a complete metric source, contraction self-map, initial point, finite iterate ledger,

adjacent-distance ledger, CauchyModulus row, finite observation windows, RegSeqRat handoff, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: banachfixedpoint, completemetric, cauchymodulus, regseqrat, real: none is bijective with $\mathsf{BanachContractionRealCompletion}^{\uparrow}$ because the packet jointly stores contraction iteration, adjacent-distance control, Cauchy-modulus extraction, finite windows, regular rational handoff, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachContractionRealCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachContractionRealCompletion}^{\uparrow}$ packet is generated from a CompleteMetricUp source, contraction self-map, initial point, finite iterate ledger, adjacent-distance ledger, CauchyModulus route, finite observation windows, RegSeqRat handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachContractionRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6636.1, Definition 6636.2, and Definition 6636.3 seed the finite contraction-iteration route from complete metric data to RegSeqRat readback and Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachContractionRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, quotient completion representatives, host function extensionality, countable choice over iterates, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction stability, adjacent-distance exactness, Cauchy-modulus extraction, window locality, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BanachContractionRealCompletionUp.

Chapter 6637

A Concrete Naming Certificate for $\mathsf{EffectiveCauchyCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, effective Cauchy completeness is read through displayed Cauchy names, explicit moduli, and finite rational approximation ledgers rather than through quotient classes or a host completeness theorem. The $\mathsf{EffectiveCauchyCompleteness}^{\uparrow}$ packet records that traditional route as NameCert data over the dyadic core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the displayed sequence-completeness boundary of chapter 1515. It gives Real and Completion consumers a named effective-completeness landing surface without asserting that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 6637.1 (Effective Cauchy completeness carrier)**.** *An* $\mathsf{EffectiveCauchyCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, R, M, L, W, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint ledger used for precision requests;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the Cauchy name being completed;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback of the same windows;*
4. *M is the effective modulus row assigning each dyadic tolerance a displayed late threshold;*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row offered as the candidate landing name;*
6. *W is the witness ledger saying that each sufficiently late regular-rational window is within the dyadic tolerance of the landing seal;*
7. *H records componentwise* hsame *transport for $D, S, R, M, L, W, C, P, N$;*
8. *C records the displayed* Cont *replay from dyadic tolerance requests through stream windows, regular readback, modulus thresholds, witness rows, and the Real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompleteness}^{\uparrow}}$ *row.*

The carrier contains no quotient Cauchy class, selected representative, countable-choice schedule, open-cover compactness principle, ambient metric-completeness premise, or proof that $\mathsf{Real}^{\uparrow}$ *is complete.*

Theorem 6637.2 (Effective Cauchy completeness NameCert obligations)**.** *For an accepted* EffectiveCauchyComplet *carrier* $E = (D, S, R, M, L, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompleteness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed dyadic, stream, regular-rational, modulus, landing, witness, transport, replay, provenance, and naming rows; classifier stability under componentwise* hsame *transport; modulus coverage for every dyadic tolerance request; witness exactness tying the late regular-rational windows to the terminal* $\mathsf{Real}^{\uparrow}$ *seal; and ledger non-escape for quotient completion, representative selection, countable choice, open-cover compactness, ambient completeness, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6637.1. The displayed tuple exposes the dyadic tolerance row, finite windows, regular rational readback, effective modulus, landing seal, witness ledger, transport, replay, provenance, and local name.

Classifier stability is componentwise. A comparison of accepted packets first transports $D, S, R, M, L, W, C, P, N$ by H before any local read is identified.

Modulus coverage and witness exactness are read in order. A dyadic tolerance request reaches M for a late threshold, then reaches S and R for the inspected windows, and finally reaches W for the comparison with L.

The rows of E are exhausted by this route. Since none of them stores a quotient class, selected representative, choice schedule, open-cover principle, ambient complete carrier, or completeness theorem for $\mathsf{Real}^{\uparrow}$, the non-escape clause follows. □

Theorem 6637.3 (Effective Cauchy completeness modulus handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{EffectiveCauchyCompleteness}^{\uparrow}$ *packet* $E = (D, S, R, M, L, W, H, C, P, N)$ *must read the dyadic tolerance ledger* D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the effective modulus row* M *before it can consume the landing seal* L*. The handoff to* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *is therefore the finite route*

$$D, S, R, M \longmapsto W, L, H, C, P, N.$$

It is not a quotient completion, selected limit, countable-choice construction, open-cover compactness argument, ambient completeness assumption, or proof that $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Start with a completion-facing tolerance request. The dyadic row D fixes the requested precision, so the consumer cannot inspect a landing seal before the precision row is displayed.

Read the Cauchy-name rows next. The finite windows S and the regular rational readback R expose the observed tail of the name, while M supplies the late threshold for that tolerance.

Only after this route is displayed can W compare the late windows with L. The structural rows H, C, P, N transport, replay, source, and name the same finite handoff for $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers.

No further row exists in the carrier. Hence the handoff cannot provide quotient completion, selected representatives, countable choice, open-cover compactness, ambient completeness, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 6637.4 (Effective Cauchy completeness ledger nonescape)**.** *An accepted* $\mathsf{EffectiveCauchyCompleteness}^{\uparrow}$ *carrier* $E = (D, S, R, M, L, W, H, C, P, N)$ *exports only the displayed effective Cauchy route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,*

Pkg, *and* NameCert. *Any consumer asking for quotient completion, a selected representative, countable choice, open-cover compactness, ambient metric completeness, or completeness of* $\mathsf{Real}^{\uparrow}$ *is returned to those finite rows.*

Proof. Project the accepted carrier. Its coordinates are precisely the dyadic tolerance ledger, stream windows, regular readback, modulus, landing seal, witness ledger, transport, replay, provenance, and local naming row.

Apply the NameCert obligation surface. It makes every effective-completeness read pass through the displayed modulus and witness rows before the terminal Real seal is visible.

Apply the modulus handoff. The completion-facing consumer receives a finite route to the displayed seal, not a second completed carrier. Since the forbidden objects are absent from the tuple, they cannot be exported by the local ledger. □

Independence witness: dyadicratcore, streamname, regseqrat, real, sequentiallycompletemetric: $\mathsf{EffectiveCauchyCompleteness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic tolerance requests, finite stream windows, regular rational readback, an effective modulus, a terminal Real seal, a witness ledger, transport, replay, provenance, and local naming in one completion-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompleteness}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveCauchyCompleteness}^{\uparrow}$ packet is generated from dyadic tolerance rows, finite stream windows, regular rational readback, an effective modulus, a terminal Real seal, witness ledgers, componentwise hsame transports, displayed Cont replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6637.1, Definition 6637.2, Definition 6637.3, and Definition 6637.4 seed the finite effective Cauchy completeness route over displayed dyadic, stream, regular rational, Real-seal, and sequential-completeness rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, representative selection, countable choice, open-cover compactness, ambient metric completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed effective Cauchy route.

Chapter 6638

A Concrete Naming Certificate for $\mathsf{PettisIntegral}^{\uparrow}$

Following Pettis and Dunford–Schwartz on weak scalar integration in locally convex and Banach-space settings, the $\mathsf{PettisIntegral}^{\uparrow}$ packet records the finite BEDC surface on which weak scalar integrals are named before any Bochner norm integrability theorem, selected vector-valued representative, quotient almost-everywhere equality, weak compactness extraction, or host dual-space completeness principle is public. It sits beside the weak-compactness handoff of chapter 6346, the measure and integral sources of chapter 92 and chapter 123, the functional-analysis carrier of chapter 94, and the bounded-operator surface of chapter 1644.

Definition 6638.1 (Pettis integral carrier)**.** *A* $\mathsf{PettisIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, I, F, B, S, R, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row naming measurable domains, measurable sets, null windows, and finite partitions visible to the packet.*
2. *I is the* $\mathsf{Integral}^{\uparrow}$ *scalar readback row for finite scalar integrals and displayed domination budgets.*
3. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *row naming the locally convex or Banach carrier, weak topology probes, and finite dual-pairing tests.*
4. *B is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row for bounded linear functionals and bounded linear probes through which scalar shadows are read.*
5. *S is the weak scalar measurability row. It records only that every displayed bounded probe reads a scalar measurable function through M, I, F, B.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-budget row storing tolerances, comparison bounds, and finite integral windows for the scalar shadows.*
7. *W is the weak scalar handoff row. It records the finite route from scalar probe integrals to the named vector-valued Pettis integral request.*
8. *H records componentwise* hsame *transport for M, I, F, B, S, R, W and the local structural rows.*
9. *C records displayed* Cont *replay from weak scalar integration requests through $M, I, F, B, S, R, W, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{PettisIntegral}^{\uparrow}$, $\mathsf{DunfordPettis}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PettisIntegral}^{\uparrow}}$ *row.*

The carrier has no coordinate for Bochner norm integrability, a selected vector-valued representative, quotient almost-everywhere equality, ambient dual-ball compactness, countable choice, or a weakly compact subsequence extraction.

Theorem 6638.2 (Pettis integral NameCert obligations)**.** *For every accepted* $\mathsf{PettisIntegral}^{\uparrow}$ *carrier*

$$Q = (M, I, F, B, S, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PettisIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, measure source compatibility through M, scalar integral readback through I, functional-analysis probe visibility through F, bounded-linear-probe visibility through B, weak scalar measurability through S, scalar-budget visibility through R, weak scalar integral handoff through W, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every weak-integration-facing consumer must read the same rows before using the handoff. It receives no Bochner integral, no selected vector representative, no quotient almost-everywhere equality, no ambient dual compactness theorem, no countable-choice schedule, and no weakly compact subsequence.

Proof. Carrier admission is projection from Definition 6638.1. The accepted packet displays exactly $M, I, F, B, S, R, W, H, C, P, N$.

The analytic rows M and I fix the measurable source and scalar integral readback. The weak-facing rows F and B restrict every observation to the displayed dual-pairing and bounded-linear-probe tests, while S records scalar measurability only through those tests.

The scalar-budget row R supplies the finite comparison data used by the scalar shadows. The handoff row W is downstream of those scalar shadows and names the Pettis integral request without selecting a vector representative or importing a Bochner theorem.

The structural rows H, C, P, N preserve the same packet under transport, replay, provenance, and naming. Since every excluded object has no carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6638.3 (Pettis integral weak scalar handoff)**.** *Every weak scalar integration consumer of an accepted* $\mathsf{PettisIntegral}^{\uparrow}$ *carrier reaches the Pettis handoff only through the displayed route*

$$M, I \longmapsto F, B, S, R \longmapsto W \longmapsto H, C, P, N.$$

Thus the consumer may read measure data, scalar integral evidence, finite weak-probe and bounded-linear-probe rows, scalar measurability, scalar budgets, the weak scalar integral handoff, transport, replay, provenance, and local naming, and it may not read Bochner norm integrability, selected vector-valued representatives, quotient almost-everywhere equality, ambient dual compactness, countable choice, or weakly compact subsequences.

Proof. Begin with a weak scalar integration read. By Definition 6638.1, the measurable and scalar integral sources are exactly M and I.

The weak scalar tests then pass through F, B, S, R. These rows expose only finite dual-pairing probes, bounded linear functionals, scalar measurability evidence, and real-valued comparison budgets.

The consumer reaches the Pettis integral request only at W. That row is a handoff from the displayed scalar shadows to the named weak integral, not an extraction of a Bochner integral or a selected vector representative from an ambient space.

Finally H, C, P, N transport, replay, package, and name the same route. Because the carrier lacks coordinates for the refused objects, no consumer can recover them from the $\mathsf{PettisIntegral}^{\uparrow}$ packet. □

Falsifiable prediction: Any $\mathsf{PettisIntegral}^{\uparrow}$ read that claims weak scalar integration while bypassing the displayed $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 6638.1.

Independence witness: Dunford-Pettis, measure, integral, functional-analysis, bounded-linear-operator: $\mathsf{PettisIntegral}^{\uparrow}$ is not bijective to any listed sibling because it stores the finite weak scalar integration handoff over scalar probe integrals without storing Bochner norm integrability, selected vector representatives, quotient almost-everywhere equality, ambient dual compactness, countable choice, or weakly compact subsequences.

Closure status for $\mathsf{NameCert}_{\mathsf{PettisIntegral}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PettisIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6638.1, Definition 6638.2, and Definition 6638.3 seed the finite weak scalar integration route over measure, integral, weak-probe, bounded-probe, scalar-measurability, scalar-budget, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PettisIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Bochner norm integrability, selected vector-valued representatives, quotient almost-everywhere equality, ambient dual compactness, countable choice, weakly compact subsequences, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, measure source compatibility, scalar integral readback, weak-probe visibility, bounded-linear-probe visibility, scalar measurability, scalar-budget visibility, handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PettisIntegralUp.

Constructive story: A $\mathsf{PettisIntegral}^{\uparrow}$ packet is generated from Measure, Integral, FunctionalAnalysis, BoundedLinearOperator, Real scalar-budget, weak scalar measurability, weak scalar integration handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6639

A Concrete Naming Certificate for $\mathsf{LebesgueNumberFunction}^{\uparrow}$

Following Lebesgue and Bishop–Bridges constructive analysis, the $\mathsf{LebesgueNumberFunction}^{\uparrow}$ packet records the finite cover-to-radius ledger used when a compact metric source supplies displayed cover rows and downstream uniform-continuity consumers need explicit positive radii. It sits after the compact metric source of chapter 129, the finite-cover Lebesgue-number surface of chapter 3606, the Lebesgue-number lemma route of chapter 2301, the compact-uniform modulus extractor of chapter 2202, the rational positivity row of chapter 37, and the dyadic tolerance core of chapter 291. The packet names a finite function ledger assigning radii to displayed cover entries; it does not assert open-cover compactness, choose a cover refinement from an ambient theorem, or hide a modulus inside host analysis.

Definition 6639.1 (LebesgueNumberFunction carrier)**.** *A* $\mathsf{LebesgueNumberFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, U, C, L, R, D, W, H, T, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *and carrying the finite compactness data available to the packet;*
2. *U is the finite cover row, listing the displayed cover entries to which radii may be assigned;*
3. *C is the compact finite-cover and Lebesgue-number row, routing the cover through the finite-cover Lebesgue-number and Lebesgue-number lemma surfaces;*
4. *L is the function ledger assigning a displayed positive radius to each cover entry that has been admitted by U and C;*
5. *R is the rational tolerance row, recording positivity and comparison data for each ledger radius through* $\mathsf{Rat}^{\uparrow}$*;*
6. *D is the dyadic tolerance row, recording endpoint and refinement budgets through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
7. *W is the finite witness-window row, recording the compact windows on which the radius assignment is checked;*
8. *H stores componentwise* hsame *transports for K, U, C, L, R, D, W and for the structural rows;*
9. *T stores displayed transport and replay routes for cover entries, radius reads, and compact-window witnesses;*

10. *P is the* Pkg *provenance over the compact metric source, finite cover row, Lebesgue-number rows, rational and dyadic tolerances, witness windows, transports, and local naming evidence;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberFunction}^{\uparrow}}$ *row.*

The carrier is exactly this finite packet. It has no coordinate for an arbitrary open-cover compactness principle, a selected refinement outside the displayed cover, a host real-valued radius function, countable choice, or an ambient uniform-continuity theorem.

Theorem 6639.2 (LebesgueNumberFunction NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberFunction}^{\uparrow}}$ *surface consists of carrier exposure for $K, U, C, L, R, D, W, H, T, P, N$, finite cover admission for every entry read by L, positive-radius ledger stability through R and D, witness-window replay through W and T, componentwise transport through H, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6639.1. The only analytic rows are the compact metric source, finite cover, compact finite-cover route, radius ledger, rational and dyadic tolerance rows, and witness windows.

Read the cover and radius obligations together. A ledger entry in L is accepted only for a cover entry already displayed by U and certified through C, while R and D record the positivity and tolerance data for the assigned radius.

The remaining rows bind the ledger to BEDC structure. Witness windows W are replayed by T, transported by H, recorded by P, and named by N, so the NameCert surface has no hidden radius function or ambient compactness proof. □

Theorem 6639.3 (LebesgueNumberFunction finite-cover handoff)**.** *Every accepted* $\mathsf{LebesgueNumberFunction}^{\uparrow}$ *packet hands a finite cover row from U through the compact finite-cover and Lebesgue-number row C before any consumer reads a radius assignment in L. The handoff preserves the same compact metric source K, rational tolerance row R, dyadic tolerance row D, witness-window row W, transport rows H, T, provenance row P, and local name N.*

Proof. Begin with the compact metric source and finite cover rows K and U. They fix the source and the displayed cover entries before the packet exposes any radius.

Use the compact finite-cover and Lebesgue-number row C. It is the only route from the cover entries to the positive-radius ledger, so a consumer cannot read L before the finite-cover handoff has occurred.

Finally preserve the structural rows. The rational and dyadic tolerance rows, finite witness windows, transports, replay routes, provenance, and local name are carried with the same cover entry, giving a handoff rather than a detached radius table. □

Theorem 6639.4 (LebesgueNumberFunction uniform-modulus boundary)**.** *A* $\mathsf{CompactUniformModulusExtractor}^{\uparrow}$ *or uniform-continuity consumer may read an accepted* $\mathsf{LebesgueNumberFunction}^{\uparrow}$ *packet only as the finite ledger $K, U, C, L, R, D, W, H, T, P, N$. It receives the displayed cover-to-radius assignments and witness windows, but receives no open-cover compactness principle, no selected host modulus, no quotient real equality, no countable-choice schedule, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the finite-cover handoff first. It supplies the compact source, displayed cover entries, Lebesgue-number route, radius ledger, tolerance rows, and witness windows as one finite packet.

A uniform-modulus consumer may reuse those rows, but only through the transports, replay routes, provenance, and local naming data. Thus the consumer receives a named finite ledger, not a function chosen from outside the packet.

The excluded principles require coordinates absent from the carrier: open-cover compactness, host modulus selection, quotient real equality, countable choice, or ambient Real completeness. Since none of these coordinates appears in F, they remain outside the uniform-modulus boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueNumberFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueNumberFunction}^{\uparrow}$ packet is generated from a compact metric source, a displayed finite cover row, compact finite-cover and Lebesgue-number rows, a positive-radius ledger, rational and dyadic tolerance rows, finite witness windows, componentwise transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueNumberFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6639.1, Definition 6639.2, Definition 6639.3, and Definition 6639.4 describe the finite cover-to-radius ledger and its consumer boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueNumberFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, selected host moduli, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier and NameCert obligation rows for the finite cover-to-radius ledger.

Chapter 6640

A Concrete Naming Certificate for $\mathsf{LocatedRealNumber}^{\uparrow}$

Following Bishop and Bridges, a located real number is a real name whose finite rational observations also carry a displayed locatedness test. The $\mathsf{LocatedRealNumber}^{\uparrow}$ packet sits between the constructive real-line interface of chapter 4041, the terminal real-name seal of chapter 38, the regular rational source of chapter 301, the stream-window schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. It records a Bishop-style located name as finite BEDC data, not as a completed host real, quotient stream, trichotomy principle, selected comparison oracle, or ambient completeness theorem.

Definition 6640.1 (Located real number carrier)**.** *A* $\mathsf{LocatedRealNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, E, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for inspected precision requests, rational intervals, and locatedness questions.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row read through S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and interval ledger used to compare requested radii, endpoint gaps, and rational enclosure witnesses.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after S, R, D are visible.*
5. *A is the* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *interface row recording the Bishop locatedness surface available to downstream real-line consumers.*
6. *H records componentwise* hsame *transport for the stream, regular-rational, dyadic, real-seal, constructive-real-line, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a locatedness request through S, R, D, E, A, H.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedRealNumber}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ConstructiveRealLine}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, E, A, H, C, P, N$. It has no coordinate for quotient equality of real names, trichotomy, a selected sign decision, a host locatedness predicate, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6640.2 (Located real number NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealNumber}^{\uparrow}$ *carrier* $L = (S, R, D, E, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealNumber}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-window visibility, regular-rational readback, dyadic tolerance and enclosure exactness, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, constructive-real-line locatedness exposure, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6640.1. The rows $S, R, D, E, A, H, C, P, N$ are the full inventory of data available to an accepted packet.

The real-name route is finite. A consumer first reads the stream schedule S, then the regular rational row R, then the dyadic tolerance and enclosure ledger D, and only then may consume the terminal real seal E.

The locatedness route is the row A. It records the constructive real-line interface attached to the same regular rational and dyadic data, so a locatedness request cannot bypass the displayed window and tolerance rows.

Finally H, C, P, N transport, replay, source, and name that same finite packet. Since no row contains quotient equality of real names, trichotomy, a selected sign decision, host locatedness, or ambient completeness, the listed rows exhaust the local certificate obligations. □

Theorem 6640.3 (Located real number RegSeqRat handoff)**.** *Every* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{LocatedRealNumber}^{\uparrow}$ *carrier must read the route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows retained before the located real-number claim is public. The exported datum is a finite Bishop-style located real name and not a quotient real, selected comparison function, trichotomy principle, host completion object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from Definition 6640.2. It makes stream-window visibility, regular-rational readback, dyadic tolerance exactness, and Real-seal nonescape mandatory rows of every accepted local certificate.

The $\mathsf{ConstructiveRealLine}^{\uparrow}$ row A is downstream of the same displayed route. It can expose locatedness only after the requested finite window, rational name row, dyadic enclosure ledger, and terminal seal have been shown.

Transport and replay do not add analytic content. The rows H, C, P, N preserve the same packet under hsame, Cont, Pkg, and NameCert, leaving no coordinate for quotient equality, trichotomy, selected comparison, host completion, or ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{LocatedRealNumber}^{\uparrow}$ read exposes a StreamName window, RegSeqRat regular rational name, DyadicRatCore tolerance and enclosure ledger, terminal RealUp seal, ConstructiveRealLine locatedness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any consumer reads located real-number data.

Independence witness: dyadicratcore, streamname, regseqrat, real, constructive-real-line: no listed sibling is bijective with $\mathsf{LocatedRealNumber}^{\uparrow}$ because this packet jointly binds finite observation windows, regular rational readback, dyadic locatedness ledgers, a Real seal, constructive real-line exposure, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealNumber}^{\uparrow}}$**.**

Constructive story: A LocatedRealNumber$^{\uparrow}$ packet is generated from StreamName windows, a RegSeqRat regular rational row, DyadicRatCore tolerance and enclosure data, a terminal RealUp seal, a ConstructiveRealLine locatedness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{LocatedRealNumber}^{\uparrow}}$, seed)

Scope closed: Definition 6640.1, Definition 6640.2, and Definition 6640.3 seed the finite Bishop-style located real-name route over DyadicRatCore, StreamName, RegSeqRat, Real, ConstructiveRealLine, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedRealNumber}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, trichotomy, selected sign decisions, host locatedness predicates, ambient Real completeness, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window visibility, regular-rational read-back, dyadic tolerance exactness, Real seal nonescape, constructive-real-line exposure, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealNumberUp.

Chapter 6641

A Concrete Naming Certificate for $\mathsf{CompactUniformLimit}^{\uparrow}$

Following Bishop and Bridges on compact-source uniform convergence, the $\mathsf{CompactUniformLimit}^{\uparrow}$ packet realizes the compact-uniform-continuity program of chapter 9237 as a finite NameCert carrier. It sits over the compact uniform-modulus row of chapter 2299, the continuous-map interface of chapter 130, the theorem handoff of chapter 2200, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names compact-source uniform limits through displayed finite moduli and readback rows; it does not import open-cover compactness, quotient equality of functions, selected host limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6641.1 (Compact uniform-limit carrier)**.** *A* $\mathsf{CompactUniformLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, F, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompactUniformModulus}^{\uparrow}$ *row, carrying the compact-source finite modulus used by every tolerance request.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed family or limiting map whose graph data are visible to the packet.*
3. *T is the* $\mathsf{UniformLimitTheorem}^{\uparrow}$ *handoff row, recording the finite continuity inheritance route available after uniform convergence is displayed.*
4. *W is the finite observation-window row for compact-source points, function stages, modulus requests, and limit-value reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational comparison windows generated from M, F, T, W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the compact modulus, continuous-map, theorem, window, and regular-rational rows have been displayed.*
7. *H records componentwise* hsame *transport for the compact-modulus, continuous-map, theorem, window, readback, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact-source uniform-limit requests through M, F, T, W, R, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformLimit}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimitTheorem}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformLimit}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, F, T, W, R, E, H, C, P, N$. It has no coordinate for an open-cover compactness theorem, quotient function equality, selected limit function, host continuity theorem, or ambient Real completeness.

Theorem 6641.2 (Compact uniform-limit NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformLimit}^{\uparrow}$ *carrier $U = (M, F, T, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformLimit}^{\uparrow}}$ *surface consists exactly of carrier admission, compact uniform-modulus exposure, continuous-map graph visibility, uniform-limit theorem handoff, finite observation-window locality, regular-rational readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6641.1. The accepted packet exposes exactly the compact modulus, continuous-map, theorem handoff, finite windows, regular-rational reads, real seal, transport, replay, provenance, and local naming rows.

The compact part is M. A tolerance request over the compact source becomes public only as a finite modulus row and is read together with the graph data in F and the inspected windows in W.

The continuity handoff is T. It can be consumed only after the compact modulus and continuous-map rows have been displayed, and its Real-facing values pass through R before the terminal seal E is read.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row stores open-cover compactness, quotient function equality, a selected host limit, host continuity, or ambient Real completeness, the listed obligations exhaust the local certificate surface. □

Theorem 6641.3 (Compact uniform-limit continuity handoff)**.** *Every continuity read exported by an accepted* $\mathsf{CompactUniformLimit}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompactUniformModulus}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{UniformLimitTheorem}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows retained. The handoff exports compact-source uniform convergence as finite modulus, continuous-map, regular-rational readback, and Real-seal data, not as a host compactness theorem, quotient function equality, selected limit, or ambient completeness principle.*

Proof. Begin with Definition 6641.2. It forces every accepted read to expose the compact uniform modulus M, the continuous-map row F, the theorem handoff T, finite windows W, regular-rational readback R, and terminal real seal E.

The continuity read is therefore downstream of the compact modulus and the graph row. The theorem handoff T may state the continuity inheritance route, but only as a displayed finite row inside the same packet.

The Real-facing values are sealed last. The regular-rational row R supplies the comparison windows before E is consumed, while H, C, P, N preserve the route under transport, replay, provenance, and local naming. No excluded host compactness, quotient equality, selected limit, or ambient completeness coordinate is available. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformLimit}^{\uparrow}$ read exposes a CompactUniformModulus row, ContinuousMap row, UniformLimitTheorem handoff, finite observation windows,

RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any consumer reads compact uniform-limit continuity.

Independence witness: compact-uniform-modulus, continuousmap, uniform-limit-theorem, regseqrat, real: no listed sibling is bijective with $\mathsf{CompactUniformLimit}^{\uparrow}$ because this packet jointly binds compact-source finite modulus data, continuous-map graph rows, uniform-limit theorem handoff, finite windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformLimit}^{\uparrow}$ packet is generated from a CompactUniformModulus row, ContinuousMap graph data, UniformLimitTheorem handoff, finite observation windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6641.1, Definition 6641.2, and Definition 6641.3 seed the compact-source uniform-limit route over CompactUniformModulus, ContinuousMap, UniformLimitTheorem, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient equality of functions, selected host limits, host continuity theorems, ambient Real completeness, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact uniform-modulus exposure, continuous-map graph visibility, uniform-limit theorem handoff, window locality, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformLimitUp.

Chapter 6642

A Concrete Naming Certificate for $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$

Following Bishop and Bridges constructive analysis, a located Cauchy limit is read through explicit finite moduli, locatedness tests, and rational windows rather than through quotient streams, countable choice, or an ambient completion theorem. The $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$ packet records that route as one NameCert carrier over the dyadic tolerances of chapter 291, the finite windows of chapter 126, the regular rational readback of chapter 301, the modulus surface of chapter 292, the located-real handoff of **??**, and the terminal seal of chapter 38.

Definition 6642.1 (Located Cauchy modulus selector carrier)**.** *A* $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, Q, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the positive dyadic radius being requested;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row scheduled for that tolerance;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows;*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row selecting the late threshold for the same tolerance;*
5. *L is the locatedness row deciding the displayed overlap or separation test at the selected threshold;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the readback, modulus, and locatedness rows are displayed;*
7. *H records componentwise* hsame *transport for $D, W, Q, M, L, E, C, P, N$;*
8. *C records displayed* Cont *replay from dyadic tolerance to stream window, from window to regular readback, from modulus and locatedness rows to the Real seal, and from the structural rows to the local name;*
9. *P records* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-stream equality, a selected host limit, countable choice, an unlocated Cauchy witness, an ambient completion theorem, or a Real seal read that bypasses the displayed modulus and locatedness rows.

Lean4 ✓ `BEDC.Derived.LocatedCauchyModulusSelectorUp.LocatedCauchyModulusSelectorTasteGate`
`single carrier alignment`

Theorem 6642.2 (Located Cauchy modulus selector NameCert obligations)**.** *For an accepted* $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$ *carrier* $S = (D, W, Q, M, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusSel}}$ *surface consists exactly of carrier admission for the displayed dyadic tolerance, stream-window, regular readback, modulus, locatedness, Real seal, transport, replay, provenance, and naming rows; classifier stability under componentwise* hsame *transport; modulus coverage for every displayed dyadic tolerance; locatedness exactness at the selected finite threshold; and non-escape for quotient streams, host limits, countable choice, unlocated witnesses, ambient completion, and seal reads outside the displayed packet.*

Proof. Carrier admission is projection from Definition 6642.1. The packet exposes only the rows $D, W, Q, M, L, E, H, C, P, N$, so every local read must begin with the displayed dyadic tolerance, window, readback, modulus, locatedness, and seal data.

The constructive selector route is finite. A dyadic tolerance request is recorded in D, scheduled as the finite window W, read back as Q, and bounded by the selected modulus threshold M. The locatedness row L is read at the same threshold before the seal row E can be offered to a Real-facing consumer.

The structural rows H, C, P, N transport, replay, source, and name exactly that route. Since the carrier contains none of the excluded coordinates, no quotient stream, host limit, choice schedule, unlocated witness, ambient completion theorem, or bypass seal can be exported by the local certificate. □

Theorem 6642.3 (Located Cauchy modulus selector Real seal handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$ *packet must read the scheduled* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row* M*, and the locatedness row* L *before it can consume the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The handoff route is therefore*

$$D, W, Q, M, L \longmapsto E, H, C, P, N.$$

It is not a quotient-stream construction, selected host limit, countable-choice route, unlocated Cauchy witness, or ambient completion theorem.

Lean4 ✓ `BEDC.Derived.LocatedCauchyModulusSelectorUp.LocatedCauchyModulusSelectorRealSealHandoff`

Proof. Start with the NameCert obligations of Definition 6642.2. They force the Real-facing read to pass through the displayed carrier rows rather than through an external completion object.

The finite analytic route then orders the rows. The dyadic tolerance D determines the requested scale, the stream window W and regular readback Q expose the inspected data, the modulus row M supplies the late threshold, and the locatedness row L decides the local located test at that threshold.

Only after those rows are displayed can E serve as the Real seal. The transport, replay, provenance, and local naming rows H, C, P, N preserve the same route, so any consumer omitting W, Q, M, or L is outside the accepted packet. □

Theorem 6642.4 (Located Cauchy modulus selector threshold induction)**.** *Every accepted tolerance request in a* $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$ *packet is discharged by finite induction over the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row* M*. The base case opens the first admissible* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and the step case extends the window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *until the selected threshold is reached. The locatedness row* L *is then read at that same threshold before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed. The derivation uses only the carrier of Definition 6642.1, the NameCert obligations of Definition 6642.2, and the Real seal handoff of Definition 6642.3; it does not use quotient streams, selected host limits, countable choice, unlocated Cauchy witnesses, or ambient completion.*

Proof. Start with the carrier row M. Since M is part of the finite packet, its selected threshold is inspected as a displayed row rather than as an external choice function.

Induct over the finite threshold named by M. In the base case, the first admissible stream window W is opened for the requested dyadic tolerance D, and the regular rational readback Q is read from that window.

In the step case, extend the displayed window by one scheduled read and extend Q by the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ readback. The induction hypothesis supplies the previous finite window and readback route, and the NameCert obligations keep the extension inside the same carrier rows.

At the selected threshold, read L before exposing E. The Real seal handoff then forces every Real-facing consumer to pass through W, Q, M, and L, so the construction has no coordinate for quotient streams, selected host limits, countable choice, unlocated Cauchy witnesses, or ambient completion. □

Independence witness: dyadicratcore, streamname, regseqrat, cauchymodulus, locatedreal, real: $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores the dyadic tolerance request, finite window schedule, regular-rational readback, selected Cauchy modulus threshold, locatedness row, Real seal, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchyModulusSelector}^{\uparrow}$ packet is generated from dyadic tolerance requests, finite stream windows, regular rational readback, selected Cauchy modulus thresholds, locatedness rows, Real seals, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6642.1, Definition 6642.2, and Definition 6642.3 seed the finite located Cauchy selector route over DyadicRatCore, StreamName, RegSeqRat, CauchyModulus, LocatedReal, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, unlocated Cauchy witnesses, ambient completion, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed located Cauchy modulus selector route.

Chapter 6643

A Concrete Naming Certificate for $\mathsf{CartesianClosedCategory}^{\uparrow}$

Following Mac Lane's account of categories with finite products and exponentials and the Lambek–Scott use of cartesian closed categories as categorical logic, the $\mathsf{CartesianClosedCategory}^{\uparrow}$ packet records the finite BEDC surface on which products, terminal objects, evaluation maps, and currying are named before any ambient category universe, host function space, quotient morphism equality, global internal language, topos classifier, or set-theoretic semantics is public. It sits between the category carrier of chapter 61, the functorial transport surface of chapter 62, the product packet of chapter 34, the tensor discipline of chapter 181, and the topos boundary of chapter 183.

Definition 6643.1 (Cartesian closed category carrier)**.** *A* $\mathsf{CartesianClosedCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, F, T, P, X, E, V, U, H, R, G, N)$$

with the following displayed rows:

1. *C is the accepted* $\mathsf{Cat}^{\uparrow}$ *row naming the object carrier, hom-carrier, identity, composition, associativity, and unit laws.*
2. *F is the* $\mathsf{Functor}^{\uparrow}$ *transport row for product and exponential reindexing along displayed morphism rows.*
3. *T is the terminal-object row, storing the displayed terminal object and its unique map rows through the classifier of C.*
4. *P is the binary-product row, read through* ***??*** *and carrying projections, pairing, product stability, and product classifier transport.*
5. *X is the exponential-object row, assigning to each displayed pair A, B an object B^A inside the same* $\mathsf{Cat}^{\uparrow}$ *carrier.*
6. *E is the evaluation row, storing each displayed evaluation morphism $B^A \times A \to B$ through the product row P and the hom-carrier row of C.*
7. *V is the currying row. It records the finite bijective read between maps $Z \times A \to B$ and maps $Z \to B^A$ as classifier-compatible hom rows, not as host function equality.*
8. *U is the product-exponential stability row, carrying componentwise stability of T, P, X, E, V under* hsame *transport in C.*

9. *H records componentwise* hsame *transport for C, F, T, P, X, E, V, U and the support rows.*
10. *R records displayed* Cont *replay for terminal, product, exponential, evaluation, currying, and stability reads.*
11. *G is the* Pkg *provenance over* $\mathsf{CartesianClosedCategory}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, *??*, $\mathsf{MonoidalCat}^{\uparrow}$, $\mathsf{Topos}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CartesianClosedCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient category of all objects, host exponential functions, quotient morphism equality, global internal language, subobject classifier, set semantics, or topos structure.

Theorem 6643.2 (Cartesian closed category NameCert obligations)**.** *For every accepted* $\mathsf{CartesianClosedCategory}^{\uparrow}$ *carrier*

$$K = (C, F, T, P, X, E, V, U, H, R, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{CartesianClosedCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, category source compatibility through C, functorial transport through F, terminal-object exactness through T, product exactness through P, exponential-object admission through X, evaluation readback through E, currying readback through V, product-exponential stability through U, componentwise transport through H, displayed replay through R, package provenance through G, and local naming through N.*

Every cartesian-closed-category consumer must read the same rows before using evaluation or currying. It receives no ambient object universe, no host function-space equality, no quotient morphism equality, no global internal language, no subobject classifier, no set-theoretic semantics, and no $\mathsf{Topos}^{\uparrow}$ *structure.*

Proof. Project the accepted carrier. The packet displays exactly $C, F, T, P, X, E, V, U, H, R, G, N$, so carrier admission supplies only those rows.

Read the categorical source first. The row C gives the visible object and morphism surface, while F transports the product and exponential rows along displayed morphisms without adding a second category carrier.

Read the cartesian structure next. The terminal row T and product row P provide the finite cartesian spine; the exponential row X is attached to the same source, not to an ambient universe of objects.

The evaluation and currying rows are downstream of that spine. The row E reads $B^A \times A \to B$ through P and the hom-carrier of C, and V records the classifier-compatible transpose route. The stability and support rows U, H, R, G, N preserve the same finite packet under transport, replay, provenance, and local naming. Since the carrier has no coordinate for the refused objects, the listed rows exhaust the local obligations. □

Theorem 6643.3 (Cartesian closed category evaluation-currying stability)**.** *Let $K = (C, F, T, P, X, E, V, U, H, R, G$ be an accepted* $\mathsf{CartesianClosedCategory}^{\uparrow}$ *carrier. Any componentwise* hsame *transport recorded by H preserves the product row P, exponential row X, evaluation row E, and currying row V before a downstream consumer may use a transpose. Thus the evaluation-currying route*

$$C, F, T, P, X \longmapsto E, V \longmapsto U, H, R, G, N$$

is stable under the displayed classifier of the carrier and cannot be replaced by host function equality, quotient morphism equality, or an external internal-language semantics.

Proof. Project the product and exponential rows from Definition 6643.1. The rows P and X are displayed over the same $\mathsf{Cat}^{\uparrow}$ row C and transported only by the functorial and classifier rows F and H.

Read evaluation before currying. The evaluation row E uses the product row P to type $B^A \times A$ and the hom-carrier row of C to type the morphism into B.

Read the currying row V next. It records the finite transpose route between displayed hom rows and is guarded by the stability row U, so componentwise transport must preserve the source product, target exponential, evaluation morphism, and transposed morphism together.

Finally replay the support rows. The Cont route R, provenance G, and local naming row N carry the same transported packet. Because no row stores host functions, quotient morphism classes, or external semantics, the stable route is exactly the displayed evaluation-currying surface. □

Falsifiable prediction: Any accepted $\mathsf{CartesianClosedCategory}^{\uparrow}$ read that uses evaluation or currying while bypassing the displayed $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, **??**, terminal-object, exponential-object, hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 6643.1.

Independence witness: category, functor, product, monoidalcat, topos: $\mathsf{CartesianClosedCategory}^{\uparrow}$ is not bijective to any listed sibling because it binds terminal objects, binary products, exponentials, evaluation, currying, product-exponential stability, transport, replay, provenance, and local naming as one finite certificate while refusing subobject classifiers and ambient internal-language semantics.

Closure status for $\mathsf{NameCert}_{\mathsf{CartesianClosedCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{CartesianClosedCategory}^{\uparrow}$ packet is generated from Category, Functor, Product, terminal-object, exponential-object, evaluation, currying, product-exponential stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CartesianClosedCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6643.1, Definition 6643.2, and Definition 6643.3 seed the finite cartesian closed category carrier and its evaluation-currying stability route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CartesianClosedCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an ambient category universe, host function-space equality, quotient morphism equality, global internal language, subobject classifier, set-theoretic semantics, $\mathsf{Topos}^{\uparrow}$ structure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, category source compatibility, functorial transport, terminal-object exactness, product exactness, exponential-object admission, evaluation readback, currying readback, stability, transport, replay, provenance, and local naming for BEDC.Derived.CartesianClosedCategoryUp.

Chapter 6644

A Concrete Naming Certificate for $\mathsf{RealCompletionWitnessTransducer}^{\uparrow}$

Following Bishop and Bridges constructive completion, the Real-completeness limit route of chapter 9238 is read through finite moduli, selected windows, regular rational readback, and seal rows rather than through quotient streams or a host completeness theorem. The $\mathsf{RealCompletionWitnessTransducer}^{\uparrow}$ packet records the diagonal-limit witness of Definition 9238.5 as one NameCert carrier whose rows are visible before any Real-facing consumer reads the completed witness. It consumes the witness-ledger sibling chapter 6279 and compares its extracted finite route with the completion extractor chapter 1725 before the diagonal-limit row is public.

Definition 6644.1 (Real completion witness transducer carrier)**.** *A* $\mathsf{RealCompletionWitnessTransducer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, M, W, D, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the regular Cauchy source row over* $\mathsf{RegSeqRat}^{\uparrow}$*;*
2. *M is the explicit modulus row assigning each requested dyadic tolerance a displayed late threshold;*
3. *W is the selected finite-window row over* $\mathsf{StreamName}^{\uparrow}$ *at that threshold;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same request;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row from the selected windows;*
6. *L is the diagonal-limit row naming the candidate produced from S, M, W, D, R;*
7. *U is the uniqueness row saying that any competing accepted witness with the same displayed convergence route is identified by the Real seal classifier;*
8. *H records componentwise* hsame *transport for $S, M, W, D, R, L, U, C, P, N$;*
9. *C records displayed* Cont *replay from the source and modulus rows through the selected windows, dyadic tolerance ledger, readback, diagonal-limit row, uniqueness row, and local name;*
10. *P records* Pkg *provenance over* $\mathsf{RealCompletionWitnessTransducer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. N is the local $\mathsf{NameCert}_{\mathsf{RealCompletionWitnessTransducer}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient real equality, selected host limits, countable choice, ambient completion, global stream equality, or a uniqueness proof outside the displayed finite route.

Theorem 6644.2 (Real completion witness transducer NameCert obligations)**.** *For an accepted* $\mathsf{RealCompletionWitnessTransducer}^{\uparrow}$ *carrier* $T = (S, M, W, D, R, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionWitn}}$ *surface consists exactly of source admission, explicit modulus exposure, selected finite-window exposure, dyadic tolerance ledger exposure, RegSeqRat readback, diagonal-limit row admission, uniqueness-row admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape for quotient real equality, selected host limits, countable choice, ambient completion, global stream equality, and undisplayed uniqueness.*

Proof. Carrier admission is projection from Definition 6644.1. The packet exposes the regular Cauchy source, explicit modulus, selected windows, dyadic tolerance ledger, regular rational readback, diagonal-limit candidate, uniqueness row, and the structural rows H, C, P, N.

The limit witness route is constructive and finite. A tolerance request reaches the modulus row M, then the selected windows W and dyadic ledger D, then the readback row R, and only then the diagonal-limit row L.

The uniqueness row U is read through the same displayed route. Componentwise transport, route replay, provenance, and local naming preserve that inventory, while the carrier lacks quotient, choice, host-limit, ambient-completion, global-stream, and hidden-uniqueness coordinates. □

Theorem 6644.3 (Real completion witness transducer diagonal route)**.** *Every accepted* $\mathsf{RealCompletionWitnessTran}$ *packet realizes the diagonal-limit witness route of Definition 9238.5 through the finite spine*

$$S, M, W, D, R \longmapsto L, U, H, C, P, N.$$

A Real-facing consumer may read the completed witness only after the regular Cauchy source, explicit modulus, selected windows, dyadic tolerance ledger, and RegSeqRat readback rows have been displayed. The route does not export quotient real equality, a selected host limit, countable choice, ambient completion, global stream equality, or a uniqueness proof outside U.

Proof. Start with the Real-completeness target Definition 9238.5. In the transducer packet, the abstract diagonal candidate is represented by the displayed row L, reached only after S, M, W, D, R have been exposed.

Apply the NameCert obligations of Definition 6644.2. They force every accepted consumer to read the same finite modulus, window, tolerance, and readback spine before the diagonal-limit row and uniqueness row become public.

The structural rows H, C, P, N then transport, replay, source, and name the same witness route. Since the excluded host and quotient objects are absent from the carrier, the diagonal witness is exported only as this finite transducer route. □

Theorem 6644.4 (Real completion witness transducer uniqueness handoff)**.** *If two accepted* $\mathsf{RealCompletionWitnessTransducer}^{\uparrow}$ *packets agree on the regular Cauchy source row S, explicit modulus row M, selected window row W, dyadic tolerance ledger D, RegSeqRat readback row R, and structural rows H, C, P, N, then any Real-facing comparison of their diagonal candidates is read through their displayed uniqueness rows U. No comparison may replace those rows by quotient real equality, global stream equality, or a host completeness theorem.*

Proof. Project both packets. Agreement on $S, M, W, D, R, H, C, P, N$ fixes the finite route that reaches the diagonal-limit row in each carrier.

The NameCert obligations make the uniqueness row U the only comparison-facing coordinate after the diagonal-limit row is displayed. Thus a Real-facing consumer must inspect U before treating the two candidates as the same completed witness.

The carrier has no quotient-equality, global-stream, or ambient-completion coordinate. Therefore any comparison that bypasses the displayed uniqueness row is not an accepted read of the transducer packet. □

Independence witness: real-completeness, streamname, dyadicratcore, regseqrat, real: RealCompletionWitnessTr is not bijective to any listed sibling because it jointly carries the regular Cauchy source, explicit modulus, selected finite windows, dyadic tolerance ledger, RegSeqRat readback, diagonal-limit row, uniqueness row, transport, replay, provenance, and local NameCert in one completion-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionWitnessTransducer}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionWitnessTransducer}^{\uparrow}$ packet is generated from a regular Cauchy source, explicit modulus, selected finite windows, dyadic tolerance ledger, RegSeqRat readback, diagonal-limit row, uniqueness row, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionWitnessTransducer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6644.1, Definition 6644.2, Definition 6644.3, and Definition 6644.4 seed the finite Real-completion witness route over modulus, window, dyadic tolerance, RegSeqRat, diagonal-limit, uniqueness, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionWitnessTransducer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected host limits, countable choice, ambient completion, global stream equality, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed Real-completion witness transducer route.

Chapter 6645

A Concrete Naming Certificate for $\mathsf{CoarseMetricSpace}^{\uparrow}$

Following Roe and Bourbaki/Kelley large-scale metric practice, the $\mathsf{CoarseMetricSpace}^{\uparrow}$ packet records coarse control as finite BEDC NameCert data over displayed metric and uniform-space rows. It reads the metric source of chapter 57, the entourage discipline of chapter 339, and the terminal distance readback surface of chapter 38. The packet gives later large-scale consumers a controlled-entourage and bounded-set route without constructing a quotient coarse category, selecting representatives, importing countable choice, or asserting an external large-scale theorem.

Definition 6645.1 (CoarseMetricSpace carrier)**.** *A* $\mathsf{CoarseMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, U, E, B, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the admitted point classifier, finite distance-query surface, and metric observation histories.*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, recording the finite entourage requests whose small-scale control is visible to the packet.*
3. *E is the controlled large-scale entourage budget, assigning displayed coarse-radius or tolerance rows to the finite entourages allowed for downstream coarse consumers.*
4. *B is the bounded-set ledger, recording the finite named bounded rows and the radius/readback witnesses by which a consumer may use them.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row for metric distances, controlled radii, and bounded-set witnesses.*
6. *H records componentwise* hsame *transport for the metric source, uniform entourage row, controlled-entourage budget, bounded-set ledger, readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from metric-distance and entourage requests through U, E, B, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CoarseMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CoarseMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, U, E, B, R, H, C, P, N$. It has no coordinate for quotient coarse-space equality, a selected net, a choice-selected bornology, a host large-scale category, or ambient metric completion.

Theorem 6645.2 (CoarseMetricSpace NameCert obligations)**.** *For every accepted* $\mathsf{CoarseMetricSpace}^{\uparrow}$ *carrier* $K = (M, U, E, B, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CoarseMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{Met}^{\uparrow}$ *source,* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, controlled large-scale entourage budget, bounded-set ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every coarse consumer must read* $M, U, E, B, R, H, C, P, N$ *before treating the packet as large-scale metric data, and every request for quotient completion, selected representatives, countable choice, host coarse categories, or ambient completeness is refused by absence from the carrier.*

Proof. Carrier admission is projection from Definition 6645.1. The tuple displays the metric source, uniform entourage row, controlled-entourage budget, bounded-set ledger, readback, transport, replay, provenance, and local name.

The control obligations are finite route inspections. A consumer first reads M for metric distances, U for entourage shape, E for large-scale control, and B for bounded-set access.

Readback and stability then pass through R, H, C, P, N. These rows transport, replay, source, and name the same finite route, so the NameCert surface contains no quotient coarse category, selected representative, countable-choice schedule, host bornology, or ambient completeness principle. □

Theorem 6645.3 (CoarseMetricSpace controlled entourage route)**.** *Let* $K = (M, U, E, B, R, H, C, P, N)$ *be an accepted* $\mathsf{CoarseMetricSpace}^{\uparrow}$ *carrier. Every controlled-entourage consumer must first display the* $\mathsf{Met}^{\uparrow}$ *source* M*, the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row* U*, the large-scale budget* E*, the bounded-set ledger* B*, and the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *readback row* R *before it can replay a coarse relation. The replay is transported only through* hsame*, continued only through* Cont*, sourced only through* Pkg*, and named only by the local* NameCert *row* N*.*

Proof. Project the accepted carrier. The only metric and uniform data available to a controlled-entourage consumer are M and U.

Read the large-scale rows next. The budget E records which displayed entourage rows are allowed at the requested scale, while B records the bounded-set ledger used by coarse consumers.

The readback row R converts the displayed distance and radius requests through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ before replay. The structural rows H, C, P, N then preserve that same route and add no selected net, quotient equality, countable choice, host large-scale category, or ambient completion object. □

Falsifiable prediction: An accepted $\mathsf{CoarseMetricSpace}^{\uparrow}$ read is refuted if a consumer obtains controlled entourage data or bounded-set evidence without displaying the MetricUp source, UniformSpace entourage row, controlled large-scale budget, bounded-set ledger, RegSeqRat/Real readback, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: metric, uniformspace, real: none is bijective to $\mathsf{CoarseMetricSpace}^{\uparrow}$ because this packet jointly carries a metric source, an entourage row, a controlled large-scale budget, bounded-set ledger data, rational and real readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CoarseMetricSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CoarseMetricSpace}^{\uparrow}$ packet is generated from a displayed MetricUp source, UniformSpace entourage row, controlled large-scale entourage budget, bounded-set ledger, RegSeqRat/Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoarseMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6645.1, Definition 6645.2, and Definition 6645.3 seed the finite coarse metric certificate over displayed metric, uniform entourage, large-scale control, boundedness, readback, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoarseMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient coarse-space equality, selected nets, host coarse categories, countable-choice schedules, ambient completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, controlled-entourage exactness, bounded-set ledger stability, readback transport, provenance non-escape, and local naming for BEDC.Derived.CoarseMetricSpaceUp.

Chapter 6646

A Concrete Naming Certificate for $\mathsf{MetricSequentialSpace}^{\uparrow}$

Following Kelley and Engelking, the $\mathsf{MetricSequentialSpace}^{\uparrow}$ packet records the classical metric-space sequentiality interface as finite BEDC data. It sits over the metric source of chapter 57, the topology neighbourhood surface of chapter 88, the sequence-limit closure route of chapter 1571, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names the displayed metric convergence route that a topology-facing sequential-closure consumer may inspect; it is not a quotient of streams, not arbitrary topological sequentiality, not a choice principle, not open-cover compactness, and not completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6646.1 (Metric sequential space carrier)**.** *A* $\mathsf{MetricSequentialSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, T, W, R, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the metric source row, recording the visible carrier, distance classifier, zero-distance boundary, and finite tolerance comparisons consumed from* $\mathsf{Met}^{\uparrow}$*.*
2. *T is the topology neighbourhood row, recording the neighbourhood names around candidate limits and the topology-facing reads supplied by the metric source.*
3. *W is the sequence window row, recording the finite* $\mathsf{StreamName}^{\uparrow}$ *schedules, inspected indices, and admitted entries used by convergence consumers.*
4. *R is the regular rational readback row, translating each displayed metric tolerance request into* $\mathsf{RegSeqRat}^{\uparrow}$ *data before any real comparison is read.*
5. *L is the limit row, recording the candidate limit point, the neighbourhood requests around it, and the metric tolerance ledger sealed through* $\mathsf{Real}^{\uparrow}$*.*
6. *H stores componentwise* hsame *transport for the metric source, topology neighbourhoods, sequence windows, regular rational readback, limit row, replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay from a sequential-closure request through D, T, W, R, L without adding a host equality or subsequence-selection route.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{SequentialClosure}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetricSequentialSpace}^{\uparrow}}$ *row.*
The carrier has no coordinate for selected subsequences, quotient streams, arbitrary topological sequentiality, open-cover compactness, detached host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6646.2 (Metric sequential space NameCert obligations)**.** *For every accepted* $\mathsf{MetricSequentialSpace}^{\uparrow}$ *carrier $M = (D, T, W, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricSequentialSpace}^{\uparrow}}$ *surface consists exactly of the metric source row D, topology neighbourhood row T, sequence window row W, regular rational readback row R, limit row L, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N.*

Proof. Project the finite BHist carrier. The metric source D supplies the distance classifier and tolerance comparisons, while the topology row T supplies the neighbourhood names that a sequential-closure consumer may ask to read.

The sequence data are displayed before any limit read. Windows are stored in W, rational readback in R, and the candidate limit ledger in L, so convergence evidence cannot be produced by a detached stream or a host-selected subsequence.

Rows H, C, P, N then transport, replay, package, and name exactly those displayed rows. Since the carrier contains no additional coordinate for quotient streams, arbitrary topological sequentiality, choice, compactness, host equality, or $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6646.3 (Metric sequential space sequential-closure handoff)**.** *Let $M = (D, T, W, R, L, H, C, P, N)$ be an accepted* $\mathsf{MetricSequentialSpace}^{\uparrow}$ *packet. Every* $\mathsf{SequentialClosure}^{\uparrow}$ *consumer of the metric candidate limit factors through*

$$D, T, W, R, L \longmapsto H, C, P, N.$$

Thus topology-facing sequential closure receives the displayed metric convergence route, finite StreamName windows, RegSeqRat readback, Real-sealed limit row, and local NameCert packaging, and receives no host closure operator.

Proof. Start with a topology-facing closure request. Carrier admission exposes the metric source D and neighbourhood row T before the request can inspect any sequence or limit data.

Replay through C then forces the request to consume the finite windows W, the regular rational readback R, and the limit ledger L. This is the same finite route needed by the $\mathsf{SequentialClosure}^{\uparrow}$ surface, but it is anchored in the metric classifier rather than in an ambient closure operator.

Transport by H and packaging by P, N preserve the displayed route. Hence the exported handoff is the stated finite factorization, with no separate topological closure, quotient stream equality, selected subsequence, compactness principle, or real-completeness theorem. □

Theorem 6646.4 (Metric sequential space nonescape)**.** *An accepted* $\mathsf{MetricSequentialSpace}^{\uparrow}$ *packet cannot export selected subsequences, quotient stream equality, arbitrary topological sequentiality, open-cover compactness, host equality of metric points, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from its sequentiality interface.*

Proof. Inspect the carrier rows of Definition 6646.1. The sequence interface is the finite window row W, the metric tolerance interface is the readback row R, and the limit interface is the displayed row L sealed through the available Real comparison data.

Apply Definition 6646.2. The local NameCert row names only $D, T, W, R, L, H, C, P, N$, and Definition 6646.3 shows that every closure consumer passes through those rows in order.

The refused principles have no BHist row, no hsame transport coordinate, no Cont replay edge, no Pkg provenance entry, and no local NameCert clause. The packet therefore exposes metric sequentiality only as the displayed finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricSequentialSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricSequentialSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6646.1, Definition 6646.2, Definition 6646.3, and Definition 6646.4 seed the finite metric sequentiality route from metric convergence data to topology-facing sequential-closure consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricSequentialSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subsequences, quotient streams, arbitrary topological sequentiality, open-cover compactness, host equality of metric points, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-to-topology neighbourhood replay, StreamName window coverage, RegSeqRat and Real readback, classifier transport, and non-escape for the same packet.

Constructive story: A $\mathsf{MetricSequentialSpace}^{\uparrow}$ packet is generated from a metric source row, topology neighbourhood row, finite StreamName window row, RegSeqRat readback row, Real-sealed limit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6647

A Concrete Naming Certificate for $\mathsf{KuratowskiClusterSet}^{\uparrow}$

From Kuratowski convergence of closed sets and Kelley–Moore–Smith net cluster-set practice, the $\mathsf{KuratowskiClusterSet}^{\uparrow}$ packet records boundary cluster evidence by finite hit–miss windows rather than by a host powerset of possible cluster points. It sits beside $\mathsf{KuratowskiConvergence}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the L10 net/filter cluster-set carrier used by completion-facing reads.

The hit–miss rows are read through chapter 6591, the net and filter source rows through chapter 3403 and chapter 1601, and the compact/metric support rows through chapter 129 and chapter 57 before the carrier exposes K_h, K_m, C, M, S to any cluster-set consumer.

Definition 6647.1 (Kuratowski cluster-set carrier)**.** *A* $\mathsf{KuratowskiClusterSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, F, K_h, K_m, C, M, B, X, R, E, T, U, P, N)$$

with the following displayed rows:

1. *S is the net or filter source row, naming either a* $\mathsf{MooreSmithNet}^{\uparrow}$ *index-window read or a* $\mathsf{FilterBase}^{\uparrow}$ *base-window read.*
2. *F records the finite source-frontier windows consumed by the cluster-set request.*
3. *K_h is the Kuratowski hit ledger: each row names a displayed source window, a metric neighborhood, and a later witness whose image meets that neighborhood.*
4. *K_m is the Kuratowski miss ledger: each row names a finite exclusion or compact containment window showing that the inspected boundary claim does not escape the displayed metric neighborhood.*
5. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *support row used when compact subwindows make the hit and miss ledgers finite.*
6. *M is the* $\mathsf{Met}^{\uparrow}$ *distance-observation row used by the hit, miss, compact-support, and Real-facing reads.*
7. *B is the cluster-hit witness row, storing only displayed later-window hits and never a selected cluster point.*
8. *X is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for source-name and observation-name replay.*

9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational row used to read metric tolerances and shrinking windows.*
10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for completion-facing consumers.*
11. *T, U, P, N are respectively componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{KuratowskiClusterSet}^{\uparrow}}$ *naming row.*

The carrier has no coordinate for a host powerset of cluster points, a selected cluster point, quotient equality of closed sets, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.KuratowskiClusterSetUp.TasteGate.KuratowskiClusterSetUp`

Theorem 6647.2 (Kuratowski cluster-set NameCert obligations)**.** *For every accepted* $\mathsf{KuratowskiClusterSet}^{\uparrow}$ *carrier*

$$K = (S, F, K_h, K_m, C, M, B, X, R, E, T, U, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KuratowskiClusterSet}^{\uparrow}}$ *surface consists exactly of net-or-filter source admission, finite frontier-window admission, Kuratowski hit-window admission, Kuratowski miss-window admission, compact and metric support, displayed cluster-hit witnessing,* $\mathsf{StreamName}^{\uparrow}$ *readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6647.1. The mathematical rows are precisely $S, F, K_h, K_m, C, M, B, X, R, E$ the structural rows are T, U, P, N.

The hit and miss obligations are separated. A hit request must read a later-window witness from K_h and B, while a miss request must read the finite exclusion or compact containment evidence from K_m together with the metric row M and compact support row C.

The readback rows X, R, E expose only names, rational tolerances, and terminal Real-facing seals downstream of those finite windows. Transport, replay, provenance, and local naming preserve the same route, so no additional NameCert clause can be supplied by a powerset, selected point, quotient, choice principle, or ambient completeness proof. □

Lean4 ✓ `BEDC.Derived.KuratowskiClusterSetUp.TasteGate.KuratowskiClusterSetTasteGate single carrier alignment`

Theorem 6647.3 (Kuratowski cluster-set net-filter handoff)**.** *Every net-facing or filter-facing cluster-set read exported by an accepted* $\mathsf{KuratowskiClusterSet}^{\uparrow}$ *carrier factors through the displayed route*

$\mathsf{MooreSmithNet}^{\uparrow}/\mathsf{FilterBase}^{\uparrow}$, $\mathsf{KuratowskiConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}$

The handoff exposes the source frontier, Kuratowski hit and miss windows, compact or metric support, cluster-hit witness, stream-name replay, regular rational tolerance row, and terminal Real seal before any completion consumer may use the cluster-set boundary. It exports no host powerset, selected cluster point, quotient closed-set equality, countable-choice functional, or ambient Real completeness argument.

Lean4 ✓ `BEDC.Derived.KuratowskiClusterSetUp.KuratowskiClusterSetNetFilterHandoff`

Proof. Begin with the source row S. A net read uses the displayed $\mathsf{MooreSmithNet}^{\uparrow}$ window and a filter read uses the displayed $\mathsf{FilterBase}^{\uparrow}$ base-window route; both are recorded as finite frontier data in F before a cluster request is available.

Next read the Kuratowski rows. The hit ledger K_h and miss ledger K_m are the only rows where the boundary condition is tested, and their metric and compact support is supplied by M and C. The cluster-hit witness row B records later-window hits rather than a selected cluster point.

Finally pass through X, R, E, T, U, P, N. These rows provide stream-name replay, regular rational tolerance readback, Real-facing sealing, transport, continuation replay, provenance, and local naming. Since the carrier contains no powerset, quotient, selected point, choice functional, or ambient completeness coordinate, the net/filter handoff is exhausted by the displayed finite route. □

Theorem 6647.4 (Kuratowski cluster-set sequential compact route)**.** *Every sequential-compact cluster consumer of an accepted* $\mathsf{KuratowskiClusterSet}^{\uparrow}$ *carrier must read the displayed sibling route through* $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *including the chapter routes of chapter 2372 and chapter 129. The consumer uses C as the compact-metric support row, M as the metric observation row, X as the stream-name replay row, R as the regular rational tolerance row, and E as the terminal Real seal before it may read the hit ledger K_h, miss ledger K_m, or cluster-hit witness row B as a sequential cluster boundary. It exports no host subsequence selector, countable-choice functional, selected cluster point, quotient closed-set equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KuratowskiClusterSetUp.KuratowskiClusterSetSequentialCompactRoute`

Proof. Begin with the compact source. The $\mathsf{SequentialCompact}^{\uparrow}$ chapter routes sequential cluster reads through displayed compact-metric and finite-window data, while the $\mathsf{CompactMetric}^{\uparrow}$ route supplies only the compact support row visible here as C.

Next expose the metric and readback rows. The carrier rows M, X, R, E provide metric observations, stream-name replay, regular rational tolerance readback, and the terminal Real seal before the Kuratowski hit and miss ledgers can be consumed.

Finally return to K_h, K_m, B, T, U, P, N. The hit and miss ledgers remain finite boundary rows transported and replayed through the same packet; they do not become a host subsequence selector, a countable-choice witness, a selected cluster point, quotient closed-set equality, or ambient Real completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiClusterSet}^{\uparrow}}$.

Constructive story: A $\mathsf{KuratowskiClusterSet}^{\uparrow}$ packet is generated from net or filter source rows, finite frontier windows, Kuratowski hit and miss ledgers, compact and metric support, cluster-hit witnesses, StreamName readback, RegSeqRat tolerance readback, Real seals, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiClusterSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6647.1, Definition 6647.2, Definition 6647.3, and Definition 6647.4 seed the L10 net/filter and sequential-compact cluster-set boundary by displayed finite rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiClusterSet}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim selected cluster points, host powersets, quotient closed-set equality, countable choice, ambient Real completeness, theorem checking, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, hit-window coverage, miss-window coverage, net/filter source handoff, compact and metric support, readback sealing, transport, replay, provenance, and local naming for BEDC.Derived.KuratowskiClusterSetUp.

Chapter 6648

A Concrete Naming Certificate for $\mathsf{BishopLocatedSubset}^{\uparrow}$

Following Bishop–Bridges constructive analysis, a located subset of the real line is read through finite evidence for membership, apartness, and distance-to-subset comparison rather than through an ambient powerset. The $\mathsf{BishopLocatedSubset}^{\uparrow}$ packet records that frontier as NameCert data over the real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the metric and located-metric distance surfaces of chapter 57 and chapter 1533, and the located-subset interface of chapter 1541. It gives Real and Completion consumers a finite subset boundary without importing host set extensionality, quotient subsets, open-cover compactness, selected nearest points, or countable choice.

Definition 6648.1 (Bishop located-subset carrier)**.** *A* $\mathsf{BishopLocatedSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, A, R, D, E, G, H, C, P, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{LocatedMetric}^{\uparrow}$ *distance row for the real-line source, including the finite distance observations used by membership and apartness queries.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *admission row, recording the displayed subset carrier and the finite membership rows for inspected* $\mathsf{Real}^{\uparrow}$ *names.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which inspected real names, membership windows, and subset-distance requests are read before any terminal real seal is consumed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for positive radii, apartness gaps, enclosure comparisons, and radius refinement.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the inspected real names and the distance witnesses attached to the subset query.*
6. *G is the located-apartness witness row: for each negative membership read it displays a positive dyadic radius whose* $\mathsf{LocatedMetric}^{\uparrow}$ *ball is disjoint from the admitted membership rows already visible through A, R, D, E.*
7. *H records componentwise* hsame *transport for the metric, located-set, readback, dyadic, real-seal, gap-witness, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a membership or apartness request through M, A, R, D, E, G, H.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedSubset}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedSubset}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, A, R, D, E, G, H, C, P, N$. It has no coordinate for a host powerset, quotient subset equality, selected complement point, open-cover compactness theorem, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6648.2 (Membership and apartness boundary)**.** *For every accepted* $\mathsf{BishopLocatedSubset}^{\uparrow}$ *carrier*

$$L = (M, A, R, D, E, G, H, C, P, N),$$

each public membership or apartness read factors through the displayed $\mathsf{LocatedSet}^{\uparrow}$ *row A, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{Real}^{\uparrow}$ *seal row E, and the located-apartness radius row G. A negative membership read exposes a positive witness radius only as a finite* $\mathsf{LocatedMetric}^{\uparrow}$ *distance comparison, not as a host complement predicate, a trichotomy decision, or a selected nearest point.*

Proof. Project the carrier of Definition 6648.1. The rows $M, A, R, D, E, G, H, C, P, N$ are the full inventory available to the local certificate.

The membership side is supplied by A and read through R, D, E. Thus an inspected real name reaches the subset row only after its regular-rational window, dyadic tolerance ledger, and terminal real seal have been displayed.

The apartness side is the row G. Its witness radius is positive because D supplies the dyadic positivity and refinement ledger, and it is a subset-facing witness because M supplies the located-metric distance comparison against the admitted rows in A.

Finally H, C, P, N transport, replay, source, and name that same finite route. Since no row stores a host complement, trichotomy split, nearest-point selector, quotient subset, or ambient completeness theorem, the stated boundary exhausts the public membership and apartness reads. □

Theorem 6648.3 (Real seal route for located subsets)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopLocatedSubset}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{LocatedMetric}^{\uparrow} \longmapsto \mathsf{LocatedSet}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows retained. The route exports a Bishop located-subset boundary over real names; it does not export host set extensionality, quotient subset membership, open-cover compactness, countable choice, selected limit values, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the distance row M. It supplies the metric and located-metric observations needed by every membership, apartness, and distance-to-subset request.

Read the subset row A next. The row records only displayed admission and membership evidence, so the consumer has a subset boundary but not an ambient powerset.

The numerical route then passes through R, D, E. The regular-rational row exposes the inspected windows, the dyadic row records the tolerance and positive-radius comparisons, and the real seal is consumed only after those finite rows are present.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Therefore the Real-facing handoff cannot bypass the finite carrier through extensional subsets, quotient representatives, open covers, selected limits, or an ambient completeness principle. □

Theorem 6648.4 (Bishop located-subset NameCert obligations)**.** *For an accepted* $\mathsf{BishopLocatedSubset}^{\uparrow}$ *carrier* $L = (M, A, R, D, E, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedSubset}^{\uparrow}}$ *surface consists exactly of carrier admission, ambient metric and located-metric distance exposure, located-subset membership rows, regular-rational readback, dyadic tolerance and positive-radius exactness, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, located-apartness witness exposure, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier. Its visible rows are precisely the metric source, located subset, regular-rational readback, dyadic tolerance ledger, real seal, gap witness, transport, replay, provenance, and local naming rows.

The carrier admission and membership obligations are M, A, R, D, E. They force every inspected real-name and subset-membership read through the same finite L10 route before any public answer is available.

The located-apartness obligation is G. It can be consumed only with the positive-radius evidence in D and the distance comparison in M, so it is a finite witness row rather than an external complement classifier.

The support rows H, C, P, N add no analytic content beyond transport, replay, provenance, and naming. Hence the listed rows exhaust the NameCert obligation surface, with no host powerset, quotient subset equality, selected nearest point, open-cover compactness, countable choice, or ambient real-completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedSubset}^{\uparrow}$ read exposes a Metric and LocatedMetric distance row, a LocatedSet membership row, RegSeqRat readback, DyadicRatCore tolerance and positive-radius data, a terminal RealUp seal, a located-apartness witness radius, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before any Real or Completion consumer reads the subset boundary.

Independence witness: real, regseqrat, dyadicratcore, metric, locatedmetric, locatedset: $\mathsf{BishopLocatedSubset}^{\uparrow}$ is not bijective with any listed sibling because it jointly binds real-name membership rows, located-apartness witness radii, located-metric distance comparisons, regular-rational readback, dyadic tolerance refinement, terminal real seals, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedSubset}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedSubset}^{\uparrow}$ packet is generated from MetricUp and LocatedMetricUp distance rows, LocatedSetUp membership rows, RegSeqRatUp readbacks, DyadicRatCoreUp tolerance and positive-radius ledgers, RealUp seal rows, located-apartness witness radii, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedSubset}^{\uparrow}}$, seed)

Scope closed: Definition 6648.1, Definition 6648.2, Definition 6648.3, and Definition 6648.4 seed the finite Bishop located-subset carrier over Real, RegSeqRat, DyadicRatCore, Metric, LocatedMetric, LocatedSet, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedSubset}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host set extensionality, quotient subset equality, open-cover compactness, selected nearest points, countable choice, ambient Real completeness, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, membership exposure, located-apartness radius exactness, regular-rational readback, dyadic tolerance transport, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedSubsetUp.

Chapter 6649

A Concrete Naming Certificate for $\mathsf{BernoulliInequality}^{\uparrow}$

Following Bernoulli and Hardy–Littlewood–Polya, the $\mathsf{BernoulliInequality}^{\uparrow}$ packet records the finite binomial lower-bound route used before Real algebra and calculus estimates read a power comparison. It sits beside the terminal real-name seal of chapter 38, the dyadic arithmetic ledger of chapter 291, and the regular rational readback surface of chapter 301. The packet exports the finite comparison route for a nonnegative base and unary exponent; it is not a host real-power theorem, a global ordered-field library, trichotomy, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6649.1 (Bernoulli inequality carrier)**.** *A* $\mathsf{BernoulliInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, N, D, Q, E, H, C, P, L)$$

with the following displayed rows:

1. *X is the nonnegative* $\mathsf{Real}^{\uparrow}$ *base row, displaying the accepted real seal for the term $1+x$ together with the proof-relevant nonnegative boundary for x.*
2. *N is the unary exponent row, recording the finite successor spine used for the power read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *binomial ledger, containing the displayed coefficient rows, nonnegative remainder rows, and tolerance budget used by the finite binomial comparison.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected base, coefficient, product, and remainder observations.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *comparison seal for the lower bound between the finite power read and $1 + Nx$.*
6. *H stores componentwise* hsame *transport for the base, exponent, dyadic binomial ledger, regular-rational readback, comparison seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the base and exponent rows through the dyadic binomial ledger, RegSeqRat readback, and Real comparison seal.*
8. *P is the* Pkg *provenance over* $\mathsf{BernoulliInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{BernoulliInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, N, D, Q, E, H, C, P, L$. It has no coordinate for host exponentiation, a selected infinite binomial series, trichotomy, quotient real equality, global ordered-field automation, or ambient Real completeness.

Theorem 6649.2 (Bernoulli inequality NameCert obligations)**.** *For every accepted* $\mathsf{BernoulliInequality}^{\uparrow}$ *carrier* $B = (X, N, D, Q, E, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{BernoulliInequality}^{\uparrow}}$ *surface consists exactly of carrier admission, nonnegative* $\mathsf{Real}^{\uparrow}$ *base exposure, unary exponent exposure, dyadic binomial-ledger exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal Real comparison sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No consumer may read a Bernoulli comparison from the packet before* $X, N, D, Q, E, H, C, P, L$ *are displayed.*

Proof. Project the carrier of Definition 6649.1. The accepted rows are exactly the nonnegative base, unary exponent, dyadic ledger, regular-rational readback, Real comparison seal, and the structural rows.

The base and exponent obligations are read from X and N. The packet therefore exposes a finite successor spine and a nonnegative Real boundary before any power comparison is public.

The binomial comparison is read from D, Q, E. The dyadic ledger records the coefficients and nonnegative remainder budget, the regular-rational row packages the inspected arithmetic observations, and the Real seal is consumed only after those rows are present.

Rows H, C, P, L transport, replay, source, and name the same finite route. Since the carrier lacks host exponentiation, global order automation, quotient equality, selected infinite series, and ambient completeness coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 6649.3 (Bernoulli dyadic binomial handoff)**.** *Every accepted* $\mathsf{BernoulliInequality}^{\uparrow}$ *comparison handoff factors through*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside the displayed carrier rows X, D, Q, E, H, C, P, L*. The dyadic binomial ledger* D *supplies the finite coefficient and nonnegative remainder budget, the RegSeqRat readback* Q *packages the inspected rational observations, and the terminal Real seal* E *exports only the finite Bernoulli lower-bound comparison for the unary exponent row* N*.*

Proof. Start with an accepted comparison request. The base row X supplies the nonnegative Real input, and the exponent row N supplies the finite successor spine.

The request then enters the dyadic binomial ledger D. That row records the coefficient and remainder budget needed for the finite binomial comparison and keeps every comparison at a displayed dyadic tolerance.

The readback row Q packages the visible arithmetic observations before the Real seal E is available. Transport, replay, provenance, and local naming are supplied by H, C, P, L and do not add any host arithmetic principle.

Thus the handoff is the finite route through the Real, DyadicRatCore, RegSeqRat, and Real rows. It does not export host powers, quotient real equality, trichotomy, an infinite binomial series, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{BernoulliInequality}^{\uparrow}$ comparison read exposes a nonnegative RealUp base row, a unary exponent row, a DyadicRatCore binomial ledger, RegSeqRat readback, a terminal RealUp comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before any lower-bound comparison is exported.

Independence witness: real, dyadicratcore, regseqrat, real-triangle-inequality, cauchy-product-tail-budget: $\mathsf{BernoulliInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a nonnegative base, unary exponent, dyadic binomial coefficient and remainder ledger, regular-rational readback, terminal Real comparison seal, transport, replay, provenance, and local NameCert in one inequality packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BernoulliInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{BernoulliInequality}^{\uparrow}$ packet is generated from a nonnegative RealUp base row, a unary exponent row, a DyadicRatCore binomial ledger, RegSeqRat readback, a terminal RealUp comparison seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BernoulliInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6649.1, Definition 6649.2, and Definition 6649.3 seed the finite Bernoulli comparison route over RealUp, DyadicRatCoreUp, RegSeqRatUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BernoulliInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host exponentiation, global ordered-field automation, trichotomy, quotient real equality, selected infinite binomial series, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nonnegative base exposure, unary exponent exposure, dyadic binomial-ledger exposure, RegSeqRat readback, Real comparison sealing, transport, replay, provenance, and local naming for BEDC.Derived.BernoulliInequalityUp.

Chapter 6650

A Concrete Naming Certificate for $\mathsf{DependentEliminatorCoverage}^{\uparrow}$

The $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ packet realizes the typed-examples coverage frontier of section 9386.6 as finite evidence separating representative gallery rows from exhaustive dependent-eliminator coverage. It sits beside the typed normal-form scheduler of chapter 6617, the closed type checker seal of chapter 2182, the dependent-codomain stability boundary of chapter 3626, and the typed-conversion residual frontier of chapter 6069. The packet records typed windows, eliminator families, conversion boundaries, gallery status, obstruction retention, transport, replay, provenance, and local naming rows; it is not a universal subject-reduction theorem, total eliminator computation theorem, quotient syntax equality, host conversion oracle, or closed consistency claim.

Definition 6650.1 (Dependent eliminator coverage carrier)**.** *A* $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (W, F, B, G, O, H, C, P, N)$$

with the following displayed rows:

1. *W is the typed-window row, recording the finite contexts, binders, dependent codomains, polymorphic instantiations, and conversion-sensitive endpoints inspected by the packet.*
2. *F is the eliminator-family row, naming the dependent identity, pair, option, list, sum, natural, boolean, and Church-encoded eliminator computations whose example coverage is being audited.*
3. *B is the conversion-boundary row, exposing beta, projection, eliminator, nested-binder movement, and type-conversion boundaries before any coverage conclusion is public.*
4. *G is the gallery-status row, distinguishing witnessed representative examples from families that still require exhaustive coverage.*
5. *O is the obstruction-retention row, retaining dependent-codomain, subject-reduction, decidable-audit, confluence-audit, and normalization-frontier blockers as visible packet data.*
6. *H records componentwise* hsame *transport for typed windows, eliminator families, conversion boundaries, gallery status, obstruction retention, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from typed-window inspection through eliminator-family reads, conversion-boundary checks, gallery-status classification, and obstruction retention.*

8. *P is the* Pkg *provenance over* $\mathsf{DependentEliminatorCoverage}^{\uparrow}$, $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$, $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$, $\mathsf{MetaCICDependentCodomainStabilityBoundary}^{\uparrow}$, $\mathsf{MetaCICTypedConversionResidualFront}$ BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DependentEliminatorCoverage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, F, B, G, O, H, C, P, N$. It has no coordinate for universal subject reduction, total eliminator computation, hidden conversion checking, quotient syntax equality, host normalization, or closed consistency.

Theorem 6650.2 (Dependent eliminator coverage NameCert obligations)**.** *For every accepted* $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ *carrier $D = (W, F, B, G, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DependentEliminatorCoverage}^{\uparrow}}$ *surface consists exactly of typed-window exposure, eliminator-family exposure, conversion-boundary exposure, gallery-status classification, obstruction-retention exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A public coverage read may report representative examples only after $W, F, B, G, O, H, C, P, N$ are displayed, and it may report exhaustive coverage only when the same rows carry the relevant family coverage witnesses rather than a gallery marker.*

Proof. Project the carrier of Definition 6650.1. The accepted rows are exactly the typed windows, eliminator families, conversion boundaries, gallery status, obstruction retention, and the structural rows.

The typed-window and eliminator-family obligations are read from W and F. They display the finite contexts, binders, dependent codomains, polymorphic instantiations, and eliminator computations under audit.

The boundary and status obligations are read from B, G, O. The conversion boundary fixes the computation endpoints being checked, the gallery row records whether the packet supplies representative examples or family coverage, and the obstruction row keeps the remaining blockers visible.

Rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier lacks universal subject reduction, total eliminator computation, hidden conversion checking, quotient syntax equality, host normalization, and closed consistency coordinates, the listed obligations exhaust the local NameCert surface. □

Theorem 6650.3 (Dependent eliminator gallery boundary)**.** *Every accepted* $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ *packet separates representative typed examples from exhaustive dependent-eliminator coverage by the displayed route*

$$W \longmapsto F \longmapsto B \longmapsto G \longmapsto O \longmapsto H, C, P, N.$$

If G marks a gallery row, the packet exports only the witnessed typed examples over the inspected windows. If G marks a family-coverage row, the packet must display the corresponding eliminator-family and conversion-boundary witnesses in F and B while retaining the obstruction row O for any dependent-codomain, subject-reduction, decidable-audit, confluence-audit, or normalization-frontier blocker.

Proof. Start with the typed-window row W. It fixes the finite contexts, binders, codomains, polymorphic instantiations, and conversion-sensitive endpoints that the packet is allowed to inspect.

The eliminator-family and conversion-boundary rows F, B then determine what computation evidence is actually displayed. Without those rows, a gallery example cannot be promoted to a family-coverage read.

The status and obstruction rows G, O supply the boundary. Gallery status keeps representative examples from being read as exhaustive coverage, while obstruction retention keeps the dependent-codomain and audit blockers visible.

Finally H, C, P, N preserve, replay, source, and name the same boundary. Thus the public read is a finite coverage packet, not a host theorem about all dependent eliminators or all conversion-sensitive programs. □

Falsifiable prediction: Any accepted $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ read that treats typed examples as exhaustive dependent-eliminator coverage without displaying typed-window, eliminator-family, conversion-boundary, gallery-status, obstruction-retention, transport, replay, provenance, and local naming rows is outside the carrier surface.

Independence witness: metacic-typedexamples, metacic-subject-reduction-obstruction, metacic-decidable-audit, metacic-confluence-audit, metacic-normalization-frontier: $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries typed windows, eliminator-family rows, conversion-boundary rows, gallery-status rows, obstruction-retention rows, transport, replay, provenance, and local NameCert rows in one coverage packet.

Lean work for $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ must provide $\mathsf{Nontrivial\ DependentEliminatorCoverage}^{\uparrow}$ and $\mathsf{FieldFaithful\ DependentEliminatorCoverage}^{\uparrow}$ instances so typed-window, eliminator-family, conversion-boundary, gallery-status, obstruction-retention, transport, replay, provenance, and local naming rows remain distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{DependentEliminatorCoverage}^{\uparrow}}$.

Constructive story: A $\mathsf{DependentEliminatorCoverage}^{\uparrow}$ packet is generated from typed-window rows, eliminator-family rows, conversion-boundary rows, gallery-status rows, obstruction-retention rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DependentEliminatorCoverage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6650.1, Definition 6650.2, and Definition 6650.3 seed the finite typed-example coverage boundary over typed windows, eliminator families, conversion boundaries, gallery status, obstruction retention, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DependentEliminatorCoverage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close universal subject reduction, total eliminator computation, hidden conversion checking, quotient syntax equality, host normalization, completed closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window exposure, eliminator-family exposure, conversion-boundary exposure, gallery-status classification, obstruction-retention exposure, Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.DependentEliminatorCoverageUp.

Chapter 6651

A Concrete Naming Certificate for $\mathsf{RealModulusSpace}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{RealModulusSpace}^{\uparrow}$ packet records a space-level family of convergence moduli as certified finite NameCert data. It sits after the finite observation surface of chapter 126, the regular rational readback of chapter 301, the single-convergence ledger of chapter 2074, and the terminal real-name seal of chapter 38. The packet packages reusable modulus families for Real and Completion consumers; it is not quotient equality of streams, a selected limit, countable choice over thresholds, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6651.1 (Real modulus space carrier)**.** *A* $\mathsf{RealModulusSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, W, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row for the displayed family of Real-facing modulus schedules.*
2. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by those schedules.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected windows.*
4. *L is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger row that binds each indexed schedule to a convergence tolerance request.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary available after the stream, regular-rational, and convergence-ledger rows have been displayed.*
6. *H records componentwise* hsame *transport for I, W, R, L, E, C, P, N.*
7. *C records displayed* Cont *replay from an index and tolerance request through the stream window, regular readback, convergence ledger, and terminal real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RealModulusSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, W, R, L, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable-choice thresholds, host real equality, or ambient completeness.

Theorem 6651.2 (Real modulus space NameCert obligations)**.** *For every accepted* $\mathsf{RealModulusSpace}^{\uparrow}$ *carrier*

$$M = (I, W, R, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealModulusSpace}^{\uparrow}}$ *surface consists exactly of finite index admission,* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback compatibility,* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger compatibility, terminal* $\mathsf{Real}^{\uparrow}$ *seal compatibility, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming for the packet.*

Proof. Project the carrier of Definition 6651.1. The analytic rows are I, W, R, L, E, and the structural rows are H, C, P, N.

The finite index row I is read before any tolerance request reaches a stream window. The rows W and R then force each inspected window through the regular-rational readback surface.

Next read the convergence ledger L and the terminal seal E. The ledger binds the indexed tolerance request to a displayed $\mathsf{RealModulusOfConvergence}^{\uparrow}$ row, and the real seal is available only after that finite route has been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no excluded host object appears as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6651.3 (Real modulus space L10 handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RealModulusSpace}^{\uparrow}$ *packet must read the finite handoff*

$$I, W, R, L, E, H, C, P, N$$

before it consumes space-level modulus data. The route passes through chapter 126, chapter 301, chapter 2074, and chapter 38. It exports a reusable finite modulus-family surface, not quotient stream equality, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 6651.2. It keeps the finite index, stream-window, regular-readback, convergence-ledger, and real-seal rows visible before a consumer may read the structural rows.

Use the four L10 neighbours named in the statement. $\mathsf{StreamName}^{\uparrow}$ supplies the finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the rational readback, $\mathsf{RealModulusOfConvergence}^{\uparrow}$ supplies the tolerance ledger, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal boundary.

The transport, replay, provenance, and local naming rows preserve that finite route for Real and Completion consumers. Because the carrier has no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient completeness, none of those objects is exported by the handoff. □

Theorem 6651.4 (Real seal nonescape for real modulus spaces)**.** *For every accepted* $\mathsf{RealModulusSpace}^{\uparrow}$ *carrier*

$$M = (I, W, R, L, E, H, C, P, N),$$

any Real or Completion consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal row* E *must first expose the finite index row* I*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger row* L*, and the structural rows* H, C, P, N*. Consequently the seal exports no quotient stream equality, selected limit, countable-choice threshold, host real equality, or ambient completeness.*

Proof. Project the carrier of Definition 6651.1. The only route to E in an accepted packet passes through I, W, R, L and then through the structural rows H, C, P, N that transport, replay, source, and name the same finite history.

The row exhaustion statement in Definition 6651.2 leaves no additional coordinate beyond those rows. The Real and Completion handoff of Definition 6651.3 then forces every consumer of the space-level modulus data to read that finite route before the terminal $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Since quotient stream equality, selected limits, countable-choice thresholds, host real equality, and ambient completeness are absent from the projected carrier, none of them can escape through the seal row. □

Falsifiable prediction: Every accepted $\mathsf{RealModulusSpace}^{\uparrow}$ consumer that reads space-level modulus data exposes $I, W, R, L, E, H, C, P, N$ before reaching a Real or Completion handoff.

Independence witness: streamname, regseqrat, real-modulus-of-convergence, real: the listed siblings supply finite windows, regular readback, single convergence ledgers, and terminal real seals, but none alone binds a space-level family of Real-facing modulus schedules together with transport, replay, provenance, and local naming in one carrier packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RealModulusSpace}^{\uparrow}$ packet is generated from finite index rows for Real-facing modulus schedules, StreamName windows, RegSeqRat readback, RealModulusOfConvergence ledgers, a terminal RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealModulusSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6651.1, Definition 6651.2, Definition 6651.3, and Definition 6651.4 seed the space-level modulus-family carrier and Real-seal nonescape route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealModulusSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient equality of streams, selected limits, countable choice over thresholds, host real equality, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exactness, regular-readback compatibility, convergence-ledger compatibility, and local naming for BEDC.Derived.RealModulusSpaceUp.

Chapter 6652

A Concrete Naming Certificate for $\mathsf{CauchyPreservingMap}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and continuity on completed metric data, the $\mathsf{CauchyPreservingMap}^{\uparrow}$ packet records the finite interface for a map that sends displayed regular Cauchy witnesses to displayed regular Cauchy witnesses before any Real-facing consumer reads a seal. It sits over the finite window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the graph-and-modulus route of chapter 130. The packet names preservation of regular Cauchy data as finite rows, not as host function equality, quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6652.1 (CauchyPreservingMap carrier)**.** *A* $\mathsf{CauchyPreservingMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, T, Q, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite source observations inspected before the map row is read.*
2. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S and the displayed tolerance ledger.*
3. *T is the target* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by applying the map route to the same source window data.*
4. *Q is the* $\mathsf{CauchyModulus}^{\uparrow}$ *preservation row, recording the displayed late-threshold handoff that turns the source regular witness into a target regular witness.*
5. *L is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-and-modulus row consumed by the preservation read.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after S, R, T, Q, L have been displayed.*
7. *H records componentwise* hsame *transport for $S, R, T, Q, L, E, C, P, N$.*
8. *C records displayed* Cont *replay from source-window requests through source readback, target readback, Cauchy-modulus preservation, continuous-map data, and the Real seal handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyPreservingMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyPreservingMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, R, T, Q, L, E, H, C, P, N$. It has no coordinate for host function equality, quotient stream equality, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6652.2 (CauchyPreservingMap NameCert obligations)**.** *For every accepted* $\mathsf{CauchyPreservingMap}^{\uparrow}$ *carrier*

$$M = (S, R, T, Q, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyPreservingMap}^{\uparrow}}$ *surface consists exactly of source* $\mathsf{StreamName}^{\uparrow}$ *window admission, source* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, target* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyModulus}^{\uparrow}$ *preservation,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-and-modulus routing,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6652.1. The mathematical rows are S, R, T, Q, L, E, and the structural rows are H, C, P, N.

The source and target regularity obligations are separated. A source read begins with the displayed $\mathsf{StreamName}^{\uparrow}$ window S and then reaches the source $\mathsf{RegSeqRat}^{\uparrow}$ row R; the map route can expose the target $\mathsf{RegSeqRat}^{\uparrow}$ row T only after the same source window has been read.

The preservation and continuity rows are then read as one finite handoff. The $\mathsf{CauchyModulus}^{\uparrow}$ row Q records the late-threshold preservation, while the $\mathsf{ContinuousMap}^{\uparrow}$ row L records the graph-and-modulus route used by the same read.

Finally E, H, C, P, N seal, transport, replay, source, and name that route. Since no additional coordinate exists, the listed rows are exactly the local NameCert obligations, and the excluded host and quotient objects cannot be exported. □

Theorem 6652.3 (CauchyPreservingMap regular sequence handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyPreservingMap}^{\uparrow}$ *packet that reads a target regular Cauchy witness must pass through*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{CauchyModulus}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

in the displayed route $S, R, T, Q, L, E, H, C, P, N$. The handoff exports the source windows, source readback, target readback, preservation modulus, continuous-map row, Real seal, transport, replay, provenance, and local naming data; it exports no host function equality, quotient stream equality, selected limit, countable choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the source window row S. It is the only source inspection coordinate of the packet, so the source $\mathsf{RegSeqRat}^{\uparrow}$ readback R and the target readback T are both attached to the displayed finite windows.

Next read the preservation route. The $\mathsf{CauchyModulus}^{\uparrow}$ row Q supplies the late-threshold handoff for regularity preservation, and the $\mathsf{ContinuousMap}^{\uparrow}$ row L supplies the graph-and-modulus data that the target read uses.

Finally pass through the Real-facing and structural rows. The seal E is reached only after S, R, T, Q, L, while H, C, P, N keep the same route under componentwise transport, displayed replay, provenance, and local naming.

The exclusions are coordinate exhaustion. The carrier contains no host function-equality row, quotient stream equality row, selected-limit row, countable-choice schedule, or ambient Real-completeness witness, so none can be read by a completion-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyPreservingMap}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyPreservingMap}^{\uparrow}$ packet is generated from source StreamName windows, source RegSeqRat readback, target RegSeqRat readback, CauchyModulus preservation, ContinuousMap graph-and-modulus data, a Real seal handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyPreservingMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6652.1, Definition 6652.2, and Definition 6652.3 seed the finite regular-Cauchy-preserving map route over StreamName, RegSeqRat, CauchyModulus, ContinuousMap, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyPreservingMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window coverage, source and target RegSeqRat readback, CauchyModulus preservation, ContinuousMap routing, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyPreservingMapUp.

Chapter 6653

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, regular Cauchy completeness is read as a finite handoff from regular rational sequences to displayed real names: a dyadic tolerance request opens only finitely many observations, the regularity row supplies the tail discipline, and the terminal real-name seal records the accepted landing name. The $\mathsf{RegularCauchyCompleteness}^{\uparrow}$ packet places that handoff over the dyadic tolerance surface of chapter 291, the finite window interface of chapter 126, the regular rational sequence route of chapter 301, and the real-name seal of chapter 38. It is a NameCert object for the RegSeqRat-to-Real boundary; it does not assert quotient completion, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6653.1 (Regular Cauchy completeness carrier)**.** *A* $\mathsf{RegularCauchyCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, R, M, L, W, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested precision and the dyadic comparisons inspected by the handoff.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the rational observations used at that precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row read from S and D before any real-facing seal is visible.*
4. *M is the regular tail modulus row assigning each displayed dyadic tolerance a finite tail threshold.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row offered as the real-name landing of the regular sequence.*
6. *W is the witness ledger recording that every late window governed by M reaches L within the displayed dyadic tolerance.*
7. *H records componentwise* hsame *transport for $D, S, R, M, L, W, C, P, N$.*
8. *C records displayed* Cont *replay from a Real or Completion tolerance request through D, M, S, R, W and then to the seal L.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompleteness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, M, L, W, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable-choice schedules, host real equality, real trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6653.2 (Regular Cauchy completeness NameCert obligations)**.** *For an accepted* RegularCauchyCompletener *carrier $Q = (D, S, R, M, L, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompleteness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed dyadic, stream, regular-rational, modulus, seal, witness, transport, replay, provenance, and local naming rows; classifier stability under componentwise* hsame *transport; modulus coverage for every dyadic tolerance request; witness exactness tying the late* $\mathsf{RegSeqRat}^{\uparrow}$ *windows to the terminal* $\mathsf{Real}^{\uparrow}$ *seal; and ledger non-escape for quotient completion, selected representatives, countable choice, host real equality, trichotomy, and ambient Real completeness.*

Proof. Carrier admission is projection from Definition 6653.1. The packet exposes precisely the dyadic tolerance row, finite stream windows, regularity row, tail modulus, terminal seal, witness ledger, and the structural rows H, C, P, N.

Classifier stability is componentwise. The transport row H can move only the displayed coordinates $D, S, R, M, L, W, C, P, N$, and the replay row C repeats the same ordered route from tolerance request to seal.

Modulus coverage and witness exactness are read in order. A dyadic tolerance request first fixes D, then the tail threshold M, then the finite windows S, the regular readback R, and the witness ledger W before L can be consumed.

The non-escape clause follows from the absence of any further coordinate. Since the carrier contains no quotient, selected representative, choice schedule, host equality, trichotomy, or ambient completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 6653.3 (Regular Cauchy completeness RegSeqRat handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{RegularCauchyCompleteness}^{\uparrow}$ *packet must read the finite route*

$$D, M, S, R, W \longmapsto L$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal is available. Thus the handoff from* $\mathsf{RegSeqRat}^{\uparrow}$ *to* $\mathsf{Real}^{\uparrow}$ *is carried by displayed dyadic tolerances, stream windows, regular tail data, and a witness ledger, not by quotienting Cauchy streams or choosing a host limit.*

Proof. Begin with the tolerance request. The dyadic ledger D fixes the precision, and the regular tail modulus M gives the finite threshold attached to that precision.

Read the finite observations next. The $\mathsf{StreamName}^{\uparrow}$ row S exposes only the inspected windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R records their regular rational discipline under the same dyadic budget.

The witness ledger W is then the only row that relates late windows to the terminal seal L. Hence the Real-facing read reaches L through the displayed finite route and has no access to quotient streams, selected limits, or host real equality. □

Theorem 6653.4 (Regular Cauchy completeness Real-seal nonescape)**.** *For every accepted* RegularCauchyComplete *carrier $Q = (D, S, R, M, L, W, H, C, P, N)$, the terminal* $\mathsf{Real}^{\uparrow}$ *seal L exports only the displayed RegSeqRat-to-Real handoff rows*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Any consumer asking for quotient completion, a selected representative, countable choice, host real equality, real trichotomy, or a theorem that $\mathsf{Real}^{\uparrow}$ *is complete is returned to $D, S, R, M, L, W, H, C, P, N$.*

Proof. Project the carrier. The Real seal is a displayed row L, and the only route to it passes through the dyadic tolerance ledger, finite windows, regularity row, tail modulus, and witness ledger.

Apply Definition 6653.2. The local NameCert surface requires every accepted read to preserve the same rows under componentwise transport and displayed continuation replay.

Apply Definition 6653.3. The RegSeqRat-to-Real boundary is therefore a finite handoff, so the excluded quotient, choice, host-equality, trichotomy, and ambient-completeness objects cannot be exported by the seal. □

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyCompleteness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic tolerance requests, StreamName finite windows, RegSeqRat regularity, a tail modulus, a terminal Real seal, a witness ledger, transport, replay, provenance, and local naming in one RegSeqRat-to-Real handoff packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompleteness}^{\uparrow}$ packet is generated from dyadic tolerance rows, StreamName finite windows, RegSeqRat regularity rows, regular tail moduli, terminal Real seals, witness ledgers, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6653.1, Definition 6653.2, Definition 6653.3, and Definition 6653.4 seed the finite RegSeqRat-to-Real completeness handoff over displayed dyadic, stream, regular-rational, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, real trichotomy, bridge checking, Lean verification, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.RegularCauchyCompletene

Chapter 6654

A Concrete Naming Certificate for $\mathsf{LocatedApartnessInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedApartnessInterval}^{\uparrow}$ packet records a located real interval equipped with visible apartness separation from exterior real names. It consumes the dyadic rational core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the located interval carrier of chapter 394, the real-apartness surface of chapter 304, and the terminal real-name seal of chapter 38. The chapter names interval separation as finite BEDC rows, not as trichotomy, quotient real equality, selected endpoints, countable choice, or ambient real completeness.

Definition 6654.1 (LocatedApartnessInterval carrier)**.** *A* $\mathsf{LocatedApartnessInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, L, U, E, S, R, D, G, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted* $\mathsf{LocatedInterval}^{\uparrow}$ *source row, exposing lower and upper endpoint reads, containment rows, interval-cell ledgers, and endpoint-window routes.*
2. *L and U are the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint seal rows of the interval source.*
3. *E is the exterior real-name row whose separation from the interval is being witnessed.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row naming the inspected endpoint and exterior-name observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to S, supplying regular rational endpoint and exterior observations.*
6. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for endpoint slack and apartness radius comparisons.*
7. *G is the* $\mathsf{ApartnessReal}^{\uparrow}$ *gap row, displaying either separation of E from the lower endpoint side or separation of E from the upper endpoint side through the same finite windows.*
8. *H records componentwise* hsame *transport for the interval source, endpoint seals, exterior row, stream windows, readbacks, dyadic tolerance row, apartness gap row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from interval membership or exterior-separation requests through $I, L, U, E, S, R, D, G, H$.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedApartnessInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedApartnessInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for real trichotomy, quotient equality of real names, chosen endpoint representatives, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6654.2 (LocatedApartnessInterval NameCert obligations)**.** *For every accepted* $\mathsf{LocatedApartnessInterval}^{\uparrow}$ *carrier $A = (I, L, U, E, S, R, D, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedApartnessInterval}^{\uparrow}}$ *surface consists exactly of these finite rows: carrier admission for the displayed packet; source-interval exactness through I, L, U; exterior-name admission through E; finite-window and regular-readback exactness through S, R; positive dyadic budget exactness through D; apartness-gap exactness through G; and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 6654.1. The interval source, endpoint seals, exterior real row, finite windows, regular readback, dyadic tolerance, apartness gap, and structural rows are precisely the displayed coordinates of the packet.

Read the interval side first. The located interval source I exposes endpoint and containment data, while L and U seal those endpoints as $\mathsf{Real}^{\uparrow}$ rows before the exterior row can be compared to them.

Read the numerical evidence next. The finite window S and regular rational readback R give the endpoint and exterior observations, and the dyadic row D supplies the positive tolerance used by the separation ledger.

Finally read the apartness and structural rows. The row G is the only apartness coordinate, and H, C, P, N only transport, replay, source, and name the same finite route. Since no excluded host-order, quotient, choice, compactness, selected-endpoint, or completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6654.3 (LocatedApartnessInterval RegSeqRat handoff)**.** *Let $A = (I, L, U, E, S, R, D, G, H, C, P, N)$ be an accepted* $\mathsf{LocatedApartnessInterval}^{\uparrow}$ *carrier. Every downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of the interval-apartness read must obtain its rational data from the same finite window row S and readback row R before consuming the dyadic tolerance row D or the apartness gap row G. The handoff reaches* $\mathsf{ApartnessReal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the displayed endpoint, exterior-name, window, readback, tolerance, transport, replay, provenance, and local naming rows.*

Proof. Begin with a downstream read of rational endpoint or exterior-name data. The carrier stores all such observations in the finite window row S and the regular rational readback row R, so a consumer has no second rational source.

Attach the dyadic budget after the readback. The tolerance row D measures endpoint slack and separation radius only for the observations already exposed by S and R.

Now read the apartness handoff. The gap row G consumes the same endpoint and exterior observations together with the positive dyadic tolerance; it does not create a new real comparison or a host interval order.

The structural rows H, C, P, N preserve this route when it is replayed toward $\mathsf{ApartnessReal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$. Thus the handoff is exactly the finite RegSeqRat route attached to the located interval packet, with no quotient real equality, selected endpoint, countable choice, trichotomy, open-cover compactness, or ambient completeness export. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedApartnessInterval}^{\uparrow}}$.

Constructive story: A LocatedApartnessInterval$^{\uparrow}$ packet is generated from a LocatedInterval source row, Real endpoint seal rows, an exterior Real row, finite StreamName windows, RegSeqRat readback, a positive DyadicRatCore tolerance row, an ApartnessReal gap row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedApartnessInterval}^{\uparrow}}$, seed)

Scope closed: Definition 6654.1, Definition 6654.2, and Definition 6654.3 seed the finite interval-apartness packet and its regular rational handoff.

Formal verification: FormalStatus(NameCert$_{\text{LocatedApartnessInterval}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim real trichotomy, quotient equality of real names, selected endpoint representatives, countable choice, open-cover compactness, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-interval exactness, exterior-name admission, finite-window readback exactness, positive dyadic budget exactness, apartness-gap exactness, and structural nonescape for BEDC.Derived.LocatedApartnessIntervalUp.

Chapter 6655

A Concrete Naming Certificate for $\mathsf{AdamsBashforthFiniteStep}^{\uparrow}$

Following Adams and Bashforth's finite multistep method tradition, the $\mathsf{AdamsBashforthFiniteStep}^{\uparrow}$ packet records an explicit ODE step whose update is read from a bounded previous-step window and a finite table of displayed derivative samples. It sits after the ODE source of chapter 193, the real readback surface of chapter 38, the regular rational tolerance route of chapter 301, the stream-name replay route of chapter 126, the dyadic arithmetic core of chapter 291, and the one-step explicit Euler packet of chapter 6231. The certificate names a finite linear multistep update; it does not assert host solution existence, convergence of a mesh family, or completeness of an ambient real line.

Definition 6655.1 (Adams-Bashforth finite-step carrier)**.** *An* $\mathsf{AdamsBashforthFiniteStep}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (O, B, W, F, S, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *source row, naming the local time-state cell, vector-field request, step index, and finite mesh window.*
2. *B is the dyadic coefficient table row, listing the Adams–Bashforth weights consumed by the displayed order and no coefficient outside that finite table.*
3. *W is the previous-step window row, recording the ordered finite list of already named time-state entries used by the multistep update.*
4. *F is the derivative-sample row, pairing each entry of W with the displayed* $\mathsf{Ode}^{\uparrow}$ *vector-field read and its* $\mathsf{StreamName}^{\uparrow}$ *replay name.*
5. *S is the explicit step-update row, reading the next state as the previous endpoint plus the dyadic weighted sum of the derivative samples.*
6. *L is the local truncation and error ledger, recording only the visible residual budget, mesh-width budget, and* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback attached to this one update.*
7. *H records componentwise* hsame *transport for the ODE source, coefficient table, previous-step window, derivative samples, update row, error ledger, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$O, B, W, F, L \longmapsto S \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{AdamsBashforthFiniteStep}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{EulerMethodFiniteStep}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AdamsBashforthFiniteStep}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their displayed transports. It has no coordinate for a host solution curve, selected limiting path, quotient equality of functions, a global ODE existence theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6655.2 (Adams-Bashforth finite-step error ledger)**.** *For every accepted* $\mathsf{AdamsBashforthFiniteStep}^{\uparrow}$ *carrier $A = (O, B, W, F, S, L, H, C, P, N)$, the visible step update consumes only the ODE source row, the dyadic coefficient table, the previous-step window, the derivative-sample rows, and the local truncation and error ledger displayed in O, B, W, F, S, L. Its exported certificate is exactly the transported and replayed* BHist, hsame, Cont, Pkg, *and* NameCert *route through H, C, P, N. It exports no global ODE existence theorem, host function equality, selected limit, quotient path equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6655.1. The only numerical rows are O, B, W, F, S, L: the ODE source, dyadic coefficient table, previous-step window, derivative samples, explicit update, and local error ledger.

The update row S is not a host function. It is a displayed read from the previous endpoint in W, the finite coefficient table B, the derivative samples F, and the local tolerance data in L. Thus every arithmetic or error request is already tied to a finite row before a downstream consumer sees the update.

Finally transport and replay through H, C, P, N. These rows preserve the same finite packet as BEDC data, so they cannot add a global existence theorem, a host equality proof, a selected limiting path, quotient path equality, or a completeness argument absent from the carrier. □

Lean4 (statement) `BEDC.Derived.AdamsBashforthFiniteStepUp`

Closure status for $\mathsf{NameCert}_{\mathsf{AdamsBashforthFiniteStep}^{\uparrow}}$.

Constructive story: An $\mathsf{AdamsBashforthFiniteStep}^{\uparrow}$ packet is generated from an Ode source row, a dyadic coefficient table, a previous-step window, derivative-sample rows, an explicit update row, a local truncation and error ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AdamsBashforthFiniteStep}^{\uparrow}}$, seed)

Scope closed: Definition 6655.1 and Definition 6655.2 seed the finite Adams–Bashforth update route over ODE, Real, RegSeqRat, StreamName, DyadicRatCore, Euler finite-step, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AdamsBashforthFiniteStep}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim global ODE existence, mesh-family convergence, host function equality, selected limits, quotient path equality, ambient Real completeness, theorem checking, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-table visibility, previous-window coverage, derivative-sample readback, explicit update exposure, local error-ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.AdamsBashforthFiniteStepUp.

Chapter 6656

A Concrete Naming Certificate for $\mathsf{CofinalCauchySubnet}^{\uparrow}$

Following Moore–Smith and Kelley, the $\mathsf{CofinalCauchySubnet}^{\uparrow}$ packet records the finite NameCert surface for a Cauchy subnet route whose reindexing data are cofinal in the source directed tail order. It sits after the Moore–Smith net carrier of chapter 3403, the Cauchy-net surface of chapter 589, the convergence handoff of chapter 1667, the finite window discipline of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is an L10 Real and Completion carrier: it names the cofinal-tail evidence needed by completion-facing consumers without choosing a global subnet, quotienting nets, adding countable choice, importing ambient compactness, identifying host values, or asserting completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6656.1 (Cofinal Cauchy subnet carrier)**.** *A* $\mathsf{CofinalCauchySubnet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, J, \phi, M, A, T, K, N, S, R, E, H, C, P, L)$$

with the following displayed rows:

1. *I is the source directed-index row inherited from the accepted* $\mathsf{MooreSmithNet}^{\uparrow}$ *surface.*
2. *J is the subnet directed-index row, carrying only the finite subnet vertices and comparisons inspected by the packet.*
3. *ϕ is the monotone reindexing row from J to I.*
4. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *source-net row, exposing finite source values and tail requests.*
5. *A is the* $\mathsf{CauchyNet}^{\uparrow}$ *common-window row on the source net.*
6. *T is the cofinal-tail ledger: for each displayed source-tail request, it gives a displayed subnet tail whose image under ϕ lies inside that source tail.*
7. *K is the Cauchy-subnet compatibility row, recording that the subnet observations read through J, ϕ, M, T inherit the displayed Cauchy windows in A.*
8. *N is the* $\mathsf{NetConvergence}^{\uparrow}$ *consumer row, available only after the cofinal and Cauchy-subnet rows have been displayed.*
9. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation-window row for the accepted subnet route.*
10. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*

11. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, read only after* $I, J, \phi, M, A, T, K, N, S, R$ *are displayed.*
12. *H records componentwise* hsame *transport for the directed, net, Cauchy, cofinal, convergence, readback, seal, replay, provenance, and local naming rows.*
13. *C records displayed* Cont *replay through the same finite cofinal Cauchy subnet route.*
14. *P is the* Pkg *provenance over* $\mathsf{CofinalCauchySubnet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
15. *L is the local* $\mathsf{NameCert}_{\mathsf{CofinalCauchySubnet}^{\uparrow}}$ *row.*

The carrier exports only these displayed rows. It has no coordinate for selected subnets, quotient-net equality, countable choice, ambient compactness, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6656.2 (Cofinal Cauchy subnet NameCert obligations)**.** *For an accepted* $\mathsf{CofinalCauchySubnet}^{\uparrow}$ *carrier* $Q = (I, J, \phi, M, A, T, K, N, S, R, E, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalCauchySubnet}^{\uparrow}}$ *surface consists exactly of carrier admission, source directed-index exposure, subnet directed-index exposure, monotone reindexing exposure, Moore–Smith source-net exposure, Cauchy common-window exposure, cofinal-tail coverage, Cauchy-subnet compatibility, NetConvergence handoff, StreamName scheduling, RegSeqRat readback, terminal Real seal exposure, componentwise transport, displayed route replay, provenance, and local naming.*

Proof. Carrier admission projects the finite packet of Definition 6656.1. The source and subnet directed rows are I, J, ϕ, while M exposes the finite Moore–Smith source-net observations.

The Cauchy and cofinal rows are A, T, K. The row A stores the common-window Cauchy evidence, T answers each displayed source-tail request by a subnet tail, and K records that the subnet observations inherit the displayed Cauchy window along that cofinal route.

The convergence and Real-facing rows are then N, S, R, E. A $\mathsf{NetConvergence}^{\uparrow}$ consumer reads only after the cofinal Cauchy-subnet route is present, and a $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal seal only after the finite StreamName and RegSeqRat rows have been displayed.

Finally H, C, P, L transport, replay, source, and name exactly the same route. Since no further coordinate is present, the listed rows exhaust the local NameCert obligations and leave no place for the excluded selection, quotient, choice, compactness, host-equality, or completeness principles. □

Theorem 6656.3 (Cofinal-tail stability)**.** *Every completion-facing read from an accepted* $\mathsf{CofinalCauchySubnet}^{\uparrow}$ *packet factors through the finite cofinal-tail route*

$$I, J, \phi, M, A \longmapsto T, K \longmapsto N, S, R, E.$$

Thus replacing a displayed source-tail request by a later displayed source tail changes only the finite witness chosen inside T; the downstream Cauchy-subnet compatibility row, NetConvergence handoff, StreamName windows, RegSeqRat readback, and terminal Real seal remain attached to the same carrier route.

Proof. Begin with the carrier inventory of Definition 6656.1. The only row that answers source-tail requests by subnet data is T, and T is read after the directed and source-net rows I, J, ϕ, M.

The Cauchy evidence is not recomputed downstream. The row K reads the common-window evidence in A through the same cofinal ledger T, so a later displayed source tail only asks T for a later displayed subnet-tail witness.

The rows N, S, R, E are downstream of T, K. Therefore convergence-facing and Real-facing consumers preserve the same cofinal Cauchy subnet route after any displayed tail refinement.

The structural rows H, C, P, L transport, replay, source, and name that route without adding a selected subnet, quotient-net equality, countable-choice coordinate, compactness principle, host equality, or completeness claim for $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: If a completion-facing consumer reads the $\mathsf{Real}^{\uparrow}$ seal of a purported $\mathsf{CofinalCauchySubnet}^{\uparrow}$ packet before displaying the cofinal-tail ledger T and the Cauchy-subnet compatibility row K, it is not reading the carrier of Definition 6656.1.

Independence witness: moore-smith-net, cauchynet, netconvergence, streamname, regseqrat, real: $\mathsf{CofinalCauchySubnet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source and subnet directed rows, monotone reindexing, source Cauchy evidence, cofinal-tail coverage, convergence handoff, finite observation windows, regular readback, terminal real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalCauchySubnet}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalCauchySubnet}^{\uparrow}$ packet is generated from source and subnet directed-index rows, a monotone reindexing row, a MooreSmithNet source row, CauchyNet common-window evidence, a cofinal-tail ledger, Cauchy-subnet compatibility, a NetConvergence handoff, StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CofinalCauchySubnet}^{\uparrow}}$, seed)

Scope closed: Definition 6656.1, Definition 6656.2, and Definition 6656.3 seed the finite cofinal Cauchy subnet carrier for L10 Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CofinalCauchySubnet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected subnets, quotient-net equality, countable choice, ambient compactness, host equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and subnet directed-index exposure, monotone reindexing exposure, Cauchy-window inheritance, cofinal-tail coverage, convergence handoff, finite readback, terminal seal ordering, transport preservation, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CofinalCauchySubnetUp

Chapter 6657

A Concrete Naming Certificate for $\mathsf{SemiDecidableRealCut}^{\uparrow}$

Following Bishop and Troelstra constructive analysis, the $\mathsf{SemiDecidableRealCut}^{\uparrow}$ packet records one-sided lower-cut evidence as finite observable data. It sits on the L10 real-name boundary after the finite observation windows of chapter 126, the regular rational readback of chapter 301, the one-sided lower ledger of chapter 1446, the located real route of **??**, and the terminal seal of chapter 38. The packet names a semi-decidable lower-cut interface: a consumer may inspect finite positive evidence that a rational lies below the represented real, but it receives no Dedekind completeness principle, quotient equality of real names, trichotomy, selected supremum, or countable-choice enumeration.

Definition 6657.1 (Semi-decidable real cut carrier)**.** *A* $\mathsf{SemiDecidableRealCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, L, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the inspected precision requests and rational lower-cut queries.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled windows.*
3. *L is the* $\mathsf{LowerReal}^{\uparrow}$ *lower-observation ledger. Each accepted entry records a rational or dyadic candidate together with finite evidence that the candidate is admitted by the lower side.*
4. *Q is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row, used only when the lower evidence is checked against a located enclosure already visible through W and R.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, consumed only after the stream, regular-rational, lower-ledger, and located-comparison rows are displayed.*
6. *H records componentwise* hsame *transport for W, R, L, Q, E and the structural rows.*
7. *C records displayed* Cont *replay of the same lower-cut query route.*
8. *P is the* Pkg *provenance over* $\mathsf{SemiDecidableRealCut}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SemiDecidableRealCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $W, R, L, Q, E, H, C, P, N$. It has no coordinate for an upper cut, quotient real equality, trichotomy, selected witnesses for all positive entries, a Dedekind-completeness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6657.2 (Semi-decidable real cut obligation surface)**.** *For an accepted* $\mathsf{SemiDecidableRealCut}^{\uparrow}$ *carrier* $S = (W, R, L, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SemiDecidableRealCut}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-window visibility, regular-rational readback, lower-ledger admission, located-comparison compatibility, terminal* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise transport, displayed replay, provenance, and local naming. These obligations are all read through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{LowerReal}^{\uparrow} \longmapsto \mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the structural rows H, C, P, N *retained.*

Proof. Carrier admission is the tuple displayed in Definition 6657.1. The only observation entry point is the finite window row W, and every regular readback is attached to that row through R.

The lower-cut evidence is the row L. It records positive lower information as finite admitted entries, while the located comparison row Q can only compare those entries against the already displayed located-real route.

The terminal seal E is downstream of W, R, L, Q. Transport and replay through H and C preserve the same finite route, and P, N source and name it. Since no carrier row stores an upper cut, quotient equality, trichotomy, selected global enumeration, Dedekind completeness, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6657.3 (Semi-decidable real cut window stability)**.** *Let* $S = (W, R, L, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{SemiDecidableRealCut}^{\uparrow}$ *carrier. Replacing a displayed lower-cut query by a later displayed finite window changes only the inspected entries of* W *and the corresponding regular-rational readback in* R*; the admitted lower-ledger row* L*, located comparison row* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise transport* H*, replay* C*, provenance* P*, and local name* N *remain attached to the same semi-decidable cut route. Thus window refinement does not create Dedekind completeness, quotient equality of real names, trichotomy, a selected dense enumeration, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite observation row W. A later displayed window is still a finite $\mathsf{StreamName}^{\uparrow}$ read, so the corresponding regular-rational data are obtained by rereading R along the same schedule discipline.

The lower evidence is not recomputed by a host predicate. It remains the displayed lower ledger L, and any located check must use the visible Q row before the terminal seal E is consumed.

Finally H, C, P, N keep the refined window in the same carrier. Componentwise transport preserves the rows, replay repeats the displayed route, provenance records the same dependencies, and the local name remains the same NameCert surface. No excluded completeness, quotient, trichotomy, selection, or choice principle is introduced by refining the finite window. □

Falsifiable prediction: A purported $\mathsf{SemiDecidableRealCut}^{\uparrow}$ consumer that reads a terminal $\mathsf{Real}^{\uparrow}$ seal without first displaying W, R, L, Q is not reading the carrier of Definition 6657.1.

Independence witness: streamname, regseqrat, lowerreal, locatedreal, real: $\mathsf{SemiDecidableRealCut}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite lower-cut query windows, regular readback, one-sided lower evidence, located comparison compatibility, terminal sealing, componentwise transport, displayed replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SemiDecidableRealCut}^{\uparrow}}$.

Constructive story: A $\mathsf{SemiDecidableRealCut}^{\uparrow}$ packet is generated from finite StreamName query windows, a RegSeqRat readback row, a LowerReal one-sided evidence ledger, a LocatedReal comparison row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SemiDecidableRealCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6657.1, Definition 6657.2, and Definition 6657.3 seed the finite semi-decidable lower-cut interface for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SemiDecidableRealCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, quotient equality of real names, trichotomy, selected suprema, selected dense enumerations, countable choice, Lean verification, bridge checking, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, lower-ledger admission, located-comparison compatibility, window stability, terminal seal ordering, componentwise transport, replay stability, provenance exhaustion, and local naming for BEDC.Derived.SemiDecidableRealCutUp.

Chapter 6658

A Concrete Naming Certificate for $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$ packet records the finite route by which bounded real-sequence data, a monotone direction, and a cofinal index schedule are presented before a Real or Completion consumer asks for subsequence extraction. It reads the bounded source of chapter 3750, the cofinal index witness of chapter 405, the monotone selected-window surface of chapter 1405, the finite observation discipline of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a finite extraction ledger for Bolzano–Weierstrass selector and compact interval subsequence routes without selecting an infinite host subsequence, quotienting stream representatives, adding countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6658.1 (Cofinal monotone subsequence carrier)**.** *A* $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, D, I, C, W, R, E, H, T, P, N)$$

with the following displayed rows:

1. *B is the bounded real-sequence source row, read from the accepted* $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ *surface.*
2. *D is the monotone direction row, recording whether the inspected windows are increasing or decreasing and storing only displayed comparison data.*
3. *I is the cofinal index schedule, read through* $\mathsf{CofinalSubsequence}^{\uparrow}$ *and exposing finite threshold-to-index witnesses.*
4. *C is the finite window row, naming the inspected source windows and selected subsequence windows used by the extraction request.*
5. *W is the monotone-window ledger, read through* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *and tied to the bounded source row and cofinal schedule.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after B, D, I, C, W have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular-rational readback has been exposed.*

8. *H records componentwise* hsame *transport for the bounded source, direction, cofinal schedule, finite windows, monotone ledger, readback, Real seal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay of the same bounded cofinal monotone route.*
10. *P is the* Pkg *provenance over* $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$, $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{MonotoneSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalMonotoneSubsequence}^{\uparrow}}$ *row.*

The carrier exports only these rows. It has no coordinate for a selected infinite subsequence, quotient stream equality, host trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6658.2 (Cofinal monotone subsequence extraction ledger)**.** *For every accepted* CofinalMonotoneSubseque *carrier $M = (B, D, I, C, W, R, E, H, T, P, N)$, every extraction-facing read must first display the bounded source row B, the direction row D, the cofinal index schedule I, the finite windows C, and the monotone-window ledger W. The schedule I answers each inspected source threshold by a later selected window, while D and W record the monotone comparisons for that displayed window. No consumer can enlarge this finite ledger into a selected infinite subsequence, quotient stream representative, countable-choice functional, or ambient compactness principle.*

Proof. Project the carrier of Definition 6658.1. The only source row is B, the only direction row is D, and the only cofinal schedule row is I.

The finite windows are then read through C and W. The row C records which source and selected windows are inspected, while W supplies the monotone comparisons inside those windows and keeps them tied to the direction row.

The structural rows H, T, P, N preserve and replay this route without adding another selector coordinate. Since the carrier has no selected infinite subsequence, quotient stream representative, countable-choice functional, or compactness row, the extraction ledger is exhausted by the displayed finite data. □

Theorem 6658.3 (Cofinal monotone subsequence Real readback)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$ *packet factors through*

$$B, D, I, C, W \longmapsto R \longmapsto E$$

together with H, T, P, N. Thus Bolzano–Weierstrass selector and compact interval subsequence consumers may reuse the bounded source, cofinal schedule, monotone-window ledger, regular-rational readback, and terminal Real seal, but they receive no independent completeness theorem, selected limit, quotient real equality, host subsequence selector, or countable-choice principle.

Proof. Begin with Definition 6658.2. It places the bounded source, direction, cofinal schedule, finite windows, and monotone ledger before any readback row can be consumed.

The regular-rational readback row R is downstream of that extraction ledger, and the terminal Real seal E is downstream of R. Therefore a Real-facing consumer sees only the displayed route from finite windows to regular-rational readback and then to the Real seal.

Transport, replay, provenance, and local naming preserve the same packet. The excluded rows are absent from the carrier, so the readback cannot become a completeness principle, selected limit, quotient equality, host subsequence selector, or countable-choice rule. □

Falsifiable prediction: Any Bolzano–Weierstrass selector or compact interval subsequence consumer that reads the $\mathsf{Real}^{\uparrow}$ seal of a purported $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$ packet before displaying B, D, I, C, W is not reading the carrier of Definition 6658.1.

Independence witness: bounded-monotone-subsequence, cofinalsubsequence, monotonesubsequence, streamname, regseqrat, real: $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded source row, a monotone direction row, a cofinal index schedule, finite selected windows, a monotone-window ledger, regular readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalMonotoneSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalMonotoneSubsequence}^{\uparrow}$ packet is generated from bounded real-sequence data, a monotone direction row, a cofinal index schedule, finite selected windows, a monotone-window ledger, RegSeqRat readback, a Real seal, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalMonotoneSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6658.1, Definition 6658.2, and Definition 6658.3 seed the finite cofinal monotone subsequence route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalMonotoneSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected infinite subsequences, quotient stream equality, host trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source exposure, cofinal schedule coverage, monotone-window extraction, regular-rational readback, terminal seal ordering, transport preservation, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CofinalMonotoneSubsequenceUp.

Chapter 6659

A Concrete Naming Certificate for $\mathsf{RegularExpression}^{\uparrow}$

Following Hopcroft–Ullman and Sipser, the $\mathsf{RegularExpression}^{\uparrow}$ packet records the finite syntax side of regular-language presentation as BEDC NameCert data. It sits beside the accepted-word surface of chapter 351, the displayed finite control of chapter 2364, the canonical deterministic consumer of chapter 6188, and the grammar boundary in chapter 356. The packet names empty, literal, union, concatenation, and Kleene-star ledgers before any consumer may read a host regular-expression oracle, a language quotient, or an unrestricted grammar.

Definition 6659.1 (RegularExpression carrier)**.** *A* $\mathsf{RegularExpression}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (\Sigma, E, L, U, C, K, H, T, P, N)$$

with the following displayed rows:

1. Σ *is the finite alphabet row.*
2. E *is the empty-language and empty-word syntax row, distinguishing the two nullary constructors as finite tags.*
3. L *is the literal-row ledger, naming each alphabet symbol used by a literal syntax leaf.*
4. U *is the union ledger, recording the two displayed subexpressions joined by each union constructor.*
5. C *is the concatenation ledger, recording the ordered pair of displayed subexpressions joined by each product constructor.*
6. K *is the Kleene-star ledger, recording the single displayed subexpression whose finite iteration surface is being named.*
7. H *records componentwise* hsame *transport for alphabet, empty, literal, union, concatenation, star, automaton handoff, replay, provenance, and local naming rows.*
8. T *records displayed* Cont *replay through the finite syntax tree and through the Thompson-style finite-automaton handoff route.*
9. P *is the* Pkg *provenance over* $\mathsf{RegularExpression}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{MinimalDfa}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularExpression}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Sigma, E, L, U, C, K, H, T, P, N$. It has no coordinate for a host equivalence test on regular expressions, an infinite language quotient, a nondeterministic branch selector, or a context-free grammar derivation tree.

Lean4 (statement) `BEDC.Derived.RegularExpressionUp`

Theorem 6659.2 (RegularExpression NameCert obligations)**.** *For every accepted* $\mathsf{RegularExpression}^{\uparrow}$ *carrier*

$$R = (\Sigma, E, L, U, C, K, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularExpression}^{\uparrow}}$ *surface consists exactly of finite alphabet exposure, empty-constructor exposure, literal-symbol exposure, union ledger replay, concatenation ledger replay, Kleene-star ledger replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may project the displayed syntax rows and their replay ledgers, but it obtains no host regular-expression equivalence oracle, language quotient, hidden automaton state, or unrestricted grammar production surface.*

Proof. Project the carrier of Definition 6659.1. The rows Σ, E, L expose the alphabet, nullary syntax constructors, and literal leaves before any compound syntax can be read.

The union, concatenation, and Kleene-star constructors are then read through U, C, K. Each row stores only finite pointers to displayed subexpressions, so the syntax ledger closes by structural descent through the displayed tree.

The rows H, T, P, N transport, replay, source, and name the same packet. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations and leave host equivalence, language quotienting, hidden automata, and context-free derivation data outside the packet. □

Theorem 6659.3 (RegularExpression Kleene automaton handoff)**.** *Every* $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, *or* $\mathsf{MinimalDfa}^{\uparrow}$ *consumer that reads the Kleene construction from an accepted* $\mathsf{RegularExpression}^{\uparrow}$ *packet first reads the displayed alphabet row, empty and literal rows, union ledger, concatenation ledger, Kleene-star ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The handoff to the finite-automaton siblings exports only a finite syntax-to-automaton construction route, while the* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *sibling may read only the regular-expression syntax boundary as a proper sub-surface of grammar syntax.*

Proof. Begin with an accepted carrier $R = (\Sigma, E, L, U, C, K, H, T, P, N)$. Structural replay over the displayed syntax tree reads empty and literal leaves from E, L, then reads union and concatenation nodes from U, C.

For a Kleene-star node, the row K supplies the single displayed subexpression whose finite iteration route is being handed to the automaton construction. The Cont row T records the finite replay path used by the finite-automaton consumer; it does not choose an external nondeterministic branch outside the displayed construction data.

The regular-language and minimal-DFA consumers may subsequently read the resulting finite presentation through their own chapters. This route does not prove arbitrary regular-expression equivalence, does not identify host language quotients, and does not turn the packet into a context-free derivation system. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularExpression}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularExpression}^{\uparrow}$ packet is generated from a finite alphabet row, empty and literal syntax rows, union, concatenation, and Kleene-star ledgers, componentwise hsame transport, displayed continuation replay, package provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{RegularExpression}\uparrow}$, seed)

Scope closed: Definition 6659.1, Definition 6659.2, and Definition 6659.3 seed the finite syntax-side certificate for RegularLanguageUp, FiniteAutomatonUp, MinimalDfaUp, and ContextFreeGrammarUp consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularExpression}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.RegularExpressionUp`

Bridge status: none

Not claimed: This chapter does not close regular-expression equivalence, host language quotients, nondeterministic branch selection, grammar derivation completeness, theorem-checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, constructor-ledger replay, Kleene-star automaton handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularExpressionUp.

Chapter 6660

A Concrete Naming Certificate for $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$

Following Bourbaki and Kelley on complete metric spaces and Bishop–Bridges on explicit Cauchy convergence, the $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$ packet records the finite route by which displayed complete-metric Cauchy data may be consumed as $\mathsf{SequentialClosure}^{\uparrow}$ evidence. It sits after the metric-space surface of chapter 4230, the Cauchy witness rows of chapter 333, the finite sequence windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the sequential-closure packet of chapter 1571. The chapter names a finite bridge from complete metric convergence data to sequential closure; it is not host completeness, quotient stream equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6660.1 (Complete metric sequential-closure carrier)**.** *A* $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, C, S, Q, L, W, R, E, J, H, K, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, including the visible distance, tolerance, and neighbourhood comparison data.*
2. *C is the complete-metric Cauchy row, naming the Cauchy requests, finite modulus windows, and convergence-readiness data admitted by the source metric presentation.*
3. *S is the displayed subset or source row whose admitted sequence entries form the sequential-closure source.*
4. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *sequence row, carrying the finite observation windows consumed by closure requests.*
5. *L is the candidate limit row supplied by the complete-metric Cauchy data, without asserting host completion or quotient equality.*
6. *W is the finite window ledger aligning Cauchy requests in C with sequence entries in Q.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for tolerance and distance data visible in M, C, Q, W.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular readback row R is displayed.*

9. *J is the* $\mathsf{SequentialClosure}^{\uparrow}$ *evidence row obtained from S, Q, L, W, R, E.*
10. *H records componentwise* hsame *transport for the metric, Cauchy, source, sequence, limit, window, readback, Real seal, sequential-closure evidence, replay, provenance, and local naming rows.*
11. *K records displayed* Cont *replay from a closure consumer through $M, C, S, Q, L, W, R, E, J, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SequentialClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricSequentialClosure}^{\uparrow}}$ *row.*

The carrier has no coordinate for host completeness of the metric space, choice of arbitrary subsequences, quotient stream equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6660.2 (Complete metric sequential-closure NameCert obligations)**.** *For every accepted* $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$ *carrier $G = (M, C, S, Q, L, W, R, E, J, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricSequentialClosure}^{\uparrow}}$ *surface consists exactly of carrier admission, complete-metric Cauchy exposure, sequence-window coverage, limit-row alignment, RegSeqRat readback, Real seal admission,* $\mathsf{SequentialClosure}^{\uparrow}$ *handoff, componentwise transport, displayed replay, package provenance, local naming, and nonescape from host completeness, choice, quotient stream equality, and compactness.*

Proof. Project the carrier. Rows M, C, S, Q, L, W expose the metric presentation, complete-metric Cauchy data, source row, sequence windows, candidate limit, and window alignment ledger.

The analytic handoff is downstream of those rows. The readback row R records the regular rational tolerance data, the Real row E seals the accepted distance comparison, and the sequential-closure row J repackages S, Q, L, W, R, E as $\mathsf{SequentialClosure}^{\uparrow}$ evidence.

The structural rows H, K, P, N then transport, replay, source, and locally name the same finite route. Since the carrier includes no host completeness, selected subsequence, quotient stream equality, open-cover compactness, or ambient Real completeness coordinate, the displayed rows exhaust the NameCert obligation surface. □

Theorem 6660.3 (Complete metric sequential-closure limit seal)**.** *Every closure-facing read of an accepted* $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$ *packet factors through*

$$M, C, S, Q, L, W \longmapsto R, E \longmapsto J \longmapsto H, K, P, N.$$

Thus the candidate limit row is sealed only after the complete-metric Cauchy windows have been aligned with displayed sequence windows, translated through $\mathsf{RegSeqRat}^{\uparrow}$, *sealed by* $\mathsf{Real}^{\uparrow}$, *and repacked as* $\mathsf{SequentialClosure}^{\uparrow}$ *evidence.*

Proof. Start with a closure-facing read of L. The carrier admits L beside the metric row M, complete-metric Cauchy row C, source row S, sequence row Q, and finite window ledger W.

The limit seal is then read through R and E. The regular readback row records the tolerance data visible in the metric and Cauchy windows, and the Real seal row certifies the accepted distance comparison only after those windows have been displayed.

Finally the row J repackages the resulting limit evidence as $\mathsf{SequentialClosure}^{\uparrow}$ data. Transport and replay through H, K, P, N preserve this order, so the consumer receives only the displayed finite seal route and not host completeness or a quotient completion. □

Theorem 6660.4 (Complete metric sequential-closure source nonescape)**.** *An accepted* CompleteMetricSequentialCl *packet exports no sequential-closure evidence unless the source row S, sequence row Q, candidate*

limit row L, finite window ledger W, regular readback row R, Real seal row E, and $\mathsf{SequentialClosure}^{\uparrow}$ *row J are all displayed in the same carrier. In particular, complete-metric Cauchy data alone cannot escape as host closure, selected limit, quotient stream equality, or open-cover compactness.*

Proof. Read the carrier rows. The complete-metric Cauchy row C is not an exported closure object by itself; it is tied to S, Q, L, W before any Real-facing or closure-facing evidence is available.

Apply the limit-seal route of Definition 6660.3. It forces every closure read through R, E, J after the metric and sequence windows have been exposed.

The nonescape claim follows from absence of coordinates. There is no row for host closure, selected limits, quotient stream equality, compactness, or ambient completeness, and H, K, P, N only preserve the displayed finite packet. Therefore source data cannot leave the carrier except through the stated sequential-closure route. □

Falsifiable prediction: Every accepted CompleteMetricSequentialClosureUp closure-facing read factors through a MetricSpace row, complete-metric Cauchy row, source row, StreamName sequence row, candidate limit row, finite window ledger, RegSeqRat readback, Real seal, SequentialClosure evidence row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metricspace, cauchyfilter, streamname, regseqrat, real, sequentialclosure: $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$ is not bijective to any listed sibling because it binds complete-metric Cauchy exposure, sequence-window alignment, limit sealing, regular readback, Real sealing, SequentialClosure handoff, transport, replay, provenance, and local naming as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricSequentialClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteMetricSequentialClosure}^{\uparrow}$ packet is generated from a MetricSpace row, complete-metric Cauchy row, source row, StreamName sequence row, candidate limit row, finite window ledger, RegSeqRat readback, Real seal, SequentialClosure evidence row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricSequentialClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6660.1, Definition 6660.2, Definition 6660.3, and Definition 6660.4 seed the finite route from complete metric Cauchy data to sequential-closure evidence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricSequentialClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host completeness, choice, quotient stream equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric Cauchy exposure, sequence-window coverage, RegSeqRat readback, Real seal admission, SequentialClosure handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompleteMetricSequentialClosureUp.

Chapter 6661

A Concrete Naming Certificate for $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$

Following Bishop–Bridges constructive arithmetic, the $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$ packet records the finite operation-input ledger that must be displayed before arithmetic on regular rational sequences is allowed to feed a Real-facing seal. It sits between the source rows of chapter 301, the finite-window service of chapter 126, the dyadic operation budget of chapter 291, and the terminal seal of chapter 38. The ledger is pre-theorem input data for the arithmetic packets of chapter 417 and chapter 461; it does not claim RealAlgOrder closure or full real arithmetic.

Definition 6661.1 (RegSeqRat operation ledger carrier)**.** *A* $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, B, W_A, W_B, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational sequence data may be used by the operation request.*
2. *W_A and W_B are synchronized* $\mathsf{StreamName}^{\uparrow}$ *window rows, exposing the same precision window for the two source reads.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation budget, recording the finite endpoint addition, multiplication, comparison, and error-allocation rows available to the operation request.*
4. *Q is the output regularity row, requiring the proposed operation output to remain a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any Real-facing consumer reads it.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary, reached only after A, B, W_A, W_B, D, Q have all been displayed.*
6. *H records componentwise* hsame *transport for the two sources, synchronized windows, dyadic budget, output regularity row, seal boundary, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an operation request through $A, B, W_A, W_B, D, Q, E, H, P, N$.*
8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegSeqRatOperationLedger}^{\uparrow}}$ *row.*

The classifier compares accepted ledgers only through $A, B, W_A, W_B, D, Q, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host real arithmetic, order trichotomy, RealAlgOrder closure, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6661.2 (RegSeqRat operation ledger NameCert obligations)**.** *For every accepted* $\mathsf{RegSeqRatOperationLed}$ *carrier* $O = (A, B, W_A, W_B, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegSeqRatOperationLedger}^{\uparrow}}$ *surface consists exactly of two-source* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, synchronized* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation-budget accounting, output regularity exposure through* Q*, the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every arithmetic consumer must read the finite route*

$$A, B, W_A, W_B, D, Q \longmapsto E \longmapsto H, C, P, N$$

before it may hand the request to $\mathsf{RegularCauchySum}^{\uparrow}$*,* $\mathsf{RegularCauchyProduct}^{\uparrow}$*, or a Real-facing seal.*

Proof. Project the carrier of Definition 6661.1. The only source rows are A and B, and the only observable schedules are the synchronized window rows W_A, W_B.

Read the operation budget next. The dyadic row D is the sole coordinate for endpoint arithmetic, comparison, and error allocation, while Q is the only row that records output regularity before a downstream seal is available.

Finally route the accepted read through E, H, C, P, N. These rows seal, transport, replay, source, and name the same finite ledger, so they cannot add quotient streams, selected limits, host real arithmetic, order trichotomy, RealAlgOrder closure, or ambient completeness. □

Theorem 6661.3 (RegSeqRat operation ledger regularity preservation)**.** *Let* $O = (A, B, W_A, W_B, D, Q, E, H, C, P$ *be an accepted* $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$ *carrier. Any operation request that is routed through the ledger preserves regular rational sequence visibility in the following sense: the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources* A, B*, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows* W_A, W_B*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget* D *must be displayed before the output regularity row* Q *is read, and* Q *must be read before the* $\mathsf{Real}^{\uparrow}$ *seal boundary* E *is available. Thus the ledger can feed* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *as pre-theorem input data, but it does not by itself prove real addition, real multiplication, ordered-field laws, quotient-stream equality, or completeness.*

Proof. Start with source visibility. The carrier exposes exactly two regular rational sequence rows and their synchronized finite windows, so a consumer cannot manufacture an operation output without first reading A, B, W_A, W_B.

Use the dyadic budget row D for the finite operation request. Endpoint arithmetic and error allocation are therefore recorded before output regularity is inspected.

The output row Q is downstream of those inputs and upstream of the seal row E. Hence any Real-facing read sees a regular rational output only through the displayed ledger. The packet can be consumed by the sum and product chapters as operation-input data, but the refused real arithmetic and order principles have no carrier coordinate here. □

Falsifiable prediction: Every accepted $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$ operation read factors through two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ operation budget, an output regularity row, a $\mathsf{Real}^{\uparrow}$ seal boundary, hsame transport, Cont replay, Pkg provenance, and local naming before $\mathsf{RegularCauchySum}^{\uparrow}$ or $\mathsf{RegularCauchyProduct}^{\uparrow}$ consumes it.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-sum, regular-cauchy-product: $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two source regular names, synchronized observation windows, dyadic operation budgeting, output regularity, a Real seal boundary, structural transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RegSeqRatOperationLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{RegSeqRatOperationLedger}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ operation budget, an output regularity row, a $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegSeqRatOperationLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6661.1, Definition 6661.2, and Definition 6661.3 seed the finite operation-input ledger for regular rational sequence arithmetic before Real-facing operation descent.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegSeqRatOperationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RealAlgOrder, ordered-field laws, complete real arithmetic, quotient-stream equality, selected limits, host real arithmetic, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, two-source regularity, synchronized window exactness, dyadic operation-budget accounting, output regularity preservation, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RegSeqRatOperationLedgerUp.

Chapter 6662

A Concrete Naming Certificate for $\mathsf{ConstructiveCauchyDini}^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the $\mathsf{ConstructiveCauchyDini}^{\uparrow}$ packet records a finite Cauchy–Dini modulus route from monotone real-valued approximation rows to a terminal real-name seal. It sits beside the compact finite-modulus surface of chapter 2299, the Cauchy-modulus boundary of chapter 1423, the constructive Dini modulus packet of chapter 3454, the regular-rational readback of chapter 301, and the terminal real-name chapter of chapter 38. The packet names only the finite route by which compact-window rows, monotone Dini rows, Cauchy modulus rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ sealing are displayed; it does not assert host completeness, quotient equality of real names, open-cover compactness, or a selected limiting function.

Definition 6662.1 (Constructive Cauchy-Dini carrier)**.** *A* $\mathsf{ConstructiveCauchyDini}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, M, W, K, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the stream-source row, listing the finite observation schedule for the monotone approximation family.*
2. *M is the monotone comparison row, recording the Dini-side order comparisons visible in the inspected windows.*
3. *W is the finite compact-window row, read through the compact uniform modulus surface and carrying only displayed finite cover or finite-net data.*
4. *K is the Cauchy modulus row, recording the finite tail budget that turns the monotone compact-window comparison into a Cauchy read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same scheduled windows and Cauchy budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after S, M, W, K, R have all been displayed.*
7. *H records componentwise* hsame *transport for the stream source, monotone comparison, compact window, Cauchy budget, readback, seal, and structural rows.*
8. *C records displayed* Cont *replay of the same finite Cauchy–Dini route.*
9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveCauchyDini}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyDini}^{\uparrow}}$ *row.*
The carrier has no coordinate for host completeness, quotient equality of functions or reals, open-cover compactness, a selected limit function, countable choice, or a non-displayed uniform convergence theorem.

Theorem 6662.2 (Constructive Cauchy-Dini NameCert obligations)**.** *For the carrier of Definition 6662.1, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyDini}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-source visibility, monotone comparison stability, finite compact-window exposure, Cauchy modulus ordering,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from the tuple $D = (S, M, W, K, R, E, H, C, P, N)$. The stream source, monotone comparison, compact window, Cauchy budget, regular readback, and terminal seal are all displayed rows of the same finite packet.

The analytic handoff is ordered. A consumer must first read the inspected stream windows in S, then the monotone comparison row M, then the compact finite-window row W, and only then the Cauchy modulus row K.

The readback and seal do not add hidden data. The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads the same window and budget, while E seals the resulting real-facing row after R is visible. The structural rows H, C, P, N transport, replay, source, and name that route without importing host completeness, quotient equality, open-cover compactness, selected limits, choice, or an unrecorded convergence theorem. □

Theorem 6662.3 (Constructive Cauchy-Dini finite-modulus handoff)**.** *Every accepted* $\mathsf{ConstructiveCauchyDini}^{\uparrow}$ *read that reaches a* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite route*

$$S, M, W, K, R, E, H, C, P, N.$$

In particular, the compact finite-modulus rows and monotone Dini rows must be displayed before the Cauchy modulus is read, and the $\mathsf{RegSeqRat}^{\uparrow}$ *readback must be displayed before the terminal real-name seal. The handoff exports no host uniform-limit theorem, quotient equality of real names, open-cover compactness proof, selected limiting function, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 6662.2. They place the stream source, monotone comparison, compact finite window, and Cauchy modulus in one displayed packet before any readback row is available.

Next read the regular-rational handoff. The row R is attached to the same scheduled windows and the same Cauchy budget, so a consumer cannot detach it from S, M, W, K.

Finally consume the terminal seal. The row E is downstream of R, and H, C, P, N keep the route componentwise transported, replayed, sourced, and named. Since the excluded host objects have no carrier coordinate, the $\mathsf{Real}^{\uparrow}$ consumer receives only the finite Cauchy–Dini modulus handoff. □

Falsifiable prediction: A purported $\mathsf{ConstructiveCauchyDini}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first displaying S, M, W, K, R is not reading the carrier of Definition 6662.1.

Independence witness: compact-uniform-modulus, realcauchymodulus, constructive-dini-modulus, regseqrat, real: $\mathsf{ConstructiveCauchyDini}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries stream source, monotone Dini comparison, compact finite-window, Cauchy modulus, regular-rational readback, terminal seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyDini}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCauchyDini}^{\uparrow}$ packet is generated from finite stream-source observations, monotone Dini comparison rows, compact finite-modulus windows, a Cauchy modulus budget, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyDini}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6662.1, Definition 6662.2, and Definition 6662.3 seed the finite Cauchy–Dini modulus route over compact-window, Cauchy-modulus, RegSeqRat, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyDini}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host uniform-limit completeness, quotient equality of real names, open-cover compactness, selected limiting functions, countable choice, Lean verification, bridge checking, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, monotone comparison stability, compact finite-window exposure, Cauchy modulus ordering, regular-rational readback, terminal seal ordering, transport preservation, replay stability, provenance exhaustion, and local naming for BEDC.Derived.ConstructiveCauchyDiniUp.

Chapter 6663

A Concrete Naming Certificate for ClosedParallelSubstitutionBudget$^{\uparrow}$

The ClosedParallelSubstitutionBudget$^{\uparrow}$ packet realizes the substitution-compatibility boundary isolated by chapter 9378 as finite NameCert data. It sits beside the compiler-facing closed substitution route of chapter 540, the primitive closed-substitution boundary of chapter 538, the confluence audit packet of chapter 735, the closed parallel diamond premise ledger of chapter 2325, and the substitution-sensitive confluence boundary of chapter 3791. The packet records the finite budget rows that must be visible before a closed parallel-diamond handoff can consume substitution compatibility; it does not claim full closed Church–Rosser, unrestricted open substitution commutation, subject reduction, evaluator soundness, quotient equality, or kernel consistency.

Definition 6663.1 (Closed parallel substitution budget carrier)**.** *A* ClosedParallelSubstitutionBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, U, L, S, D, J, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed source and target term-window row, recording only closed MetaCIC terms inspected by the budget.*
2. *U is the closed substitution compiler row, read through* ClosedTermSubstitutionCompiler$^{\uparrow}$ *and carrying the checked closed shift and substitution slices available to the packet.*
3. *L is the primitive closed-substitution boundary row, read through* ClosedSubstitutionBoundary$^{\uparrow}$ *and retaining the source-closedness, value-closedness, shift, and substitute rows.*
4. *S is the substitution-budget ledger, listing the finite residual-substitution compatibility checks required by the closed parallel branch under inspection.*
5. *D is the closed parallel diamond premise row, read through* ClosedParallelDiamondPremiseLedger$^{\uparrow}$ *and not promoted to a full diamond theorem.*
6. *J is the confluence-audit handoff row, reading* MetaCICConfluenceAuditPacket$^{\uparrow}$ *and* MetaCICConfluenceSubstituti *as boundary packets for the same finite budget.*
7. *H records componentwise* hsame *transport for T, U, L, S, D, J and the structural rows.*
8. *C records displayed* Cont *replay from closed term windows to compiler rows, boundary rows, substitution-budget rows, premise-ledger rows, and confluence-audit handoff rows.*

9. *P is the* Pkg *provenance over* ClosedParallelSubstitutionBudget$^{\uparrow}$, ClosedTermSubstitutionCompiler$^{\uparrow}$, ClosedSubstitutionBoundary$^{\uparrow}$, MetaCICConfluenceAuditPacket$^{\uparrow}$, ClosedParallelDiamondPremiseLedger$^{\uparrow}$, MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{ClosedParallelSubstitutionBudget}^{\uparrow}}$ *row.*

The carrier has no coordinate for full closed Church–Rosser, unrestricted open-term substitution commutation, subject reduction, evaluator soundness, quotient conversion equality, kernel consistency, or a hidden parallel-diamond theorem.

Theorem 6663.2 (Closed parallel substitution budget obligations)**.** *For the carrier of Definition 6663.1, the local* NameCert$_{\text{ClosedParallelSubstitutionBudget}^{\uparrow}}$ *surface consists exactly of carrier admission, closed term-window visibility, closed compiler handoff, primitive closed-substitution boundary exposure, finite residual-substitution budget listing, closed parallel diamond premise retention, confluence-audit handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission projects the tuple $B = (T, U, L, S, D, J, H, C, P, N)$. The closed term windows, compiler row, primitive boundary row, substitution-budget ledger, premise ledger, and confluence-audit handoff are all displayed in one finite packet.

The substitution budget is read before the diamond handoff. The compiler row U and primitive boundary row L expose the closed substitution material, and the ledger S records the finite residual-substitution checks that are available to the inspected closed parallel branch.

The premise row D remains a premise row. It may be handed to confluence-audit consumers through J, transported through H, replayed through C, sourced by P, and named by N, but those structural rows do not create full closed Church–Rosser, open substitution commutation, subject reduction, evaluator soundness, quotient equality, kernel consistency, or a hidden diamond theorem. □

Theorem 6663.3 (Closed parallel substitution budget diamond handoff)**.** *Every accepted* ClosedParallelSubstitution *read that reaches a closed parallel-diamond or closed-star-confluence consumer factors through the finite route*

$$T, U, L, S, D, J, H, C, P, N.$$

The substitution-budget ledger S must be visible before the closed parallel diamond premise row D is consumed, and the confluence-audit handoff J may cite only the displayed budget and boundary rows. The handoff exports no full closed Church–Rosser theorem, unrestricted substitution compatibility, subject-reduction theorem, evaluator soundness, quotient conversion equality, kernel consistency, or hidden confluence oracle.

Proof. Start with the NameCert obligations of Definition 6663.2. They place the closed term windows, closed substitution compiler row, primitive boundary row, substitution-budget ledger, and closed parallel diamond premise in a single displayed packet.

Next consume the budget. The row S is the only place where residual-substitution compatibility checks are listed, so a diamond-facing consumer cannot bypass S on the way to D.

Finally route the handoff through J, H, C, P, N. The confluence audit packet and substitution-boundary packet are read as boundary packets for the same displayed budget. Since the excluded confluence, substitution, typing, evaluator, quotient, and kernel-correctness objects have no carrier coordinate, the handoff remains a finite premise-budget route. □

Falsifiable prediction: A purported $\mathsf{ClosedParallelSubstitutionBudget}^{\uparrow}$ consumer that exports a closed parallel diamond or closed Church–Rosser result without displaying T, U, L, S, D, J is not reading the carrier of Definition 6663.1.

Independence witness: closedtermsubstitutioncompiler, closedsubstitutionboundary, metacicconfluenceauditpacket, closedparalleldiamondpremiseledger, metacicconfluencesubstitutionboundary: no listed sibling jointly carries closed term windows, compiler slices, primitive closed-substitution rows, finite residual-substitution budget, closed parallel diamond premise retention, confluence-audit handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedParallelSubstitutionBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedParallelSubstitutionBudget}^{\uparrow}$ packet is generated from closed term-window rows, closed substitution compiler rows, primitive closed-substitution boundary rows, finite residual-substitution budget rows, closed parallel diamond premise rows, confluence-audit handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedParallelSubstitutionBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6663.1, Definition 6663.2, and Definition 6663.3 seed the finite substitution-budget route for closed parallel-diamond and confluence-audit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedParallelSubstitutionBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full closed Church–Rosser, unrestricted substitution compatibility, subject reduction, evaluator soundness, quotient conversion equality, kernel consistency, Lean verification, bridge checking, or a hidden confluence theorem.

Upgrade path: Obligation closure requires checked carrier admission, closed compiler handoff, primitive boundary exposure, finite budget listing, premise retention, confluence-audit handoff, transport preservation, replay stability, provenance exhaustion, and local naming for BEDC.Derived.ClosedParallelSubstitutionBudgetUp.

Chapter 6664

A Concrete Naming Certificate for $\mathsf{InitialTopology}^{\uparrow}$

Following Bourbaki and Kelley on initial topologies, the $\mathsf{InitialTopology}^{\uparrow}$ packet records the finite BEDC surface where a source carrier is named by the weakest displayed topology making a finite family of maps continuous. It is adjacent to the topology carrier of chapter 88 and the continuous-map handoff of chapter 130: the chapter names only finite inverse-image subbasis generation, finite intersection and union ledgers, transport, replay, provenance, and local naming.

Definition 6664.1 (Initial topology carrier)**.** *An* $\mathsf{InitialTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, I, T, F, B, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the source carrier row whose points receive the generated topology;*
2. *I is the finite index row for the displayed family of target spaces;*
3. *T assigns to each index in I a* $\mathsf{Topology}^{\uparrow}$ *target row with its named open-row classifier;*
4. *F assigns to each index a displayed map from S to the corresponding target carrier;*
5. *B is the subbasic inverse-image ledger, listing the rows $F_i^{-1}(V)$ for target opens V named by T_i;*
6. *U is the finite intersection and finite union ledger generated from B, with entries named as source opens and no appeal to an arbitrary open-set powerset;*
7. *H records componentwise* hsame *transport for S, I, T, F, B, U and the local certificate rows;*
8. *C records displayed* Cont *replay, showing that each F_i reads source opens through B and U before it is consumed as continuous;*
9. *P is the* Pkg *provenance over* $\mathsf{InitialTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{InitialTopology}^{\uparrow}}$ *row.*

The classifier compares two packets only through these rows. It has no coordinate for an ambient powerset topology on S, a choice-selected open basis, an infinite subbasis closure, or a host proof that a larger topology is available.

Theorem 6664.2 (Initial topology NameCert obligations)**.** *For an accepted* $\mathsf{InitialTopology}^{\uparrow}$ *carrier* $Q = (S, I, T, F, B, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{InitialTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the source row, finite index row, target topology rows, displayed map rows, subbasic inverse-image ledger, finite intersection and union ledger, componentwise transport, continuation replay, provenance, and local naming. Its classifier stability is generated by the same rows, and its exactness claim is limited to the statement that every displayed source open is generated from the inverse images in* B *by the finite ledger* U*.*

Proof. Project the carrier of Definition 6664.1. The source, index, target, map, subbasic, and finite-generation rows are the only rows from which the local certificate can read.

The subbasic rows are fixed before the generated source-open rows are read. Each entry of B is an inverse image of a target-open row along a displayed map in F, and each entry of U is obtained from finitely many such rows by the listed intersection and union constructors.

Transport and replay add no new open rows. The hsame row moves the displayed data componentwise, the Cont row replays the same inverse-image route, and the Pkg and NameCert rows source and name the finite packet. Thus no ambient powerset topology, selected basis, or infinite closure operation enters the obligation surface. □

Theorem 6664.3 (Initial topology continuous-map handoff)**.** *Let* $Q = (S, I, T, F, B, U, H, C, P, N)$ *be an accepted* $\mathsf{InitialTopology}^{\uparrow}$ *carrier. For each index in* I*, any downstream* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer of the displayed map row* F_i *must first read the target topology row* T_i*, the inverse-image subbasis ledger* B*, the finite generation ledger* U*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* N*. The handoff exports continuity of the named maps only through the generated source topology and not through a detached ambient topology on* S*.*

Proof. Start with a request for the continuous-map row associated to F_i. Carrier admission exposes the corresponding target topology row T_i and the subbasic inverse-image entries in B before any continuity read is available.

The source topology read then passes through U. This ledger is finite and generated from the displayed inverse images, so the consumer receives exactly the source-open rows needed to replay the inverse-image test for F_i.

Finally apply the structural rows. The hsame row keeps the same source, target, map, and generated-open entries attached; the Cont row records the replay order; and P, N source and name the packet. Hence the $\mathsf{ContinuousMap}^{\uparrow}$ handoff is the finite initial-topology route, not an external topology assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{InitialTopology}^{\uparrow}}$**.**

Constructive story: An $\mathsf{InitialTopology}^{\uparrow}$ packet is generated from a source carrier, finite index row, target topology rows, displayed maps, inverse-image subbasis ledger, finite intersection and union ledger, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{InitialTopology}^{\uparrow}}$, seed)

Scope closed: Definition 6664.1, Definition 6664.2, and Definition 6664.3 seed the finite initial-topology route from displayed target opens to generated source opens and downstream continuous-map consumption.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{InitialTopology}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim an ambient powerset topology, selected open basis, infinite subbasis closure, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, subbasic inverse-image exactness, finite generation, continuous-map handoff, transport replay, provenance, and consumer refusal for BEDC.Derived.InitialTopologyUp.

Chapter 6665

A Concrete Naming Certificate for $\mathsf{CompactGraphContinuity}^{\uparrow}$

Following Kelley and Bishop–Bridges, compact graph continuity is the finite certificate route by which a displayed closed-graph packet over a compact metric source yields a uniform-modulus handoff without appealing to a host quotient of functions or an external open-cover selection. The $\mathsf{CompactGraphContinuity}^{\uparrow}$ packet sits over the compact metric source of chapter 129, the continuous-map surface of chapter 130, and the tolerance-only consumer of chapter 369. It also reads the metric and real endpoint rows used by those chapters before exposing any graph-continuity conclusion.

Definition 6665.1 (Compact graph continuity carrier)**.** *A* $\mathsf{CompactGraphContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, \Gamma, M, Q, W, R, U, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including displayed finite covers, center histories, metric balls, and source-point classifier transport.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed map whose graph is being inspected.*
3. *Γ is the graph row: it records finite source-target observations, graph membership readback, and graph classifier stability under the source and target classifiers.*
4. *M is the target metric row for graph-value comparisons and endpoint separation tests.*
5. *Q is the finite compact-cover query row that turns a source tolerance request into a displayed finite list of graph tests.*
6. *W is the closed-graph witness row, recording that every failed target separation is detected by one of the displayed graph tests.*
7. *R is the regular rational or dyadic comparison row used to read the graph tests as finite tolerance inequalities.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from K, F, Γ, M, Q, W, R.*
9. *H stores componentwise* hsame *transport for compact source rows, continuous-map rows, graph rows, metric endpoints, compact-cover queries, closed-graph witnesses, rational comparisons, uniform-modulus handoffs, replay, provenance, and local naming.*

10. *C stores displayed* Cont *replay from a requested tolerance through the rows $K, F, \Gamma, M, Q, W, R, H$ to the handoff row U.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactGraphContinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactGraphContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host equality of maps, quotient equality of graphs, open-cover compactness outside K, a choice-selected graph neighbourhood, or ambient completeness of the target.

Lean4 ✓ `BEDC.Derived.CompactGraphContinuityUp.CompactGraphContinuityTasteGate single carrier alignment`

Theorem 6665.2 (Compact graph continuity NameCert obligations)**.** *For every accepted* CompactGraphContinuity *carrier*

$$G = (K, F, \Gamma, M, Q, W, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactGraphContinuity}^{\uparrow}}$ *obligations are exactly compact metric source exposure, ContinuousMap row exposure, finite graph membership readback, source-target graph classifier stability, target-metric separation detection, finite compact-cover query exactness, closed-graph witness exactness, rational tolerance readback, UniformModulus handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6665.1. The admitted packet exposes $K, F, \Gamma, M, Q, W, R, U, H, C, P, N$ and no other theorem-facing row.

The source part is K, F, Γ, M. These rows identify the compact metric source, the displayed continuous map, the finite graph observations, and the target metric comparisons consumed by graph separation tests.

The compactness and graph-closure part is Q, W, R. The query row names only finitely many compact-cover and graph tests for a tolerance request; the closed-graph witness row explains why a missing target neighbourhood is detected by those tests; and the rational row makes the resulting inequalities public.

Finally U, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for host map equality, quotient graph equality, external open-cover compactness, selected graph neighbourhoods, or ambient target completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6665.3 (Compact graph continuity uniform-modulus handoff)**.** *Every accepted* CompactGraphContinuity *packet exports a* $\mathsf{UniformModulus}^{\uparrow}$ *row only after the consumer has read the compact metric source of chapter 129, the displayed continuous-map row of chapter 130, the finite graph row, the target metric separation tests, the compact-cover query row, the closed-graph witness row, and the rational tolerance readback. Thus the handoff to chapter 369 is a finite graph/modulus obligation surface, not an ambient closed-graph theorem for arbitrary host maps.*

Proof. Start with an accepted carrier $G = (K, F, \Gamma, M, Q, W, R, U, H, C, P, N)$. A tolerance request reaches the replay row C, which exposes the compact metric source K, the continuous-map row F, the graph row Γ, and the target metric comparison row M.

The compact-cover query Q then reduces the request to finitely many displayed graph tests. The closed-graph witness W and the rational comparison row R certify those tests inside the same packet.

Only after this finite route is visible does the row U become a public $\mathsf{UniformModulus}^{\uparrow}$ handoff. Transport and provenance through H, P, N keep the route attached to the same local name, so a downstream consumer cannot replace it by host map equality, quotient graph equality, external open-cover compactness, selected neighbourhoods, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CompactGraphContinuity}^{\uparrow}$ read that exports a $\mathsf{UniformModulus}^{\uparrow}$ row must first expose the compact metric source, continuous-map row, finite graph row, target metric separation row, compact-cover query, closed-graph witness, rational tolerance readback, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: compactmetric, continuousmap, uniformmodulus, metric, real: CompactGraphContinuity is not bijective to any listed sibling because it jointly carries compact finite-cover data, one displayed continuous-map row, graph membership and graph-stability rows, target separation tests, compact-cover graph queries, closed-graph witnesses, rational tolerance readback, UniformModulus handoff, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactGraphContinuity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactGraphContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6665.1, Definition 6665.2, and Definition 6665.3 seed the finite closed-graph-to-uniform-modulus route over compact metric, ContinuousMap, UniformModulus, Metric, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactGraphContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an ambient closed-graph theorem, quotient equality of graphs, host equality of maps, external open-cover compactness, selected graph neighbourhoods, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact source exposure, continuous-map exposure, graph classifier stability, target separation detection, finite compact-cover query exactness, closed-graph witness exactness, rational tolerance readback, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactGraphContinuityUp.

Constructive story: A $\mathsf{CompactGraphContinuity}^{\uparrow}$ packet is generated from CompactMetric finite-cover rows, ContinuousMap graph rows, target Metric separation tests, compact-cover graph queries, closed-graph witnesses, rational tolerance readbacks, UniformModulus handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6666

A Concrete Naming Certificate for MetaCICResidualCheckerNormalizationBudget$^{\uparrow}$

The MetaCICResidualCheckerNormalizationBudget$^{\uparrow}$ packet realizes the normalization audit map of chapter 9383 as finite checker, fuel, obstruction, transport, replay, provenance, and local naming rows for candidate-mediated strong normalization. It sits beside the frontier carrier of chapter 892, the candidate-mediated SN route of chapter 5163, the finite confluence window of chapter 6027, the candidate diamond budget of chapter 6552, and the typed normal-form scheduler of chapter 6617. The packet is a residual-checker budget surface; it is not an unconditional normalization theorem, residual confluence theorem, subject-reduction theorem, evaluator oracle, quotient syntax equality, or closed consistency proof.

Definition 6666.1 (MetaCIC residual-checker normalization budget carrier)**.** *A* MetaCICResidualCheckerNormaliza *carrier is a finite* BHist *packet*

$$B = (T, A, S, F, R, J, O, X, H, C, P, N)$$

with the following displayed rows:

1. *T is the sealed closed typed term row inspected by the normalization audit.*
2. *A is the candidate-mediated strong-normalization evidence row, including candidate membership, closed-candidate evidence, Pi adequacy, application adequacy, and no-infinite-reduction projections.*
3. *S is the residual checker row, recording the finite residual windows, local residual-substitution checks, and confluence-boundary verdicts consumed before a normal endpoint is trusted.*
4. *F is the fuel row, storing the finite normalization budget, residual-checker budget, and replay-window budget for the current audit request.*
5. *R is the route row from candidate-mediated SN evidence to residual-checker inspection.*
6. *J is the finite join or refusal row, retaining local joins when the checker sees them and explicit obstruction data when it does not.*
7. *O is the obstruction row for missing candidate evidence, fuel exhaustion, failed residual substitution, failed local join, failed closedness transport, and failed endpoint seal.*
8. *X is the export row that exposes only the budgeted normalization result or its displayed obstruction.*

9. *H records componentwise* hsame *transport for the closed term, candidate evidence, residual checker, fuel, route, join/refusal row, obstruction, export row, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from an audit request through T, A, S, F, R, J, O, H to X.*
11. *P is the* Pkg *provenance over* MetaCICResidualCheckerNormalizationBudget$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, CandidateMediatedSN$^{\uparrow}$, FiniteWindowConfluence$^{\uparrow}$, MetaCICCandidateDiamondBudget$^{\uparrow}$, MetaCICTypedNormalFor BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, S, F, R, J, O, X, H, C, P, N$. It has no coordinate for evidence-free global SN, unrestricted residual confluence, subject-reduction transport, quotient syntax equality, hidden evaluator state, host reduction oracles, or closed consistency.

Theorem 6666.2 (MetaCIC residual-checker normalization budget obligations)**.** *For every accepted* MetaCICResidualCheckerNormalizationBudget$^{\uparrow}$ *carrier*

$$B = (T, A, S, F, R, J, O, X, H, C, P, N),$$

the local NameCert$_{\text{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}}$ *obligations are exactly carrier admission, sealed closed-term exposure, candidate-mediated SN evidence exposure, residual-checker window exposure, fuel-budget exactness, candidate-to-checker route replay, finite join or refusal exactness, obstruction retention, budgeted export nonescape, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6666.1. The accepted packet exposes exactly the closed term, candidate evidence, residual checker, fuel budget, route, join/refusal row, obstruction, export, transport, replay, provenance, and local naming rows.

The normalization side is T, A, F, R. A public read must display the sealed closed term, the candidate-mediated SN evidence, the finite fuel, and the route that carries that evidence to the checker.

The residual side is S, J, O. The checker sees only finite residual windows; it exports local joins when they are present and keeps failed residual substitution, failed local joins, failed closedness transport, and failed endpoint seals as visible obstruction rows.

Finally X, H, C, P, N export and preserve the same budgeted route. Since no carrier coordinate supplies evidence-free global SN, unrestricted residual confluence, subject-reduction transport, quotient syntax equality, hidden evaluator state, host reduction oracles, or closed consistency, the listed obligations exhaust the local NameCert surface. □

Theorem 6666.3 (MetaCIC residual-checker budget boundary)**.** *Every accepted* MetaCICResidualCheckerNormaliza *consumer factors through*

$$\text{MetaCICNormalizationFrontier}^{\uparrow} \longmapsto \text{CandidateMediatedSN}^{\uparrow} \longmapsto \text{FiniteWindowConfluence}^{\uparrow} \longmapsto \text{MetaCICCandidateDia}$$

before it may read a budgeted normalization export. The export row X contains a finite normal endpoint only when the candidate evidence, fuel row, residual-checker row, join/refusal row, obstruction row, transport, replay, provenance, and local name are all displayed; otherwise it contains the displayed obstruction.

Proof. Start with the frontier row and the closed typed term T. The candidate row A supplies the only SN evidence that the packet accepts, and the fuel row F records the finite budget attached to that evidence.

Replay R sends this candidate route to the residual checker S. The checker can only consume finite windows, so the join/refusal row J either displays the relevant local join data or records why the route stops at the residual boundary.

The obstruction row O is retained in the export row X whenever candidate evidence, fuel, residual substitution, local joining, closedness transport, or endpoint sealing fails. Transport and replay through H, C, P, N keep the same finite packet attached to the local name, so the excluded global SN, residual confluence, subject reduction, quotient syntax, evaluator, oracle, and consistency claims cannot be exported. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}$ read that exposes a budgeted normalization endpoint while omitting the sealed closed term, candidate-mediated SN evidence, residual checker, fuel, route replay, join/refusal row, obstruction row, hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the packet.

Independence witness: metacicnormalizationaudit, metacic-confluence-residual-checker, metacicnormalizationfrontier, candidate-mediated-sn: $\mathsf{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries candidate-mediated SN evidence, residual-checker windows, finite fuel, local join or refusal rows, obstruction rows, transport, replay, provenance, and local naming in one budgeted normalization surface.

Lean `TasteGate.lean` for $\mathsf{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}$ must later include Nontrivial and FieldFaithful instances so the candidate, checker, fuel, route, join/refusal, obstruction, export, replay, provenance, and local naming rows remain distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6666.1, Definition 6666.2, and Definition 6666.3 seed the finite residual-checker normalization budget route through closed terms, candidate evidence, checker windows, fuel, obstruction, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close evidence-free global SN, unrestricted residual confluence, subject-reduction transport, quotient syntax equality, hidden evaluator state, host reduction oracles, closed consistency, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sealed closed-term exposure, candidate-mediated SN exposure, residual-checker window exposure, fuel exactness, route replay, join/refusal exactness, obstruction retention, export nonescape, Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualCheckerNormalizationBudgetUp.

Constructive story: A $\mathsf{MetaCICResidualCheckerNormalizationBudget}^{\uparrow}$ packet is generated from a sealed closed term, candidate-mediated SN evidence, residual-checker windows, finite fuel, route replay, join or refusal rows, obstruction rows, export rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6667

A Concrete Naming Certificate for $\mathsf{SequentialOrderTopology}^{\uparrow}$

Following Kelley and Engelking topology together with Bishop–Bridges sequence practice, the $\mathsf{SequentialOrderTopology}^{\uparrow}$ packet records the finite order/topology interface whose open reads are tested through displayed sequence windows. It sits beside the real order-topology packet of chapter 1890 and the dyadic order-topology packet of chapter 6612; it gives L10 consumers a sequence-window route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the $\mathsf{Real}^{\uparrow}$ seal without asserting Real completeness, trichotomy, host subsets, selected limits, or open-cover compactness.

Definition 6667.1 (Sequential order topology carrier)**.** *A* $\mathsf{SequentialOrderTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(O, T, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Order}^{\uparrow}$ *source row, including only the order comparisons and endpoint probes admitted by the local carrier.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *generated-open row whose opens are read from the displayed order intervals and not from host subset predicates.*
3. *S is the sequence-window source row, carrying the finite observation surface that downstream* $\mathsf{StreamName}^{\uparrow}$ *consumers may inspect.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite sequence names and index windows used to test sequential openness.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, attaching regular rational observations to the displayed sequence windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, used only as the terminal real-name boundary for sequence reads that have already passed through O, T, S, W, R.*
7. *H records componentwise* hsame *transport for the order, topology, sequence-window, stream-name, regular-readback, Real-seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from order intervals through generated opens, sequence windows, regular rational readback, the Real seal, and the local naming row.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialOrderTopology}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialOrderTopology}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, order trichotomy, host subset equality, selected limits, arbitrary open-cover compactness, quotient sequence equality, or a bridge certificate.

Theorem 6667.2 (Sequential order topology NameCert obligations)**.** *For an accepted* $\mathsf{SequentialOrderTopology}^{\uparrow}$ *carrier* $(O, T, S, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}$ *surface consists of five obligations:*

1. *carrier admission for the displayed* $\mathsf{Order}^{\uparrow}$ *source,* $\mathsf{Topology}^{\uparrow}$ *generated-open row, sequence-window source,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*

2. *order-row stability, requiring every comparison used by a sequential-open read to pass through the displayed order row O before the topology row accepts it;*

3. *sequential-open readback, requiring every open read tested by a sequence to display S, W, R before reaching the generated-open row or the Real seal;*

4. *topology compatibility, requiring the topology row T to record only generated opens whose interval and sequence-window witnesses are replayed through C;*

5. *nonescape, stating that no Real completeness, trichotomy, host subset predicate, selected limit, open-cover compactness principle, quotient sequence equality, or bridge certificate is exported by the packet.*

Proof. Carrier admission is projection from Definition 6667.1. The tuple displays exactly one order row, one topology row, one sequence source, one stream-window row, one regular rational readback, one Real seal, and the structural transport, replay, provenance, and naming rows.

Order-row stability follows from the placement of O before T, W, R, E. A consumer cannot test interval membership, endpoint order, or order-generated openness without reading the displayed order row first.

Sequential-open readback is the route through S, W, R. The stream windows and regular rational observations are displayed before any sequence-facing open read reaches the topology row or the Real seal.

Topology compatibility is supplied by T and C. The topology row records generated opens from the displayed order and sequence-window witnesses, while the replay row preserves that route rather than replacing it by a host subset predicate.

Finally inspect the carrier inventory. The excluded completeness, trichotomy, selected-limit, open-cover, quotient, and bridge data are absent from the tuple, so no local NameCert projection can export them. □

Theorem 6667.3 (Sequential order topology StreamName handoff)**.** *Every sequence-convergence read consumed from an accepted* $\mathsf{SequentialOrderTopology}^{\uparrow}$ *packet passes through the finite route*

$$S \longrightarrow W \longrightarrow R \longrightarrow E \longrightarrow H, C, P, N.$$

Thus a convergence-facing consumer sees $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal as displayed rows of the same packet before it can use the order/topology interface.*

Proof. Project the carrier. The only sequence source is S, the only stream-window row is W, and the only regular rational readback row is R, so a sequence-convergence request has no alternate entry point.

Read the handoff in order. The finite windows in W name the sequence observations, R attaches the regular rational readback needed by L10 completion consumers, and E records only the Real-seal boundary reached by those displayed rows.

Replay through H, C, P, N. These rows transport, replay, source, and name the same handoff, while the sibling order-topology chapters chapter 1890 and chapter 6612 supply point/order topology neighbours rather than a replacement for this sequence-window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialOrderTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialOrderTopology}^{\uparrow}$ packet is generated from displayed Order, Topology, sequence-window, StreamName, RegSeqRat, Real-seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialOrderTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6667.1, Definition 6667.2, and Definition 6667.3 seed the finite sequential order-topology route through order, generated-open, sequence-window, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialOrderTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, host subsets, selected limits, quotient sequence equality, open-cover compactness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, order-row stability, sequential-open readback, topology compatibility, StreamName handoff, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.SequentialOrderTopologyUp.

Chapter 6668

A Concrete Naming Certificate for $\mathsf{HermiteInterpolation}^{\uparrow}$

Following Hermite interpolation, the $\mathsf{HermiteInterpolation}^{\uparrow}$ packet records the finite route from displayed nodes, values, and derivative jets to a polynomial whose formal derivatives match those displayed jets at the same nodes. It refines the node-and-value surface of chapter 4206, consumes the coefficient-list carrier of chapter 50, and routes Real-facing reads through chapter 38, chapter 301, and chapter 291. It is also separate from the orthogonal-family recurrence packet of chapter 6236: the present certificate names interpolation jets, not the Hermite polynomial family.

The BEDC carrier is finite. It stores the node list, the per-node jet-height list, the displayed derivative values, the confluent basis construction, the assembled polynomial, the matching and uniqueness checks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row. Every consumer must see those rows before reading a Hermite interpolant as a Real-facing polynomial approximation or calculus datum.

Definition 6668.1 (Hermite interpolation carrier)**.** *A* $\mathsf{HermiteInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, J, V, D, L, E, U, H, C, P, N)$$

with the following visible rows:

1. *X is a nonempty finite node row, with pairwise-distinctness data for the displayed nodes.*
2. *J is the jet-height row, assigning each node a finite number of formal derivative levels to be matched.*
3. *V is the displayed jet-value table, recording one scalar value for every pair (x_i, k) with $0 \leq k < J_i$.*
4. *D is the denominator and confluent-limit ledger, routing the nonzero node differences and repeated-node derivative factors through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
5. *L is the Lagrange spine row imported from* $\mathsf{LagrangeInterpolation}^{\uparrow}$*, recording the ordinary node basis before the confluent jet rows are attached.*
6. *E is the confluent basis row, displaying the finite* $\mathsf{Poly}^{\uparrow}$ *coefficient lists whose formal derivatives realize the Kronecker jet pattern on X.*

7. *U is the assembly, jet-matching, and degree-bounded uniqueness row for the finite sum of displayed jet values times the basis polynomials.*
8. *H records componentwise* hsame *transport for node, jet-height, jet-value, denominator, Lagrange-spine, basis, assembly, replay, provenance, and local-name rows.*
9. *C records the displayed* Cont *routes that replay denominator formation, confluent basis construction, polynomial differentiation, jet evaluation, and uniqueness comparison from the same finite packet.*
10. *P is the* Pkg *provenance over* $\mathsf{HermiteInterpolation}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{LagrangeInterpolation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HermiteInterpolation}^{\uparrow}}$ *row.*

The carrier predicate is $\mathsf{HermiteInterpolationLedger}(X, J, V, D, L, E, U, H, C, P, N)$. *Two accepted packets classify together exactly when the eleven displayed rows are transported by H and replay through the same routes named by C and P.*

Theorem 6668.2 (Hermite interpolation NameCert obligations)**.** *For an accepted* $\mathsf{HermiteInterpolation}^{\uparrow}$ *packet $K = (X, J, V, D, L, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HermiteInterpolation}^{\uparrow}}$ *obligation surface consists exactly of the finite carrier and classifier rows of Definition 6668.1, the node and jet-height rows X, J, the jet-value table V, the denominator and confluent-limit ledger D, the Lagrange spine row L, the confluent* $\mathsf{Poly}^{\uparrow}$ *basis rows E, the assembly and uniqueness row U, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local naming row N. No host differentiability oracle, quotient polynomial equality, infinite jet family, selected Real representative, or ambient completeness datum is exported.*

Proof. Read the carrier of Definition 6668.1. The rows X, J, V supply the finite interpolation table: nodes, the number of derivatives requested at each node, and the displayed values for those derivative levels.

The construction rows are D, L, E, U. The denominator ledger D supplies the finite nonzero and confluent data, L supplies the ordinary Lagrange spine, E displays the polynomial coefficient lists for the confluent basis, and U assembles the interpolant and records the degree-bounded comparison.

The structural rows H, C, P, N transport, replay, source, and name only the displayed packet. Since the carrier has no additional coordinate for a host derivative operation, selected Real representative, quotient equality, or completion argument, the listed rows exhaust the local NameCert obligations. □

Theorem 6668.3 (Hermite interpolation jet matching)**.** *Every jet-matching read exported by an accepted* $\mathsf{HermiteInterpolation}^{\uparrow}$ *packet factors through the finite route*

$$X, J, V, D \longmapsto L \longmapsto E \longmapsto U \longmapsto N.$$

The route first verifies the distinct node row and the finite jet-height schedule, then builds the confluent basis from the Lagrange spine inside $\mathsf{Poly}^{\uparrow}$, *evaluates the required formal derivatives at the displayed nodes, assembles the interpolating polynomial, and exposes the local* $\mathsf{NameCert}_{\mathsf{HermiteInterpolation}^{\uparrow}}$ *row. A consumer cannot bypass this route by appealing to ambient smooth functions, an external divided-difference table, quotient polynomial equality, or a Real-completion selector.*

Proof. Start with an accepted packet $K = (X, J, V, D, L, E, U, H, C, P, N)$. The rows X and J determine a finite set of jet positions, and V supplies exactly one displayed value for each such position.

Next inspect D and L. The denominator and confluent-limit ledger makes repeated-node factors explicit, while the Lagrange spine supplies the ordinary interpolation basis from which the confluent basis is built.

Now use E and U. The row E records the finite polynomial coefficient lists whose formal derivatives have the required Kronecker jet pattern, and U forms the finite linear combination using the displayed jet values. The same row records the degree-bounded uniqueness comparison, so a second accepted polynomial with the same jet table has the same displayed coefficient-list read.

Finally transport and replay through H, C, P, N. These rows preserve the same node, jet, denominator, basis, assembly, provenance, and local name. Thus every exported jet-matching read follows the displayed finite route and has no coordinate from which an ambient analytic or completion argument could be read. □

Falsifiable prediction: Every accepted $\mathsf{HermiteInterpolation}^{\uparrow}$ read that claims a Hermite interpolating polynomial factors through finite node rows, jet-height rows, jet-value rows, denominator and confluent-limit ledgers, a $\mathsf{LagrangeInterpolation}^{\uparrow}$ spine, normalized $\mathsf{Poly}^{\uparrow}$ basis rows, assembly and uniqueness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row.

Independence witness: polynomial, lagrange-interpolation, hermite-polynomial, real, regseqrat, dyadicratcore: $\mathsf{HermiteInterpolation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite node rows, finite jet schedules, displayed derivative values, confluent denominator data, a Lagrange spine, confluent polynomial basis rows, jet-matching assembly, uniqueness, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HermiteInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{HermiteInterpolation}^{\uparrow}$ packet is generated from finite node rows, finite jet-height rows, displayed jet-value rows, denominator and confluent-limit ledgers, a Lagrange interpolation spine, normalized polynomial basis rows, jet-matching assembly rows, uniqueness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HermiteInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6668.1, Definition 6668.2, and Definition 6668.3 seed the finite Hermite interpolation carrier, local NameCert obligation surface, and polynomial jet-matching route over displayed nodes, jet schedules, jet values, denominators, confluent basis polynomials, assembly rows, uniqueness rows, transport, replay, provenance, local naming, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HermiteInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ambient smooth-function interpolation, quotient polynomial equality, infinite jet families, selected Real representatives, analytic divided-difference tables, host differentiability oracles, field-completion arguments, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, node distinctness, jet-height finiteness, denominator and confluent-limit routing, Lagrange-spine exposure, confluent basis construction, jet evaluation replay, assembly, uniqueness-row replay, transport, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.HermiteInterpolationUp.

Chapter 6669

A Concrete Naming Certificate for $\mathsf{BirkhoffInterpolation}^{\uparrow}$

Following Birkhoff and de Boor, the $\mathsf{BirkhoffInterpolation}^{\uparrow}$ packet records the finite interpolation route in which only a displayed lacunary subset of derivative conditions is imposed. It sits beside the ordinary node-value route of chapter 4206 and the confluent jet route of chapter 6668; the present carrier names the mask that selects derivative orders rather than requiring every derivative level below a jet height. Its construction consumes the coefficient-list surface of chapter 50, the displayed derivative surface of chapter 122, the finite matrix ledger of chapter 49, and the linear-system route of chapter 48.

The packet is a finite BHist ledger. It displays nodes, a derivative-order mask, the lacunary value table, a polynomial basis, a finite matrix and linear-system ledger, assembly, transport, replay, provenance, and a local $\mathsf{NameCert}$ row before any consumer can read a Birkhoff interpolant. It is not ordinary Lagrange interpolation, because the mask may request derivative rows; it is not confluent Hermite interpolation, because the mask need not contain every lower derivative order at each node.

Definition 6669.1 (Birkhoff interpolation carrier)**.** *A* $\mathsf{BirkhoffInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, M, V, P, A, L, S, H, C, R, N)$$

with the following displayed rows:

1. *X is a finite node row, with pairwise-distinctness data for the displayed nodes.*
2. *M is the derivative-order mask row, recording a finite set of pairs (x_i, k) at which a derivative condition is requested.*
3. *V is the lacunary value table, assigning one scalar value to each selected pair in M.*
4. *P is the polynomial-basis row, displaying the finite* $\mathsf{Poly}^{\uparrow}$ *coefficient lists used for the unknown interpolant.*
5. *A is the finite matrix ledger whose entries are obtained by applying the requested* $\mathsf{Derivative}^{\uparrow}$ *orders from M to the basis row P and evaluating at the nodes X.*
6. *L is the* $\mathsf{LinMap}^{\uparrow}$ *linear-system row, recording the matrix map, right-hand side, solvability witness, and uniqueness witness when the Birkhoff pattern is poised.*

7. *S is the assembly row, transporting the solved coefficient vector back to a* $\mathsf{Poly}^{\uparrow}$ *coefficient list and recording the requested derivative matches against V.*
8. *H records componentwise* hsame *transport for node, mask, value, basis, matrix, linear-system, assembly, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay for derivative evaluation, matrix assembly, linear-system solution, polynomial assembly, and lacunary derivative checking.*
10. *R is the* Pkg *provenance over* $\mathsf{BirkhoffInterpolation}^{\uparrow}$, $\mathsf{LagrangeInterpolation}^{\uparrow}$, $\mathsf{HermiteInterpolation}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BirkhoffInterpolation}^{\uparrow}}$ *row.*

The carrier predicate is $\mathsf{BirkhoffInterpolationLedger}(X, M, V, P, A, L, S, H, C, R, N)$. *Two accepted packets classify together exactly when the eleven displayed rows are transported by H and replay through the same routes named by C and R.*

Lean4 ✓ `BEDC.Derived.BirkhoffInterpolationUp.BirkhoffInterpolationTasteGate single carrier alignment`

Theorem 6669.2 (Birkhoff interpolation NameCert obligations)**.** *For an accepted* $\mathsf{BirkhoffInterpolation}^{\uparrow}$ *packet $B = (X, M, V, P, A, L, S, H, C, R, N)$, the local* $\mathsf{NameCert}_{\mathsf{BirkhoffInterpolation}^{\uparrow}}$ *obligation surface consists exactly of the finite carrier and classifier rows of Definition 6669.1, the node row X, derivative-order mask M, lacunary value table V, polynomial-basis row P, matrix ledger A, linear-system row L, assembly and derivative-match row S, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance R, and the local naming row N. No host differentiability oracle, unstated determinant inverse, quotient polynomial equality, complete Hermite jet table, ordinary Lagrange-only table, or ambient completeness datum is exported.*

Proof. Read the carrier of Definition 6669.1. The rows X, M, V supply the finite interpolation request: nodes, the selected derivative orders, and one displayed value for each selected request.

The construction rows are P, A, L, S. The polynomial-basis row gives coefficient-list unknowns, the matrix row evaluates the selected derivative orders on those basis elements, the linear-system row records solvability and uniqueness for the displayed finite matrix, and the assembly row returns the solved coefficient vector as a polynomial satisfying the lacunary table.

The structural rows H, C, R, N transport, replay, source, and name only this displayed packet. Since the carrier has no further coordinate for a host derivative oracle, determinant inverse outside the matrix ledger, quotient polynomial equality, complete Hermite table, or Lagrange-only interpolation table, the listed rows exhaust the local NameCert obligations. □

Theorem 6669.3 (Birkhoff interpolation lacunary derivative route)**.** *Every derivative-match read exported by an accepted* $\mathsf{BirkhoffInterpolation}^{\uparrow}$ *packet factors through the finite route*

$$X, M, V, P \longmapsto A \longmapsto L \longmapsto S \longmapsto N.$$

The route first displays the node row and derivative-order mask, then evaluates the requested derivative orders against the polynomial basis to form a finite $\mathsf{Mat}^{\uparrow}$ *ledger, solves the displayed* $\mathsf{LinMap}^{\uparrow}$ *system, assembles the polynomial, checks the selected derivative rows against the lacunary value table, and exposes the local* $\mathsf{NameCert}_{\mathsf{BirkhoffInterpolation}^{\uparrow}}$ *row. A consumer cannot replace this route with ordinary Lagrange interpolation, a full Hermite jet table, an ambient smooth-function argument, or an unstated matrix inverse.*

Proof. Start with an accepted packet $B = (X, M, V, P, A, L, S, H, C, R, N)$. The mask row M determines exactly which derivative requests are visible, and V supplies values only for those selected requests.

Next inspect P and A. The basis row is a finite $\mathsf{Poly}^{\uparrow}$ coefficient-list row, and A is obtained by applying the displayed $\mathsf{Derivative}^{\uparrow}$ orders from M to that basis and evaluating at the nodes in X.

Use the linear-system row L and assembly row S. The solved finite system supplies the coefficient vector, while S repacks it as a polynomial and checks precisely the derivative rows selected by M.

Finally transport and replay through H, C, R, N. These rows preserve the same node, mask, value, basis, matrix, linear-system, assembly, provenance, and local name, so every exported lacunary derivative read follows the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{BirkhoffInterpolation}^{\uparrow}$ read that claims a Birkhoff interpolating polynomial factors through finite node rows, derivative-order mask rows, lacunary value rows, polynomial-basis rows, finite $\mathsf{Mat}^{\uparrow}$ ledgers, $\mathsf{LinMap}^{\uparrow}$ solution rows, assembly rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row.

Independence witness: lagrange-interpolation, hermite-interpolation, polynomial, derivative, matrix, linearmap: $\mathsf{BirkhoffInterpolation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite node data, a lacunary derivative-order mask, selected derivative values, polynomial basis rows, a derivative-evaluation matrix, a linear-system ledger, assembly, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{BirkhoffInterpolation}^{\uparrow}$ packet is generated from finite node rows, derivative-order mask rows, lacunary value rows, polynomial-basis rows, finite derivative-evaluation matrix rows, linear-system rows, assembly rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6669.1, Definition 6669.2, and Definition 6669.3 seed the finite Birkhoff interpolation carrier, local NameCert obligation surface, and lacunary derivative route over displayed nodes, masks, values, basis polynomials, matrix ledgers, linear-system rows, assembly rows, transport, replay, provenance, local naming, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ordinary Lagrange-only interpolation, complete Hermite jet interpolation, host differentiability oracles, unstated determinant inverses, quotient polynomial equality, selected Real representatives, field-completion arguments, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, node distinctness, mask finiteness, lacunary value exposure, polynomial basis construction, derivative-evaluation matrix routing, linear-system solution rows, assembly, lacunary derivative replay, transport, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.BirkhoffInterpolationUp.

Chapter 6670

A Concrete Naming Certificate for $\mathsf{BaireDenseOpen}^{\uparrow}$

Following Baire and Bishop–Bridges, the $\mathsf{BaireDenseOpen}^{\uparrow}$ packet records the finite dense-open schedule that a constructive Baire-category argument may inspect before any generic-point or residual-set conclusion is asserted. It sits beside the Baire metric carrier of chapter 1602, the complete-metric handoff of chapter 128, the topology carrier of chapter 88, the stream-window interface of chapter 126, and the regular rational readback of chapter 301. The packet names dense-open requests, finite complete-metric windows, StreamName schedules, RegSeqRat readbacks, transport, replay, provenance, and local naming; it does not choose a generic point, take an ambient countable intersection, or import open-cover compactness.

Definition 6670.1 (Baire dense-open schedule carrier)**.** *A* $\mathsf{BaireDenseOpen}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, W, S, R, T, C, H, P, N)$$

with the following displayed rows:

1. *D is the dense-open request row, recording the finite list of open predicates, dense-witness obligations, and inspected refinement indices.*
2. *W is the complete-metric window row, recording the displayed ball, radius, refinement, and nonempty-witness data available from* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{BaireMetric}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row controlling which dense-open requests and complete-metric windows may be inspected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational radii, shrinkage witnesses, and tolerance comparisons attached to W.*
5. *T is the topology row, recording that each inspected dense-open request is read through the displayed* $\mathsf{Topology}^{\uparrow}$ *basis and not through an ambient host set.*
6. *C records displayed* Cont *replay from D, S to W, from W to R, and from T to the local dense-open read.*
7. *H records componentwise* hsame *transport for dense-open rows, complete-metric windows, schedules, rational readback, topology rows, replay, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{BaireDenseOpen}^{\uparrow}$*,* $\mathsf{BaireMetric}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BaireDenseOpen}^\uparrow}$ *row.*

The classifier compares accepted packets only through $D, W, S, R, T, C, H, P, N$. It has no coordinate for a choice-selected generic point, a completed residual set, open-cover compactness, quotient equality of names, or ambient completeness beyond the displayed complete-metric windows.

Theorem 6670.2 (Baire dense-open schedule obligation surface)**.** *For every accepted* $\mathsf{BaireDenseOpen}^\uparrow$ *carrier $G = (D, W, S, R, T, C, H, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireDenseOpen}^\uparrow}$ *surface consists exactly of five finite rows:*

1. *dense-open request admission through D, including the displayed open rows, dense-witness obligations, and inspected refinement indices;*
2. *complete-metric window admission through W, with BaireMetric and CompleteMetric radii exposed before any schedule read is consumed;*
3. *finite observation scheduling through S and rational readback through R, so every inspected radius and shrinkage claim is replayed through StreamName and RegSeqRat rows;*
4. *topology and replay compatibility through T, C, H, preserving the same dense-open and window rows under* Cont *replay and componentwise* hsame *transport;*
5. *provenance and local naming through P, N, attaching the packet to the BaireMetric, CompleteMetric, Topology, StreamName, and RegSeqRat sources named in this chapter.*

The surface explicitly refuses a choice-selected generic point, open-cover compactness, quotient equality of names, and ambient completeness not already displayed in the complete-metric window row.

Proof. Project the carrier of Definition 6670.1. The dense-open row D and complete-metric window row W are the only mathematical rows visible before replay, so a consumer must name the inspected open predicates and the corresponding finite metric windows.

Next read the schedule and rational rows. The $\mathsf{StreamName}^\uparrow$ schedule S determines which entries of D and W are inspected, while the $\mathsf{RegSeqRat}^\uparrow$ row R records the rational radius and shrinkage readback for those entries.

Finally apply the topology, transport, replay, provenance, and local naming rows T, C, H, P, N. These rows preserve the displayed packet and do not add a selector, a host intersection, quotient equality, or an ambient completeness theorem. The five listed rows therefore exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{BaireDenseOpen}^\uparrow$ read exposes a finite dense-open schedule, complete-metric window row, StreamName schedule, and RegSeqRat readback before any Baire-category consumer may cite the packet.

Independence witness: bairemetric, completemetric, topology, streamname, regseqrat: $\mathsf{BaireDenseOpen}^\uparrow$ is not bijective to any listed sibling because it jointly carries dense-open request rows, complete-metric window rows, schedule rows, rational readback, topology replay, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireDenseOpen}^\uparrow}$**.**

Constructive story: A $\mathsf{BaireDenseOpen}^\uparrow$ packet is generated from finite dense-open request rows, complete-metric window rows, StreamName schedules, RegSeqRat rational readback, topology replay, componentwise transport, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireDenseOpen}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 6670.1 and Definition 6670.2 seed the finite dense-open schedule surface over displayed BaireMetric, CompleteMetric, Topology, StreamName, RegSeqRat, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BaireDenseOpen}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close choice-selected generic points, open-cover compactness, quotient equality of names, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open row exactness, complete-metric window stability, StreamName schedule replay, RegSeqRat readback, topology compatibility, and local NameCert rows for BEDC.Derived.BaireDenseOpenUp.

Chapter 6671

A Concrete Naming Certificate for $\mathsf{KKMFiniteCover}^{\uparrow}$

Following Knaster, Kuratowski, and Mazurkiewicz, the $\mathsf{KKMFiniteCover}^{\uparrow}$ packet records the finite simplex-cover boundary used in the KKM lemma as displayed NameCert data. It sits beside the finite labelled-simplex route of chapter 2003, the convex-set carrier of chapter 208, the compactness surface of chapter 60, the continuous-map rows of chapter 130, and the simplicial approximation route of chapter 3402. The packet names only finite face-cover ledgers, classifier rows, transport, replay, provenance, and local naming; it does not assert arbitrary open-cover compactness, nonconstructive point selection, quotient closed-set equality, or host topological completeness.

Definition 6671.1 (KKM finite-cover carrier)**.** *A* $\mathsf{KKMFiniteCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, F, V, L, C_0, A, T, R, P, N)$$

with the following displayed rows:

1. *S is the finite simplex inventory row, read through the same finite-face surface used by* $\mathsf{SpernerLemma}^{\uparrow}$ *and* $\mathsf{SimplicialApproximation}^{\uparrow}$*.*
2. *F is the face-incidence ledger: each row names a face of the simplex and the finite set of vertices spanning that face.*
3. *V is the vertex-indexed cover row assigning to each displayed vertex a cover cell row.*
4. *L is the face-preserving classifier row, asserting that every displayed face is covered by the cells indexed by its own vertices.*
5. *C_0 is the* $\mathsf{ConvexSet}^{\uparrow}$ *support row for the carried simplex and its face hulls.*
6. *A is the* $\mathsf{Compact}^{\uparrow}$ *finite-subcover support row for the displayed simplex boundary.*
7. *T is the* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{SimplicialApproximation}^{\uparrow}$ *handoff row used when a consumer reads the cover through a subdivision or approximation route.*
8. *R is the* $\mathsf{SpernerLemma}^{\uparrow}$ *readback row converting the face-preserving cover classifier into the labelled-simplex obstruction route.*
9. *P is the* Pkg *provenance over* $\mathsf{KKMFiniteCover}^{\uparrow}$*,* $\mathsf{SpernerLemma}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{SimplicialApproximation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KKMFiniteCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary open cover, a selected point in an intersection, quotient equality of closed sets, countable choice, or ambient compactness outside the displayed finite simplex rows.

Theorem 6671.2 (KKM finite-cover NameCert obligations)**.** *For every accepted* $\mathsf{KKMFiniteCover}^{\uparrow}$ *carrier* $K = (S, F, V, L, C_0, A, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KKMFiniteCover}^{\uparrow}}$ *surface consists exactly of finite simplex admission, face-incidence exactness, vertex-cover row admission, face-preserving classifier stability, convex-face support, compact finite-boundary support, continuous or simplicial approximation handoff, Sperner readback, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Thus every finite-cover obligation factors through*

$$\mathsf{SpernerLemma}^{\uparrow}, \quad \mathsf{ConvexSet}^{\uparrow}, \quad \mathsf{Compact}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{SimplicialApproximation}^{\uparrow}.$$

No obligation is discharged by nonconstructive selection, arbitrary open-cover compactness, quotient cover equality, countable choice, or a host intersection theorem.

Proof. Project the carrier. The finite simplex and face-incidence rows S, F determine the only faces visible to the packet, while V, L record the vertex-indexed cover cells and the face-preserving classifier over those same rows.

Use the convex and compact support rows. The $\mathsf{ConvexSet}^{\uparrow}$ row C_0 supplies the finite face-hull surface, and the $\mathsf{Compact}^{\uparrow}$ row A supplies only the displayed finite-boundary support; neither row introduces arbitrary open-cover compactness or selected intersection points.

Route consumers through the finite topology dependencies. The $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{SimplicialApproximation}^{\uparrow}$ row T exposes subdivision or approximation reads, and the $\mathsf{SpernerLemma}^{\uparrow}$ row R supplies the labelled-simplex obstruction route already isolated by chapter 2003.

Finally preserve the packet through P, N and the displayed structural rows. Componentwise hsame transport and Cont replay keep the cover classifier attached to the same finite face ledger, so every admitted NameCert read factors through the named sibling certificates and no stronger compactness or selection principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{KKMFiniteCover}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KKMFiniteCover}^{\uparrow}$ packet is generated from a finite simplex inventory, face-incidence ledger, vertex-indexed cover rows, a face-preserving classifier, ConvexSetUp support, CompactUp finite-boundary support, ContinuousMapUp and SimplicialApproximationUp handoff rows, SpernerLemmaUp readback, structural transport, replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KKMFiniteCover}^{\uparrow}}$, seed)

Scope closed: Definition 6671.1 and Definition 6671.2 seed the finite KKM cover route through SpernerLemmaUp, ConvexSetUp, CompactUp, ContinuousMapUp, SimplicialApproximationUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KKMFiniteCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, nonconstructive selection of an intersection point, quotient cover equality, countable choice, or a checked Lean certificate for the KKM packet.

Upgrade path: Obligation closure requires checked carrier admission, face-preserving classifier stability, finite-cover handoff, Sperner readback, structural replay, provenance exhaustion, and local naming for the same packet.

Chapter 6672

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$ packet records the finite tail-collapse surface used when a regular Cauchy rational name is read only through sufficiently late windows. It sits over the finite observation service of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the paired-tail uniqueness packet of chapter 3942. The packet supplies Real and completion routes with displayed tail-collapse data; it does not identify quotient streams, select host limits, invoke countable choice, use trichotomy, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6672.1 (Regular Cauchy tail-collapse carrier)**.** *A* $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, S, D, W, Q, U, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name whose late tail is being collapsed.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule exposing the finite tail windows used by the collapse request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the displayed scale and the finite tail threshold.*
4. *W is the selected finite tail window after the threshold named by D.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the collapsed tail data.*
6. *U is the* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *sibling row used only to compare paired tail windows after the same dyadic threshold has been displayed.*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row exposed after R, S, D, W, Q, U have been read.*
8. *H records componentwise* hsame *transport for the source name, schedule, dyadic threshold, tail window, readback, uniqueness sibling row, seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay for any Real or completion consumer through the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailCollapse}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, S, D, W, Q, U, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCollapseUp.RegularCauchyTailCollapseTasteGate single carrier alignment`

Theorem 6672.2 (Regular Cauchy tail-collapse NameCert obligations)**.** *For every accepted* RegularCauchyTailColla *carrier $T = (R, S, D, W, Q, U, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailCollapse}^{\uparrow}}$ *surface consists exactly of source* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold accounting, collapsed-tail* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *paired-tail witness, the downstream* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier through Definition 6672.1. The analytic rows are R, S, D, W, Q, U, E: the source regular name, the displayed schedule, the dyadic threshold, the finite tail window, the collapsed regular readback, the paired-tail uniqueness witness, and the terminal Real-facing seal.

The structural rows are H, C, P, N. They transport, replay, source, and name the same finite route, so the certificate surface has no remaining coordinate from which a quotient stream equality, selected host limit, choice schedule, trichotomy decision, or ambient completeness principle could be read. □

Theorem 6672.3 (Regular Cauchy tail-collapse handoff)**.** *Every Real or completion consumer of an accepted* $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow} + \mathsf{DyadicRatCore}^{\uparrow} + \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchyLimitUniqueness}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $S, D, R, W, Q, U, E, H, C, P, N$. The handoff therefore supplies RegSeqRat and RealUp completion arguments with a named tail-collapse packet while refusing quotient stream equality, selected limits, countable choice, trichotomy, and ambient Real completeness.

Proof. Begin with a consumer request. The schedule row S and tolerance row D display the finite threshold before any late tail entries are available, and the window row W records exactly the exposed tail segment.

Read the regular rational data through R and Q. The source name and collapsed-tail readback are both $\mathsf{RegSeqRat}^{\uparrow}$ rows, so no host stream quotient or selected limit is introduced at this stage.

Use the sibling $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ row U only after the same threshold and window have been displayed. The route can then expose the $\mathsf{Real}^{\uparrow}$ seal row E, and H, C, P, N preserve, replay, source, and name that finite packet for downstream Real and completion routes. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$ consumer read factors through a StreamName schedule, DyadicRatCore threshold ledger, RegSeqRat source row, finite tail window, collapsed RegSeqRat readback, RegularCauchyLimitUniqueness paired-tail witness, RealUp seal, transport, replay, provenance, and local NameCert row.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-limit-uniqueness: $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source regular name, finite tail schedule, displayed dyadic threshold, collapsed readback, paired-tail uniqueness witness, Real seal boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailCollapse}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailCollapse}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName tail schedule, DyadicRatCore threshold ledger, finite tail window, collapsed RegSeqRat readback, RegularCauchyLimitUniqueness paired-tail witness, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailCollapse}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6672.1, Definition 6672.2, and Definition 6672.3 seed the finite tail-collapse route consumed by RegSeqRat and RealUp completion arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailCollapse}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold accounting, collapsed-tail readback, paired-tail uniqueness handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailColla

Chapter 6673

A Concrete Naming Certificate for $\mathsf{SuslinTree}^{\uparrow}$

Following Suslin's tree problem and standard set-theoretic order theory, the $\mathsf{SuslinTree}^{\uparrow}$ packet records the visible order-theoretic surface of a height-ω_1 tree with no displayed uncountable chain and no displayed uncountable antichain. It sits beside the $\mathsf{AronszajnTree}^{\uparrow}$ obstruction of chapter 6341, the $\mathsf{Tree}^{\uparrow}$ source of chapter 119, the $\mathsf{POSet}^{\uparrow}$ comparison surface of chapter 53, the unary $\mathsf{Order}^{\uparrow}$ read of chapter 1378, the membership discipline of chapter 111, and the ordinal-analysis ledger of chapter 6247. The packet names the finite BEDC route through tree source, partial-order comparison, level accounting, chain-boundary refusal, antichain-boundary refusal, transport, replay, provenance, and local naming; it does not assert Suslin's hypothesis, construct a Suslin tree in any host universe, choose a club, or decide independence from the usual axioms of set theory.

Definition 6673.1 (Suslin tree carrier)**.** *A* $\mathsf{SuslinTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, O, L, C, A, H, K, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Tree}^{\uparrow}$ *source row, naming the tree nodes, predecessor route, root discipline, and displayed level map.*
2. *O is the* $\mathsf{POSet}^{\uparrow}$ *and* $\mathsf{Order}^{\uparrow}$ *comparison row, recording the tree order as a partial-order read with finite predecessor comparison data.*
3. *L is the level-accounting row, exposing the countable displayed levels and the ordinal-height interface used by* $\mathsf{OrdinalAnalysis}^{\uparrow}$*.*
4. *C is the chain-boundary row, recording that no displayed uncountable chain route is exported by the packet.*
5. *A is the antichain-boundary row, recording that no displayed uncountable antichain route is exported by the packet.*
6. *H stores componentwise* hsame *transport for the tree source, order comparison, level ledger, chain boundary, antichain boundary, continuation, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from order and level requests through T, O, L, C, A.*
8. *P is the* Pkg *provenance over* $\mathsf{SuslinTree}^{\uparrow}$*,* $\mathsf{AronszajnTree}^{\uparrow}$*,* $\mathsf{Tree}^{\uparrow}$*,* $\mathsf{POSet}^{\uparrow}$*,* $\mathsf{Order}^{\uparrow}$*,* $\mathsf{Set}^{\uparrow}$*,* $\mathsf{OrdinalAnalysis}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{SuslinTree}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $T, O, L, C, A, H, K, P, N$. It has no coordinate for a host construction of ω_1, a selected club, a forcing extension, a proof or refutation of Suslin's hypothesis, Kurepa splitting, a maximal antichain selector, or a detached set-theoretic universe.

Theorem 6673.2 (Suslin tree NameCert obligations)**.** *For every accepted* $\mathsf{SuslinTree}^{\uparrow}$ *carrier $S = (T, O, L, C, A, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SuslinTree}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tree source, order comparison, level ledger, chain boundary, antichain boundary, transport, replay, provenance, and local naming rows; tree-source visibility through T; partial-order and unary-order visibility through O; level accounting through L; chain and antichain boundary visibility through C, A; componentwise transport through H; displayed continuation through K; package provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6673.1. The accepted inventory is exactly $T, O, L, C, A, H, K, P, N$, so every consumer must read the tree source, order comparison, level ledger, and two boundary rows before the local name is available.

The sibling anchors supply only their displayed surfaces. The Aronszajn-tree chapter chapter 6341 supplies the height-ω_1 branch-boundary comparison, while the tree, poset, order, set, and ordinal-analysis chapters supply source, comparison, membership, and level-accounting rows.

Rows H, K, P, N preserve and replay that same finite route. Since no carrier coordinate names a host universe, forcing construction, selected club, maximal antichain selector, or decision of Suslin's hypothesis, none of those endpoints can be exported by the NameCert obligations. □

Theorem 6673.3 (Suslin tree chain–antichain boundary)**.** *Every order, set, or ordinal-analysis consumer of an accepted* $\mathsf{SuslinTree}^{\uparrow}$ *carrier must read both boundary rows*

$$C, A$$

after the displayed tree source, partial-order comparison, and level ledger rows T, O, L. The row C blocks an exported uncountable chain route, and the row A blocks an exported uncountable antichain route. The packet therefore records the Suslin-tree chain–antichain boundary as finite NameCert data beside $\mathsf{AronszajnTree}^{\uparrow}$*, without deciding Suslin's hypothesis, constructing a host Suslin tree, choosing a club, selecting a maximal antichain, or importing a detached set-theoretic universe.*

Proof. Start with Definition 6673.2. It requires the source row T, the order row O, and the level row L before either boundary can be read.

Read the two boundary rows separately. The chain boundary C refuses an exported uncountable branch or chain route, while the antichain boundary A refuses an exported uncountable antichain route. Keeping both rows visible is what distinguishes the Suslin-tree packet from the sibling $\mathsf{AronszajnTree}^{\uparrow}$ route.

Finally apply the structural rows of Definition 6673.1. Transport, replay, provenance, and local naming preserve only the displayed boundary packet. They cannot add a host construction, force a set-theoretic decision, choose a club, select a maximal antichain, or import any detached universe data. □

Falsifiable prediction: Every accepted $\mathsf{SuslinTree}^{\uparrow}$ order-facing read factors through a TreeUp source row, POSetUp and OrderUp comparison row, level-accounting row, chain-boundary row, antichain-boundary row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: aronszajn-tree, tree, poset, order, set, ordinal-analysis: $\mathsf{SuslinTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a tree source, order comparison, level ledger, no-uncountable-chain boundary, no-uncountable-antichain boundary, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SuslinTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SuslinTree}^{\uparrow}$ packet is generated from a displayed TreeUp source, POSetUp and OrderUp comparison row, level-accounting ledger, chain-boundary row, antichain-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SuslinTree}^{\uparrow}}$, seed)

Scope closed: Definition 6673.1, Definition 6673.2, and Definition 6673.3 seed the finite Suslin-tree order-boundary packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SuslinTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, Suslin's hypothesis, host construction of a Suslin tree, forcing independence, club selection, maximal antichain selection, or ambient set-theoretic completeness.

Upgrade path: Obligation closure requires checked carrier admission, tree-source discipline, order-comparison exactness, level-ledger visibility, chain-boundary nonescape, antichain-boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SuslinTreeUp.

Chapter 6674

A Concrete Naming Certificate for $\mathsf{TaylorPolynomial}^{\uparrow}$

Following Taylor's classical finite polynomial approximation in differential calculus, the $\mathsf{TaylorPolynomial}^{\uparrow}$ packet records the finite jet-to-polynomial object used between derivative observations and theorem-facing Taylor estimates. It sits beside the real-name boundary of chapter 38, the polynomial carrier of chapter 50, the derivative observation row of chapter 122, the calculus substrate of chapter 3632, and the Taylor theorem route of chapter 5898. The packet names a finite Taylor polynomial certificate for one displayed center, order, coefficient ledger, polynomial assembly row, and evaluation handoff; it does not import a host smooth-function space, analytic convergence, quotient equality of real functions, or an infinite Taylor series.

Definition 6674.1 (Taylor polynomial carrier)**.** *A* $\mathsf{TaylorPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (c, k, D, J, P, V, Q, E, H, C, G, N)$$

with the following displayed rows:

1. *c is the named* $\mathsf{Real}^{\uparrow}$ *center row and k is the finite order row.*
2. *D is the* $\mathsf{Derivative}^{\uparrow}$ *observation row naming exactly the derivative data used for orders at most k.*
3. *J is the finite jet ledger. Each coefficient row cites c, k, D and the dyadic rational arithmetic used to normalize the displayed derivative read.*
4. *P is the* $\mathsf{Poly}^{\uparrow}$ *assembly row whose coefficients are exactly the rows of J.*
5. *V is the finite evaluation handoff. It records the polynomial value requests, the local displacement from c, and the coefficient rows of P consumed by each request.*
6. *Q lists the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for coefficients, displacements, and finite polynomial values.*
7. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seals for the center, coefficient reads, and polynomial values.*
8. *H records componentwise* hsame *transport for the center, order, derivative source, jet ledger, polynomial assembly, evaluation handoff, readback rows, endpoint seals, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from every Taylor-polynomial read through $c, k, D, J, P, V, Q, E, H, G, N$.*

10. *G is the* Pkg *provenance over* $\mathsf{TaylorPolynomial}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TaylorPolynomial}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $c, k, D, J, P, V, Q, E, H, C, G, N$. It has no coordinate for a host function, an infinite Taylor series, analytic convergence, quotient equality of functions, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TaylorPolynomialUp.TaylorPolynomialTasteGate single carrier alignment`

Theorem 6674.2 (Taylor polynomial NameCert obligations)**.** *For every accepted* $\mathsf{TaylorPolynomial}^{\uparrow}$ *carrier*

$$T = (c, k, D, J, P, V, Q, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{TaylorPolynomial}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed center, finite order, derivative source, jet ledger, polynomial assembly, evaluation handoff, readback rows, endpoint seals, transport, replay, provenance, and local naming rows;*
2. *derivative-to-coefficient routing, requiring every coefficient in J to cite the* $\mathsf{Derivative}^{\uparrow}$ *row D at the center c and finite order k;*
3. *polynomial assembly exactness, requiring P to use exactly the coefficient rows displayed in J and no hidden host polynomial;*
4. *evaluation handoff exactness, requiring every row of V to consume only the displayed displacement from c, the assembled polynomial row P, and finite coefficient arithmetic;*
5. *regular and real readback, requiring Q to expose regular rational reads before the terminal* $\mathsf{Real}^{\uparrow}$ *seals in E are consumed;*
6. *structural stability, requiring H, C, G, N to transport, replay, source, and name only the rows already listed.*

No $\mathsf{TaylorPolynomial}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 6674.1. The theorem-facing rows are exactly c, k, D, J, P, V, Q, E, and the structural rows are exactly H, C, G, N.

The coefficient route is finite. Each row of J is attached to the displayed derivative source D, the center c, and the finite order k, so a coefficient consumer cannot replace it by a host smooth-function expansion or by an infinite Taylor series.

The polynomial and evaluation rows are then forced. The row P assembles precisely the listed coefficient ledger J, while V reads finite polynomial values from P and the displayed displacement from c.

Finally Q, E, H, C, G, N seal the route. Regular rational readback precedes the terminal real seals, and transport, replay, provenance, and local naming preserve exactly the same finite packet. Since no carrier coordinate names analytic convergence, quotient function equality, selected limits, or ambient real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6674.3 (Taylor polynomial jet route)**.** *Every accepted* $\mathsf{TaylorPolynomial}^{\uparrow}$ *carrier exports a coefficient only through the finite route*

$$\mathsf{Calculus}^{\uparrow}, \mathsf{Derivative}^{\uparrow} \longmapsto J \longmapsto \mathsf{Poly}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More precisely, a consumer must first read the center c, finite order k, derivative row D, jet ledger J, polynomial row P, readback row Q, endpoint seals E, transport H, replay C, provenance G, and local naming row N before it may consume a displayed Taylor coefficient. The export is a finite jet read, not a host differentiability theorem, analytic convergence claim, quotient equality of functions, selected limit, or ambient real-completeness row.

Proof. Start with an accepted carrier $T = (c, k, D, J, P, V, Q, E, H, C, G, N)$. The only derivative source is D, and the order bound is the displayed finite row k.

Read the coefficient ledger J. Each coefficient row is already tied to c, k, D and to finite dyadic arithmetic, so the route stays inside the displayed calculus and derivative surface.

Then pass through P, Q, E, H, C, G, N. The assembled polynomial records the same finite ledger, regular rational readback exposes coefficient data before real sealing, and the structural rows preserve the packet. Therefore every coefficient export factors through the stated finite route. □

Theorem 6674.4 (Taylor polynomial polynomial handoff)**.** *Every accepted* $\mathsf{TaylorPolynomial}^{\uparrow}$ *carrier hands a polynomial value to downstream calculus or Taylor-theorem consumers only through the displayed rows*

$$c, k, D, J, P, V, Q, E, H, C, G, N.$$

The handoff exports a finite $\mathsf{Poly}^{\uparrow}$ *object with named center, finite order, coefficient ledger, evaluation requests, regular rational readbacks, and terminal real seals. It does not export a Taylor theorem remainder, analytic convergence, a selected germ, quotient equality of functions, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the assembled polynomial row P from the accepted carrier. By Definition 6674.2, that row is assembled only from the displayed jet ledger J, and J is routed through the finite derivative source D at c and order k.

Next read the evaluation handoff V and the readback rows Q, E. Each value request consumes the polynomial row and the displayed displacement from the center, then passes through regular rational readback before any terminal real seal is visible.

The remaining rows H, C, G, N transport, replay, source, and name the same packet. Since the carrier contains no remainder row, analytic convergence row, selected germ, quotient function equality, countable-choice row, or ambient real-completeness row, every downstream polynomial handoff is exhausted by the displayed finite data. □

Falsifiable prediction: Every accepted $\mathsf{TaylorPolynomial}^{\uparrow}$ coefficient or value read factors through a displayed center, finite order, DerivativeUp source, finite jet ledger, PolynomialUp assembly row, evaluation handoff, RegSeqRat readback, Real endpoint seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: real, polynomial, derivative, calculus, taylor-theorem: $\mathsf{TaylorPolynomial}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds one center, one finite order, derivative observations, a coefficient ledger, a polynomial assembly row, evaluation requests, readback rows, endpoint seals, transport, replay, provenance, and local naming in one finite-jet certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{TaylorPolynomial}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TaylorPolynomial}^{\uparrow}$ packet is generated from a displayed $\mathsf{Real}^{\uparrow}$ center, finite order, $\mathsf{Derivative}^{\uparrow}$ source over the $\mathsf{Calculus}^{\uparrow}$ substrate, finite coefficient ledger, $\mathsf{Poly}^{\uparrow}$ assembly row, evaluation handoff, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{Real}^{\uparrow}$ endpoint seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{TaylorPolynomial}\uparrow}$, seed)

Scope closed: Definition 6674.1, Definition 6674.2, Definition 6674.3, and Definition 6674.4 seed the finite Taylor-polynomial route from derivative observations to polynomial coefficients and value handoffs.

Formal verification: FormalStatus(NameCert$_{\mathsf{TaylorPolynomial}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Taylor theorem remainders, analytic convergence, selected germs, quotient equality of functions, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-to-coefficient routing, polynomial assembly exactness, evaluation handoff exactness, regular and real readback, transport and replay stability, and nonescape for BEDC.Derived.TaylorPolynomialUp.

Chapter 6675

A Concrete Naming Certificate for $\mathsf{FiniteDisjunctionStabilization}^{\uparrow}$

Following Bishop and Bridges/Troelstra constructive analysis, the $\mathsf{FiniteDisjunctionStabilization}^{\uparrow}$ packet records the finite boundary object used when an inspected real-name route stabilizes a bounded disjunction without importing LLPO, WLPO, Markov principle, trichotomy, or quotient real equality. It sits beside the Ishihara route of chapter 1665, the boundary packets of chapter 1978 and chapter 1666, the lower-cut surface of chapter 6657, the finite window route of chapter 126, the regular readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a reviewable finite branch window for real-boundary consumers; it does not choose a branch by a semi-classical principle.

Definition 6675.1 (FiniteDisjunctionStabilization carrier)**.** *A* $\mathsf{FiniteDisjunctionStabilization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite branch-window row. It names the bounded disjunction entries and the displayed inspection depth.*
2. *I is the* $\mathsf{IshiharaTrick}^{\uparrow}$ *inspection row, read only as a finite route over the displayed branch window.*
3. *L is the lower-cut evidence row supplied through* $\mathsf{SemiDecidableRealCut}^{\uparrow}$*.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling the finite comparison scale.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row exposing the requested real-name windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row attached to the displayed windows and dyadic tolerance.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after B, I, L, D, W, R have been replayed.*
8. *H records componentwise* hsame *transport for branch windows, Ishihara inspection, lower-cut evidence, dyadic tolerance, stream schedule, regular readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the branch window, inspection row, lower-cut row, tolerance row, schedule row, readback row, and Real seal.*

10. *P is the* Pkg *provenance over* FiniteDisjunctionStabilization$^{\uparrow}$, IshiharaTrick$^{\uparrow}$, LLPOBoundary$^{\uparrow}$, MarkovPrincipleBoundary$^{\uparrow}$, SemiDecidableRealCut$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{FiniteDisjunctionStabilization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, I, L, D, W, R, E, H, C, P, N$. It has no coordinate for LLPO, WLPO, Markov principle as an axiom, trichotomy, quotient real equality, selected limits, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6675.2 (FiniteDisjunctionStabilization NameCert obligations)**.** *For every accepted* FiniteDisjunctionStab *carrier $S = (B, I, L, D, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{FiniteDisjunctionStabilization}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite branch window, Ishihara inspection, lower-cut evidence, dyadic tolerance, stream schedule, regular readback, Real seal, componentwise transport, displayed replay, provenance, and local naming rows; branch-window stability under* hsame*; replay order through C; provenance through P; and the refusal of semi-classical branch selection outside the displayed finite rows.*

Proof. Project the carrier of Definition 6675.1. The analytic rows are B, I, L, D, W, R, E, and the structural rows are H, C, P, N.

The replay row C forces every read to begin with the finite branch window before it reaches Ishihara inspection, lower-cut evidence, dyadic tolerance, stream windows, regular readback, and the Real seal. Transport by H preserves exactly that order under classifier movement.

The provenance row P names the sibling boundaries only as sources for the displayed route. Since the carrier contains no independent branch selector, excluded-middle row, quotient real equality row, selected limit, choice selector, or completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 6675.3 (FiniteDisjunctionStabilization branch window)**.** *Every accepted* FiniteDisjunctionStabilization$^{\uparrow}$ *read factors through the finite branch window B before any Ishihara inspection, lower-cut evidence, dyadic tolerance, stream schedule, regular readback, or Real seal is visible. Thus a consumer may stabilize only the displayed finite disjunction window, not an unbounded search over real names.*

Proof. Start from a consumer request. Carrier admission exposes B as the unique branch-window coordinate, and the continuation row C places it before I, L, D, W, R, E.

The Ishihara row I is therefore read as an inspection of the displayed finite window, while L, D, W, R supply only the lower-cut, tolerance, schedule, and readback rows needed to make that window meaningful at the requested scale.

Since the Real seal E appears after those rows, no consumer can bypass the finite window by asking for quotient real equality, trichotomy, selected limits, or Real$^{\uparrow}$ completeness. □

Theorem 6675.4 (FiniteDisjunctionStabilization real-boundary route)**.** *Every Real-facing consumer of an accepted* FiniteDisjunctionStabilization$^{\uparrow}$ *carrier must read the route*

$$B, I, L, D, W, R \longmapsto E \longmapsto H, C, P, N.$$

The boundary exported to Real and completion-facing chapters is a finite stabilization certificate over displayed cuts, dyadic tolerances, stream windows, and regular readback; it is not LLPO, WLPO, Markov principle as an axiom, trichotomy, quotient real equality, a selected limit, countable choice, or Real$^{\uparrow}$ *completeness.*

Proof. Read the branch-window theorem first. It confines the request to the displayed finite disjunction window and its Ishihara inspection row.

Next attach the lower-cut and dyadic rows. The lower-cut evidence L and tolerance row D determine which finite stream windows W and regular readback rows R may be inspected before the Real seal is visible.

Finally replay the Real-facing route through E, H, C, P, N. The seal records that the displayed finite route is available to downstream consumers; it does not add a semi-classical principle or any ambient completeness object. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDisjunctionStabilization}^{\uparrow}$ read factors through a finite branch window, Ishihara inspection row, semi-decidable lower-cut evidence, DyadicRatCore tolerance, StreamName schedule, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: ishihara-trick, llpo-boundary, markov-principle-boundary, semi-decidable-real-cut, streamname, regseqrat, dyadicratcore, real: $\mathsf{FiniteDisjunctionStabilization}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite branch-window stabilization, real-boundary inspection, lower-cut evidence, dyadic tolerance, stream and regular readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDisjunctionStabilization}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDisjunctionStabilization}^{\uparrow}$ packet is generated from a finite branch window, Ishihara inspection row, semi-decidable lower-cut evidence, DyadicRatCore tolerance row, StreamName schedule, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDisjunctionStabilization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6675.1, Definition 6675.2, Definition 6675.3, and Definition 6675.4 seed the finite real-boundary route for disjunction stabilization.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDisjunctionStabilization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close LLPO, WLPO, Markov principle as an axiom, trichotomy, quotient real equality, selected limits, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch-window stability, Ishihara inspection routing, lower-cut and dyadic tolerance accounting, stream and regular readback, Real-seal nonescape, and structural replay for BEDC.Derived.FiniteDisjunctionStabilizationUp.

Chapter 6676

A Concrete Naming Certificate for $\mathsf{CompactGridModulusExtraction}^{\uparrow}$

Following Bishop-style compact metric finite-net arguments, the $\mathsf{CompactGridModulusExtraction}^{\uparrow}$ packet realizes the compact-grid route of chapter 9237 as finite NameCert data. It sits beside compact metric coverage in chapter 129, continuous-map pointwise control in chapter 130, the uniform-modulus consumer of chapter 369, the dyadic tolerance ledger of chapter 291, rational lower-bound readback in chapter 37, and the terminal real-name seal of chapter 38. The packet records a finite compact-net grid and modulus extraction boundary without importing open-cover compactness, selected subcovers, countable choice, or ambient real completeness.

Definition 6676.1 (Compact grid modulus extraction carrier)**.** *A* $\mathsf{CompactGridModulusExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, D, Q, M, U, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including the displayed grid centers and coverage witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row over the same compact metric source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid-tolerance row used to compare source distances and target tolerances.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row over the finite grid radii.*
5. *M is the extracted modulus-candidate row produced from K, F, D, Q.*
6. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for Real-valued compact-continuity consumers.*
8. *H records componentwise* hsame *transport for compact grid data, continuous-map pointwise rows, dyadic tolerances, rational folds, extracted modulus candidates, UniformModulus handoff, Real seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay through the compact grid, pointwise modulus, dyadic tolerance, rational fold, extracted modulus row, UniformModulus handoff, and Real seal.*

10. *P is the* Pkg *provenance over* CompactGridModulusExtraction$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CompactGridModulusExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, D, Q, M, U, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected subcovers, countable choice, quotient real equality, selected limits, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6676.2 (Compact grid modulus extraction NameCert obligations)**.** *For every accepted* CompactGridModulusExtraction$^{\uparrow}$ *carrier $G = (K, F, D, Q, M, U, E, H, C, P, N)$, the local* NameCert$_{\text{CompactGridModulusE}}$ *surface consists exactly of carrier admission for the compact finite grid, continuous-map pointwise rows, dyadic tolerance row, rational lower-bound fold, extracted modulus candidate, UniformModulus handoff, Real seal, transport, replay, provenance, and local naming rows; finite-net coverage accounting; lower-bound stability under* hsame*; handoff exactness to* UniformModulus$^{\uparrow}$*; and refusal of open-cover or choice-selected compactness outside the displayed grid.*

Proof. Project the carrier of Definition 6676.1. The construction rows are K, F, D, Q, M, U, E, and the structural rows are H, C, P, N.

The compact grid row K supplies only displayed centers and coverage witnesses. The continuous-map row F supplies pointwise modulus data over those centers, while D and Q record the dyadic and rational lower-bound calculations needed to extract M.

The replay row C sends the extracted candidate to UniformModulus$^{\uparrow}$ through U and then to Real-valued consumers through E. Transport, provenance, and local naming preserve that same finite packet, so no open-cover compactness, selected subcover, choice selector, quotient real equality, selected limit, or ambient completeness row is present. □

Theorem 6676.3 (Compact grid modulus extraction finite-net handoff)**.** *Every accepted* CompactGridModulusExtra *carrier hands compact coverage to the modulus extractor only through the displayed finite route*

$$K, F, D, Q \longmapsto M.$$

The handoff uses compact metric grid centers, continuous-map pointwise rows, dyadic tolerances, and a rational lower-bound fold; it does not use open-cover compactness, a selected subcover, sequential compactness, or countable choice.

Proof. Start from the compact grid row K. It exposes a finite net with displayed coverage witnesses rather than an arbitrary open cover.

Attach the continuous-map row F at each displayed grid center. The pointwise radius data is then compared through the dyadic tolerance row D and folded through the rational lower-bound row Q.

The extracted row M is therefore downstream of the finite grid and lower-bound fold. Since no carrier coordinate names an open cover, selected subcover, sequential compactness witness, or choice selector, the finite-net handoff is the only compactness source available. □

Theorem 6676.4 (Compact grid modulus extraction uniform-modulus boundary)**.** *Every* UniformModulus$^{\uparrow}$ *consumer of an accepted* CompactGridModulusExtraction$^{\uparrow}$ *carrier reads the boundary*

$$K, F, D, Q, M \longmapsto U \longmapsto E, H, C, P, N.$$

The exported modulus is a finite compact-grid extraction from compact metric coverage, continuous pointwise rows, dyadic tolerances, and rational lower bounds. It is not an ambient Heine–Cantor oracle, quotient real equality, selected limit, countable-choice selector, or Real$^{\uparrow}$ *completeness.*

Proof. Use the finite-net handoff theorem to place M after K, F, D, Q. This ensures that the candidate modulus is derived from the displayed grid route.

The UniformModulus row U receives only that candidate and the structural replay data. The Real seal E is downstream of the same handoff and can be inspected only after the finite grid extraction has been displayed.

Finally read H, C, P, N. These rows transport, replay, source, and name the same packet, so the boundary contains no ambient uniform-continuity theorem, quotient real equality, selected limit, choice selector, or real-completeness row. □

Falsifiable prediction: Every accepted $\mathsf{CompactGridModulusExtraction}^{\uparrow}$ read factors through CompactMetric finite grid data, ContinuousMap pointwise-modulus rows, DyadicRatCore tolerance, RatUp lower-bound fold, an extracted modulus candidate, UniformModulus handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: compactmetric, continuousmap, uniformmodulus, dyadicratcore, rat, real: $\mathsf{CompactGridModulusExtraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite-net coverage, pointwise continuous rows, dyadic grid tolerance, rational lower-bound fold, extracted modulus candidate, UniformModulus handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactGridModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactGridModulusExtraction}^{\uparrow}$ packet is generated from CompactMetric finite grid data, ContinuousMap pointwise-modulus rows, DyadicRatCore tolerance, RatUp lower-bound fold, an extracted modulus candidate, UniformModulus handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactGridModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6676.1, Definition 6676.2, Definition 6676.3, and Definition 6676.4 seed the finite compact-grid route from compact metric coverage to UniformModulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactGridModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, sequential compactness, quotient real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-grid coverage accounting, pointwise-modulus routing, dyadic tolerance and rational lower-bound stability, UniformModulus handoff exactness, Real-seal nonescape, and structural replay for BEDC.Derived.CompactGridModulusExtractionUp.

Chapter 6677

A Concrete Naming Certificate for $\mathsf{BishopChoiceBar}^{\uparrow}$

Following Bishop and Bridges on constructive choice principles under explicit finite information, the $\mathsf{BishopChoiceBar}^{\uparrow}$ packet records the bar-controlled boundary at which a completion-facing consumer may use inspected finite prefixes and a local selection ledger without acquiring countable choice. It sits on the L10 Real and Completion route beside the finite stream-name interface of chapter 126, the Cauchy-modulus schedule discipline of chapter 292, the choice-free limit schedule of chapter 650, the fan theorem boundary of chapter 400, and the lawless sequence prefix surface of chapter 1495. The packet names only the displayed bar coverage, inspected windows, selected-window ledger, and structural rows; it does not claim countable choice, a full fan theorem, $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, or selected global limits.

Definition 6677.1 (Bishop choice bar carrier)**.** *A* $\mathsf{BishopChoiceBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, M, A, W, L, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the finite prefix windows that the completion-facing request is allowed to inspect.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *request row, recording the displayed precision threshold and the finite bound at which the bar is queried.*
3. *A is the bar-admission row. It records finite bar coverage for the inspected prefix family and cites the fan-boundary sibling only as a displayed finite coverage discipline.*
4. *W is the selected-window row. It lists the windows actually read after S, M, A have been exposed.*
5. *L is the selected-window ledger. It records that every selected window in W is justified by a visible bar hit and remains inside the choice-free limit schedule.*
6. *D is the lawless-prefix compatibility row, ensuring that prefix reads use only displayed finite observations and no global law for the stream.*
7. *H records componentwise* hsame *transport for source, modulus, bar-admission, selected-window, ledger, lawless-prefix, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from completion-facing requests through $S, M, A, W, L, D, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopChoiceBar}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{LawlessSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopChoiceBar}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, M, A, W, L, D, H, C, P, N$. It has no coordinate for countable choice, an arbitrary fan theorem, quotient stream equality, selected global limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6677.2 (Bishop choice bar NameCert obligations)**.** *For every accepted* $\mathsf{BishopChoiceBar}^{\uparrow}$ *carrier $B = (S, M, A, W, L, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopChoiceBar}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed stream source, Cauchy-modulus request, bar-admission row, selected-window row, selected-window ledger, lawless-prefix compatibility row, transport, replay, provenance, and local naming rows;*

2. *finite bar coverage, requiring A to cover only the inspected prefix family visible through S and the precision threshold visible through M;*

3. *selected-window ledger exactness, requiring every row of W to cite a visible bar hit in A and a schedule edge in the choice-free limit route before any completion-facing read is consumed;*

4. *lawless-prefix compatibility, requiring D to keep prefix observations finite and to forbid replacement by a global stream law;*

5. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the rows already listed;*

6. *non-escape, forbidding countable choice, a full fan theorem, quotient stream equality, selected global limits, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the local surface.*

No $\mathsf{BishopChoiceBar}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 6677.1. The accepted inventory is exactly $S, M, A, W, L, D, H, C, P, N$, so every local naming read must pass through the displayed stream source, modulus request, finite bar row, selected windows, ledger, and lawless-prefix compatibility row.

The bar row is finite. It covers only the inspected prefix family exposed by S at the threshold exposed by M, and its citation of the fan-theorem sibling is only the displayed finite coverage discipline needed for those prefixes.

The selected-window ledger is then forced. Each selected window in W is justified by a visible hit in A and is replayed through the choice-free limit schedule, so the packet records a bounded local selection rather than a selector over all requests.

The lawless-prefix and structural rows close the route. The row D forbids replacing finite observations by a global stream law, while H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for countable choice, a full fan theorem, quotient stream equality, selected global limits, host real equality, or ambient real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6677.3 (Bishop choice bar L10 dependency route)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopChoiceBar}^{\uparrow}$ *carrier reads bar-controlled choice data only through the finite route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{CauchyModulus}^{\uparrow} \longmapsto A \longmapsto W, L \longmapsto \mathsf{ChoiceFreeLimitSchedule}^{\uparrow}.$$

The route may expose finite bar coverage and selected-window ledgers for inspected prefixes. It does not export countable choice, a full fan theorem, $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, host stream equality, or a selected global limit.*

Proof. Start with an accepted packet $B = (S, M, A, W, L, D, H, C, P, N)$. A completion-facing request first reads the stream source S and the Cauchy-modulus threshold M, so the inspected prefix family and precision bound are fixed before any selection row is visible.

Next read the bar row A and the selected-window data W, L. The bar row supplies finite coverage for those inspected prefixes, and the ledger records only the windows justified by visible bar hits. This is the point where local bar-controlled choice is available.

Finally replay the selected windows through the choice-free limit schedule and the structural rows D, H, C, P, N. The lawless-prefix row keeps the stream access finite, and the replay/provenance/name rows preserve the same packet. None of these rows contains a coordinate for countable choice, a full fan theorem, quotient stream equality, host equality, selected global limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so no completion-facing consumer can export them. □

Falsifiable prediction: Every accepted $\mathsf{BishopChoiceBar}^{\uparrow}$ completion-facing read factors through a StreamNameUp source row, CauchyModulusUp request row, finite bar-admission row, selected-window row, selected-window ledger, lawless-prefix compatibility row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, cauchymodulus, choice-free-limit-schedule, fantheorem, lawlesssequence: $\mathsf{BishopChoiceBar}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite bar coverage, selected-window ledgers, lawless-prefix compatibility, transport, replay, provenance, and local NameCert rows for the L10 completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopChoiceBar}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopChoiceBar}^{\uparrow}$ packet is generated from a StreamNameUp source row, CauchyModulusUp request row, finite bar-admission row, selected-window row, selected-window ledger, lawless-prefix compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopChoiceBar}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6677.1, Definition 6677.2, and Definition 6677.3 seed the finite bar-controlled local choice surface for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopChoiceBar}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, the full fan theorem, $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected global limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bar coverage, selected-window ledger exactness, lawless-prefix compatibility, transport, replay, provenance, and local naming for BEDC.Derived.BishopChoiceBarUp.

Chapter 6678

A Concrete Naming Certificate for HyperbolicBoundaryShadowTransport$^{\uparrow}$

The HyperbolicBoundaryShadowTransport$^{\uparrow}$ packet realizes the boundary-shadow transport branch of chapter 9463 as finite NameCert rows. It sits after the boundary-shadow carrier of chapter 3813, the boundary-transport route of chapter 6595, the ray-boundary surface of chapter 6470, the disk metric readback of chapter 6209, and the terminal Real-name boundary of chapter 38. The packet names a transported boundary shadow through displayed disk, boundary, metric, and Real-facing rows; it is not an interior-center collapse, a selected ideal endpoint, quotient boundary equality, physical observer motion, or global hyperbolic compactification.

Falsifiable prediction: Every accepted HyperbolicBoundaryShadowTransport$^{\uparrow}$ read is refuted if it collapses a boundary-shadow transport to an interior-center row without displaying HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicBoundaryTransport$^{\uparrow}$, GromovBoundary$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, Real$^{\uparrow}$, nontriviality, field-faithful metric readback, componentwise hsame transport, Cont replay, provenance, and local NameCert rows.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-boundary-transport, gromov-boundary, poincare-disk-metric, real: the boundary-shadow sibling records shadow readout without transport alignment; the boundary-transport sibling records fixed-boundary transport without shadow readout; the Gromov-boundary sibling records ray-boundary equivalence without disk-shadow transport; the Poincare disk metric sibling records metric readback without transported boundary shadows; and the Real sibling seals numerical data without a hyperbolic boundary carrier. None is bijective to HyperbolicBoundaryShadowTransport$^{\uparrow}$.

Definition 6678.1 (Hyperbolic boundary shadow transport carrier)**.** *A* HyperbolicBoundaryShadowTransport$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, U, G, D, E, L, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row naming the boundary-shadow readout attached to displayed disk observations.*
2. *U is the* HyperbolicBoundaryTransport$^{\uparrow}$ *row transporting the boundary commitment while preserving the visible far-end boundary reading.*
3. *G is the* GromovBoundary$^{\uparrow}$ *row carrying the ray-boundary token through the transported shadow.*

4. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-metric readback row used to refuse interior-center collapse.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the metric and boundary-shadow readback.*
6. *L is the nontrivial and field-faithful ledger: it records that the disk metric read is nonzero on the transported boundary-shadow separation and that the Real-facing metric coordinate is read through the displayed field-faithful route rather than through a collapsed center.*
7. *F is the refusal row, excluding interior-center collapse, selected ideal endpoints, quotient boundary equality, physical observer motion, and global hyperbolic compactification.*
8. *H records componentwise* hsame *transport for boundary-shadow, boundary-transport, Gromov-boundary, disk-metric, Real-seal, ledger, refusal, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from shadow readout through boundary transport, Gromov-boundary token, disk-metric readback, Real seal, nontrivial field-faithful ledger, refusal, provenance, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, U, G, D, E, L, F, H, C, P, N$. It has no coordinate for an interior-center collapse, selected ideal endpoint, quotient boundary equality, physical observer motion, completed hyperbolic compactification, Lean verification, or bridge checking.

Theorem 6678.2 (Hyperbolic boundary shadow transport NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}$ *carrier $T = (S, U, G, D, E, L, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, boundary-transport preservation, Gromov-boundary token exposure, Poincare disk metric readback, Real-seal handoff, nontrivial and field-faithful metric ledger, refusal exactness, componentwise transport, displayed replay, package provenance, and local naming through $S, U, G, D, E, L, F, H, C, P, N$.*

Every public read of the transported shadow factors through

$$\mathsf{HyperbolicBoundaryShadow}^{\uparrow} \longmapsto \mathsf{HyperbolicBoundaryTransport}^{\uparrow} \longmapsto \mathsf{GromovBoundary}^{\uparrow} \longmapsto \mathsf{PoincareDiskMetric}^{\uparrow} \longmapsto$$

together with the nontrivial field-faithful ledger and the structural $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$ *rows.*

Proof. Project the carrier of Definition 6678.1. Rows S, U, G, D, E are the visible geometric and Real-facing route, while L, F, H, C, P, N record ledger, refusal, transport, replay, provenance, and naming.

Read the boundary-shadow row S first and transport it through U. The Gromov-boundary token G is then the only boundary token available to the transported shadow route.

The disk-metric and Real-facing rows are downstream. Row D supplies the $\mathsf{PoincareDiskMetric}^{\uparrow}$ readback, row E seals the numerical boundary, and row L records the nontrivial field-faithful route expected by the future TasteGate surface.

Finally use F, H, C, P, N to repack the public certificate. Because the excluded objects have no coordinate in the carrier, the packet cannot collapse the transported shadow to an interior center or export quotient boundary equality, physical observer motion, selected ideal endpoints, or global compactification. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow, HyperbolicBoundaryTransport, GromovBoundary, PoincareDiskMetric, RealUp seal, nontrivial field-faithful ledger, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6678.1, Definition 6678.2, the falsifiable prediction, and the independence witness seed the finite boundary-shadow transport route over shadow, transport, boundary, disk-metric, Real-seal, ledger, refusal, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close interior-center collapse, selected ideal endpoints, quotient boundary equality, physical observer motion, global hyperbolic compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shadow admission, boundary-transport preservation, Gromov-boundary token exposure, Poincare disk metric readback, Real-seal handoff, nontrivial and field-faithful ledger exactness, refusal coverage, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicBoundaryShadowTransportUp.

Chapter 6679

A Concrete Naming Certificate for $\mathsf{MorseBottLemma}^{\uparrow}$

Following Bott's nondegenerate critical-manifold form and standard Morse theory, the $\mathsf{MorseBottLemma}^{\uparrow}$ packet records the local normal-form route for a nondegenerate critical submanifold as finite BEDC certificate data. It sits beside the isolated critical-point packet of chapter 6418, the Morse-theory surface of chapter 3533, the manifold chart rows of chapter 96, the derivative ledger of chapter 122, the vector-space coordinate carrier of chapter 47, and the terminal real-name seal of chapter 38. The packet names only displayed critical-submanifold, normal-bundle, transverse Hessian, tubular-coordinate, quadratic normal-form, transport, replay, provenance, and local naming rows; it does not import a host smooth tubular-neighbourhood theorem, quotient germs, global flow data, or analytic compactness.

Definition 6679.1 (Morse–Bott lemma carrier)**.** *A* $\mathsf{MorseBottLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, S, N, Q, T, L, H, C, R, P, A)$$

with the following displayed rows:

1. *X is the* $\mathsf{Manifold}^{\uparrow}$ *chart-source row, naming the displayed neighbourhood, chart window, coordinate dimension, and local domain in which the critical submanifold is inspected.*
2. *S is the critical-submanifold row, recording the displayed submanifold chart, tangent directions, normal directions, and derivative-vanishing witness along the submanifold through the* $\mathsf{Derivative}^{\uparrow}$ *ledger.*
3. *N is the normal-bundle row, storing the finite transverse coordinate carrier and the projection from the ambient chart to the normal coordinates.*
4. *Q is the transverse Hessian-signature row, storing the nondegenerate normal quadratic form, its positive and negative normal counts, and the vector-space coordinate rows used to read them.*
5. *T is the tubular-coordinate row, recording the admitted local coordinate transformation from the ambient chart to submanifold coordinates together with normal coordinates.*
6. *L is the Morse–Bott normal-form row, displaying the equation that reads the function as its submanifold value plus the signed square sum in the normal coordinates determined by Q after T has been admitted.*

7. *H records componentwise* hsame *transport for chart, critical-submanifold, normal-bundle, transverse Hessian, tubular-coordinate, normal-form, replay, Real readback, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a normal-form query through $X, S, N, Q, T, L, H, R, P, A$.*
9. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row, exposing scalar values only after the chart, submanifold, normal-bundle, transverse Hessian, tubular-coordinate, and quadratic normal-form rows have been displayed.*
10. *P is the* Pkg *provenance over* $\mathsf{MorseBottLemma}^{\uparrow}$, $\mathsf{MorseLemma}^{\uparrow}$, $\mathsf{MorseTheory}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *A is the local* $\mathsf{NameCert}_{\mathsf{MorseBottLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, N, Q, T, L, H, C, R, P, A$. It has no coordinate for a host tubular-neighbourhood theorem, selected atlas, quotient germ equality, global compactness, or ambient smooth-manifold semantics.

Theorem 6679.2 (Morse–Bott lemma NameCert obligations)**.** *For every accepted* $\mathsf{MorseBottLemma}^{\uparrow}$ *carrier $B = (X, S, N, Q, T, L, H, C, R, P, A)$, the local* $\mathsf{NameCert}_{\mathsf{MorseBottLemma}^{\uparrow}}$ *surface consists exactly of chart-source admission, critical-submanifold exposure, normal-bundle projection, transverse Hessian nondegeneracy, tubular-coordinate admission, quadratic normal-form readback, componentwise* hsame *transport, displayed* Cont *replay,* $\mathsf{Real}^{\uparrow}$ *readback,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6679.1. The displayed rows are exactly $X, S, N, Q, T, L, H, C, R, P, A$, so each accepted packet exposes the chart, critical-submanifold, normal-bundle, transverse Hessian, tubular-coordinate, and normal-form data as finite BEDC rows.

The normal-form row L is downstream of the transverse rows. It may be read only after the critical submanifold S, the normal-bundle projection N, the nondegenerate transverse Hessian row Q, and the tubular-coordinate row T have been displayed.

The structural rows H, C, R, P, A transport, replay, read back, source, and name that same finite route. Since no coordinate contains a host tubular-neighbourhood theorem, quotient germ equality, selected atlas, or ambient compactness theorem, the listed rows form the full local NameCert surface. □

Theorem 6679.3 (Morse–Bott critical-manifold handoff)**.** *Every accepted* $\mathsf{MorseBottLemma}^{\uparrow}$ *normal-form read specializes to the isolated critical-point route of chapter 6418 when the displayed critical submanifold row is a singleton and the normal-bundle row exhausts the ambient chart directions. In general, the handoff keeps the tangent directions inside the critical-submanifold row and sends only the transverse normal coordinates through the Hessian-signature and quadratic normal-form rows.*

Proof. Begin with the rows S and N of Definition 6679.1. The critical-submanifold row stores the tangent directions along which the function is constant to first order, while the normal-bundle row stores the transverse coordinate carrier.

If S is a singleton and N exhausts the ambient chart directions, the carrier has no remaining tangent directions. The rows $X, N, Q, T, L, H, C, R, P, A$ then present exactly the isolated chart, nondegenerate Hessian, local-coordinate, quadratic normal-form, transport, replay, Real readback, provenance, and naming route used by $\mathsf{MorseLemma}^{\uparrow}$.

For a positive-dimensional critical submanifold, the tangent rows remain in S and are not sent to the signed square sum. Only the normal coordinates pass through Q and L, so the packet records Bott's critical-manifold normal form without collapsing it to an isolated critical point. □

Falsifiable prediction: Every accepted $\mathsf{MorseBottLemma}^{\uparrow}$ normal-form read exposes chart, critical-submanifold, normal-bundle, transverse Hessian, tubular-coordinate, quadratic normal-form, componentwise transport, displayed replay, Real readback, provenance, and local NameCert rows before any Morse-theory consumer reads the local model.

Independence witness: morse-lemma, morse-theory, manifold, derivative, real, vecspace: $\mathsf{MorseBottLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a critical-submanifold row, normal-bundle projection, transverse Hessian signature, tubular-coordinate row, quadratic normal-form row, transport, replay, Real readback, provenance, and local naming as one finite packet.

The Lean follow-up namespace is expected at `BEDC.Derived.MorseBottLemmaUp`. It must preserve the critical-submanifold, normal-bundle, transverse Hessian, tubular-coordinate, normal-form, transport, replay, Real readback, provenance, and local NameCert rows before any checked marker may cite the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MorseBottLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{MorseBottLemma}^{\uparrow}$ packet is generated from manifold chart rows, critical-submanifold rows, normal-bundle projection rows, transverse Hessian rows, tubular-coordinate rows, quadratic normal-form rows, componentwise transport, displayed replay, Real readback, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MorseBottLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6679.1, Definition 6679.2, and Definition 6679.3 seed the finite critical-manifold normal-form route consumed by Morse-theory packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MorseBottLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host smooth-manifold Morse–Bott theory, selected tubular neighbourhoods, quotient germs, analytic compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, critical-submanifold exposure, normal-bundle exactness, transverse Hessian coverage, tubular-coordinate admission, normal-form readback, transport stability, replay stability, Real readback, provenance exhaustion, and local naming for BEDC.Derived.MorseBottLemmaUp.

Chapter 6680

A Concrete Naming Certificate for $\mathsf{ChoquetIntegral}^{\uparrow}$

Following Choquet's capacity integral and Bishop–Bridges constructive measure theory, the $\mathsf{ChoquetIntegral}^{\uparrow}$ packet records the finite NameCert surface for integrating nonnegative simple-function envelopes against a displayed finite capacity. It consumes the measure carrier of chapter 92, the terminal real-name seal of chapter 38, and the compact-convex probability boundary of chapter 6611. The chapter names only capacity rows, simple-function envelope rows, finite cut-level ledgers, Real readback, transport, replay, provenance, and local naming; it does not assert countable additivity, a monotone-convergence theorem, quotient equality of functions, selected measurable representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6680.1 (Choquet integral carrier)**.** *A* $\mathsf{ChoquetIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, A, S, L, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row naming the measurable carrier, measurable-set requests, and finite measure-read interface visible to the packet.*
2. *A is the finite capacity row, recording monotone set-capacity observations over the displayed measurable rows without adding countable additivity.*
3. *S is the simple-function envelope row, a finite list of level values and measurable support rows used to bound the integrand from below and above.*
4. *L is the cut-level ledger, recording the inspected threshold rows, support inclusions, and finite envelope comparisons used by the Choquet read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *handoff row, sealing finite sums, capacity weights, and envelope bounds as displayed real-name data.*
6. *H records componentwise* hsame *transport for measure, capacity, simple envelope, cut-level, Real handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a capacity-integral request through the same finite rows.*
8. *P is the* Pkg *provenance over* $\mathsf{ChoquetIntegral}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ChoquetSimplex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ChoquetIntegral}^\uparrow}$ *row.*

The classifier compares accepted packets only through $M, A, S, L, R, H, C, P, N$. It has no coordinate for an ambient integral value, countable additivity, selected measurable representatives, host almost-everywhere equality, quotient simple functions, or completeness of $\mathsf{Real}^\uparrow$.

Theorem 6680.2 (Choquet integral NameCert obligations)**.** *For every accepted* $\mathsf{ChoquetIntegral}^\uparrow$ *carrier $I = (M, A, S, L, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChoquetIntegral}^\uparrow}$ *surface consists exactly of measure-source admission through M, finite capacity admission through A, simple-function envelope admission through S, cut-level ledger exactness through L, Real handoff through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Any Choquet-integral consumer must display those rows before exporting an integral-facing certificate.*

Proof. Project the carrier of Definition 6680.1. The measure row M is the only source for measurable-set requests, and the capacity row A is the only source for monotone finite set-capacity observations.

Read the simple-function envelope next. The row S supplies the finite level values and support rows, while L records the inspected cut levels and support-inclusion comparisons used by the Choquet read.

The Real handoff is downstream of those finite rows. The row R seals capacity weights, finite sums, and envelope bounds only after M, A, S, L have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no ambient integral value, countable-additivity theorem, selected measurable representative, host almost-everywhere equality, quotient simple-function equality, or $\mathsf{Real}^\uparrow$ completeness row, the listed rows exhaust the local certificate surface. □

Theorem 6680.3 (Choquet integral capacity handoff)**.** *Every* $\mathsf{Real}^\uparrow$ *value exported by an accepted* $\mathsf{ChoquetIntegral}^\uparrow$ *carrier factors through the finite route*

$$\mathsf{Measure}^\uparrow, \mathsf{ChoquetSimplex}^\uparrow \longmapsto \mathsf{ChoquetIntegral}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The route first displays the measure source M, finite capacity row A, simple-function envelope row S, and cut-level ledger L; only then may the Real handoff row R, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row export a real-name boundary. The handoff exports no monotone-convergence theorem, countable-additive extension, selected representative, quotient equality, or ambient completeness claim.*

Proof. Start with the carrier inventory of Definition 6680.1. The only analytic rows before the real-name boundary are M, A, S, L: measure-source observations, finite capacity observations, simple-function envelopes, and cut-level ledgers.

Use the NameCert obligations of Definition 6680.2. They force Real readback through R only after the displayed finite capacity and envelope route is available.

The Choquet simplex sibling supplies the compact-convex probability boundary cited by the provenance row, while the measure and Real siblings supply the measurable-source and terminal real-name rows. Transport, replay, provenance, and local naming preserve that same route, so a consumer cannot replace it by host measure theory or by an unrecorded real completeness principle. □

Falsifiable prediction: A consumer that claims a $\mathsf{ChoquetIntegral}^\uparrow$ real-name output while omitting the finite capacity row, simple-function envelope row, cut-level ledger, $\mathsf{Real}^\uparrow$ handoff, hsame, Cont, Pkg, or $\mathsf{NameCert}$ rows refutes the carrier of Definition 6680.1.

Independence witness: measure, real, choquet-simplex: $\mathsf{ChoquetIntegral}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries measure-source rows, finite capacity rows, simple-function envelope rows, cut-level ledgers, Real handoff, transport, replay, provenance, and local naming while refusing countable additivity, selected representatives, quotient simple functions, and ambient real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ChoquetIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoquetIntegral}^{\uparrow}$ packet is generated from a MeasureUp source, a finite capacity row, a simple-function envelope row, a cut-level ledger, a RealUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoquetIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6680.1, Definition 6680.2, and Definition 6680.3 seed the capacity-integral certificate over measure, capacity, simple-envelope, cut-level, Real handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoquetIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable additivity, monotone convergence, selected measurable representatives, quotient equality of simple functions, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, measure-source exposure, finite capacity monotonicity, simple-function envelope exactness, cut-level ledger exactness, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.ChoquetIntegralUp.

Chapter 6681

A Concrete Naming Certificate for $\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}$ packet presents the rational grid used by countable real approximation as finite rational-window data. It sits over the $\mathsf{Rat}^{\uparrow}$ row of chapter 37 and the dyadic arithmetic ledger of chapter 291, feeds the finite windows of chapter 126, and supplies the rational readback surface used by chapter 301 and chapter 38. The packet is a constructive grid certificate; it is not a Dedekind-cut presentation, not a quotient class of Cauchy names, not a countable-choice schedule, and not a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 6681.1 (Bishop countable dense rational grid carrier)**.** *A* $\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (Q, D, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *rational-coordinate row, storing the visible numerator, denominator, sign, and comparison data used by the current grid window.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, recording dyadic tolerances, midpoint steps, and interval refinements compatible with Q.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *request-window row. It records which rational grid points and tolerance scales are currently inspected.*
4. *S is the successor-window row. It lists the finite neighboring rational grid candidates obtained by one dyadic refinement of the current window.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, translating each inspected grid window into regular rational readback data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *boundary row. It records only the finite real-window comparisons needed to read a candidate as a real approximation.*
7. *H records componentwise* hsame *transport for rational coordinates, dyadic scales, StreamName windows, successor windows, regular-rational handoff, real-boundary reads, continuation, provenance, and local naming.*
8. *C records displayed* Cont *replay from a grid request through Q, D, W, S, R, E.*

9. *P is the* Pkg *provenance over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the rows $Q, D, W, S, R, E, H, C, P, N$. It has no coordinate for Dedekind cuts, quotient equality of Cauchy names, countable choice, host enumeration of all rationals, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6681.2 (Bishop countable dense rational grid NameCert obligations)**.** *For every accepted* $\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}$ *carrier $G = (Q, D, W, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCounta}}$ *surface consists exactly of carrier admission for the ten displayed rows, rational-coordinate visibility through Q, dyadic scale compatibility through D, finite StreamName request coverage through W, one-step neighbor coverage through S, regular rational readback through R, finite Real-window boundary through E, componentwise transport through H, continuation replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6681.1. The only positive approximation data are the rational coordinate row Q, the dyadic scale row D, the finite request window W, and the successor-window row S.

Perform finite window induction over W. The base window reads the currently displayed rational coordinate and dyadic tolerance. The step case refines the dyadic scale once, reads the neighboring rational candidates in S, and keeps each candidate attached to the same rational and dyadic rows.

The readback rows are downstream. The row R translates the displayed grid window into regular rational data before E exposes any finite real-boundary comparison. Transport, continuation, provenance, and local naming through H, C, P, N package that route and do not add any hidden cut, quotient, choice, global enumeration, or completeness coordinate. □

Theorem 6681.3 (Bishop countable dense rational grid Real-window handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}$ *packet must pass through the finite route*

$$Q, D, W, S, R, E \longmapsto H, C, P, N.$$

Thus a real-window consumer may read rational grid points, dyadic tolerances, regular-rational readback, and finite real-boundary comparisons, but it receives no Dedekind cut, no quotient class of Cauchy names, no countable-choice schedule, no host enumeration of all rationals, and no $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a downstream request. Carrier admission exposes Q, D, W, S as finite grid data: a rational coordinate, a dyadic tolerance, the currently inspected StreamName window, and the neighboring candidates obtained by the displayed refinement step.

Replay the request through C. The regular-rational handoff R is read only after the rational and dyadic rows have been displayed, and the Real boundary row E is read only as a finite comparison attached to that same handoff.

Finally transport and package the route through H, P, N. Since the carrier has no field for cuts, quotient equality, countable choice, host enumeration, or completeness, the handoff remains a finite rational-grid window into $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6681.1, Definition 6681.2, and Definition 6681.3 seed the finite rational-grid window over $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, quotient equality of Cauchy names, countable choice, host enumeration of all rationals, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-coordinate visibility, dyadic scale compatibility, finite StreamName coverage, regular-rational handoff, Real-window nonescape, and local NameCert exactness for the same packet.

Constructive story: A $\mathsf{BishopCountableDenseRationalGrid}^{\uparrow}$ packet is generated from Rat coordinates, DyadicRatCore tolerance scales, finite StreamName request windows, successor grid windows, RegSeqRat readback, Real boundary rows, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 6682

A Concrete Naming Certificate for $\mathsf{SignedDigitIntervalBisection}^{\uparrow}$

Bishop–Bridges constructive analysis and signed-digit interval methods read bisection as a finite schedule of inspected endpoint windows, not as a selected point of an ambient complete real line. The $\mathsf{SignedDigitIntervalBisection}^{\uparrow}$ packet sits between the signed-digit interval carrier of chapter 3830, the finite signed-digit window surface of chapter 316, the signed-digit real endpoint route of chapter 363, the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the closed bounded interval carrier of chapter 1591. The packet records interval bisection as finite NameCert data for Real and Completion consumers; it does not form quotient streams, choose representatives, invoke countable choice, use trichotomy, or import ambient Real completeness.

Definition 6682.1 (Signed digit interval bisection carrier)**.** *A* $\mathsf{SignedDigitIntervalBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, K, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower signed-endpoint row, carrying the finite signed-digit endpoint windows admitted by* $\mathsf{SignedDigitIntervalReal}^{\uparrow}$ *and* $\mathsf{SignedDigitStream}^{\uparrow}$*.*
2. *U is the upper signed-endpoint row, carrying the matching finite signed-digit endpoint windows for the upper side of the interval.*
3. *K is the bisection schedule row, recording the finite left/right bisection decisions and the midpoint requests already inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *enclosure ledger, recording normalized dyadic endpoint and midpoint rows for the scheduled bisection cuts.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the endpoint and midpoint windows opened by the schedule.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the normalized signed endpoints and midpoint enclosures.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the signed endpoints, bisection schedule, dyadic enclosure ledger, windows, and regular readback have been displayed.*

8. *H records componentwise* hsame *transport for signed endpoint rows, bisection schedules, dyadic enclosure rows, window rows, readback rows, seal rows, replay rows, provenance, and local naming.*
9. *C records displayed* Cont *replay from a bisection request through signed endpoint windows, dyadic midpoint normalization, enclosure refinement, regular readback, and the terminal seal.*
10. *P is the* Pkg *provenance over* $\mathsf{SignedDigitIntervalBisection}^{\uparrow}$, $\mathsf{SignedDigitIntervalReal}^{\uparrow}$, $\mathsf{SignedDigitStream}^{\uparrow}$, $\mathsf{SignedDigitReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDigitIntervalBisection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, K, D, W, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a chosen infinite signed-digit expansion, real trichotomy, countable choice, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6682.2 (Signed digit interval bisection NameCert obligations)**.** *For every accepted* $\mathsf{SignedDigitIntervalBisection}^{\uparrow}$ *carrier*

$$B = (L, U, K, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SignedDigitIntervalBisection}^{\uparrow}}$ *obligations are exhausted by carrier admission for the displayed rows; signed-endpoint admission through L, U; bisection-schedule admission through K; dyadic midpoint and enclosure admission through D; finite-window admission through W; regular rational readback through R; terminal Real sealing through E; componentwise transport through H; continuation replay through C; package provenance through P; and local naming through N.*

No obligation may call on quotient streams, chosen representatives, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.

Proof. Project the carrier of Definition 6682.1. The endpoint rows L, U and the schedule row K are the only sources for bisection data, and the window row W records the finite observations allowed by that schedule.

The dyadic enclosure row D normalizes endpoint and midpoint observations before any readback is consumed. Thus the bisection route is ledger-first: midpoint refinement is displayed as dyadic enclosure data rather than as a host order comparison or an infinite choice of sides.

The regular readback and seal rows R, E then receive only the displayed enclosure route. The structural rows H, C, P, N transport, replay, source, and name the same packet, so the listed rows exhaust the local certificate and leave the excluded principles outside the carrier. □

Theorem 6682.3 (Signed digit interval bisection nested interval route)**.** *Every accepted* SignedDigitIntervalBisectior *packet routes its bisection schedule as a finite nested closed-interval read*

$$\mathsf{SignedDigitIntervalReal}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The route keeps each midpoint refinement attached to the same signed endpoint rows and the same closed bounded interval provenance before any Real-facing consumer reads the terminal seal.

Proof. Start with the signed endpoint rows. The interval source is supplied by $\mathsf{SignedDigitIntervalReal}^{\uparrow}$, with the lower and upper endpoint windows carried by L and U.

Apply the bisection schedule row K and the dyadic enclosure ledger D. Each scheduled midpoint request refines the displayed closed interval by a finite dyadic row, so nestedness is witnessed by endpoint and midpoint enclosure data rather than by a completed intersection point.

Finally read through W, R, E, H, C, P, N. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback keep the nested route finite, while the $\mathsf{Real}^{\uparrow}$ seal and structural rows preserve the same packet for downstream consumers. The route imports no quotient stream, chosen representative, countable-choice schedule, trichotomy branch, or ambient Real completeness theorem. □

Theorem 6682.4 (Signed digit interval bisection Real seal nonescape)**.** *No* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{SignedDigitIntervalBisection}^{\uparrow}$ *packet can bypass the displayed route*

$$L, U, K, D, W, R, E, H, C, P, N.$$

Thus every Real-facing consumer receives only signed endpoint rows, the finite bisection schedule, the dyadic enclosure ledger, StreamName windows, RegSeqRat readback, transport, replay, provenance, and local naming; it receives no quotient stream equality, chosen infinite expansion, selected representative, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.

Proof. Begin with carrier projection. The terminal seal row E is not a detached real object; it is displayed only after L, U, K, D, W, R have been read in the accepted packet.

Use the nested interval route above. It identifies the path to the seal with signed endpoints, scheduled bisection decisions, dyadic midpoint enclosures, finite windows, and regular rational readback.

The structural rows H, C, P, N then preserve and name that same route. Since the carrier contains no quotient stream coordinate, representative chooser, countable-choice schedule, trichotomy row, compactness object, or ambient completeness witness, none of those objects can escape through the terminal seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDigitIntervalBisection}^{\uparrow}}$.

Constructive story: A $\mathsf{SignedDigitIntervalBisection}^{\uparrow}$ packet is generated from signed endpoint rows, a bisection schedule, DyadicRatCore enclosure rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SignedDigitIntervalBisection}^{\uparrow}}$, seed)

Scope closed: Definition 6682.1, Definition 6682.2, Definition 6682.3, and Definition 6682.4 seed the finite signed-digit interval bisection route from endpoint windows to RealUp seal data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SignedDigitIntervalBisection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, chosen signed-digit representatives, countable choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bisection schedule admission, dyadic enclosure exactness, regular readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SignedDigitIntervalBise

Chapter 6683

A Concrete Naming Certificate for $\mathsf{ChoiceFreeDisplayedCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley completion language, the ChoiceFreeDisplayedComple packet records the displayed limit interface used by completion arguments that inspect finite Cauchy data without quotienting names or selecting representatives. It sits over the $\mathsf{Cauchy}^{\uparrow}$ carrier of chapter 3413, the $\mathsf{StreamName}^{\uparrow}$ finite windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the sequence-completeness service of chapter 1515, the complete-metric boundary of chapter 128, the metric-completion route of chapter 1506, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers a finite displayed-completion landing surface while refusing quotient completion equality, selected representatives, countable-choice schedules, ambient completeness, and any claim that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 6683.1 (Choice-free displayed completion carrier)**.** *A* $\mathsf{ChoiceFreeDisplayedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, S, R, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row naming the admitted carrier, distance observations, and finite metric request histories.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the Cauchy name under inspection.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows.*
4. *M is the modulus-threshold row assigning each requested tolerance a displayed late index.*
5. *L is the displayed limit row offered to* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers only after X, S, R, M have been read.*
6. *E is the late-distance ledger. For each displayed tolerance and every sufficiently late window, it records the metric-distance comparison from the readback row to L.*
7. *H records componentwise* hsame *transport for the metric source, stream windows, regular readback, modulus threshold, displayed limit, late-distance ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through X, S, R, M, E, L and then through the structural rows.*

9. *P is the* Pkg *provenance over* ChoiceFreeDisplayedCompletion$^\uparrow$, Cauchy$^\uparrow$, Met$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, SequentiallyCompleteMetric$^\uparrow$, CompleteMetric$^\uparrow$, MetricCompletion$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{ChoiceFreeDisplayedCompletion}^\uparrow}$ *row.*

The carrier has no coordinate for quotient completion equality, a selected representative of a Cauchy class, a countable-choice schedule, ambient completeness, or a proof that Real$^\uparrow$ *is complete.*

Theorem 6683.2 (Choice-free displayed completion NameCert obligations)**.** *For an accepted* ChoiceFreeDisplayedCompletion$^\uparrow$ *carrier $D = (X, S, R, M, L, E, H, C, P, N)$, the local* NameCert$_{\text{ChoiceFreeDisplayedComple}}$ *surface consists exactly of carrier admission for the metric source, stream-window, regular-rational readback, modulus-threshold, displayed-limit, late-distance, transport, replay, provenance, and naming rows; classifier stability under componentwise* hsame *transport; modulus coverage for every displayed tolerance request; late-distance exactness for the displayed limit; consumer handoff to* SequentiallyCompleteMetric$^\uparrow$, CompleteMetric$^\uparrow$, MetricCompletion$^\uparrow$, *and* Real$^\uparrow$ *through the same rows; and ledger refusal for quotient completion equality, selected representatives, countable-choice schedules, ambient completeness, and completeness of* Real$^\uparrow$.

Proof. Project the carrier definition. The packet exposes exactly the rows $X, S, R, M, L, E, H, C, P, N$, so carrier admission and the local naming row are read from the displayed tuple.

Classifier stability is componentwise. Any accepted transport first identifies the metric source, stream windows, regular readback, modulus threshold, displayed limit, late-distance ledger, replay, provenance, and local name through H before the packet can be compared.

Modulus coverage and late-distance exactness are read in sequence. A tolerance request reaches the displayed threshold row M, then inspects the windows S and readback R, and only then reads the ledger E comparing late values with L inside the metric source X.

The consumer handoff is the same finite route replayed by C and sourced by P, N. Since none of the rows stores quotient equality, a selected representative, a choice schedule, an ambient complete carrier, or a completeness theorem for Real$^\uparrow$, the ledger refusal follows from carrier exhaustion. □

Theorem 6683.3 (Choice-free displayed completion limit handoff)**.** *Every completion-facing consumer of an accepted* ChoiceFreeDisplayedCompletion$^\uparrow$ *packet $D = (X, S, R, M, L, E, H, C, P, N)$ receives the displayed limit only through the route*

$$X, S, R, M, E \longmapsto L \longmapsto H, C, P, N.$$

The handoff supplies metric source data, stream windows, regular rational readback, a modulus threshold, a displayed limit, a late-distance ledger, hsame *transport,* Cont *replay,* Pkg *provenance, and a local* NameCert *row. It does not supply quotient completion equality, selected representatives, countable-choice schedules, ambient completeness, or a claim that* Real$^\uparrow$ *is complete.*

Proof. Start with a completion-facing request. The metric source row X fixes the distance observations available to the request, and the stream-window row S fixes the inspected Cauchy data.

Read R and M next. The regular rational row supplies the finite readback of the displayed windows, while the modulus row supplies the late threshold for the requested tolerance.

The late-distance ledger E is then the only row that compares late readbacks with the displayed limit row L. Thus a SequentiallyCompleteMetric$^\uparrow$, CompleteMetric$^\uparrow$, MetricCompletion$^\uparrow$, or Real$^\uparrow$ consumer can reach L only after the metric, stream, readback, threshold, and distance-ledger rows are visible.

Finally H, C, P, N transport, replay, source, and name exactly that route. The carrier has no further coordinate, so the handoff cannot be read as quotient completion equality, a representative selector, a countable-choice schedule, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$. □

Independence witness: cauchy, streamname, regseqrat, sequentiallycompletemetric, completemetric, metriccompletion, real: $\mathsf{ChoiceFreeDisplayedCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries metric source data, stream windows, regular rational readback, a modulus threshold, a displayed limit, a late-distance ledger, transport, replay, provenance, and local NameCert rows as one choice-free displayed completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceFreeDisplayedCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoiceFreeDisplayedCompletion}^{\uparrow}$ packet is generated from metric source rows, Cauchy StreamName windows, RegSeqRat readback, displayed modulus thresholds, displayed limit rows, late-distance ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceFreeDisplayedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6683.1, Definition 6683.2, and Definition 6683.3 seed the finite displayed-completion route over Metric, Cauchy, StreamName, RegSeqRat, SequentiallyCompleteMetric, CompleteMetric, MetricCompletion, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceFreeDisplayedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable-choice schedules, ambient completeness, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed completion route.

Chapter 6684

A Concrete Naming Certificate for $\mathsf{SignedDigitRealExpansion}^{\uparrow}$

Following Bishop and Bridges and the signed-digit representation tradition in constructive analysis, the $\mathsf{SignedDigitRealExpansion}^{\uparrow}$ packet records a real name as finite signed-digit prefix windows with dyadic error control. It sits beside the finite bisection route of chapter 6682, the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a non-quotient signed-digit route from finite prefixes to regular Cauchy data; it does not select an infinite expansion, quotient streams, invoke countable choice, use trichotomy, or assert ambient Real completeness.

Definition 6684.1 (Signed digit real expansion carrier)**.** *A* $\mathsf{SignedDigitRealExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, W, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the signed-digit alphabet row, admitting only the digits $-1, 0, 1$ and the finite prefix words already opened by the consumer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording which signed-digit prefixes are visible at the current inspection depth.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *value-and-radius ledger attached to each visible prefix.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, reading the dyadic prefix ledger as a regular rational Cauchy name.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the signed-digit prefix, window, dyadic, and regular-readback rows have been displayed.*
6. *H records componentwise* hsame *transport for prefix words, windows, dyadic ledgers, regular readback, the Real seal, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a prefix request through finite signed-digit windows, dyadic normalization, regular readback, and the terminal Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{SignedDigitRealExpansion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{SignedDigitRealExpansion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, W, D, Q, R, H, C, P, N$. It has no coordinate for quotient stream equality, a selected infinite signed-digit representative, countable choice, real trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6684.2 (Signed digit real expansion prefix stability)**.** *For every accepted* $\mathsf{SignedDigitRealExpansion}^{\uparrow}$ *carrier $E = (S, W, D, Q, R, H, C, P, N)$, extending the visible signed-digit prefix by one admitted digit preserves the same Real-facing route only when the enlarged prefix remains in S, the window row W records the enlarged inspection depth, and the dyadic ledger D records the refined value-and-radius row. The extension is then transported through Q, R, H, C, P, N and exports no chosen infinite expansion or quotient equality of streams.*

Proof. Project the carrier of Definition 6684.1. Prefix data live in S, and visible inspection depth lives in W, so a prefix extension cannot be read unless both rows display the enlarged finite word and its window.

Use the dyadic ledger row D. It supplies the normalized dyadic value and radius for the enlarged prefix before any regular rational readback is available.

Finally read through Q, R, H, C, P, N. Regular readback and the Real seal preserve the same finite prefix route, while transport, replay, provenance, and local naming add no row for an infinite representative, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness. □

Theorem 6684.3 (Signed digit real expansion RegSeqRat handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{SignedDigitRealExpansion}^{\uparrow}$ *packet must pass from finite signed-digit prefixes through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D to the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q before the* $\mathsf{Real}^{\uparrow}$ *seal R is consumed. Thus the signed-digit expansion route hands off to regular Cauchy data as the finite BEDC row family*

$$S, W, D, Q, R, H, C, P, N.$$

It is not a quotient construction of real numbers, not a selected stream representative, not a countable-choice principle, and not an ambient completeness theorem.

Proof. Begin with the finite prefix and window rows S, W. They record only the signed digits and the finite inspection depths currently visible to the consumer.

Apply the dyadic ledger D. Each prefix is read as a dyadic value with an explicit radius, so the next consumer receives toleranced rational data rather than a host real value.

The handoff to Q packages those dyadic rows as a $\mathsf{RegSeqRat}^{\uparrow}$ readback. Only after this regular rational row is displayed may the terminal seal R be consumed.

The structural rows H, C, P, N preserve the same route. Since the carrier has no coordinate for quotient streams, selected infinite representatives, countable choice, trichotomy, host real equality, or ambient completeness, the handoff remains a finite signed-digit-to-regular-Cauchy route. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDigitRealExpansion}^{\uparrow}}$.

Constructive story: A $\mathsf{SignedDigitRealExpansion}^{\uparrow}$ packet is generated from signed-digit alphabet rows, finite StreamName prefix windows, DyadicRatCore value-and-radius rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SignedDigitRealExpansion}^{\uparrow}}$, seed)

Scope closed: Definition 6684.1, Definition 6684.2, and Definition 6684.3 seed the finite signed-digit prefix route from window inspection to regular Cauchy Real-seal data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SignedDigitRealExpansion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, selected infinite signed-digit representatives, countable choice, trichotomy, host real equality, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, prefix-window stability, dyadic value-and-radius exactness, RegSeqRat handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SignedDigitRealExpa

Chapter 6685

A Concrete Naming Certificate for $\mathsf{RegularCauchyArithmetic}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RegularCauchyArithmetic}^{\uparrow}$ packet records the finite arithmetic surface used when regular Cauchy names are added, multiplied, negated, compared against displayed dyadic tolerances, and sealed for $\mathsf{Real}^{\uparrow}$ consumers without quotienting the names. It sits over the $\mathsf{Cauchy}^{\uparrow}$ carrier of chapter 3413, the $\mathsf{RegSeqRat}^{\uparrow}$ rational readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ finite windows of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet gives L10 Real and Completion consumers an arithmetic carrier between regular rational sequences and the Real seal while refusing quotient real equality, selected representatives, trichotomy, countable-choice schedules, ambient completeness, and unrestricted field algebra over host reals.

Definition 6685.1 (Regular Cauchy arithmetic carrier)**.** *A* $\mathsf{RegularCauchyArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Y, S, T, R, Q, D, O, W, E, H, C, P, N)$$

with the following rows:

1. *X and Y are the two* $\mathsf{Cauchy}^{\uparrow}$ *source-name rows admitted for arithmetic.*
2. *S and T are the corresponding* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows.*
3. *R and Q are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the same windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the displayed radii used for arithmetic error budgets.*
5. *O is the operation row naming which of addition, multiplication, unary negation, distance comparison, or constant insertion is being performed.*
6. *W is the regular-Cauchy output window row produced from R, Q, D, O.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the source names, stream windows, rational readbacks, tolerance ledger, operation row, and output window have been read.*
8. *H records componentwise* hsame *transport for the source names, stream windows, regular readbacks, tolerance ledger, operation row, output window, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an arithmetic request through $X, Y, S, T, R, Q, D, O, W, E$ and then through the structural rows.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyArithmetic}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyArithmetic}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of Cauchy names, selected representatives, trichotomy, countable-choice schedules, ambient completeness, or host-real field algebra.

Theorem 6685.2 (Regular Cauchy arithmetic NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyArithmetic}^{\uparrow}$ *carrier $A = (X, Y, S, T, R, Q, D, O, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyArithmetic}^{\uparrow}}$ *surface consists exactly of carrier admission for the two Cauchy source names, their finite stream windows, their regular rational readbacks, the dyadic tolerance ledger, the displayed operation row, the regular-Cauchy output window, the terminal Real seal, transport, replay, provenance, and local naming; classifier stability under componentwise* hsame *transport; arithmetic tolerance coverage for the operation named by O; exact routing from R, Q, D, O into W; Real-facing nonescape through E; and ledger refusal for quotient name equality, selected representatives, trichotomy, countable-choice schedules, ambient completeness, and host-real field algebra.*

Proof. Project the carrier definition. The rows $X, Y, S, T, R, Q, D, O, W, E, H, C, P, N$ are the only displayed coordinates, so carrier admission, operation routing, provenance, and local naming are read directly from the packet.

Classifier stability is componentwise. Transport through H must preserve both source names, both stream windows, both regular readbacks, the dyadic tolerance ledger, the operation row, the output window, the Real seal, replay, provenance, and local naming before two arithmetic packets can be identified.

Arithmetic coverage is finite. The operation row O selects the displayed arithmetic task, the tolerance ledger D supplies the requested dyadic budget, and the regular readbacks R, Q provide the rational data from which W is built.

Finally E, C, P, N seal, replay, source, and name the same route. Since no carrier coordinate stores quotient equality, selected representatives, trichotomy, countable choice, ambient completeness, or host-real field algebra, the refusal clauses follow by carrier exhaustion. □

Theorem 6685.3 (RegSeqRat route for regular Cauchy arithmetic)**.** *Every accepted* $\mathsf{RegularCauchyArithmetic}^{\uparrow}$ *arithmetic read factors through the displayed route*

$$\mathsf{Cauchy}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ O,\ W.$$

In carrier notation, the output window W can be consumed only after X, Y, S, T, R, Q, D, O are visible. Thus downstream $\mathsf{RegSeqRat}^{\uparrow}$ *consumers receive the two source readbacks, the dyadic error ledger, the operation row, transport, replay, provenance, and local naming, but receive no quotient stream equality, selected representative, external rational sequence, trichotomy, countable-choice schedule, or ambient completeness witness.*

Proof. Start with an arithmetic request. The two source rows X, Y admit only Cauchy-name data, while S, T determine the finite windows inspected by the request.

The request then reads R, Q and D. These rows supply regular rational readback and dyadic tolerance budgets before the operation row O is applied.

The output window W is therefore produced inside the displayed route, and H, C, P, N transport, replay, source, and name exactly that route. No additional carrier coordinate is available for quotient stream equality, selected representatives, external rational streams, trichotomy, choice schedules, or ambient completeness. □

Theorem 6685.4 (Regular Cauchy arithmetic Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyArithmetic}^{\uparrow}$ *packet must expose the two Cauchy source rows, both stream-window rows, both* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the displayed operation row, and the regular-Cauchy output window before the terminal seal row* E *is read. The Real seal exports the named arithmetic packet and refuses quotient real equality, selected representatives, trichotomy, countable-choice schedules, ambient completeness, and unrestricted host-real algebra.*

Proof. Use the NameCert obligations to order the visible rows. A Real-facing read starts with X, Y, S, T, then consumes R, Q, D, O, and only then reaches the output window W.

The seal row E is terminal by definition of the carrier route. It can certify the displayed arithmetic packet for $\mathsf{Real}^{\uparrow}$ consumers, but it cannot introduce data absent from the preceding rows.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route. The excluded quotient, representative, trichotomy, choice, completeness, and host-algebra objects have no coordinate in the packet, so the seal cannot escape to them. □

Independence witness: cauchy, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyArithmetic}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two Cauchy source names, stream windows, regular rational readbacks, a dyadic arithmetic tolerance ledger, an operation row, an output window, a Real seal, transport, replay, provenance, and local NameCert rows as one arithmetic packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyArithmetic}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyArithmetic}^{\uparrow}$ packet is generated from two Cauchy source rows, StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a displayed arithmetic operation row, a regular-Cauchy output window, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyArithmetic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6685.1, Definition 6685.2, Definition 6685.3, and Definition 6685.4 seed the finite arithmetic route over Cauchy, StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyArithmetic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, trichotomy, countable-choice schedules, ambient completeness, host-real algebra, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the regular Cauchy arithmetic route.

Chapter 6686

A Concrete Naming Certificate for $\mathsf{CauchyOrderCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyOrderCompletion}^{\uparrow}$ packet records the order-aware Cauchy completion route used by L10 Real and Completion consumers as finite NameCert data. It reads the Cauchy carrier of chapter 3413, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance arithmetic of chapter 291, the constructive order surface of chapter 4069, and the terminal real-name seal of chapter 38. The packet gives completion-facing consumers a displayed order-stable landing route, while refusing quotient completion equality, selected limits, trichotomy, host real equality, countable-choice schedules, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6686.1 (Cauchy order completion carrier)**.** *A* $\mathsf{CauchyOrderCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, S, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Cauchy}^{\uparrow}$ *source row, naming the accepted Cauchy packet whose completion-facing order route is being inspected.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row attached to the same Cauchy source.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger used to compare displayed readbacks.*
5. *Q is the order-comparison row, read through* $\mathsf{RegularCauchyOrder}^{\uparrow}$ *and carrying only displayed lower, upper, and apartness-facing comparisons of the regular Cauchy names.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the Cauchy source, stream windows, rational readback, dyadic tolerance ledger, and order-comparison row have been displayed.*
7. *H records componentwise* hsame *transport for $X, S, R, D, Q, E, C, P, N$.*
8. *C records displayed* Cont *replay from an order or completion request through X, S, R, D, Q, E and the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyOrderCompletion}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyOrderCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, a selected limit, trichotomy, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6686.2 (Cauchy order completion NameCert obligations)**.** *For an accepted* $\mathsf{CauchyOrderCompletion}^{\uparrow}$ *carrier* $O = (X, S, R, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyOrderCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row, stream-window row, RegSeqRat readback row, DyadicRatCore tolerance ledger, order-comparison row, Real seal, componentwise transport, displayed replay, provenance, and local naming. No local obligation may replace those rows by quotient completion equality, a selected limit, trichotomy, host real equality, countable choice, or ambient Real completeness.*

Proof. Project the carrier definition. The packet exposes exactly $X, S, R, D, Q, E, H, C, P, N$, so carrier admission and local naming are reads of the displayed tuple.

The Cauchy and readback rows are opened first. The source row X fixes the accepted Cauchy packet, S fixes the inspected windows, R fixes the regular rational values, and D fixes the dyadic tolerance ledger.

The order-comparison and seal rows are downstream. The row Q reads only the displayed regular Cauchy order data, and E seals that same route for Real-facing consumers.

Finally H, C, P, N transport, replay, source, and name the route. Since the excluded host and quotient objects are absent from the carrier, they cannot become NameCert obligations. □

Theorem 6686.3 (Cauchy order completion regular seal route)**.** *Every Real-facing consumer of an accepted* $\mathsf{CauchyOrderCompletion}^{\uparrow}$ *packet reaches the terminal seal through the finite route*

$$\mathsf{Cauchy}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegularCauchyOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The seal is therefore a displayed completion boundary for regular Cauchy order data, not a quotient completion, selected representative, host equality test, or ambient completeness theorem.

Proof. Begin with the NameCert obligations above. They force every accepted read to expose the Cauchy source, stream windows, regular rational readback, dyadic tolerance ledger, order-comparison row, and structural rows before the Real seal is consumed.

The route is regular because R is the only readback row and Q reads order data only through the regular Cauchy order surface. The dyadic ledger D remains attached to those same readbacks.

The seal row E is terminal for this finite route. It does not add quotient completion equality, a representative selector, host real equality, or an ambient completeness proof because no such coordinate appears in the packet. □

Theorem 6686.4 (Cauchy order completion order stability)**.** *If an accepted* $\mathsf{CauchyOrderCompletion}^{\uparrow}$ *packet is transported componentwise through* hsame*, then its Cauchy source row, stream windows, RegSeqRat readback, DyadicRatCore tolerance ledger, order-comparison row, Real seal, replay, provenance, and local name move together as one order-stable completion route. In particular, the transported packet preserves displayed order comparisons without importing trichotomy, quotient stream equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the transport row H. It is componentwise over the same carrier coordinates $X, S, R, D, Q, E, C, P, N$, so a transported packet cannot move the order-comparison row apart from the Cauchy source and readback rows.

The replay row C preserves the request route from X, S, R, D, Q to the terminal seal E. Provenance and local naming then source the transported packet through P, N.

The refused principles have no carrier coordinate and no replay row. Hence order stability is exactly stability of the displayed finite route under hsame transport. □

Theorem 6686.5 (Cauchy order completion Real consumer handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyOrderCompletion}^{\uparrow}$ *packet receives the displayed Cauchy source, finite stream windows, regular rational readback, dyadic tolerance ledger, order-comparison row, terminal Real seal, transport, replay, provenance, and local naming rows. The handoff exports no quotient completion equality, selected limit, host real equality, trichotomy principle, countable-choice schedule, or ambient completeness witness.*

Proof. Apply the regular seal route. It places the Real-facing endpoint after the Cauchy source, stream windows, regular readback, dyadic tolerance ledger, and order-comparison row.

Use order stability for transported reads. Any consumer that reaches the endpoint after transport still reads the same $X, S, R, D, Q, E, H, C, P, N$ route.

The carrier inventory supplies the exclusions. Since the packet contains no quotient equality, selected limit, host equality, trichotomy, choice, or completeness coordinate, the Real consumer receives only the displayed order-stable completion route. □

Falsifiable prediction: An accepted $\mathsf{CauchyOrderCompletion}^{\uparrow}$ read is refuted if a Real-facing order-completion consumer reaches the seal without first displaying the Cauchy source row, StreamName window row, RegSeqRat readback row, DyadicRatCore tolerance ledger, RegularCauchyOrder comparison row, transport, replay, provenance, and local NameCert row.

Independence witness: cauchy, streamname, regseqrat, dyadicratcore, regularcauchyorder, real: $\mathsf{CauchyOrderCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds Cauchy source data, finite windows, regular rational readback, dyadic order tolerances, a regular Cauchy order-comparison row, and a terminal Real seal as one completion-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyOrderCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyOrderCompletion}^{\uparrow}$ packet is generated from Cauchy source rows, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance and comparison ledgers, RegularCauchyOrder comparison rows, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyOrderCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6686.1, Definition 6686.2, Definition 6686.3, Definition 6686.4, and Definition 6686.5 seed the order-aware Cauchy completion route over Cauchy, StreamName, RegSeqRat, DyadicRatCore, RegularCauchyOrder, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyOrderCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, trichotomy, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.CauchyOrderCompletionU

Chapter 6687

A Concrete Naming Certificate for $\mathsf{AttouchWetsConvergence}^{\uparrow}$

Following Attouch and Wets on variational convergence, the $\mathsf{AttouchWetsConvergence}^{\uparrow}$ packet records local bounded-window convergence of displayed closed metric figures as finite L10 NameCert data. It sits after the bounded observation topology of chapter 4358, the closed-set hit–miss route of chapter 6591, the metric source of chapter 57, the Hausdorff-distance boundary of chapter 3653, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed bounded windows, local distance ledgers, Kuratowski handoff rows, transport, replay, provenance, and local naming; it does not assert a host closed-set topology, selected nearest points, choice-based compactness, quotient equality of closed figures, or ambient hyperspace completion.

Definition 6687.1 (AttouchWetsConvergence carrier)**.** *An* $\mathsf{AttouchWetsConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, T, W, K, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row for the ambient metric classifier and its finite distance observations.*
2. *T is the* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *bounded-window row naming the inspected local balls and their tolerance schedule.*
3. *W is the finite window ledger recording the displayed closed-set observations inside each bounded ball.*
4. *K is the* $\mathsf{KuratowskiConvergence}^{\uparrow}$ *handoff row that reads lower-hit and upper-miss evidence from the same displayed windows.*
5. *D is the local distance ledger, comparing the bounded-window observations by* $\mathsf{HausdorffDistance}^{\uparrow}$ *rows and rational tolerance entries.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for window radii, tolerance thresholds, and distance comparisons.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, W, K, D, Q have been displayed.*
8. *H stores componentwise* hsame *transport for source, topology, window, Kuratowski handoff, distance, readback, Real seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a bounded-window convergence request through the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{AttouchWetsConvergence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{AttouchWetsTopology}^{\uparrow}$, $\mathsf{KuratowskiConvergence}^{\uparrow}$, $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AttouchWetsConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host hyperspace topology, arbitrary closed-set quotient, selected projection, choice-based compactness principle, or completed hyperspace carrier.

Theorem 6687.2 (AttouchWetsConvergence NameCert obligations)**.** *For every accepted* $\mathsf{AttouchWetsConvergence}^{\uparrow}$ *carrier $A = (X, T, W, K, D, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AttouchWetsConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission; metric-source exposure through X; bounded-window topology exposure through T; finite window coverage through W; Kuratowski lower-hit and upper-miss handoff through K; local Hausdorff-distance comparison through D; regular rational readback through Q; terminal Real sealing through R; componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

Proof. Project the accepted carrier of Definition 6687.1. The rows $X, T, W, K, D, Q, R, H, C, P, N$ are the only displayed coordinates available to the local NameCert.

The source and window obligations are X, T, W. They fix the ambient metric classifier, the bounded local balls, and the closed-set observations inspected inside those balls.

The convergence handoff obligations are K, D, Q, R. The Kuratowski row reads lower-hit and upper-miss evidence, the distance ledger records local Hausdorff comparisons, the regular row records the rational thresholds, and the Real seal is visible only after those finite rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores a host hyperspace topology, arbitrary closed-set quotient, selected projection, choice-based compactness principle, or completed hyperspace carrier, none of those objects belongs to the local NameCert surface. □

Theorem 6687.3 (AttouchWetsConvergence Kuratowski handoff)**.** *Every Kuratowski-facing consumer of an accepted* $\mathsf{AttouchWetsConvergence}^{\uparrow}$ *packet reads the finite route*

$$X, T, W \longmapsto K \longmapsto D, Q, R \longmapsto H, C, P, N.$$

Thus the consumer receives lower-hit and upper-miss evidence only after the $\mathsf{AttouchWetsTopology}^{\uparrow}$ *bounded-window row and the displayed window ledger have been exposed, and it reaches* $\mathsf{Real}^{\uparrow}$ *only through regular rational readback and the local distance ledger.*

Proof. Start from the metric and topology rows. The metric source X supplies the ambient distance classifier, while T names the bounded Attouch–Wets windows in which convergence is inspected.

Read the finite window ledger next. The row W lists the displayed closed-set observations available inside those bounded balls; no Kuratowski consumer can inspect a hit or miss claim before this ledger is present.

Apply the Kuratowski handoff row K. It consumes the displayed windows as lower-hit and upper-miss evidence, and the distance and regular rows D, Q provide the bounded Hausdorff and rational tolerance comparisons before the terminal Real seal R is visible.

The structural rows H, C, P, N preserve the route as local BEDC data. Therefore the handoff supplies a finite convergence packet rather than host closed-set topology, quotient equality, selected nearest points, choice-based compactness, or ambient hyperspace completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{AttouchWetsConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AttouchWetsConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6687.1, Definition 6687.2, and Definition 6687.3 seed the finite bounded-window convergence route over metric, Attouch–Wets topology, Kuratowski handoff, local Hausdorff-distance, regular rational, Real seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AttouchWetsConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host closed-set topology, arbitrary hyperspace compactness, selected nearest points, quotient equality of closed figures, ambient hyperspace completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window coverage, Kuratowski handoff exactness, local distance-ledger coverage, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.AttouchWetsConvergenceUp.

Constructive story: An $\mathsf{AttouchWetsConvergence}^{\uparrow}$ packet is generated from a MetricUp source row, an AttouchWetsTopologyUp bounded-window row, finite closed-set observation windows, a KuratowskiConvergenceUp handoff row, local HausdorffDistanceUp comparisons, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6688

A Concrete Naming Certificate for $\mathsf{MilmanPettis}^{\uparrow}$

Following Milman and Pettis, the $\mathsf{MilmanPettis}^{\uparrow}$ packet records the finite route by which a uniformly convex Banach-space surface may be handed to a reflexive Banach consumer. It sits over the Banach carrier of **??**, the modulus surface of chapter 5831, the weak-observation interface of chapter 3597, the scalar seal of chapter 38, and the reflexive handoff of chapter 4101. The packet names only the displayed uniform-convexity, weak-window, scalar-budget, transport, continuation, provenance, local naming, and reflexive-handoff rows; it does not import Hahn–Banach separation, selected weak cluster points, quotient double-dual equality, or host weak compactness.

Definition 6688.1 (Milman–Pettis carrier)**.** *A* $\mathsf{MilmanPettis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, U, W, R, D, H, C, P, N, E)$$

with the following displayed rows:

1. *B is the* $\mathsf{BanachSpace}^{\uparrow}$ *row whose complete normed-space route is read before any convexity conclusion is inspected.*
2. *U is the* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *row, carrying the displayed modulus of convexity over the same Banach surface.*
3. *W is the* $\mathsf{WeakTopology}^{\uparrow}$ *observation row, restricted to finite scalar-functional windows.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-budget row used for norm, midpoint, separation, and modulus tolerances.*
5. *D is the* $\mathsf{ReflexiveBanach}^{\uparrow}$ *handoff row, available only after B, U, W, R have been replayed.*
6. *H records componentwise* hsame *transport for the Banach, uniform-convexity, weak-topology, scalar-budget, reflexive-handoff, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Milman–Pettis request through B, U, W, R, D, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MilmanPettis}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ReflexiveBanach}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MilmanPettis}^{\uparrow}}$ *row.*
10. *E is the ledger-refusal row excluding host weak compactness, selected weak limits, quotient double-dual equality, and choice over bounded nets.*

The classifier compares accepted packets only through $B, U, W, R, D, H, C, P, N, E$.

Theorem 6688.2 (Milman–Pettis NameCert obligations)**.** *For every accepted* $\mathsf{MilmanPettis}^{\uparrow}$ *carrier* $M = (B, U, W, R, D, H, C, P, N, E)$*, the local* $\mathsf{NameCert}_{\mathsf{MilmanPettis}^{\uparrow}}$ *surface consists exactly of carrier admission for the Banach row, uniformly convex row, weak-topology row, Real scalar-budget row, reflexive handoff row, transport, continuation, provenance, local naming, and refusal ledger. A consumer may read the Milman–Pettis route only by exposing* $\mathsf{BanachSpace}^{\uparrow}$*,* $\mathsf{UniformlyConvexSpace}^{\uparrow}$*,* $\mathsf{WeakTopology}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ReflexiveBanach}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows in that order.*

Proof. Project the carrier of Definition 6688.1. The analytic rows are B, U, W, R, D: Banach completeness, uniform convexity, weak finite observations, scalar budgets, and the reflexive handoff.

The structural rows H, C, P, N transport, replay, source, and name those analytic rows as one finite packet. The refusal row E has no carrier slot for host weak compactness, selected weak limits, quotient double-dual equality, or choice over bounded nets.

Thus the local NameCert surface is exhausted by the displayed rows. Any accepted consumer must replay the Banach, uniformly convex, weak-topology, scalar-budget, and reflexive-handoff route before reading the local certificate. □

Theorem 6688.3 (Milman–Pettis reflexive handoff)**.** *Every reflexivity-facing consumer of an accepted* $\mathsf{MilmanPettis}^{\uparrow}$ *packet factors through*

$$\mathsf{BanachSpace}^{\uparrow},\ \mathsf{UniformlyConvexSpace}^{\uparrow},\ \mathsf{WeakTopology}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{ReflexiveBanach}^{\uparrow}.$$

In carrier notation, the row D can be read only after the Banach row B, the uniform-convexity row U, the weak-observation row W, and the Real scalar-budget row R are visible. The handoff exports a displayed $\mathsf{ReflexiveBanach}^{\uparrow}$ *route and refuses host weak compactness, selected weak cluster points, quotient double-dual equality, and choice.*

Proof. Begin with the Banach and uniform-convexity rows. The Banach row B supplies the complete normed-space surface, while U supplies the modulus-of-convexity row over that same surface.

Read weak observations and scalar budgets next. The row W restricts weak-topology access to finite scalar-functional windows, and R records the Real-valued norm, midpoint, and tolerance budgets used by the convexity route.

Only after those rows are present does the reflexive handoff row D become visible. Transport through H, replay through C, and provenance through P, N keep the handoff inside the finite packet, while E records that no host compactness theorem, selected weak limit, quotient double-dual equality, or choice principle is exported. □

Independence witness: banachspace, uniformly-convex-space, weak-topology, real, reflexive-banach: $\mathsf{MilmanPettis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Banach completeness, uniform convexity, weak finite observations, Real scalar budgets, a reflexive handoff, transport, replay, provenance, local naming, and refusal rows as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MilmanPettis}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MilmanPettis}^{\uparrow}$ packet is generated from BanachSpace rows, UniformlyConvexSpace rows, WeakTopology finite-observation rows, Real scalar-budget rows, a ReflexiveBanach handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, local NameCert rows, and a refusal ledger.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MilmanPettis}^{\uparrow}}$, seed)

Scope closed: Definition 6688.1, Definition 6688.2, and Definition 6688.3 seed the finite route from uniform convexity over a Banach surface to the reflexive Banach handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MilmanPettis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Hahn–Banach separation, host weak compactness, selected weak cluster points, quotient double-dual equality, choice over bounded nets, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scalar-budget exactness, weak-window compatibility, reflexive-handoff nonescape, transport, replay, provenance, local naming, and refusal rows for BEDC.Derived.MilmanPettisUp.

Chapter 6689

A Concrete Naming Certificate for $\mathsf{ModulusOfConvexity}^{\uparrow}$

Following Bishop, Clarkson, and the uniformly convex Banach-space tradition, the $\mathsf{ModulusOfConvexity}^{\uparrow}$ packet records the finite tolerance surface that witnesses how midpoint separation forces a norm drop. It sits over the Banach carrier of **??**, the norm rows of chapter 89, the convex-set rows of chapter 208, the scalar seal of chapter 38, and the Milman–Pettis consumer of chapter 6688. The packet names only displayed norm bounds, midpoint convexity, Real tolerance budgets, transport, replay, provenance, local naming, and uniform-convexity handoff rows; it does not import host compactness, selected minimizers, Hahn–Banach separation, quotient norm equality, or a completed ambient Banach theorem.

Definition 6689.1 (Modulus of convexity carrier)**.** *A* $\mathsf{ModulusOfConvexity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, N, K, R, E, M, H, C, P, L, U)$$

with the following displayed rows:

1. *B is the* $\mathsf{BanachSpace}^{\uparrow}$ *row whose complete normed-space surface is read before any modulus value is inspected.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *row for the norm, unit-ball boundary, midpoint norm, and comparison windows.*
3. *K is the* $\mathsf{ConvexSet}^{\uparrow}$ *row naming the unit-ball and midpoint convexity surface used by the modulus read.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance row carrying the positive separation budget, midpoint-drop budget, and comparison precision.*
5. *E is the separation row saying that two displayed unit-ball points are at least the tolerance named by R apart.*
6. *M is the modulus row returning a displayed positive drop budget for the midpoint norm.*
7. *H records componentwise* hsame *transport for the Banach, norm, convex-set, Real tolerance, separation, modulus, continuation, provenance, local naming, and handoff rows.*
8. *C records displayed* Cont *replay from a modulus request through $B, N, K, R, E, M, H, P, L, U$.*
9. *P is the* Pkg *provenance over* $\mathsf{ModulusOfConvexity}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *L is the local* $\mathsf{NameCert}_{\mathsf{ModulusOfConvexity}^{\uparrow}}$ *row.*
11. *U is the uniform-convexity handoff row made available to* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *and* $\mathsf{MilmanPettis}^{\uparrow}$ *consumers.*

The classifier compares accepted packets only through $B, N, K, R, E, M, H, C, P, L, U$.

Theorem 6689.2 (Modulus of convexity NameCert obligations)**.** *For every accepted* $\mathsf{ModulusOfConvexity}^{\uparrow}$ *carrier $D = (B, N, K, R, E, M, H, C, P, L, U)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusOfConvexity}^{\uparrow}}$ *surface consists exactly of carrier admission for the Banach row, norm row, convex unit-ball row, Real tolerance row, separation row, modulus-drop row, transport, continuation, provenance, local naming, and uniform-convexity handoff. A consumer may read the modulus route only by exposing* $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows in that order.*

Proof. Project the carrier of Definition 6689.1. The analytic rows are B, N, K, R, E, M: Banach completeness, norm access, unit-ball convexity, Real tolerance budgets, displayed separation, and the midpoint-drop modulus.

The structural rows H, C, P, L transport, replay, source, and name those analytic rows as one finite packet. They do not add host compactness, selected minimizers, quotient norm equality, or ambient separation.

The handoff row U is therefore readable only after the displayed modulus rows are present. This exhausts the local NameCert surface and fixes the consumer order through the finite BEDC rows. □

Theorem 6689.3 (Modulus of convexity uniform-convexity handoff)**.** *Every uniformly convex Banach-space consumer of an accepted* $\mathsf{ModulusOfConvexity}^{\uparrow}$ *packet factors through*

$$\mathsf{BanachSpace}^{\uparrow},\ \mathsf{Norm}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformlyConvexSpace}^{\uparrow}.$$

In carrier notation, the handoff row U can be read only after the Banach row B, norm row N, convex-set row K, tolerance row R, separation row E, and modulus-drop row M are visible. The same handoff is the modulus surface consumed by the Milman–Pettis route.

Proof. Begin with the Banach and norm rows. The row B supplies the complete normed-space surface, while N supplies the unit-ball, distance, midpoint, and comparison windows used by the modulus read.

Read the convexity and scalar rows next. The row K restricts the midpoint operation to the displayed convex unit-ball surface, and R supplies the Real-valued separation and midpoint-drop tolerances.

Only after E and M expose the separation-to-drop relation does U become available. Transport through H, replay through C, and provenance through P, L keep the handoff inside the same finite packet, so $\mathsf{UniformlyConvexSpace}^{\uparrow}$ and $\mathsf{MilmanPettis}^{\uparrow}$ receive a displayed modulus route rather than an ambient Banach-space theorem. □

Independence witness: banachspace, norm, convexset, real, milman-pettis: $\mathsf{ModulusOfConvexity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Banach completeness, norm windows, convex unit-ball rows, Real tolerance budgets, separation, midpoint-drop data, transport, replay, provenance, local naming, and a uniform-convexity handoff as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfConvexity}^{\uparrow}}$**.**

Constructive story: A ModulusOfConvexity$^{\uparrow}$ packet is generated from BanachSpace rows, Norm rows, ConvexSet unit-ball rows, Real tolerance rows, separation rows, midpoint-drop rows, displayed hsame transport, displayed Cont replay, Pkg provenance, local NameCert rows, and a uniform-convexity handoff.

Theory closure: TheoryGate(NameCert$_{\text{ModulusOfConvexity}^{\uparrow}}$, seed)

Scope closed: Definition 6689.1, Definition 6689.2, and Definition 6689.3 seed the finite route from a Banach norm and convex unit-ball surface to a uniform-convexity modulus handoff.

Formal verification: FormalStatus(NameCert$_{\text{ModulusOfConvexity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host compactness, selected minimizers, Hahn–Banach separation, quotient norm equality, ambient Banach-space uniform convexity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, midpoint-drop nonescape, uniform-convexity handoff, transport, replay, provenance, and local naming for BEDC.Derived.ModulusOfConvexityUp.

Chapter 6690

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$

The $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$ packet realizes the diagonal-limit branch of section 9238.1 as one finite exchange certificate. It sits beside the StreamName windows of chapter 126, the DyadicRatCore tolerance ledger of chapter 291, the RegSeqRat readback route of chapter 301, and the Real seal of chapter 38. The packet names paired diagonal-window choices, tail-meet compatibility, real-seal congruence, transport, continuation, provenance, and local naming without introducing quotient streams, selected limits, countable choice, or ambient Real completeness.

Definition 6690.1 (Regular Cauchy diagonal-exchange carrier)**.** *A* $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, D, R, Q, T, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row containing the two inspected diagonal windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row recording the paired tolerance budgets and the comparison scale.*
3. *R and Q are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the diagonal windows.*
4. *T is the regular-cauchy tail-meet row that synchronizes the two windows before the exchange is accepted.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, D, R, Q, T have been replayed.*
6. *H records componentwise* hsame *transport for the window, tolerance, readback, tail-meet, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an exchange request through $S, D, R, Q, T, L, H, P, N$.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, Q, T, L, H, C, P, N$.

Lean4 (definition) `BEDC.Derived.RegularCauchyDiagonalExchangeUp`

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalExchangeUp.RegularCauchyDiagonalExchangeTasteGate`
`single carrier alignment`

Theorem 6690.2 (Regular Cauchy diagonal-exchange NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$ *carrier* $E = (S, D, R, Q, T, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExc}}$ *surface consists exactly of carrier admission for StreamName windows, DyadicRatCore tolerances, paired RegSeqRat readbacks, the regular-cauchy tail-meet row, the terminal Real seal, componentwise transport, continuation replay, provenance, and local naming. No accepted exchange may expose the Real seal before the rows*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

are visible in the packet.

Proof. Project the carrier of Definition 6690.1. The diagonal-window row S, tolerance row D, readback rows R, Q, tail-meet row T, and Real seal row L are the only analytic coordinates.

The structural rows H, C, P, N transport, replay, source, and name the same finite exchange. Since the classifier has no additional coordinate, quotient streams, selected limits, countable-choice schedules, and ambient completeness cannot be read from the packet.

Therefore every accepted Real-seal read is downstream of the displayed StreamName, DyadicRatCore, RegSeqRat, Real, transport, continuation, provenance, and naming rows. □

Theorem 6690.3 (Regular Cauchy diagonal-window exchange)**.** *Every accepted* $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$ *packet turns a paired diagonal-window read into a Real-facing seal only through the finite route*

$$S, D, R, Q \longmapsto T \longmapsto L \longmapsto H, C, P, N.$$

The route records diagonal-limit compatibility and regular-cauchy tail-meet synchronization before the Real seal is exposed, and it exports no quotient-stream equality or selected limit.

Proof. Begin with the two windows carried by S. The tolerance row D fixes the dyadic scale at which the windows are compared, while R and Q read the corresponding regular rational data.

The tail-meet row T is then consumed before L is visible. It is the packet-local synchronization witness for diagonal-limit compatibility, so the exchange is not a detached choice of a subsequence or a selected limit.

Finally H, C, P, N keep the accepted route inside the same finite packet. The Real seal is therefore a terminal row of the exchange certificate rather than a proof of quotient-stream equality or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$ exchange read exposes $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows before a $\mathsf{Real}^{\uparrow}$ seal can be read.

Independence witness: regularcauchysequence, diagonal-limit-compatibility, regular-cauchy-tail-meet, real-seal-congruence: $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries paired diagonal windows, dyadic tolerances, paired regular readbacks, tail-meet synchronization, Real-seal congruence, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}$ packet is generated from paired StreamName diagonal windows, DyadicRatCore tolerance budgets, paired RegSeqRat readbacks, a regular-cauchy tail-meet row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalExchange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6690.1, Definition 6690.2, and Definition 6690.3 seed the finite exchange route from paired diagonal windows to a Real seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyDiagonalExchange}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RegularCauchyDiagonalExchangeUp.RegularCauchyDiagonalExchangeTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not close quotient-stream equality, selected limits, countable-choice schedules, ambient Real completeness, or bridge checking.

Upgrade path: Axiom-clean closure requires the same diagonal-exchange TasteGate target to pass the transitive axiom-purity audit.

Chapter 6691

A Concrete Naming Certificate for $\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}$ packet records the finite error-envelope rows used when dyadic estimates are opened, regular Cauchy tails are compared, and a $\mathsf{Real}^{\uparrow}$ seal is read without appealing to quotient stream equality, selected limits, or ambient completeness. It sits over the dyadic arithmetic core of chapter 291, the finite observation discipline of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, the displayed tail-estimate surface of chapter 1825, and the split-budget packet of chapter 1761. The packet gives Real-and-Completion consumers a named finite envelope carrier between local dyadic bounds and regular Cauchy tail reads.

Definition 6691.1 (Dyadic regular error-envelope carrier)**.** *A* $\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, B, W_0, W_1, D_0, D_1, D_\Delta, R_0, R_1, T, A, H, C, P, N)$$

with the following displayed rows:

1. *Q is the requested regular tail tolerance presented by the downstream Real-or-completion consumer.*
2. *B is the* $\mathsf{DyadicErrorBudget}^{\uparrow}$ *row that splits the visible dyadic slack for the two regular reads.*
3. *W_0 and W_1 are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened before the two approximants are inspected.*
4. *D_0 and D_1 are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-error rows read from those windows.*
5. *D_Δ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row recording the displayed dyadic envelope between the two endpoint-error rows and Q.*
6. *R_0 and R_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the two finite windows.*
7. *T is the* $\mathsf{CauchyEstimate}^{\uparrow}$ *tail-estimate row saying that the same envelope controls the regular Cauchy tail request.*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic envelope, regular readback, and tail-estimate rows have been displayed.*
9. *H records componentwise* hsame *transport for the request, budget, windows, dyadic rows, regular readbacks, tail estimate, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the request through the budget, windows, dyadic envelope, regular readbacks, tail estimate, and Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}$, $\mathsf{DyadicErrorBudget}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, trichotomy, detached completion evidence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.DyadicRegularErrorEnvelopeUp`

Theorem 6691.2 (Dyadic regular error-envelope stability)**.** *For every accepted* $\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}$ *carrier* $E = (Q, B, W_0, W_1, D_0, D_1, D_\Delta, R_0, R_1, T, A, H, C, P, N)$*, any refinement of the two finite windows that preserves the displayed budget row* B*, dyadic endpoint rows* D_0, D_1*, envelope row* D_Δ*, regular readbacks* R_0, R_1*, and tail-estimate row* T *preserves the same error-envelope route under* hsame*,* Cont*,* Pkg*, and local* NameCert *naming.*

Proof. Project the carrier of Definition 6691.1. The only analytic coordinates are the request, budget, two windows, three dyadic rows, two regular readbacks, tail estimate, and Real seal.

Window refinement can therefore be read only through W_0, W_1 and their attached rows R_0, R_1. The dyadic comparison still passes through D_0, D_1, D_Δ against the same request Q and budget row B.

The row T records that this displayed dyadic envelope is the tail-estimate surface consumed by the regular Cauchy route. The structural rows H, C, P, N transport, replay, source, and name that same route, so no hidden selector, quotient equality, or completion principle can change the envelope while the packet remains accepted. □

Theorem 6691.3 (Dyadic regular error-envelope Real readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read of an accepted* $\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}$ *packet must factor through*

$$Q, B \longmapsto W_0, W_1 \longmapsto D_0, D_1, D_\Delta \longmapsto R_0, R_1, T \longmapsto A, H, C, P, N.$$

Thus the Real seal is downstream of the displayed dyadic budget, finite windows, regular readbacks, and Cauchy-estimate envelope; it is not a quotient-real equality, selected limit, countable-choice, or ambient-completeness export.

Proof. Read the request and budget rows first. The carrier gives the downstream tolerance Q exactly one displayed dyadic budget row B, so the slack available to the Real-facing read is finite before any stream data is inspected.

Next open the two finite windows and their dyadic rows. The rows $W_0, W_1, D_0, D_1, D_\Delta$ expose the endpoint errors and the comparison envelope, while R_0, R_1 attach the regular-rational readbacks required by the Cauchy tail route.

Finally T feeds the displayed envelope to the Cauchy-estimate surface and A seals the result as a Real-facing row. Transport, replay, provenance, and local naming preserve the same finite route, and the carrier contains no coordinate from which a stronger Real or completion principle could be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicRegularErrorEnvelope}^{\uparrow}$ packet is generated from a regular tail request, one DyadicErrorBudget split, two StreamName windows, three DyadicRatCore envelope rows, two RegSeqRat readbacks, one CauchyEstimate tail row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicRegularErrorEnvelope}\uparrow}$, seed)

Scope closed: Definition 6691.1, Definition 6691.2, and Definition 6691.3 seed the finite dyadic envelope route between displayed error budgets, regular Cauchy readbacks, Cauchy-estimate tails, and Real sealing.

Formal verification: FormalStatus(NameCert$_{\text{DyadicRegularErrorEnvelope}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.DyadicRegularErrorEnvelopeUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, envelope stability, regular readback, Cauchy-estimate handoff, Real-seal compatibility, transport, replay, provenance, and local naming for BEDC.Derived.DyadicRegularErrorEnvelopeUp.

Chapter 6692

A Concrete Naming Certificate for MetacicClosedBetaTraceEnvelope$^{\uparrow}$

The MetacicClosedBetaTraceEnvelope$^{\uparrow}$ packet realizes the ClosurePreservation audit map of chapter 9381 as finite beta-chain, substitution, and ClosedAt replay data. It sits beside the closed beta path of chapter 797, the MetaCIC closure trace of chapter 795, the closed-term substitution compiler of chapter 540, and the kernel acceptance trace of chapter 557. The carrier is not a subject-reduction theorem: it records closedness preservation along an accepted beta-star route before any typed transport claim is allowed.

Definition 6692.1 (MetaCIC closed beta trace-envelope carrier)**.** *A* MetacicClosedBetaTraceEnvelope$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, T, B, S_b, K, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source closed term row, including the displayed ClosedAt boundary.*
2. *T is the target term row reached by the accepted beta-star route.*
3. *B is the finite beta-chain row, listing the one-step beta moves and congruence positions used by the route.*
4. *S_b is the substitution replay row used by beta-redex contractions.*
5. *K is the ClosedAt preservation row for the source, every intermediate beta-chain node, and the target.*
6. *R records the replay order of shift, variable-substitution, full-substitution, beta-step, and beta-star closedness witnesses.*
7. *A is the kernel-acceptance trace row saying that the displayed replay is the accepted audit route.*
8. *H records componentwise* hsame *transport for source, target, beta-chain, substitution, closedness, replay, acceptance, route, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same closed beta trace route.*
10. *P is the* Pkg *provenance over* MetacicClosedBetaTraceEnvelope$^{\uparrow}$*, MetaCIC closure trace, closed-term substitution compiler, TasteGate audit trace, kernel acceptance trace,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetacicClosedBetaTraceEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for subject reduction, typed conversion, dependent codomain transport, hidden beta normalization, quotienting of traces, or acceptance outside the displayed kernel route.

Lean4 (statement) `BEDC.Derived.MetacicClosedBetaTraceEnvelopeUp`

Theorem 6692.2 (MetaCIC closed beta trace-envelope preservation)**.** *For every accepted* MetacicClosedBetaTraceE *carrier $E = (S, T, B, S_b, K, R, A, H, C, P, N)$, the target row T is read as closed only by replaying the displayed beta-star route B, the substitution replay row S_b, the ClosedAt chain K, and the witness order R. The result cannot be obtained from an unrecorded subject-reduction step, typed conversion rule, hidden normalization oracle, or quotient trace identity.*

Proof. Project the carrier. The source and target rows are connected by the finite beta-chain row B, and beta-redex contractions can read substitution data only through S_b.

The closedness claim is then the row K replayed in the order R. It follows the shift, variable-substitution, full-substitution, beta-step, and beta-star preservation witnesses named in the audit map, without inspecting typing judgments.

Finally A, H, C, P, N accept, transport, replay, source, and name the same finite route. Since the carrier omits typed conversion, dependent codomain transport, hidden normalization, and quotient trace identity, the accepted envelope preserves only the displayed closedness route. □

Theorem 6692.3 (MetaCIC closed beta trace-envelope vision handoff)**.** *The* $\mathsf{MetacicClosedBetaTraceEnvelope}^{\uparrow}$ *packet hands chapter 9381 to concrete NameCert consumers by packaging beta-star route data, substitution replay, ClosedAt preservation rows, kernel acceptance, transport, displayed continuation replay, provenance, and local naming as one finite carrier. A later Lean-facing gate may require 'TasteGate.lean' to provide Nontrivial* $\mathsf{MetacicClosedBetaTraceEnvelope}^{\uparrow}$ *and FieldFaithful* $\mathsf{MetacicClosedBetaTraceEnvelope}^{\uparrow}$*, but the paper carrier already fixes the finite rows those gates must inspect.*

Proof. Use Definition 6692.1. Its rows name the source, target, beta-chain, substitution replay, ClosedAt replay, acceptance trace, transport, route, provenance, and local certificate explicitly.

The handoff is finite because every audit row is a displayed BHist coordinate. Downstream TasteGate obligations can test nontriviality and field faithfulness against those rows, while any typed subject-reduction claim must land in a separate packet with its own dependent transport data. □

Falsifiable prediction: Every accepted $\mathsf{MetacicClosedBetaTraceEnvelope}^{\uparrow}$ packet replays a beta-star closedness preservation route through displayed beta-chain, substitution, ClosedAt, and kernel-acceptance rows; an accepted packet whose target closedness cannot be replayed from those rows refutes this chapter.

Independence witness: metacicclosuretrace, closedtermsubstitutioncompiler, tastegateaudittrace, kernelacceptancetrace: the closed beta trace envelope carries a source-target beta-chain row, a substitution replay row, a ClosedAt chain row, and a kernel-acceptance row simultaneously, while each named sibling omits at least one of those rows, so no row-preserving bijection can identify the carriers.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicClosedBetaTraceEnvelope}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{MetacicClosedBetaTraceEnvelope}^{\uparrow}$ packet is generated from source and target closed-term rows, a beta-chain row, substitution replay, ClosedAt preservation replay, kernel acceptance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetacicClosedBetaTraceEnvelope}\uparrow}$, seed)

Scope closed: Definition 6692.1, Definition 6692.2, and Definition 6692.3 seed the finite closed beta trace envelope over beta-star, substitution, ClosedAt replay, and kernel acceptance rows.

Formal verification: FormalStatus(NameCert$_{\text{MetacicClosedBetaTraceEnvelope}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.MetacicClosedBetaTraceEnvelopeUp`

Bridge status: none

Not claimed: This chapter does not close subject reduction, typed conversion, dependent codomain transport, hidden normalization, quotient trace identity, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked beta-chain replay, substitution replay, ClosedAt preservation, kernel acceptance, transport, route replay, provenance, local naming, and TasteGate nontriviality and field-faithfulness obligations for BEDC.Derived.MetacicClosedBetaTraceEnvelopeUp.

Chapter 6693

A Concrete Naming Certificate for $\mathsf{SkorokhodTopology}^{\uparrow}$

Following Skorokhod and Billingsley on the topology of cadlag path spaces, the $\mathsf{SkorokhodTopology}^{\uparrow}$ packet records the finite naming surface used to compare right-continuous paths with left limits by displayed time-change, window, and real-name data. It sits after the cadlag path carrier of chapter 5968, the metric interface of chapter 57, the finite observation schedule of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The certificate gives stochastic-process consumers a path-space topology route without importing selected path limits, host path equality, quotient-by-time-change equality, Borel measure construction, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6693.1 (Skorokhod topology carrier)**.** *A* $\mathsf{SkorokhodTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, M, S, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CadlagRealFunction}^{\uparrow}$ *source row naming the path packet whose right-continuity and left-limit windows are already displayed.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row used only as a finite tolerance interface on path-window observations.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for domain windows, jump-neighborhood windows, and time-change probes.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational observations along the displayed schedule.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling mesh size, time-change displacement, path-window error, and real-name readback precision.*
6. *L is the Skorokhod-lag row. It records finite monotone time-change probes and their mesh/tolerance obligations, not a selected homeomorphism of the host interval.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the cadlag source, metric comparison row, observation schedule, rational readback, dyadic tolerance ledger, and lag row have been displayed.*
8. *H records componentwise* hsame *transport for the cadlag source, metric comparison, schedule, readback, tolerance, lag, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a path-topology request through $K, M, S, R, D, L, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{SkorokhodTopology}^{\uparrow}$, $\mathsf{CadlagRealFunction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SkorokhodTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, S, R, D, L, E, H, C, P, N$. It has no coordinate for host path equality, quotient path equality, selected time changes, selected limits, Borel sigma-algebras, compactness, tightness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6693.2 (Skorokhod topology NameCert obligations)**.** *For every accepted* $\mathsf{SkorokhodTopology}^{\uparrow}$ *carrier $T = (K, M, S, R, D, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SkorokhodTopology}^{\uparrow}}$ *surface consists exactly of carrier admission, cadlag-source admission through K, metric comparison admission through M, finite observation schedule exposure through S, regular rational readback through R, dyadic tolerance control through D, finite Skorokhod-lag obligation through L, terminal real-seal ordering through E, componentwise transport through H, displayed replay through C, package provenance through P, local naming through N, and ledger refusal for host path equality, quotient path equality, selected time changes, selected limits, measure-theoretic structure, compactness, tightness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The analytic rows are K, M, S, R, D, L, E, and the structural rows are H, C, P, N.

The cadlag source K supplies right-continuity and left-limit window obligations from chapter 5968. The metric comparison row M, stream schedule S, rational readback R, and dyadic ledger D provide the finite data on which a topology consumer may compare path-window observations.

The lag row L is downstream of those data. It records finite time-change probes and their tolerance obligations, while the terminal seal E is reached only after the displayed route has passed through K, M, S, R, D, L.

Componentwise transport, replay, provenance, and local naming preserve the same packet. Since no coordinate stores selected time changes, quotient path equality, measure-theoretic structure, compactness, tightness, or ambient real completeness, the NameCert obligations are exactly the listed finite rows. □

Theorem 6693.3 (Skorokhod topology cadlag modulus handoff)**.** *Every path-topology consumer of an accepted* $\mathsf{SkorokhodTopology}^{\uparrow}$ *packet must first read the* $\mathsf{CadlagRealFunction}^{\uparrow}$ *source row, then the* $\mathsf{Met}^{\uparrow}$ *comparison row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before it can consume the Skorokhod-lag row and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus the handoff is a finite cadlag-modulus route rather than a host equality of paths, a quotient equality under time changes, a selected limiting path, a measure-theoretic compactness theorem, or an ambient completeness principle.*

Proof. Let $T = (K, M, S, R, D, L, E, H, C, P, N)$ be accepted. A path-topology request reaches the cadlag source row K before any comparison row is available, so the request begins with displayed right-continuity and left-limit windows.

Next the request reads M, S, R, D. These rows give the metric tolerance interface, finite observation schedule, regular rational readback, and dyadic precision ledger needed to state a finite comparison between path windows.

Only then may the request consume the lag row L and the terminal seal E. The lag row records time-change probes as displayed finite obligations, while the seal row remains downstream of cadlag, metric, schedule, readback, and tolerance data.

Transport through H and replay through C preserve the same route, and P, N package and name it. The excluded host equality, quotient equality, selected-limit, measure-theoretic, compactness, and completeness conclusions have no carrier row to read. □

Closure status for $\mathsf{NameCert}_{\mathsf{SkorokhodTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{SkorokhodTopology}^{\uparrow}$ packet is generated from a CadlagRealFunction source row, Metric comparison row, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, finite Skorokhod-lag row, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SkorokhodTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6693.1, Definition 6693.2, and Definition 6693.3 seed the finite cadlag path-topology route over displayed time-change probes and terminal Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SkorokhodTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host path equality, quotient path equality, selected time changes, selected limits, Borel measure construction, compactness, tightness, Lean verification, bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, cadlag-source admission, metric comparison admission, stream-window exposure, rational readback, dyadic tolerance control, Skorokhod-lag obligations, transport, replay, provenance, and local naming for BEDC.Derived.SkorokhodTopologyUp.

Chapter 6694

A Concrete Naming Certificate for $\mathsf{JordanHolder}^{\uparrow}$

Following Jordan and Holder, the $\mathsf{JordanHolder}^{\uparrow}$ packet reconstructs finite-group composition-series data as a BEDC NameCert surface. It sits beside the group carrier of chapter 41, the subgroup carrier of chapter 80, the quotient-group carrier of chapter 82, and the Sylow packet of chapter 3728. Those sibling chapters supply group operations, subgroup containment, quotient-factor rows, and prime-power subgroup witnesses; this chapter records how a composition-series certificate names the factor rows without importing a classification theorem, a selected series, or an unrecorded isomorphism oracle.

Definition 6694.1 (Jordan-Holder carrier)**.** *A* $\mathsf{JordanHolder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (G, S, Q, F, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{Group}^{\uparrow}$ *source row, carrying the multiplication, unit, inverse, and finite carrier window.*
2. *S is the composition-series row, listing the finite chain of* $\mathsf{Subgroup}^{\uparrow}$ *entries from the trivial subgroup to G.*
3. *Q is the quotient-factor row, recording each adjacent* $\mathsf{QuotientGroup}^{\uparrow}$ *factor exposed by the chain.*
4. *F is the simple-factor classifier row, recording that each displayed quotient factor has no non-trivial normal-subgroup row inside the factor surface.*
5. *E is the factor-equivalence ledger, comparing two displayed composition-series rows only through finite permutations and componentwise quotient-factor equivalences.*
6. *H records componentwise* hsame *transport for the group source, series, quotient factors, simple-factor classifiers, equivalence ledger, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from the group source through the series and factor rows.*
8. *P is the* Pkg *provenance over* $\mathsf{JordanHolder}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{QuotientGroup}^{\uparrow}$, $\mathsf{Sylow}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanHolder}^{\uparrow}}$ *row.*

The carrier has no coordinate for a chosen canonical composition series, a complete finite-simple-group classifier, an unrecorded quotient isomorphism, or a proof that two arbitrary chains are equal outside the displayed factor ledger.

Theorem 6694.2 (Jordan-Holder NameCert obligation surface)**.** *For an accepted* $\mathsf{JordanHolder}^{\uparrow}$ *packet* $J = (G, S, Q, F, E, H, C, P, N)$*, the local NameCert obligation surface consists exactly of the finite group source row* G*, composition-series row* S*, quotient-factor row* Q*, simple-factor classifier row* F*, factor-equivalence ledger* E*, componentwise transport row* H*, replay row* C*, package row* P*, and local naming row* N*. Any consumer that drops one of these rows leaves the composition-series certificate and receives neither a quotient-factor certificate nor a Jordan-Holder comparison route.*

Proof. Project the carrier of Definition 6694.1. The group source, subgroup chain, quotient factors, simple-factor classifiers, and factor-equivalence ledger are displayed as distinct finite rows.

The sibling surfaces determine what each row may export. The group row is read through chapter 41, the series entries through chapter 80, and the adjacent factors through chapter 82.

The structural rows H, C, P, N then transport, replay, source, and name the same packet. Since no canonical-series selector or hidden quotient-isomorphism oracle is present, deleting any displayed row exits the certificate surface. □

Theorem 6694.3 (Jordan-Holder composition-series route)**.** *Every composition-series consumer of an accepted* $\mathsf{JordanHolder}^{\uparrow}$ *packet must read the finite route*

$$G \to S \to Q \to F \to E \to H, C, P, N.$$

The route may cite the Sylow packet only as prime-power subgroup provenance for displayed finite-group rows, and it may cite quotient factors only through the adjacent $\mathsf{QuotientGroup}^{\uparrow}$ *rows in* Q*. It does not export a classification of finite simple groups, a chosen canonical series, or an equality of arbitrary composition-series lists outside the factor-equivalence ledger* E*.*

Proof. Start with the source group row G and the displayed chain S. Each adjacent pair in the chain supplies a quotient-factor request, so the consumer reaches the factor row Q before any comparison is available.

Read the simple-factor classifier row F and the factor-equivalence ledger E. The classifier confines each factor to the displayed quotient surface, while E records comparison only by finite reindexing and componentwise factor equivalence.

Finally replay through H, C, P, N. Provenance may cite chapter 3728 for finite prime-power subgroup rows, but the replay has no coordinate for a canonical composition series, a finite-simple-group classification theorem, or an external quotient-isomorphism oracle. □

Closure status for $\mathsf{NameCert}_{\mathsf{JordanHolder}^{\uparrow}}$**.**

Constructive story: A $\mathsf{JordanHolder}^{\uparrow}$ packet is generated from a finite group source, a composition-series chain, adjacent quotient factors, simple-factor classifier rows, factor-equivalence ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanHolder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6694.1, Definition 6694.2, and Definition 6694.3 seed the finite composition-series certificate surface over $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{QuotientGroup}^{\uparrow}$, $\mathsf{Sylow}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanHolder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, classification of finite simple groups, canonical composition-series selection, or equality of arbitrary series outside the displayed factor ledger.

Upgrade path: Obligation closure requires checked carrier admission, quotient-factor exactness, simple-factor classifier stability, factor-equivalence transport, replay, provenance, and local naming for BEDC.Derived.JordanHolderUp.

Chapter 6695

Bishop Cauchy Real Envelope NameCert Construction

Following Bishop and Bridges, the $\mathsf{BishopCauchyRealEnvelope}^{\uparrow}$ packet records the finite envelope boundary at which regular Cauchy data may face $\mathsf{Real}^{\uparrow}$ without becoming a quotient-real construction or a selected limiting value. It sits after the finite observation discipline of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, the effective rate realization route of chapter 1673, the rational approximation window of chapter 1668, and the four-face completion interface of chapter 1844. The envelope gives Real-and-Completion consumers a single finite boundary for stream windows, dyadic budgets, regular-Cauchy witnesses, rational approximants, Real seals, and ledger projections.

Definition 6695.1 (Bishop Cauchy real envelope carrier)**.** *A* $\mathsf{BishopCauchyRealEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, D, R, A, B, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *stream-window row exposing exactly the finite observation windows opened by the Real-facing request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row controlling endpoint scale, tail radius, comparison precision, and rational readback budget.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy witness row read only through the displayed stream windows and dyadic budget.*
4. *A is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *rational approximation row attached to the same S, D, R data.*
5. *B is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the stream, dyadic, regular-Cauchy, and rational approximation rows have been displayed.*
6. *L is the ledger projection row. It records the finite completion-interface read through* $\mathsf{CauchyRateRealization}^{\uparrow}$ *and* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$*, and it stores no chosen limit or quotient representative.*
7. *H records componentwise* hsame *transport for the stream window, dyadic budget, regular-Cauchy witness, rational approximation, Real seal, ledger projection, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from an envelope request through $S, D, R, A, B, L, H, P, N$.*
9. *P is the* Pkg *provenance over* BishopCauchyRealEnvelope$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealRationalApproximation$^{\uparrow}$, CauchyRateRealization$^{\uparrow}$, CauchyRealCompletionInterface$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopCauchyRealEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, A, B, L, H, C, P, N$. It has no coordinate for quotient reals, selected limits, countable choice, trichotomy, host real equality, ambient Real$^{\uparrow}$ *completeness, or bridge credentials.*

Theorem 6695.2 (Bishop Cauchy real envelope obligation surface)**.** *For every accepted* BishopCauchyRealEnvelope$^{\uparrow}$ *carrier $E = (S, D, R, A, B, L, H, C, P, N)$, the local* NameCert$_{\text{BishopCauchyRealEnvelope}^{\uparrow}}$ *surface consists exactly of five obligation families:*

1. *carrier display, requiring the stream-window, dyadic-budget, regular-Cauchy witness, rational approximation, Real seal, ledger projection, transport, replay, provenance, and local naming rows to be present;*
2. *classifier stability, requiring accepted packets to be compared only through the displayed rows $S, D, R, A, B, L, H, C, P, N$;*
3. *envelope transport, requiring every* hsame *transport and every* Cont*-compatible finite observation replay to preserve the same stream windows, dyadic budget, regular witness, rational approximation, Real seal, and ledger projection;*
4. *ledger exactness, requiring the projection row L to factor through the Cauchy-rate realization and four-face completion-interface rows before the Real seal can be consumed;*
5. *no quotient or choice use, requiring the certificate to export no quotient real, selected limit, countable-choice selector, trichotomy datum, host real equality proof, ambient completeness theorem, or bridge credential.*

No local obligation is stored outside these five families.

Proof. Project the accepted carrier. The analytic rows are exactly S, D, R, A, B, L, and the structural rows are exactly H, C, P, N.

Carrier display and classifier stability are immediate from the displayed packet: every accepted comparison has access only to those ten rows. The regular-Cauchy witness R is downstream of the stream window and dyadic budget, the rational approximation A is attached to the same finite data, and the Real seal B appears only after those rows have been read.

Transport and replay use the structural rows. The hsame row H moves each displayed coordinate componentwise, while the Cont row C replays the same finite observation route for later consumers.

The ledger row L is the only completion-facing projection. It records the finite Cauchy-rate and completion-interface handoff, so ledger exactness cannot add a second Real coordinate or a selected limit.

The excluded principles have no carrier row and no continuation route. Hence quotient reals, selected limits, countable choice, trichotomy, host real equality, ambient completeness, and bridge credentials cannot become local NameCert obligations. □

Theorem 6695.3 (Bishop Cauchy real envelope scope)**.** *Every accepted* BishopCauchyRealEnvelope$^{\uparrow}$ *consumer depends only on the sibling route through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$,

$\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRateRealization}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, *and* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$. *Its public read is exhausted by the rows* $S, D, R, A, B, L, H, C, P, N$, *so the envelope does not depend on quotient reals, selected limits, countable choice, trichotomy, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Read the provenance row P of the accepted carrier. It names exactly the sibling surfaces $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{CauchyRateRealization}^{\uparrow}$, $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the analytic dependency route.

The carrier rows realize that route in order. A consumer first receives the finite stream window and dyadic budget, then the regular-Cauchy witness, rational approximation, Real seal, and ledger projection. The structural rows transport, replay, source, and name the same packet.

Apply the obligation surface of Definition 6695.2. Since no accepted row stores any excluded principle, the public scope is exhausted by the listed sibling route and carrier rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyRealEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyRealEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6695.1, Definition 6695.2, and Definition 6695.3 seed the finite envelope boundary for Real-facing regular Cauchy data over stream windows, dyadic budgets, regular witnesses, rational approximation, Real seals, and ledger projection rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyRealEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.BishopCauchyRealEnvelopeUp`

Bridge status: none

Not claimed: This chapter does not claim quotient reals, selected limits, countable choice, trichotomy, ambient Real completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier display, classifier stability, hsame and Cont-compatible envelope transport, ledger exactness, and no-quotient/no-choice nonescape for BEDC.Derived.BishopCauchyRealEnvelopeUp.

Constructive story: A $\mathsf{BishopCauchyRealEnvelope}^{\uparrow}$ packet is generated from a $\mathsf{StreamName}^{\uparrow}$ stream-window row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance-budget row, a $\mathsf{RegSeqRat}^{\uparrow}$ regular-Cauchy witness row, a $\mathsf{RealRationalApproximation}^{\uparrow}$ rational approximation row, a terminal $\mathsf{Real}^{\uparrow}$ seal, a completion-facing ledger projection, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6696

A Concrete Naming Certificate for $\mathsf{FiniteUnionBound}^{\uparrow}$

Following Boole's inequality and elementary finite probability, the $\mathsf{FiniteUnionBound}^{\uparrow}$ packet records finite union-bound data over displayed $\mathsf{ProbSpace}^{\uparrow}$ event windows, not a sigma-completion or almost-sure quotient. It sits after the probability-space source of chapter 184, the random-variable observation surface of chapter 185, and the distribution readback surface of chapter 186; the finite ledger is then available to the Borel–Cantelli route of chapter 2357.

Definition 6696.1 (FiniteUnionBound carrier)**.** *A* $\mathsf{FiniteUnionBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (\Omega, E, W, S, B, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row naming the probability carrier from which every event probability is read.*
2. E *is the finite event-family row, listing the displayed event names and their membership readbacks.*
3. W *is the finite union-window row, recording the inspected finite subfamily and the displayed union event produced from it.*
4. S *is the probability-sum ledger, recording the finite sum of the probabilities of the events listed by* W*.*
5. B *is the bound-comparison row, recording that the probability of the displayed union event is bounded by the ledger value in* S*.*
6. H *records componentwise* hsame *transport for the probability source, event family, union window, sum ledger, bound comparison, replay, provenance, and local naming rows.*
7. C *records the displayed* Cont *replay by which downstream consumers read* Ω, E, W, S, B *in that order.*
8. P *is the* Pkg *provenance over* $\mathsf{FiniteUnionBound}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteUnionBound}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a completed sigma-algebra, countable union, quotient almost-sure equality, independence converse, limiting theorem, or host probability space outside the displayed finite event rows.

Theorem 6696.2 (FiniteUnionBound NameCert obligations)**.** *For every accepted* $\mathsf{FiniteUnionBound}^{\uparrow}$ *carrier* $U = (\Omega, E, W, S, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteUnionBound}^{\uparrow}}$ *surface consists exactly of five finite obligation rows: carrier exposure for the displayed tuple; event-window exactness linking* E *and* W *to the union event read in* Ω*; probability-sum ledger exposure through* S*; bound-comparison exposure through* B*; and transport, replay, provenance, and local naming through* H, C, P, N*. No finite union-bound obligation is stored outside these rows.*

Proof. Project the accepted carrier. The tuple $U = (\Omega, E, W, S, B, H, C, P, N)$ exposes the probability source, event family, union window, sum ledger, comparison row, transport, replay, provenance, and local naming rows.

Read the event-window row before the probability ledger. The window W selects only entries from E and names the displayed finite union event in the source Ω, so the bound has a fixed finite domain.

The sum and comparison rows then give the certificate surface. The row S lists the finite probability sum, and B compares the probability of the displayed union event with that ledger value. Transport through H and replay through C preserve exactly these rows, while P, N record provenance and naming.

Since no remaining coordinate names a sigma-completion, countable union, quotient almost-sure equality, independence converse, or limiting theorem, the five listed obligations exhaust the local certificate. □

Theorem 6696.3 (FiniteUnionBound window-sum ledger)**.** *Every finite union read of an accepted* $\mathsf{FiniteUnionBound}^{\uparrow}$ *packet factors through the displayed route*

$$\Omega,\ E,\ W,\ S,\ B.$$

The event family and union window determine the inspected finite subfamily before the probability-sum ledger is available, and the bound comparison reads only that ledger. Thus a consumer cannot replace the finite event-window sum by an ambient countable union, external subadditivity oracle, or quotient event equality while preserving the packet.

Proof. Start with the finite event-family row E and the window row W. They determine the displayed union event and the finite list of event probabilities to be inspected in Ω.

The probability-sum ledger S is then the only row that records the bound value. The comparison row B reads the union-event probability and compares it with that value, so every accepted finite union read has passed through the same window-sum ledger.

Finally H, C, P, N transport, replay, source, and name the route without adding another probability object. Coordinate exhaustion excludes countable unions, external subadditivity, and quotient event equality from the accepted read. □

Theorem 6696.4 (FiniteUnionBound Borel–Cantelli handoff)**.** *Every* $\mathsf{BorelCantelli}^{\uparrow}$*-facing consumer that requests a finite union estimate receives the* $\mathsf{FiniteUnionBound}^{\uparrow}$ *ledger before any tail-sum reasoning is exposed. The handoff supplies the probability source row* Ω*, finite event family* E*, union window* W*, probability-sum ledger* S*, bound comparison* B*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row; it supplies no sigma-completion, countable-choice selector, almost-sure quotient equality, independence converse, or infinite limiting theorem.*

Proof. Project the accepted $\mathsf{FiniteUnionBound}^{\uparrow}$ packet and read the route of Definition 6696.3. A Borel–Cantelli finite-window request first receives Ω, E, W, S, B as displayed rows.

Only after this finite ledger is present may the downstream Borel–Cantelli packet ask for a tail-sum route. The handoff therefore separates the Boole-inequality ledger from the later tail-event accounting.

Transport, replay, provenance, and naming are inherited through H, C, P, N. Since the handoff has no coordinate for sigma-completion, countable choice, almost-sure quotient equality, independence converse, or an infinite limiting theorem, none of those claims is exported to the Borel–Cantelli consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteUnionBound}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteUnionBound}^{\uparrow}$ packet is generated from a probability source row, finite event-family row, finite union-window row, probability-sum ledger, bound-comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteUnionBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6696.1, Definition 6696.2, Definition 6696.3, and Definition 6696.4 seed the finite Boole-inequality ledger and its Borel–Cantelli-facing handoff over displayed probability windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteUnionBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sigma-completion, countable choice, quotient almost-sure equality, an independence converse, an infinite limiting theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, event-window exactness, probability-sum ledger stability, bound-comparison exactness, Borel–Cantelli handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteUnionBoundUp.

Chapter 6697

A Concrete Naming Certificate for $\mathsf{BanachLimit}^{\uparrow}$

Following Banach and the classical theory of invariant means, the $\mathsf{BanachLimit}^{\uparrow}$ packet records a displayed shift-invariant positive extension row for bounded scalar sequences as finite NameCert data. It factors the Banach-internal limit surface of chapter 90 through the regular real-name route of chapter 38, the finite observation schedule of chapter 126, and the regular rational readback of chapter 301. The packet names only the finite carrier, norm-bound, positivity, shift, normalization, Real-seal, transport, replay, provenance, and local naming rows; it does not claim Hahn–Banach existence, ultrafilters, choice, quotient sequence equality, or ambient dual-space completeness.

Definition 6697.1 (Banach limit carrier)**.** *A* $\mathsf{BanachLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, A, N, P, S, U, E, H, C, Q, K)$$

with the following displayed rows:

1. *B is the bounded-sequence input row, naming the finite scalar sequence windows and the bound request that a consumer is allowed to inspect.*
2. *A is the* $\mathsf{Banach}^{\uparrow}$ *or Banach-space ambient row whose scalar and norm surface is already displayed by chapter 90.*
3. *N is the norm-bound ledger, recording that the value row is read only through the displayed bound of the bounded input sequence.*
4. *P is the positivity ledger, recording that pointwise nonnegative inspected windows are sent to a nonnegative displayed* $\mathsf{Real}^{\uparrow}$ *value row.*
5. *S is the shift-invariance row, comparing the original bounded sequence window with the one-step shifted window through the same local packet.*
6. *U is the normalization row for the constant-one sequence, binding the displayed value to the terminal real-name seal for* 1*.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks for the inspected scalar windows have been displayed.*
8. *H records componentwise* hsame *transport for B, A, N, P, S, U, E.*
9. *C records displayed* Cont *replay from bounded-sequence requests through norm-bound, positivity, shift, normalization, stream-window, regular-rational, and real-seal rows.*

10. *Q is the* Pkg *provenance over* $\mathsf{BanachLimit}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *K is the local* $\mathsf{NameCert}_{\mathsf{BanachLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a Hahn–Banach extension theorem, an ultrafilter, a choice-selected invariant mean, quotient equality of bounded sequences, a host dual-space element, or ambient completeness of a dual carrier.

Theorem 6697.2 (Banach limit NameCert obligations)**.** *For every accepted* $\mathsf{BanachLimit}^{\uparrow}$ *carrier*

$$L = (B, A, N, P, S, U, E, H, C, Q, K),$$

the local $\mathsf{NameCert}_{\mathsf{BanachLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-sequence input row, Banach ambient row, norm-bound ledger, positivity ledger, shift-invariance row, normalization row, Real-seal row, componentwise transport, displayed replay, provenance, and local naming. The packet also records that positivity, shift invariance, and normalization are read only through the displayed finite rows P, S, U after the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows feeding E have been exposed.*

Proof. Project the carrier of Definition 6697.1. The tuple $B, A, N, P, S, U, E, H, C, Q, K$ is the whole accepted packet, so the bounded-sequence source, Banach ambient row, norm-bound ledger, positivity ledger, shift row, normalization row, Real seal, transport, replay, provenance, and local naming are the only available certificate fields.

The scalar readback is forced through E. That row is downstream of the finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback named in the carrier, so a consumer cannot replace the displayed real-name route by host real equality, quotient sequence equality, or an anonymous dual-space functional.

The functional constraints are likewise local. Positivity is read through P, shift invariance through S, and normalization through U; each row is transported by H and replayed by C inside the same packet. Since Q and K source and name only these rows, no Hahn–Banach theorem, ultrafilter, choice selector, or ambient dual-space completeness claim is exported. □

Theorem 6697.3 (Banach limit shift-invariant boundary)**.** *Every shift-invariant read of an accepted* $\mathsf{BanachLimit}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{bounded\ sequence},\ \mathsf{Banach}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

and through the rows B, A, S, E, H, C, Q, K of Definition 6697.1. The conclusion is only that the named packet compares the original and shifted bounded-sequence windows through its local shift row; it is not an existence theorem for Banach limits and not a route to Hahn–Banach, ultrafilters, selected invariant means, quotient sequence equality, host equality, or ambient dual-space completeness.

Proof. Start with the NameCert obligations of Definition 6697.2. They expose the bounded-sequence input B, the Banach ambient row A, and the Real-facing readback route before the shift row can be consumed.

Read the shift row S through the displayed continuation C. The continuation keeps the original and shifted sequence windows inside the same $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observation route before the value row reaches the $\mathsf{Real}^{\uparrow}$ seal E.

Transport through H preserves the same rows, and provenance and local naming through Q, K keep the comparison attached to the packet. Therefore the shift-invariant boundary is exactly

the finite row S over the displayed source windows. The excluded existence, ultrafilter, choice, quotient, host-equality, and dual-completeness claims have no carrier coordinate from which they could be read. □

Falsifiable prediction: Every accepted $\mathsf{BanachLimit}^{\uparrow}$ consumer must expose the bounded-sequence row, Banach ambient row, norm-bound ledger, positivity row, shift row, normalization row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise transport, replay, provenance, and local NameCert row before any invariant-mean read is public.

Independence witness: banach, real, streamname, regseqrat: $\mathsf{BanachLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds bounded-sequence input, Banach ambient data, norm-bound control, positivity, shift invariance, normalization, Real sealing, transport, replay, provenance, and local naming into one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachLimit}^{\uparrow}$ packet is generated from bounded-sequence windows, a Banach ambient row, norm-bound, positivity, shift-invariance, normalization, StreamName, RegSeqRat, and Real-seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6697.1, Definition 6697.2, and Definition 6697.3 seed the finite Banach-limit packet over bounded-sequence, Banach, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach existence, ultrafilters, choice, quotient sequence equality, ambient dual-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, norm-bound exactness, positivity preservation, shift-row stability, normalization readback, Real-seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.BanachLimitUp.

Chapter 6698

A Concrete Naming Certificate for $\mathsf{RiemannSphere}^{\uparrow}$

Following Ahlfors on the extended complex plane and fractional linear transformations, the $\mathsf{RiemannSphere}^{\uparrow}$ packet records the compact projective complex line as finite NameCert data. It sits between the complex arithmetic carrier of chapter 39, the homogeneous-line classifier of chapter 207, the projective zero-locus surface of chapter 155, and the fractional-linear consumer of chapter 5110. The packet names the sphere carrier without importing quotient projective equality, a host compact complex manifold, selected affine charts, or an ambient equality between affine and projective presentations.

Definition 6698.1 (Riemann sphere carrier)**.** *A* $\mathsf{RiemannSphere}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (C, P, A, I, Q, H, T, G, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Complex}^{\uparrow}$ *affine coordinate row used for the finite chart* $[z : 1]$*.*
2. *P is the* $\mathsf{ProjectiveSpace}^{\uparrow}$ *homogeneous-line row over the complex scalar carrier.*
3. *A is the affine-chart admission row, recording the displayed inclusion of complex coordinates into homogeneous coordinates.*
4. *I is the infinity row* $[1 : 0]$*, stored as a named projective endpoint rather than as a quotient class.*
5. *Q is the compact projective coverage ledger, recording that every inspected point request is routed through the affine chart row or through the infinity row.*
6. *H records componentwise* hsame *transport for complex, projective, affine-chart, infinity, coverage, provenance, and local naming rows.*
7. *T records displayed* Cont *replay from affine complex reads through the projective line row and from projective endpoint reads through the compact coverage ledger.*
8. *G is the* Pkg *provenance over* $\mathsf{RiemannSphere}^{\uparrow}$*,* $\mathsf{Complex}^{\uparrow}$*,* $\mathsf{ProjectiveSpace}^{\uparrow}$*,* $\mathsf{ProjectiveVar}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannSphere}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, P, A, I, Q, H, T, G, N$. It has no coordinate for quotient equality of projective representatives, a selected atlas isomorphism, a host complex-surface object, or ambient compactness.

Theorem 6698.2 (Riemann sphere NameCert obligations)**.** *For every accepted* $\mathsf{RiemannSphere}^{\uparrow}$ *carrier* $S = (C, P, A, I, Q, H, T, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RiemannSphere}^{\uparrow}}$ *surface consists exactly of complex affine-coordinate exposure, projective homogeneous-line exposure, affine-chart admission, infinity endpoint exposure, compact projective coverage, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted consumer must inspect those rows before treating the packet as the extended complex plane.*

Proof. Project the carrier of Definition 6698.1. The complex row C is the only affine source, and the projective row P is the only homogeneous-line source available to the packet.

The affine chart row A and infinity row I then split the public point reads into two displayed routes. The coverage ledger Q records that a point request reaches the carrier only through one of those routes, so no unrecorded quotient representative or host point set is available.

The structural rows H, T, G, N transport, replay, source, and name exactly the same finite packet. Since no row contains host compactness, a selected atlas equality, quotient projective equality, or an ambient complex surface, the listed rows are the full NameCert obligation surface. □

Theorem 6698.3 (Riemann sphere projective-complex handoff)**.** *Every* $\mathsf{Complex}^{\uparrow}$ *affine read exported by an accepted* $\mathsf{RiemannSphere}^{\uparrow}$ *carrier factors through the displayed projective line route*

$$\mathsf{Complex}^{\uparrow},\ \mathsf{ProjectiveSpace}^{\uparrow},\ \mathsf{ProjectiveVar}^{\uparrow}$$

before a downstream projective or fractional-linear consumer may inspect it. The affine chart row A sends complex coordinates to homogeneous coordinates, the infinity row I supplies the complementary endpoint, and the coverage ledger Q keeps both reads inside BHist, hsame, Cont, Pkg*, and* NameCert *data. The handoff does not assert quotient projective equality, a host Riemann-sphere object, or ambient compact complex completeness.*

Proof. Begin with an affine read of the complex coordinate row C. The carrier admits it to the projective surface only through the chart row A, so a downstream projective consumer must first display the $\mathsf{ProjectiveSpace}^{\uparrow}$ row P.

The projective-side read then passes through the same homogeneous-line and projective-variety route named in the provenance row G. The infinity row I is carried separately, and the coverage ledger Q records that affine and infinity reads jointly exhaust the inspected point requests without identifying their representatives by an external quotient.

Finally use H, T, N to transport, replay, and name the packet. Because the excluded host objects have no coordinate in S, a $\mathsf{MobiusTransform}^{\uparrow}$ or projective consumer receives only this finite projective-complex handoff. □

Falsifiable prediction: Any accepted $\mathsf{RiemannSphere}^{\uparrow}$ consumer that omits the $\mathsf{Complex}^{\uparrow}$ affine row, the $\mathsf{ProjectiveSpace}^{\uparrow}$ homogeneous-line row, the affine-chart row, the infinity row, the coverage ledger, Pkg provenance, or the local NameCert row refutes Definition 6698.2.

Independence witness: complex, projectivespace, projectivevar, mobius-transform: $\mathsf{RiemannSphere}^{\uparrow}$ is not bijective with any listed sibling because it jointly binds affine complex coordinates, a projective homogeneous line, a distinguished infinity endpoint, compact coverage, transport, replay, provenance, and local naming into one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSphere}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannSphere}^{\uparrow}$ packet is generated from a ComplexUp affine coordinate row, a ProjectiveSpaceUp homogeneous-line row, affine-chart admission, an infinity endpoint, compact projective coverage, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannSphere}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6698.1, Definition 6698.2, and Definition 6698.3 seed the finite projective-complex carrier over affine complex coordinates, homogeneous-line data, infinity, coverage, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannSphere}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient projective equality, a selected atlas, host compact complex manifolds, ambient complex-surface equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, affine-chart exactness, infinity endpoint stability, compact coverage, projective-complex handoff, transport, replay, provenance, and local naming for BEDC.Derived.RiemannSphereUp.

Chapter 6699

Cauchy Sign-Flip Budget NameCert Construction

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchySignFlipBudget}^{\uparrow}$ packet records the finite sign-flip budget consumed when a regular Cauchy rational name is negated and then sealed as a Real-facing name. It sits after the finite observation windows of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, the displayed negation route of chapter 459, and the terminal real-name seal of chapter 38. The packet gives later Real algebra certificates a finite budget object for sign reversal, rather than treating negation as an ambient completed-real operation.

Definition 6699.1 (Cauchy sign-flip budget carrier)**.** *A* $\mathsf{CauchySignFlipBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, D, R, F, G, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite source windows opened by a requested negation read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row recording endpoint scale, requested precision, and the sign-flipped dyadic tolerance rows attached to S.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source regular rational name over the same windows.*
4. *F is the finite sign-flip ledger, pairing each displayed dyadic endpoint in D with its negated endpoint and the same tolerance request.*
5. *G is the* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *consumer row that reads S, D, R, F before any downstream algebraic consumer may use the negated name.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular readback, dyadic sign-flip ledger, and negation consumer row have been displayed.*
7. *H records componentwise* hsame *transport for the window, dyadic budget, readback, sign-flip ledger, negation consumer, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite sign-flip request through $S, D, R, F, G, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySignFlipBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchySignFlipBudget}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, D, R, F, G, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real negation, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credentials.*

Theorem 6699.2 (Cauchy sign-flip budget window stability)**.** *Let $B = (S, D, R, F, G, E, H, C, P, N)$ and $B' = (S', D', R', F', G', E', H', C', P', N')$ be accepted* $\mathsf{CauchySignFlipBudget}^{\uparrow}$ *carriers. If the* $\mathsf{StreamName}^{\uparrow}$ *window rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and structural rows agree under the displayed* hsame *and* Cont *transport, then the sign-flip ledger and terminal Real-seal route cannot diverge. Every public negation read is forced through the same finite route*

$$S \longmapsto D \longmapsto R \longmapsto F \longmapsto G \longmapsto E$$

and its transported counterpart for B'.

Proof. Project both carriers through Definition 6699.1. The public analytic coordinates are exactly the window row, dyadic budget row, regular readback row, sign-flip ledger, negation consumer row, and Real seal row.

The assumed hsame and Cont agreement identifies the source windows, the dyadic tolerance budget, and the regular readback. Since F has no independent coordinate beyond the displayed dyadic endpoint sign reversal over those rows, the sign-flip ledger is transported with the same finite windows.

The $\mathsf{RegularCauchyNegation}^{\uparrow}$ row G is downstream of S, D, R, F, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of G. Thus a Real-facing consumer cannot select a second negation route or a second seal route. The transported packet B' follows the same argument with primed rows. □

Theorem 6699.3 (Cauchy sign-flip budget Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *algebra, apartness, sum, difference, or additive-inverse consumer of an accepted* $\mathsf{CauchySignFlipBudget}^{\uparrow}$ *carrier must expose the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *sign-flip budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *consumer row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. The packet exports no quotient stream equality, selected host limit, completed-real inverse law, trichotomy, ambient completeness, or bridge credential.*

Proof. Start from the carrier inventory of Definition 6699.1. The sign-flip budget is displayed before the negation consumer row, and the negation consumer row is displayed before the terminal Real seal.

Apply Definition 6699.2. Any later algebraic or apartness read preserves the same finite window and dyadic-budget route under the stored transport and replay rows.

The excluded objects have no carrier coordinate and no provenance row. Hence they cannot be exported by the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{CauchySignFlipBudget}^{\uparrow}$ read must expose StreamName windows, DyadicRatCore sign-flip budget rows, RegSeqRat readback, RegularCauchyNegation consumer rows, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: streamname, dyadicratcore, regseqrat, regularcauchynegation, real: $\mathsf{CauchySignFlipBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores the finite

windows, dyadic sign-flip budget, regular readback, negation consumer row, terminal Real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySignFlipBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySignFlipBudget}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore sign-flip budget rows, RegSeqRat readback, RegularCauchyNegation consumer rows, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySignFlipBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6699.1, Definition 6699.2, and Definition 6699.3 seed the finite sign-flip budget consumed by regular Cauchy negation and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySignFlipBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real negation, completed-real inverse laws, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window stability, dyadic sign-flip budget preservation, RegSeqRat readback, RegularCauchyNegation consumption, Real-seal nonescape, transport, replay, provenance, and local naming for $\mathsf{CauchySignFlipBudget}^{\uparrow}$.

Chapter 6700

Hyperbolic Horocycle Return Ledger NameCert Construction

Following the classical horocycle and geodesic-flow tradition of Hedlund, Hopf, and Anosov, the $\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}$ packet records a finite return ledger for a boundary-anchored horocycle read. It sits after the horocycle carrier of chapter 3534, the Busemann-boundary rows of chapter 3732, the Busemann-cocycle route of chapter 4134, the visual-metric read of chapter 3866, the geodesic-flow packet of chapter 3856, and the boundary-transport row of chapter 6595. The packet names finite return bookkeeping for boundary, Busemann, visual-metric, horosphere-flow, and transport rows; it is not a global recurrence theorem, an invariant measure construction, a quotient boundary flow, or a selected complete orbit.

Definition 6700.1 (Hyperbolic horocycle-return ledger carrier)**.** *A* $\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, B, K, V, F, T, R, A, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *source row naming the boundary-tangent horocycle read.*
2. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary-height row attached to the same ideal endpoint.*
3. *K is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *comparison row recording finite Busemann displacement between the departure and return windows.*
4. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *visual-metric row read along the same boundary anchor.*
5. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *horosphere-flow row, displaying the finite flow segment inspected by the return request.*
6. *T is the* $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ *row preserving the boundary anchor and transported visual-metric read.*
7. *R is the return ledger row. It records the departure window, return window, Busemann displacement, visual-metric comparison, and horocycle source row as one finite packet.*
8. *A is the nonescape row, refusing any read that turns the finite return ledger into a global recurrence theorem, invariant measure, quotient boundary flow, selected complete orbit, or physical observer trajectory.*

9. *H records componentwise* hsame *transport for horocycle, Busemann boundary, Busemann cocycle, visual metric, geodesic flow, boundary transport, return ledger, refusal, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through the horocycle source, boundary height, cocycle comparison, visual-metric read, flow segment, boundary transport, return ledger, refusal, provenance, and local naming.*

11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{HyperbolicBusemannBou}$ $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, B, K, V, F, T, R, A, H, C, P, N$. It has no coordinate for global recurrence, invariant measures, quotient boundary-flow equality, selected complete orbits, physical observer motion, Lean verification, or bridge checking.

Theorem 6700.2 (Hyperbolic horocycle-return transport nonescape)**.** *For every accepted* HyperbolicHorocycleRetu *carrier $L = (Q, B, K, V, F, T, R, A, H, C, P, N)$, any transported return read must preserve the displayed boundary anchor, Busemann displacement, visual-metric row, horocycle source, and finite geodesic-flow segment before the return ledger R can be consumed. A consumer receives the route*

$$Q \longmapsto B \longmapsto K \longmapsto V \longmapsto F \longmapsto T \longmapsto R$$

together with A, H, C, P, N, and receives no global recurrence theorem, invariant measure, quotient boundary-flow equality, selected complete orbit, or physical observer trajectory.

Proof. Project the accepted carrier through Definition 6700.1. Rows Q, B, K, V, F, T are the visible geometric inputs to the return ledger.

The Busemann rows control the boundary-height comparison. Row B fixes the boundary-height read, and row K records the finite displacement between the departure and return windows. The visual-metric row V and boundary-transport row T keep the same boundary anchor visible through the read.

The flow row F supplies only the inspected finite geodesic-flow segment. The return ledger R packages this segment with the horocycle source and Busemann displacement, so it cannot add a selected complete orbit or a global recurrence assertion.

Finally, A, H, C, P, N refuse excluded routes and transport the displayed packet. Since none of the excluded objects has a carrier coordinate, transported return reads remain inside the finite NameCert surface. □

Theorem 6700.3 (Hyperbolic horocycle-return ledger obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleReturn}}$ *surface consists exactly of horocycle source admission, Busemann-boundary admission, Busemann-cocycle displacement comparison, visual-metric readback, finite geodesic-flow segment admission, boundary-transport preservation, return-ledger exactness, nonescape refusal, componentwise transport, displayed replay, package provenance, and local naming. No obligation is stored outside $Q, B, K, V, F, T, R, A, H, C, P, N$.*

Proof. Read the carrier inventory in Definition 6700.1. Each listed obligation is the admission or preservation condition for one displayed row.

Apply Definition 6700.2. It prevents the return ledger from being consumed before the horocycle, boundary, Busemann, visual-metric, flow, and transport rows have been displayed.

The structural rows H, C, P, N only transport, replay, source, and name that same route. Therefore the local NameCert surface is exhausted by the stated rows. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}$ read must expose horocycle source rows, Busemann-boundary rows, Busemann-cocycle displacement rows, visual-metric rows, finite geodesic-flow rows, boundary-transport rows, a return ledger, nonescape refusal, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: hyperbolic-horocycle, hyperbolic-busemann-boundary, hyperbolic-busemann-cocycle, hyperbolic-visual-metric, hyperbolic-geodesic-flow, hyperbolic-boundary-transport: HyperbolicHorocycleRe is not bijective to any listed sibling because it jointly stores the return window, Busemann displacement, visual-metric comparison, finite flow segment, boundary transport, refusal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}$ packet is generated from HyperbolicHorocycle source rows, HyperbolicBusemannBoundary height rows, HyperbolicBusemannCocycle displacement rows, HyperbolicVisualMetric readback, HyperbolicGeodesicFlow finite segments, HyperbolicBoundaryTransport preservation, a return ledger, nonescape refusal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6700.1, Definition 6700.2, and Definition 6700.3 seed the finite horocycle-return ledger over boundary, Busemann, visual-metric, horosphere-flow, transport, refusal, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global recurrence, invariant measures, quotient boundary-flow equality, selected complete orbits, physical observer motion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Busemann displacement comparison, visual-metric readback, finite flow-segment admission, boundary-transport preservation, return-ledger exactness, nonescape refusal, transport, replay, provenance, and local naming for $\mathsf{HyperbolicHorocycleReturnLedger}^{\uparrow}$.

Chapter 6701

A Concrete Naming Certificate for $\mathsf{IntervalHalvingTree}^{\uparrow}$

Following Bishop and Bridges on constructive bisection methods, the $\mathsf{IntervalHalvingTree}^{\uparrow}$ packet records the finite binary tree of interval halves inspected before a Real and Completion consumer reads a regular rational name. It sits after the dyadic endpoint arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. It also neighbors the bisection-tree surface of chapter 1465, the located interval bisection route of chapter 5546, and the nested interval surfaces of chapter 320 and chapter 2308. The packet names a constructive halving tree as finite NameCert data; it does not assert ambient real completeness, an infinite branch selector, quotient stream equality, trichotomy, or countable choice.

Definition 6701.1 (Interval halving tree carrier)**.** *An* $\mathsf{IntervalHalvingTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the finite rooted halving-tree row. Each node records a rational interval window, its depth, and the visible left/right child slots that have been opened by the construction.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for endpoints, midpoints, dyadic diameter bounds, child containment, and tolerance comparisons along every displayed edge of R.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names the finite node, endpoint, midpoint, sign, and tolerance observations a downstream consumer may inspect.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed chain of scheduled intervals and dyadic diameter bounds.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, D, S, Q have been displayed.*
6. *H records componentwise* hsame *transport for tree nodes, dyadic ledgers, stream schedules, regular-rational handoffs, real seals, replay rows, provenance, and local naming.*
7. *C records displayed* Cont *replay from a halving-tree request through R, D, S, Q, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{IntervalHalvingTree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{IntervalBisectionTree}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{IntervalHalvingTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine displayed rows. It has no coordinate for a completed branch, host interval equality, quotient stream equality, selected real limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6701.2 (Interval halving tree NameCert obligations)**.** *For every accepted* $\mathsf{IntervalHalvingTree}^{\uparrow}$ *carrier*

$$T = (R, D, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalHalvingTree}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite rooted halving tree R, dyadic midpoint and containment arithmetic through D, finite observation scheduling through S, regular rational readback through Q, terminal real-name sealing through E, componentwise transport through H, continuation replay through C, package provenance through P, and local naming through N.*

Every bisection or nested-interval consumer must read the same displayed rows before it can use the tree as a certificate. The packet exports no infinite branch selector, quotient stream equality, host interval equality, countable choice, trichotomy, or ambient real-completeness row.

Proof. Project the carrier of Definition 6701.1. The projection exposes one finite rooted tree, one dyadic arithmetic ledger, one stream schedule, one regular-rational handoff, one real-seal row, and the structural rows.

The tree row R supplies the opened nodes and child slots. The dyadic ledger D checks that every displayed child is a midpoint half of its parent interval and that every exposed diameter comparison is a dyadic tolerance comparison.

The schedule row S fixes which finite observations may be read. The row Q repacks any displayed branch segment as a regular rational readback only after R, D, S have been inspected, and E seals the same route as a real-facing row.

Finally H, C, P, N transport, replay, source, and name the displayed packet. Since the carrier has no coordinate for an unbounded branch or host equality, the listed rows exhaust the local NameCert obligations. □

Theorem 6701.3 (Interval halving tree RegSeqRat handoff)**.** *Every Real and Completion consumer of an accepted* $\mathsf{IntervalHalvingTree}^{\uparrow}$ *packet factors through the finite route*

$$R, D \longmapsto S \longmapsto Q \longmapsto E, H, C, P, N.$$

Thus the $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q is downstream from the displayed halving tree, midpoint arithmetic, and finite observation schedule, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is downstream from Q. No consumer can use the packet as a completed real, a selected infinite branch, or an ambient nested-interval theorem without leaving the carrier.*

Proof. Start with the displayed halving tree R and the dyadic ledger D. They provide the only interval nodes, midpoint checks, containment checks, and diameter comparisons available to the packet.

Read the finite schedule S. It determines which node observations and tolerance requests are opened for the downstream handoff, so the regular rational row cannot inspect an unlisted branch or hidden endpoint.

The row Q is then the $\mathsf{RegSeqRat}^{\uparrow}$ handoff for the scheduled branch segment. The real-seal row E is reached only after that handoff, and the rows H, C, P, N preserve the same finite route under transport, replay, provenance, and naming.

Consequently Real and Completion consumers receive a displayed bisection-tree certificate whose finite route is compatible with the DyadicRatCore, StreamName, RegSeqRat, Real, IntervalBisectionTree, and NestedInterval sibling surfaces. The packet supplies no ambient completeness or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalHalvingTree}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalHalvingTree}^{\uparrow}$ packet is generated from a finite rooted halving tree, dyadic midpoint and containment ledgers, StreamName schedules, RegSeqRat handoff rows, Real seal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalHalvingTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6701.1, Definition 6701.2, and Definition 6701.3 seed the finite bisection-tree certificate used by Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalHalvingTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge status, ambient real completeness, infinite branch selection, quotient stream equality, host interval equality, countable choice, or trichotomy.

Upgrade path: Obligation closure requires checked carrier admission, dyadic midpoint exactness, child containment, schedule compatibility, regular rational handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.IntervalHalvingTreeUp.

Chapter 6702

A Concrete Naming Certificate for CauchyCondensationIntegralCriterion$^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the CauchyCondensationIntegralCriterion$^{\uparrow}$ packet records the finite criterion route that carries a monotone positive series source through Cauchy condensation and then through an integral-test handoff before any Real or Completion consumer reads convergence data. It consumes the condensation test of chapter 1478, the integral-test surface of chapter 2259, the bridge packet of chapter 6071, and the L10 readback corridor of chapter 291, chapter 301, and chapter 38. The certificate names the criterion as displayed finite data; it does not choose a completed sum, an improper integral value, a quotient series equality, countable-choice schedules, or ambient Real$^{\uparrow}$ completeness.

Definition 6702.1 (CauchyCondensationIntegralCriterion carrier)**.** *A* CauchyCondensationIntegralCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, D, C, I, B, W, Q, R, H, T, P, N)$$

with the following displayed rows:

1. *S is the positive decreasing series-source row, recording only inspected term windows, positivity witnesses, and monotonicity comparisons.*
2. *M is the dyadic condensation block row supplied by the condensation test route.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *scale ledger, carrying powers-of-two windows, endpoint comparisons, and dyadic tolerance slack.*
4. *C is the condensation criterion row, exposing the finite reduction from the source tail to the dyadic block tail.*
5. *I is the integral-test row, recording finite interval cells and monotone majorant or minorant comparisons.*
6. *B is the bridge row that matches the condensation blocks with integral windows through the existing condensation-integral route.*
7. *W is the finite readback schedule for Real and Completion consumers.*
8. *Q is the* RegSeqRat$^{\uparrow}$ *readback row reached from S, M, D, C, I, B, W.*
9. *R is the terminal* Real$^{\uparrow}$ *seal row read only after the regular-rational handoff is visible.*

10. *H records componentwise* hsame *transport for source, condensation, dyadic, integral, bridge, readback, seal, replay, provenance, and local naming rows.*
11. *T records displayed* Cont *replay from the criterion request through the source, condensation, integral, bridge, readback, and seal rows.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}$, $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{CauchyIntegralTest}^{\uparrow}$, $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, D, C, I, B, W, Q, R, H, T, P, N$. It has no coordinate for a host improper integral, selected infinite sum, quotient equality of series, countable choice, trichotomy, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6702.2 (CauchyCondensationIntegralCriterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}$ *carrier $K = (S, M, D, C, I, B, W, Q, R, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed thirteen-row packet; positive monotone source exposure through S; condensation block exposure through M; dyadic scale exposure through D; condensation reduction through C; integral-test exposure through I; bridge exposure through B; finite schedule exposure through W;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q;* $\mathsf{Real}^{\uparrow}$ *sealing through R; componentwise* hsame *transport through H; displayed* Cont *replay through T; provenance through P; and local naming through N.*

Proof. Project the carrier rows from Definition 6702.1. The analytic route is exactly $S, M, D, C, I, B, W, Q, R$, and H, T, P, N are the structural certificate rows.

The source and condensation rows are read first. The condensation test sibling supplies the finite dyadic block route, while the dyadic row records the scale data needed to compare those blocks.

The integral side is then read through I and B. The integral-test sibling supplies finite interval cells, and the condensation-integral bridge orders the handoff before regular-rational readback is consumed.

Finally W, Q, R, H, T, P, N schedule, read back, seal, transport, replay, source, and name the same finite route. Since none of the excluded host objects is a carrier coordinate, none is a NameCert obligation of the criterion packet. □

Theorem 6702.3 (CauchyCondensationIntegralCriterion condensation-to-integral handoff)**.** *Every accepted* $\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}$ *carrier sends a positive decreasing series source to an integral-test comparison only through the displayed route*

$$S, M, D \longmapsto C \longmapsto I, B \longmapsto W, Q, R.$$

The condensation side is anchored by chapter 1478; the integral side is anchored by chapter 2259; and the bridge is anchored by chapter 6071. The route exports no selected subseries, host integral object, quotient series equality, or ambient completeness principle.

Proof. Begin with the source rows S, M, D. The source row displays only inspected monotone positive term windows, while the dyadic row fixes the finite powers-of-two scale on which condensation blocks are read.

Use the condensation test route. It places the block comparison inside C before any integral window is inspected, so the consumer cannot skip directly from the source series to a host convergence theorem.

Next use the integral-test and bridge rows. The row I provides finite interval cells, and B matches those cells with the condensation blocks through the sibling bridge.

The readback rows W, Q, R then keep the conclusion inside finite schedules, regular rational readback, and the terminal Real seal. The carrier has no coordinate for the excluded host objects, so the handoff is exactly the displayed finite route. □

Theorem 6702.4 (CauchyCondensationIntegralCriterion RegSeqRat Real nonescape)**.** *Every Real-facing or Completion-facing read of an accepted* $\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}$ *carrier reaches the terminal seal R only after the route*

$$S, M, D, C, I, B, W, Q, R$$

has exposed the source, condensation, dyadic, integral, bridge, schedule, and $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, together with structural rows H, T, P, N. Thus the criterion supplies a finite L10 convergence-read boundary and not an ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Apply Definition 6702.3. It places the analytic comparison behind the source, condensation, dyadic, integral, bridge, and finite schedule rows.

The regular rational readback row Q is downstream of that comparison. A Real-facing consumer therefore sees only the scheduled regular-rational read before the terminal seal R is public.

The structural rows preserve the same route under hsame, Cont, provenance, and local naming. Because the carrier has no row for quotient series equality, selected limits, countable-choice schedules, host real equality, or ambient completeness, the Real and Completion boundary cannot escape the displayed $S, M, D, C, I, B, W, Q, R$ route. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the positive monotone source row, condensation block row, dyadic scale row, condensation reduction row, integral-test row, bridge row, finite schedule, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: cauchy-condensation-test, cauchy-integral-test, cauchy-condensation-integral-bridge, dyadicratcore, regseqrat, real: no listed sibling supplies the whole criterion packet $K = (S, M, D, C, I, B, W, Q, R, H, T, P, N)$, because each sibling contributes only a condensation row, integral row, bridge row, dyadic ledger, regular readback, or terminal seal while this chapter binds them into one finite criterion certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}$ packet is generated from positive monotone series-source rows, condensation block rows, DyadicRatCore scale rows, condensation criterion rows, integral-test rows, condensation-integral bridge rows, finite schedules, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6702.1, Definition 6702.2, Definition 6702.3, and Definition 6702.4 seed the finite criterion route over condensation blocks, integral windows, RegSeqRat readback, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, ambient improper integration, selected infinite sums, quotient series equality, countable choice, trichotomy, host real equality, Real completeness, or a completed summability theorem.

Upgrade path: Obligation closure requires checked carrier admission, condensation-test exactness, integral-test handoff, bridge exactness, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCondensationIntegralCriterionUp.

Chapter 6703

A Concrete Naming Certificate for ChernoffFiniteExponentialBound$^{\uparrow}$

Following Chernoff's finite exponential-bound method, the ChernoffFiniteExponentialBound$^{\uparrow}$ packet records the finite moment-generating-function route by which an exponential Markov row bounds a displayed tail event. It sits after the probability source of chapter 184, the random-variable rows of chapter 185, the law and range summaries of chapter 186, the finite independence ledger of chapter 187, the dyadic exponential arithmetic of chapter 291, the terminal real seal of chapter 38, and the bounded finite-sum concentration surface of chapter 5726. The packet names only the finite MGF and exponential Markov route; it is not an asymptotic optimizer, countable-choice scheme, ambient measure-completion theorem, quotient event-equality principle, or ambient Real$^{\uparrow}$ completeness result.

Definition 6703.1 (Chernoff finite exponential-bound carrier)**.** *A* ChernoffFiniteExponentialBound$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (P, X, D, I, \lambda, M, A, E, R, H, T, Q, N)$$

with the following visible rows:

1. *P is the source* ProbSpace$^{\uparrow}$ *row carrying the event classifier and total-mass normalization;*
2. *X is the finite* RandomVar$^{\uparrow}$ *family whose displayed tail event is inspected;*
3. *D is the* Distribution$^{\uparrow}$ *row exposing the finite law or range summary needed for each exponential moment;*
4. *I is the finite* Independence$^{\uparrow}$ *ledger used only when the MGF row is factorized over the displayed family;*
5. *λ is the positive dyadic or real parameter row admitted for the exponential Markov read;*
6. *M is the finite MGF row, recording each displayed expectation of* $\exp(\lambda X_i)$ *or the single displayed expectation used by the packet;*
7. *A is the exponential Markov comparison row identifying the tail event with the exponential superlevel event;*
8. *E is the* DyadicRatCore$^{\uparrow}$ *arithmetic row naming the exponential numerator, denominator, product, and slack comparison used in the bound;*

9. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the resulting probability bound;*
10. *H records componentwise* hsame *transport for the probability, random-variable, distribution, independence, MGF, dyadic, and real rows;*
11. *T records the displayed* Cont *replay of the finite exponential-bound route;*
12. *Q is the* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HoeffdingFiniteSum}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ChernoffFiniteExponentialBound}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through these displayed rows. It has no coordinate for an asymptotic limiting parameter, a selected optimizing λ, countable products, completed measure algebras, quotient-level event equality, or an ambient real-completeness oracle.

Theorem 6703.2 (Chernoff finite exponential-bound NameCert obligations)**.** *For every accepted* $\mathsf{ChernoffFiniteExponentialBound}^{\uparrow}$ *carrier $C = (P, X, D, I, \lambda, M, A, E, R, H, T, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChernoffFiniteE}}$ *surface consists exactly of the finite carrier rows of Definition 6703.1. Carrier admission displays the probability source, finite random-variable family, distribution summary, finite independence ledger when present, positive parameter row, finite MGF row, exponential Markov comparison, dyadic exponential arithmetic, terminal real probability seal, componentwise transports, continuation replay, package provenance, and local naming row.*

Proof. Project the accepted carrier. Each row named by the certificate is one of the coordinates of C, so carrier formation is finite and visible.

The classifier clause is componentwise. It transports the probability source, each random-variable row, the distribution summaries, the independence ledger when the MGF is factorized, the parameter row, the MGF comparison, the dyadic arithmetic row, and the terminal real seal along the displayed hsame coordinates.

Ledger exactness follows from the same projection. Since no coordinate of C names an optimizing search, countable product, measure completion, quotient event equality, or ambient real-completeness principle, none of those objects can enter the local certificate surface. □

Theorem 6703.3 (Chernoff finite MGF handoff)**.** *Every tail-bound consumer of an accepted* $\mathsf{ChernoffFiniteExponentialBound}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{ProbSpace}^{\uparrow}, \mathsf{RandomVar}^{\uparrow}, \mathsf{Distribution}^{\uparrow}, \mathsf{Independence}^{\uparrow}, \lambda, M, A, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, H, T, Q, N.$$

The handoff first exposes the finite probability and random-variable rows, then the displayed MGF row and exponential Markov comparison, and only then the dyadic arithmetic and terminal real bound. The route may reuse bounded finite-sum data from $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *as an input range ledger, but it does not export Hoeffding's bounded-sum surface as a Chernoff optimizer or as an ambient limiting theorem.*

Proof. Begin with Definition 6703.2. It places all probability, random-variable, distribution, independence, parameter, MGF, dyadic, real, transport, replay, provenance, and naming rows inside the accepted carrier.

The exponential Markov step reads only the displayed tail event, the positive parameter row, and the MGF row. If independence is used, it is the finite ledger I already present in the packet, so the factorization has no countable or choice-selected component.

Finally the dyadic arithmetic row E and the real seal R translate the MGF comparison into the exported probability bound. Because the route terminates at those displayed rows, downstream

consumers receive a finite exponential-bound packet and not an asymptotic optimization principle, measure-completion object, quotient event equality, or ambient real-completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChernoffFiniteExponentialBound}^{\uparrow}}$.

Constructive story: A $\mathsf{ChernoffFiniteExponentialBound}^{\uparrow}$ packet is generated from a probability source row, finite random-variable family, distribution summary, finite independence ledger when used, positive parameter row, finite MGF row, exponential Markov comparison, dyadic exponential arithmetic, RealUp probability seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChernoffFiniteExponentialBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6703.1, Definition 6703.2, and Definition 6703.3 seed the finite MGF and exponential Markov route through displayed probability, random-variable, distribution, independence, dyadic, real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChernoffFiniteExponentialBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close asymptotic optimization, countable choice, ambient measure completion, quotient event equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite MGF exposure, exponential Markov comparison, dyadic arithmetic exactness, terminal real sealing, transport, replay, provenance, and local naming for BEDC.Derived.ChernoffFiniteExponentialBoundUp.

Chapter 6704

A Concrete Naming Certificate for EffectiveModulusCompactFamily$^{\uparrow}$

Following Bishop-style compact metric uniform-continuity arguments, the EffectiveModulusCompactFamily$^{\uparrow}$ packet records the finite-net, tolerance-request, covering-number, and explicit modulus rows for a compact family of maps as one NameCert surface. It sits over the compact finite-net source of chapter 129, the uniform-continuity request surface of chapter 391, the tolerance-only output of chapter 369, and the covering-budget ledger of chapter 5209. The packet is a finite data surface; it is not an open-cover compactness principle, a selected center family, a host function-space compactness theorem, or a choice-selected modulus oracle.

Definition 6704.1 (Effective modulus compact family carrier)**.** *An* EffectiveModulusCompactFamily$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, U, M, Q, W, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-net data row, including displayed centers, cover radii, and located membership witnesses for the compact metric source.*
2. *U is the* UniformContinuity$^{\uparrow}$ *tolerance-request row, listing the target tolerances and the local continuity requests visible to the family consumer.*
3. *M is the* UniformModulus$^{\uparrow}$ *explicit modulus row extracted from the finite compact source and the displayed tolerance requests.*
4. *Q is the* FiniteMetricEntropy$^{\uparrow}$ *covering-number row, recording the finite covering budget used by the same net and tolerance data.*
5. *W is the family-window row, naming the inspected family members and the finite source windows over which K, U, M, Q are read.*
6. *H records componentwise* hsame *transport for compact finite nets, tolerance requests, explicit modulus rows, covering-number rows, family windows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a tolerance request through K, U, Q, W, H, P, N to the modulus row M.*
8. *P is the* Pkg *provenance over* EffectiveModulusCompactFamily$^{\uparrow}$, CompactMetric$^{\uparrow}$, UniformContinuity$^{\uparrow}$, UniformModulus$^{\uparrow}$, FiniteMetricEntropy$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{EffectiveModulusCompactFamily}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, U, M, Q, W, H, C, P, N$. It has no coordinate for open-cover compactness, selected centers outside the displayed net, host equality of maps, countable choice over the family, ambient completeness, or a modulus chosen outside the packet.

Lean4 ✓ `BEDC.Derived.EffectiveModulusCompactFamilyUp.EffectiveModulusCompactFamilyTasteGate`
`single carrier alignment`

Theorem 6704.2 (Effective modulus compact family NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveModulusCompactFamily}^{\uparrow}$ *carrier*

$$E = (K, U, M, Q, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveModulusCompactFamily}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, uniform-continuity tolerance-request admission through U, explicit modulus-row exposure through M, finite covering-budget exposure through Q, family-window discipline through W, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6704.1. Its accepted coordinates are precisely the compact finite-net row, uniform-continuity tolerance row, explicit modulus row, covering-budget row, family-window row, and structural rows.

The analytic rows are read in dependency order. The compact source K supplies the finite-net support, U supplies the tolerance request, Q supplies the finite covering budget attached to the same net, and M records the explicit output row read by the uniform-modulus consumer.

The structural rows W, H, C, P, N keep the family members, transport, replay, provenance, and local name attached to the same finite route. Since the carrier has no coordinate for open-cover compactness, selected centers, host map equality, countable choice, ambient completeness, or an external modulus selector, the listed rows exhaust the NameCert obligations. □

Theorem 6704.3 (Effective modulus compact family finite-net handoff)**.** *Every downstream* $\mathsf{UniformModulus}^{\uparrow}$ *read from an accepted* $\mathsf{EffectiveModulusCompactFamily}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{UniformContinuity}^{\uparrow} \longmapsto \mathsf{FiniteMetricEntropy}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

Concretely, the consumer reads the compact finite-net support K, the tolerance requests U, the covering-number row Q, the family-window row W, and the structural rows H, C, P, N before it reads the explicit modulus row M. The handoff exports no open-cover compactness proof, no selected subcover, no host function-space compactness, no countable-choice schedule, and no modulus outside the displayed packet.

Proof. Begin with an accepted carrier $E = (K, U, M, Q, W, H, C, P, N)$. The compact source K is the only row that supplies finite centers and cover radii, so the handoff starts with displayed finite-net support rather than an open-cover compactness proof.

Read the tolerance and covering rows next. The row U names the target requests, and Q records the finite covering budget for the same source windows; together they determine the finite data from which the explicit modulus row can be consumed.

Finally replay the route through W, H, C, P, N and read M. The family-window, transport, replay, provenance, and naming rows preserve the same packet, so a downstream consumer cannot replace the displayed handoff by selected centers, host map equality, a choice schedule, ambient completeness, or an external modulus oracle. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveModulusCompactFamily}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveModulusCompactFamily}^{\uparrow}$ packet is generated from CompactMetricUp finite-net data, UniformContinuityUp tolerance requests, UniformModulusUp explicit modulus rows, FiniteMetricEntropyUp covering-number rows, a family-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveModulusCompactFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6704.1, Definition 6704.2, and Definition 6704.3 seed the compact-family finite-net handoff over explicit modulus and covering-budget rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveModulusCompactFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host function-space compactness, countable choice over the family, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exactness, tolerance-request exactness, explicit modulus-row exposure, covering-budget visibility, family-window discipline, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveModulusCompactFamilyUp.

Chapter 6705

A Concrete Naming Certificate for $\mathsf{HermiteNormalForm}^{\uparrow}$

Following Hermite and the constructive integer-matrix normal-form tradition, the $\mathsf{HermiteNormalForm}^{\uparrow}$ packet records the finite row-reduction certificate by which an integer matrix is read as a triangular Hermite row. It consumes the integer arithmetic surface of chapter 31, the matrix carrier of chapter 49, the finite module-row discipline of chapter 46, and the Smith sibling comparison row of chapter 2262. The chapter names a row-reduction certificate and its triangular readback; it does not claim a selected column basis, quotient-module classification, a host Euclidean algorithm, or equality outside displayed integer row operations.

Definition 6705.1 (Hermite normal form carrier)**.** *A* $\mathsf{HermiteNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, U, T, P, D, R, S, C, Q, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *source row, recording the finite integer matrix entries, row and column bounds, and the integer-entry provenance inherited from* $\mathsf{Int}^{\uparrow}$*.*
2. *U is the unimodular row-operation ledger. It lists row swaps, sign changes, and displayed integer row additions, together with the inverse-operation rows that certify unimodular replay.*
3. *T is the triangular Hermite row, exposing the terminal row-echelon shape, pivot columns, zero-below-pivot witnesses, and bounded residue entries above each pivot.*
4. *P is the pivot divisibility row, recording the displayed divisibility and residue constraints that make the pivot data a Hermite readback rather than an arbitrary triangular matrix.*
5. *D is the* $\mathsf{SmithNormalForm}^{\uparrow}$ *comparison row, carrying the sibling diagonal-divisibility read used only to compare invariant factors and not to replace the row-reduction trace.*
6. *R records componentwise* hsame *transport for source entries, row-operation ledgers, triangular readback, pivot divisibility, Smith comparison, continuation rows, provenance, and local naming.*
7. *S records displayed* Cont *replay from source matrix inspection through unimodular row playback, triangular readback, pivot-divisibility checking, Smith sibling comparison, and local naming.*
8. *C is the* Pkg *provenance over* $\mathsf{HermiteNormalForm}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{Int}^{\uparrow}$*,* $\mathsf{Module}^{\uparrow}$*,* $\mathsf{SmithNormalForm}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

9. *Q is the nonescape row, recording that no hidden column operations, selected quotient basis, ambient Euclidean-domain theorem, or external normal-form uniqueness claim is exported by the packet.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HermiteNormalForm}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrecorded row operations, column reduction, quotient-module equality, selected bases, host algorithmic termination, or matrix equality outside the displayed integer row-operation ledger.

Theorem 6705.2 (Hermite normal form NameCert obligations)**.** *For every accepted* $\mathsf{HermiteNormalForm}^{\uparrow}$ *carrier $H = (M, U, T, P, D, R, S, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HermiteNormalForm}^{\uparrow}}$ *surface consists exactly of carrier admission, row-operation exactness, triangular readback, pivot divisibility, Smith sibling compatibility, componentwise transport, displayed continuation replay, provenance, and nonescape through the local naming row.*

Proof. Project the carrier rows. Carrier admission exposes exactly $M, U, T, P, D, R, S, C, Q, N$, so every accepted Hermite readback begins with the displayed matrix source and the displayed integer row-operation ledger.

Row-operation exactness is forced by U. Each row swap, sign change, or integer row addition names its source row, target row, coefficient data, and inverse row, so the triangular row T can be read only after the ledger has replayed those operations.

The pivot obligations are then visible in P. These rows record the divisibility and residue constraints attached to the pivot columns, while the Smith sibling row D supplies only a comparison route for invariant-factor compatibility.

Finally R, S, C, Q, N transport, replay, source, bound, and name the same finite packet. Because Q refuses hidden column operations, quotient-module equality, selected bases, and external normal-form uniqueness, the listed rows exhaust the local NameCert surface. □

Theorem 6705.3 (Hermite normal form row-reduction readback)**.** *For every accepted* $\mathsf{HermiteNormalForm}^{\uparrow}$ *carrier $H = (M, U, T, P, D, R, S, C, Q, N)$, any exported triangular readback factors through the route*

$$\mathsf{Mat}^{\uparrow}, \mathsf{Int}^{\uparrow} \longmapsto \mathsf{Module}^{\uparrow} \longmapsto \mathsf{SmithNormalForm}^{\uparrow} \longmapsto T.$$

Thus the consumer sees the source integer matrix, finite module row discipline, Smith sibling comparison, and only then the triangular Hermite row exposed by T.

Proof. Open the source row M. Its entries and finite bounds are supplied through $\mathsf{Mat}^{\uparrow}$ and $\mathsf{Int}^{\uparrow}$, so the row-operation ledger U has no independent arithmetic source.

The finite module discipline is read before the normal-form comparison. It fixes which row operations are admitted as module-row transformations and keeps the replay inside displayed integer rows.

The Smith sibling row D is then available only as a compatibility read for invariant-factor data. It does not replace the Hermite row ledger or introduce column operations.

Consequently the triangular row T is exposed only after the source matrix, integer entries, module-row discipline, and Smith comparison have been read. The nonescape row Q blocks any shorter route through host equality or an ambient normal-form theorem. □

Falsifiable prediction: Every accepted $\mathsf{HermiteNormalForm}^{\uparrow}$ triangular read factors through one $\mathsf{Mat}^{\uparrow}$ source row, one $\mathsf{Int}^{\uparrow}$ entry row, one unimodular row-operation ledger, one triangular readback row, one pivot-divisibility row, one $\mathsf{SmithNormalForm}^{\uparrow}$ comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: matrix, int, module, smithnormalform: $\mathsf{HermiteNormalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries unimodular row playback, triangular Hermite readback, pivot divisibility, Smith comparison, and nonescape as one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HermiteNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{HermiteNormalForm}^{\uparrow}$ packet is generated from a finite MatrixUp source row over IntUp entries, a unimodular row-operation ledger, a triangular Hermite row, a pivot-divisibility row, a SmithNormalFormUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, nonescape, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HermiteNormalForm}^{\uparrow}}$, seed)

Scope closed: Definition 6705.1, Definition 6705.2, and Definition 6705.3 seed the finite Hermite normal form certificate surface over displayed integer matrix, module-row, and Smith comparison rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HermiteNormalForm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected column bases, quotient-module classification, host Euclidean algorithms, hidden column operations, ambient normal-form uniqueness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row-operation exactness, triangular readback, pivot divisibility, Smith sibling compatibility, transport, replay, provenance, and nonescape for BEDC.Derived.HermiteNormalFormUp.

Chapter 6706

A Concrete Naming Certificate for $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$

Following Lebesgue, Vitali, Besicovitch, and Bishop–Bridges constructive measure theory, the $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$ packet names the finite basis-and-covering interface that a later differentiation theorem may consume before any almost-everywhere conclusion is read. It sits between the Vitali selection surface of chapter 2184, the finite-cover ledger of chapter 2166, the bounded-overlap boundary of chapter 6339, the measurable local-average rows of chapter 92, the dyadic tolerance rows of chapter 291, the terminal real-name rows of chapter 38, and the theorem packet of chapter 4153. The packet records basis admission and finite cover handoff only; it does not assert measure completion, an almost-everywhere quotient, countable-choice selectors, or selected representatives of functions.

Definition 6706.1 (Lebesgue differentiation basis carrier)**.** *A* $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (B_0, V, E, M, A, D, R, H, C, P, N)$$

with the following displayed rows:

1. *B_0 is the basis-row ledger, naming the displayed balls or intervals, their centers, their radii, and the local nesting requests used by the differentiation basis.*
2. *V is the* $\mathsf{VitaliCover}^{\uparrow}$ *and* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *selection row, recording finite subfamily requests, disjointness tests, and cover-cell membership.*
3. *E is the* $\mathsf{BesicovitchCovering}^{\uparrow}$ *finite-overlap row, recording bounded multiplicity for the same displayed basis cells.*
4. *M is the* $\mathsf{Measure}^{\uparrow}$ *local-measure row inspected by basis cells and finite selections.*
5. *A records local-average rows for the displayed cells, without choosing a host function representative outside the packet.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for radius, overlap, measure, average, and exceptional-budget comparisons.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for local measure values, average values, and displayed error budgets.*
8. *H records componentwise* hsame *transport for basis cells, Vitali rows, Besicovitch rows, measure rows, averages, tolerances, real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the route from basis-cell requests through* B_0, V, E, M, A, D, R.
10. *P is the* Pkg *provenance over* $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$, $\mathsf{VitaliCover}^{\uparrow}$, $\mathsf{FiniteVitaliCover}^{\uparrow}$, $\mathsf{BesicovitchCovering}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationBasis}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B_0, V, E, M, A, D, R, H, C, P, N$. It has no coordinate for a completed measure algebra, an almost-everywhere quotient, a countable basis selector, a selected function representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6706.2 (Lebesgue differentiation basis NameCert obligations)**.** *For every accepted* $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$ *carrier*

$$B = (B_0, V, E, M, A, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationBasis}^{\uparrow}}$ *surface consists exactly of basis-cell admission, Vitali finite-selection rows, Besicovitch finite-overlap rows, Measure local-average rows, DyadicRatCore tolerance rows, Real seals, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6706.1. The displayed rows $B_0, V, E, M, A, D, R, H, C, P, N$ are the whole certificate surface.

The basis and covering rows are read first. The basis ledger B_0 exposes only displayed balls or intervals, while V routes every finite selection through the $\mathsf{VitaliCover}^{\uparrow}$ and $\mathsf{FiniteVitaliCover}^{\uparrow}$ surfaces named by chapter 2184.

The overlap and averaging rows then attach the basis to measure-facing consumers. The Besicovitch row E bounds finite multiplicity, and M, A, D, R provide the local-measure, local-average, dyadic-tolerance, and real-seal reads.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no further row is present, the NameCert obligations export no measure completion, almost-everywhere quotient, countable-choice selector, selected function representative, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 6706.3 (Lebesgue differentiation basis finite-cover handoff)**.** *Every basis read accepted by a* $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$ *packet factors through the route*

$$\mathsf{VitaliCover}^{\uparrow},\ \mathsf{FiniteVitaliCover}^{\uparrow},\ \mathsf{BesicovitchCovering}^{\uparrow},\ \mathsf{Measure}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{LebesgueDifferentiation}$$

before it is offered to the theorem-level $\mathsf{LebesgueDifferentiation}^{\uparrow}$ *packet of chapter 4153. The handoff exports finite basis admission, finite selection, finite overlap, local measure, local average, tolerance, seal, transport, replay, provenance, and naming rows only.*

Proof. Start with an accepted carrier $B = (B_0, V, E, M, A, D, R, H, C, P, N)$. A theorem-level differentiation consumer can inspect basis cells only through the displayed basis ledger B_0.

The covering handoff is forced through V and E. The Vitali rows supply finite candidate selection and finite cover-cell exposure, while the Besicovitch row supplies the bounded-overlap comparison needed before local averages are consumed.

The measure-facing read is then forced through M, A, D, R. These rows expose local measure values, local averages, dyadic tolerances, and real seals for the same finite cells; they do not choose null-set representatives or complete the measure space.

The structural rows H, C, P, N carry this route into the $\mathsf{LebesgueDifferentiation}^{\uparrow}$ consumer. Thus the handoff stays finite and cannot insert an almost-everywhere quotient, countable-choice selector, selected function representative, measure completion, or ambient real-completeness row. □

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$ packet is generated from basis-cell rows, Vitali and finite-Vitali selection rows, Besicovitch finite-overlap rows, Measure local-average rows, DyadicRatCore tolerance rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6706.1, Definition 6706.2, and Definition 6706.3 seed the finite differentiation-basis route for later Lebesgue differentiation consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim almost-everywhere quotient equality, measure completion, countable-choice basis selectors, selected function representatives, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Vitali selection routing, Besicovitch finite-overlap routing, Measure local-average routing, dyadic tolerance sealing, Real nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LebesgueDifferentiationBasisUp.

Chapter 6707

A Concrete Naming Certificate for HyperbolicShadowing$^{\uparrow}$

The HyperbolicShadowing$^{\uparrow}$ packet realizes the quasi-geodesic fellow-traveller route of chapter 9463 as finite shadowing data. It sits after the metric comparison rows of chapter 3474, the quasi-geodesic shadow packet of chapter 5802, the Morse-boundary stability rows of chapter 6040, and the boundary-window route of chapter 3813. The packet names finite fellow-traveller windows, boundary attachments, Busemann tolerance rows, and local NameCert data only; it does not complete an ideal boundary, select a global geodesic representative, quotient paths, import a host hyperbolic space, or identify the observer-expansion reading with physical dynamics.

Definition 6707.1 (Hyperbolic shadowing carrier)**.** *A* HyperbolicShadowing$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, Q, F, B, U, D, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* HyperbolicMetric$^{\uparrow}$ *row, exposing the finite metric comparisons used to read a quasi-geodesic route.*
2. *Q is the* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *row, recording the route samples, distortion budget, boundary endpoint, and visual shadow window being shadowed.*
3. *F is the fellow-traveller row, naming the finite comparison windows in which the route and the shadowing geodesic remain within the displayed tolerance.*
4. *B is the* MorseBoundary$^{\uparrow}$ *row that records the stability gauge and boundary-facing direction used by the fellow-traveller comparison.*
5. *U is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row, recording the finite boundary-shadow window attached to the same endpoint data.*
6. *D is the Busemann-tolerance row, carrying additive comparison budgets for the route, shadow window, and boundary attachment.*
7. *R is the* Real$^{\uparrow}$ *seal row for metric distances, tolerance budgets, and Busemann comparisons.*
8. *H records componentwise* hsame *transport for metric, quasi-geodesic, fellow-traveller, Morse-boundary, boundary-shadow, Busemann, Real, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a shadowing request through M, Q, F, B, U, D, R.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicShadowing}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$, $\mathsf{MorseBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicShadowing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, Q, F, B, U, D, R, H, C, P, N$. It has no coordinate for completed ideal-boundary quotients, selected global geodesics, quotient path equality, host hyperbolic compactification, physical observer trajectories, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6707.2 (Hyperbolic shadowing NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicShadowing}^{\uparrow}$ *carrier*

$$S = (M, Q, F, B, U, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicShadowing}^{\uparrow}}$ *surface consists exactly of HyperbolicMetric comparison rows, HyperbolicQuasiGeodesicShadow route rows, finite fellow-traveller windows, MorseBoundary stability rows, HyperbolicBoundaryShadow attachment rows, Busemann tolerance rows, Real seals, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6707.1. The rows $M, Q, F, B, U, D, R, H, C, P, N$ are the complete certificate surface.

The route and metric rows are read first. The metric row M supplies only displayed distance comparisons, and Q supplies the finite quasi-geodesic shadow data already named by chapter 5802.

The fellow-traveller and boundary rows then bind the shadowing claim. The row F records finite comparison windows, while B and U attach those windows to the Morse-boundary and boundary-shadow surfaces.

Finally D, R, H, C, P, N compare, seal, transport, replay, source, and name the same route. Since no host coordinate is present, the obligations cannot export completed boundaries, selected global geodesics, quotient path equality, physical observer dynamics, or ambient real completeness. □

Theorem 6707.3 (Hyperbolic shadowing fellow-traveller handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicShadowing}^{\uparrow}$ *carrier must read the route*

$$\mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow},\ \mathsf{MorseBoundary}^{\uparrow},\ \mathsf{HyperbolicBoundaryShadow}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Hy}$$

through finite metric comparisons, quasi-geodesic shadow rows, fellow-traveller windows, Morse stability, boundary-shadow attachment, Busemann tolerance, Real seals, transport, replay, provenance, and local naming. The handoff realizes the hyperbolic observer-expansion shadow route as finite NameCert data.

Proof. Begin with an accepted carrier $S = (M, Q, F, B, U, D, R, H, C, P, N)$. A shadowing consumer can inspect the quasi-geodesic route only after the metric row M and the quasi-geodesic shadow row Q have been displayed.

The fellow-traveller comparison is then forced through F. This row names finite comparison windows and does not select a global geodesic representative or quotient path class.

The boundary-facing evidence is read through B, U, D, R. The Morse-boundary row supplies a finite stability gauge, the boundary-shadow row supplies the endpoint window, the Busemann row supplies the additive tolerance, and the Real row seals the displayed comparisons.

The structural rows H, C, P, N transport, replay, source, and name that finite route for observer-expansion consumers. No completed ideal boundary, host hyperbolic compactification, physical observer trajectory, quotient geodesic equality, or ambient completeness row can be inserted into the handoff. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicShadowing}^{\uparrow}$ observer-expansion read factors through finite $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$, $\mathsf{MorseBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, fellow-traveller, Busemann-tolerance, transport, replay, provenance, and local naming rows.

Independence witness: hyperbolicmetric, hyperbolic-quasi-geodesic-shadow, morse-boundary, hyperbolic-boundary-shadow, hyperbolic-observer-expansion: no listed sibling is bijective to $\mathsf{HyperbolicShadowing}^{\uparrow}$ because this packet binds metric comparisons, quasi-geodesic route samples, fellow-traveller windows, Morse stability, boundary-shadow attachment, Busemann tolerance, Real seals, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicShadowing}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicShadowing}^{\uparrow}$ packet is generated from HyperbolicMetric comparison rows, HyperbolicQuasiGeodesicShadow route rows, finite fellow-traveller windows, MorseBoundary stability rows, HyperbolicBoundaryShadow attachment rows, Busemann tolerance rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicShadowing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6707.1, Definition 6707.2, and Definition 6707.3 seed the finite hyperbolic shadowing route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicShadowing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed boundary quotients, selected global geodesics, quotient path equality, host hyperbolic compactification, physical observer trajectories, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric comparison routing, quasi-geodesic shadow routing, fellow-traveller windows, MorseBoundary stability, HyperbolicBoundaryShadow attachment, Busemann tolerance, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicShadowingUp.

Chapter 6708

A Concrete Naming Certificate for $\mathsf{FiniteGaugeCover}^{\uparrow}$

Following Cousin, Henstock, and Kurzweil, the $\mathsf{FiniteGaugeCover}^{\uparrow}$ packet records the finite gauge-cover surface used by constructive gauge integration. It sits between the local cover extraction of $\mathsf{CousinLemma}^{\uparrow}$ and $\mathsf{CousinCover}^{\uparrow}$, the tagged-sum rows of $\mathsf{RiemannSumGauge}^{\uparrow}$, the integral endpoint of $\mathsf{GaugeIntegral}^{\uparrow}$, and the arithmetic readback rows of $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. Its mesh-control row also consumes the finite lower-bound cover sibling of chapter 452: finite gauge cells reuse that lower-bound ledger before the $\mathsf{RiemannSumGauge}^{\uparrow}$ and $\mathsf{GaugeIntegral}^{\uparrow}$ handoffs inspect tagged sums and endpoints. The packet names only finite gauge cells, tagged witnesses, dyadic mesh control, readback, handoff, transport, provenance, and local naming; it does not import open-cover compactness, hidden point choice, quotient cover equality, or ambient real completeness.

Definition 6708.1 (Finite gauge-cover carrier)**.** *A* $\mathsf{FiniteGaugeCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, C, T, M, Q, E, U, R, I, H, P, N)$$

with the following displayed rows:

1. *D is the gauge row, naming the local positive-radius data inspected by the cover.*
2. *C is the finite cell ledger: each accepted cell carries its interval row, center row, and gauge-admissibility witness.*
3. *T is the tag row, pairing each finite cell with the displayed point used by the tagged partition.*
4. *M is the mesh-control row, exposing only finite refinements of the displayed cells.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row used to compare radii, endpoints, and mesh bounds.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the terminal value read inspected by the integration consumer.*
7. *U is the* $\mathsf{CousinLemma}^{\uparrow}$ *and* $\mathsf{CousinCover}^{\uparrow}$ *handoff row, recording the finite cover obtained from the displayed gauge data.*
8. *R is the* $\mathsf{RiemannSumGauge}^{\uparrow}$ *handoff row for tagged sums over the same cells and tags.*
9. *I is the* $\mathsf{GaugeIntegral}^{\uparrow}$ *handoff row exposed only after U, R, Q, E have been displayed.*
10. *H is the componentwise* hsame *transport row for gauge, cover, tag, mesh, readback, seal, and handoff coordinates.*

11. *P is the* Pkg *provenance over* $\mathsf{FiniteGaugeCover}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteGaugeCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, selected subcovers outside the displayed finite ledger, quotient equality of covers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.FiniteGaugeCoverUp`

Theorem 6708.2 (Finite gauge-cover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteGaugeCover}^{\uparrow}$ *carrier* $G = (D, C, T, M, Q, E, U, R, I, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteGaugeCover}^{\uparrow}}$ *surface consists exactly of gauge-row admission, finite cell-ledger exactness, tag admission, finite mesh control,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal exposure,* $\mathsf{CousinLemma}^{\uparrow}$ *and* $\mathsf{CousinCover}^{\uparrow}$ *finite-cover handoff,* $\mathsf{RiemannSumGauge}^{\uparrow}$ *tagged-sum handoff,* $\mathsf{GaugeIntegral}^{\uparrow}$ *endpoint handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. No obligation is discharged by open-cover compactness, host subcover selection, quotient cover equality, countable choice, or ambient real completeness.*

Proof. Project the carrier into its displayed rows. The gauge, finite cell ledger, tag row, and mesh row expose the only cover data visible to a consumer.

Read the arithmetic boundary through Q and E. The $\mathsf{DyadicRatCore}^{\uparrow}$ row compares the finite radii and mesh bounds, and the $\mathsf{Real}^{\uparrow}$ seal is reached only as the terminal value read.

Finally use the named handoff rows. The Cousin rows supply finite-cover extraction, the Riemann-sum row supplies tagged-sum use, and the gauge-integral row is visible only after those rows are present. Componentwise transport and replay therefore keep every NameCert obligation inside the listed packet. □

Lean4 ✓ `BEDC.Derived.FiniteGaugeCoverUp.FiniteGaugeCover namecert obligations`

Theorem 6708.3 (Cousin finite-cover handoff)**.** *Let* $G = (D, C, T, M, Q, E, U, R, I, H, P, N)$ *be an accepted* $\mathsf{FiniteGaugeCover}^{\uparrow}$ *carrier. Any consumer read that uses G as a cover witness for* $\mathsf{CousinLemma}^{\uparrow}$ *or* $\mathsf{CousinCover}^{\uparrow}$ *must first expose the gauge row D, finite cell ledger C, tag row T, mesh row M, dyadic readback Q, and handoff row U. The read exports only the displayed finite cover and no arbitrary open cover, hidden refinement selector, quotient cover equality, or choice-like subcover operation.*

Proof. Begin with the cover-facing rows D, C, T, M. These rows determine the finite ledger that the Cousin consumer is allowed to inspect.

The dyadic row Q supplies the finite arithmetic comparison needed to check that each tagged cell is gauge-admissible. The handoff row U then records the Cousin read over that same finite ledger.

Since the packet has no row for an ambient open-cover object or selected subcover outside C, T, M, any accepted read remains within the displayed finite cover surface. □

Theorem 6708.4 (Gauge-integral nonescape)**.** *Let* $G = (D, C, T, M, Q, E, U, R, I, H, P, N)$ *be an accepted* $\mathsf{FiniteGaugeCover}^{\uparrow}$ *carrier. Every* $\mathsf{GaugeIntegral}^{\uparrow}$ *consumer read that factors through G must pass through the* $\mathsf{CousinLemma}^{\uparrow}$ *and* $\mathsf{CousinCover}^{\uparrow}$ *handoff U, the* $\mathsf{RiemannSumGauge}^{\uparrow}$ *handoff R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback Q, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E before reaching I. It cannot replace those rows by open-cover compactness, an ambient real-completeness theorem, quotient stream equality, or a host limit selector.*

Proof. The integral-facing read starts from the same finite cover rows used by the Cousin handoff. Thus U is visible before a tagged-sum or integral endpoint can be consumed.

Next the tagged-sum handoff R reads the finite tags and cells, while Q and E provide the arithmetic and real-name boundary. These rows are the only path from finite cover data to the displayed endpoint row I.

The transport, replay, provenance, and local naming rows preserve this path componentwise. Therefore the consumer receives the finite gauge-integration route and no stronger compactness, equality, choice, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteGaugeCover}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteGaugeCover}^{\uparrow}$ packet is generated from gauge rows, finite cell ledgers, tag rows, mesh-control rows, DyadicRatCore readback, RealUp seals, CousinLemmaUp and CousinCoverUp handoffs, RiemannSumGaugeUp tagged-sum handoffs, GaugeIntegralUp endpoint handoffs, structural transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteGaugeCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6708.1, Definition 6708.2, Definition 6708.3, and Definition 6708.4 seed the finite gauge-cover route through CousinLemmaUp, CousinCoverUp, GaugeIntegralUp, RiemannSumGaugeUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteGaugeCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, quotient cover equality, hidden subcover selection, countable choice, ambient RealUp completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, gauge-cell exactness, Cousin handoff, Riemann-sum handoff, GaugeIntegral nonescape, structural replay, provenance exhaustion, and local naming for the same packet.

Chapter 6709

A Concrete Naming Certificate for $\mathsf{WeierstrassRootTest}^{\uparrow}$

Following Cauchy and Hadamard, the $\mathsf{WeierstrassRootTest}^{\uparrow}$ packet records the traditional root-test convergence route as finite BEDC certificate data over regular Cauchy tails. It sits between the displayed root-bound handoff of chapter 1481, the majorant schedule of chapter 1774, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the finite majorant route needed by Real and Completion consumers; it does not assert selected limits, quotient sequence equality, countable choice, or ambient Real completeness.

Definition 6709.1 (Weierstrass root-test carrier)**.** *A* $\mathsf{WeierstrassRootTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (A, Q, M, D, T, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the inspected series or tail-source row whose terms are read through finite windows.*
2. *Q is the root-bound witness row, recording a displayed dyadic bound strictly below the unit scale and a finite entry index after which the bound applies.*
3. *M is the finite modulus row assigning each precision request a tail threshold beyond the root-bound entry index.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the root-bound row with the requested tail precision.*
5. *T is the* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *handoff row that turns A, Q, M, D into a regular Cauchy tail route.*
6. *B is the* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *majorant row, displaying the geometric majorant schedule consumed by the tail estimate.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the root-test handoff and the majorant row have both been exposed.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only from the displayed regular readback row.*
9. *H records componentwise* hsame *transport for the source, root-bound, modulus, tolerance, root-test handoff, majorant, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a root-bound request through* $A, Q, M, D, T, B, R, E, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{WeierstrassRootTest}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{WeierstrassRootTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a selected limit, quotient sequence equality, countable-choice tail selector, ambient Real completeness, host limsup theorem, or detached summation object.

Theorem 6709.2 (Weierstrass root-test NameCert obligations)**.** *For every accepted* $\mathsf{WeierstrassRootTest}^{\uparrow}$ *carrier* $W = (A, Q, M, D, T, B, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WeierstrassRootTest}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed twelve-row packet, root-bound exposure through* Q*, modulus exposure through* M*, dyadic tolerance exactness through* D*,* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *handoff through* T*,* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *tail-majorant exposure through* B*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{Real}^{\uparrow}$ *seal non-escape through* E*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6709.1. The displayed rows are exactly $A, Q, M, D, T, B, R, E, H, C, P, N$, so every local obligation must be read from one of those rows.

Read the root-bound portion first. The row Q supplies the dyadic bound and entry index, M supplies the finite threshold for the requested precision, and D records the dyadic comparisons used by that request.

Apply the root-test and majorant rows. The handoff T is the $\mathsf{RegularCauchyRootTest}^{\uparrow}$ route from the displayed root-bound data to a regular Cauchy tail, while B is the $\mathsf{CauchyMajorantSeries}^{\uparrow}$ schedule that records the finite tail majorant consumed by the same request.

The rows R and E are downstream endpoints. The regular readback R is available only after T and B, and the terminal seal E is available only after R.

Finally use H, C, P, N to transport, replay, source, and name the same route. Since the carrier contains no selected limit, quotient sequence equality, countable-choice tail selector, ambient Real completeness, host limsup theorem, or detached summation object, the listed rows exhaust the local NameCert surface. □

Theorem 6709.3 (Weierstrass root-test tail majorant)**.** *Every Real or Completion-facing consumer of an accepted* $\mathsf{WeierstrassRootTest}^{\uparrow}$ *carrier must read the finite route*

$$A, Q, M, D \longmapsto \mathsf{RegularCauchyRootTest}^{\uparrow}(T) \longmapsto \mathsf{CauchyMajorantSeries}^{\uparrow}(B) \longmapsto \mathsf{RegSeqRat}^{\uparrow}(R) \longmapsto \mathsf{Real}^{\uparrow}(E)$$

before it can use the exported convergence surface. The route gives a regular-Cauchy root-test majorant, not a selected limiting value, quotient sequence equality, countable-choice schedule, ambient Real completeness, host limsup theorem, or detached infinite summation object.

Proof. Start with a precision request against the carrier. The rows Q, M, D display the root-bound, finite threshold, and dyadic tolerance data attached to the source row A.

Use Definition 1481.3. It identifies the root-test handoff T as a regular Cauchy tail route read only from the displayed source, root-bound, modulus, and dyadic rows.

Next use Definition 1774.3. The majorant row B supplies the finite tail-control schedule that a Real or Completion consumer must inspect before any endpoint readback is available.

The readback row R and seal row E then terminate the route through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. Transport, replay, provenance, and local naming preserve this order, so no consumer receives selected limits, quotient sequence equality, countable choice, ambient Real completeness, a host limsup theorem, or an unrecorded summation object. □

Falsifiable prediction: Every accepted $\mathsf{WeierstrassRootTest}^{\uparrow}$ endpoint read factors through a root-bound witness, finite modulus, DyadicRatCore tolerance ledger, RegularCauchyRootTest handoff, CauchyMajorantSeries tail schedule, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: regular-cauchy-root-test, cauchy-majorant-series, regseqrat, dyadicrat-core, real: $\mathsf{WeierstrassRootTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries root-bound data, a finite modulus, dyadic tolerance comparisons, regular-Cauchy root-test handoff, majorant schedule, regular readback, Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{WeierstrassRootTest}^{\uparrow}}$.

Constructive story: A $\mathsf{WeierstrassRootTest}^{\uparrow}$ packet is generated from a displayed source row, root-bound witness, finite modulus, DyadicRatCore tolerance ledger, RegularCauchyRootTest handoff, CauchyMajorantSeries tail-majorant row, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeierstrassRootTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6709.1, Definition 6709.2, and Definition 6709.3 seed the finite root-test majorant route from displayed root-bound data through regular Cauchy readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeierstrassRootTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient sequence equality, countable choice, ambient Real completeness, host limsup theorems, detached infinite summation objects, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, root-bound exactness, modulus coverage, dyadic tolerance exactness, root-test handoff, majorant tail control, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.WeierstrassRootTestUp.

Chapter 6710

A Concrete Naming Certificate for DvoretzkyFiniteDimensionalSection$^{\uparrow}$

Following Dvoretzky's finite-dimensional almost-Euclidean section theorem and Milman's finite-dimensional formulation, the DvoretzkyFiniteDimensionalSection$^{\uparrow}$ packet records displayed witness data for a fixed finite normed-space window. It sits over the Banach carrier of chapter 90, the inner-product comparison rows of chapter 86, the vector-space carrier of chapter 47, the metric rows of chapter 57, and the terminal real-name seal of chapter 38. The packet is a finite BEDC witness surface; it does not assert a global Dvoretzky existence theorem, a choice-selected subspace, a measure concentration theorem, or ambient Banach-space completeness.

Definition 6710.1 (Dvoretzky finite-dimensional section carrier)**.** *A* DvoretzkyFiniteDimensionalSection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (V, N, I, M, E, D, H, C, P, Q)$$

with the following displayed rows:

1. *V is the finite* VecSpace$^{\uparrow}$ *window: a named finite vector list, its span rules, scalar reads, and the finite coordinate table used by the section.*
2. *N is the normed-space row inherited from the local* BanachSpace$^{\uparrow}$ *surface, restricted to the displayed window and not to an ambient complete Banach object.*
3. *I is the* InnerProduct$^{\uparrow}$ *and Euclidean-candidate row, recording the comparison form, Gram entries, and the finite Euclidean norm candidate on the same section window.*
4. *M is the* Met$^{\uparrow}$ *comparison row, recording the finite metric reads for the norm row and the Euclidean-candidate row.*
5. *E is the* Real$^{\uparrow}$ *scalar seal for all displayed norm, inner-product, distance, and distortion values.*
6. *D is the distortion ledger, consisting of explicit real-sealed lower and upper comparison entries for the displayed window.*
7. *H stores componentwise* hsame *transport for V, N, I, M, E, D.*
8. *C stores displayed* Cont *replay from vector-space coordinates to norm, metric, inner-product, and distortion reads.*
9. *P is the* Pkg *provenance over* DvoretzkyFiniteDimensionalSection$^{\uparrow}$, BanachSpace$^{\uparrow}$, InnerProduct$^{\uparrow}$, VecSpace$^{\uparrow}$, Met$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. Q is the local $\mathsf{NameCert}_{\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}}$ *row.*
The classifier reads only $V, N, I, M, E, D, H, C, P, Q$. It has no coordinate for an arbitrary ambient Banach space, a selected high-dimensional subspace, a concentration argument, quotient equality of norms, or a completed infinite-dimensional object.

Lean4 ✓ `BEDC.Derived.DvoretzkyFiniteDimensionalSectionUp.DvoretzkyFiniteDimensionalSectionTasteGate`
`single carrier alignment`

Theorem 6710.2 (Dvoretzky finite-dimensional section obligations)**.** *For every accepted* DvoretzkyFiniteDimensional *carrier $B = (V, N, I, M, E, D, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}}$ *obligation surface consists exactly of carrier admission, finite vector-space window exposure, normed-space row restriction, Euclidean-candidate row display, metric comparison row display,* $\mathsf{Real}^{\uparrow}$ *scalar sealing, distortion-ledger readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6710.1. The finite vector-space source is V, the norm row is N, the Euclidean-candidate row is I, the metric comparison row is M, and the Real-sealed distortion ledger is E, D.

The structural rows H, C, P, Q transport, replay, source, and name those displayed rows. They do not add a second source of norm comparison or a hidden subspace selector.

Thus every accepted obligation is read from $V, N, I, M, E, D, H, C, P, Q$. Any global existence theorem, concentration estimate, selected subspace, quotient norm equality, or ambient completeness principle would require a coordinate not present in the packet. □

Theorem 6710.3 (Dvoretzky Euclidean window readback)**.** *Every public Euclidean-window read exported by an accepted* $\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}$ *carrier exposes the same finite vector-space window V, norm row N, inner-product candidate I, metric comparison row M,* $\mathsf{Real}^{\uparrow}$ *scalar seal E, distortion ledger D, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row Q before any section claim is public. The read is finite witness data only; it does not promote the packet to a global Dvoretzky theorem or to a choice-selected ambient subspace.*

Proof. Start from the carrier rows of Definition 6710.1. A Euclidean-window consumer must first read the finite coordinate window V and the two comparison surfaces N and I.

Next read M, E, D. These rows place every metric and distortion value behind the displayed metric comparison and the terminal real-name seal, so the consumer sees finite comparison entries rather than an ambient norm theorem.

Finally use H, C, P, Q to transport, replay, source, and name the same rows. Since the carrier has no global existence, concentration, selected-subspace, quotient-equality, or completeness coordinate, the public read remains the displayed finite witness packet. □

Falsifiable prediction: A purported $\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}$ read that omits the displayed finite vector-space window, Euclidean-candidate row, metric comparison row, or Real-sealed distortion ledger is not accepted by this carrier.

Independence witness: banach, innerproduct, vecspace, metric, real: the Banach carrier lacks the Euclidean-candidate and distortion rows, the inner-product row lacks the normed-space and Banach provenance rows, the vector-space carrier lacks the metric and Real-sealed distortion ledger, the metric row lacks the vector-space and inner-product source rows, and the Real seal lacks the section window and comparison ledger; none alone carries $V, N, I, M, E, D, H, C, P, Q$.

Closure status for $\mathsf{NameCert}_{\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}}$.

Constructive story: A $\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}$ packet is generated from a finite vector-space window, normed-space row, Euclidean-candidate row, metric comparison row, Real scalar seal, distortion ledger, transport, replay, provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6710.1, Definition 6710.2, and Definition 6710.3 bind the finite witness packet and its Euclidean-window readback boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DvoretzkyFiniteDimensionalSection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim a global Dvoretzky existence theorem, choice-selected subspace, measure concentration theorem, quotient norm equality, ambient Banach-space completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability for the section and distortion rows, ledger nonescape, and local NameCert coverage for the displayed finite witness packet.

Chapter 6711

A Concrete Naming Certificate for $\mathsf{FreydMitchellEmbedding}^{\uparrow}$

Following Freyd and Mitchell, the $\mathsf{FreydMitchellEmbedding}^{\uparrow}$ packet records the finite certificate surface needed to name the exact embedding route from a small abelian category into a module category. It depends on the abelian-category carrier of chapter 176, the functor carrier of chapter 62, and the module carrier of chapter 46; it also uses the natural-transformation interface of chapter 63 to keep comparison rows explicit.

6711.1 Carrier

Definition 6711.1 (FreydMitchellEmbeddingUp displayed carrier)**.** *A* $\mathsf{FreydMitchellEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{F} = (A, R, M, E, X, K, C, H, P, N)$$

with the following displayed rows.

1. *A is an* $\mathsf{AbelianCat}^{\uparrow}$ *source row whose object, morphism, zero, biproduct, kernel, cokernel, image, coimage, and factorisation data are the visible rows of chapter 176.*
2. *R is the ring or algebra row over which the target module category is displayed.*
3. *M is a* $\mathsf{Module}^{\uparrow}$ *target row naming the module carrier, hom rows, additive structure, scalar action, and componentwise* hsame *transport inherited from chapter 46.*
4. *E is a* $\mathsf{Functor}^{\uparrow}$ *row from A into the displayed module category; it contains object mapping, morphism mapping, identity preservation, composition preservation, and codomain classifier transport.*
5. *X is an exactness ledger: for every visible kernel, cokernel, image, coimage, and epi–mono factorisation row in A, the image under E is recorded as the corresponding kernel, cokernel, image, coimage, or exact sequence row in M.*
6. *K is a faithfulness ledger: if two displayed morphisms of A have the same transported module morphism under E, the ledger returns the original morphism-classifier equality in A.*
7. *C is a comparison row for naturality and finite diagram compatibility, expressed through* $\mathsf{NatTrans}^{\uparrow}$ *rows when two displayed finite diagrams in A are transported into M.*

8. *H is componentwise* hsame *transport for A, R, M, E, X, K, C.*
9. *P is package provenance tying the carrier to the finite source presentation, the target module presentation, and the embedding rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FreydMitchellEmbedding}^{\uparrow}}$ *row.*

The carrier names the finite BEDC obligation surface for an exact faithful embedding packet. It does not assert that every small abelian category admits such a packet, nor does it construct a universal module category from arbitrary external data.

Theorem 6711.2 (FreydMitchellEmbeddingUp NameCert obligations)**.** *For the carrier of Definition 6711.1, the local* $\mathsf{NameCert}_{\mathsf{FreydMitchellEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for $\mathcal{F} = (A, R, M, E, X, K, C, H, P, N)$; source admission through* $\mathsf{NameCert}_{\mathsf{AbelianCat}^{\uparrow}}$*; target admission through* $\mathsf{NameCert}_{\mathsf{Module}^{\uparrow}}$*; embedding admission through* $\mathsf{NameCert}_{\mathsf{Functor}^{\uparrow}}$*; naturality comparison through* $\mathsf{NameCert}_{\mathsf{NatTrans}^{\uparrow}}$*; exactness replay through X; faithfulness replay through K; componentwise transport through H; provenance through P; and local naming through N.*

Proof. Read the abelian-category source row first. Its additive, kernel, cokernel, image, coimage, and factorisation fields are the only exactness rows that the embedding packet is allowed to consume.

Next read the target module row and the functor row. The module row supplies the additive target hom structure and scalar action, while the functor row supplies object mapping, morphism mapping, identity preservation, and composition preservation. These are the rows on which the exactness ledger X and the faithfulness ledger K are indexed.

Finally read the comparison, transport, provenance, and name rows. The $\mathsf{NatTrans}^{\uparrow}$ comparison row records finite diagram compatibility; H transports every displayed component; P records the finite source and target presentations; and N names the packet. Repacking these rows gives precisely the displayed $\mathsf{NameCert}_{\mathsf{FreydMitchellEmbedding}^{\uparrow}}$ surface and no full embedding existence theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{FreydMitchellEmbedding}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FreydMitchellEmbedding}^{\uparrow}$ packet is generated from an abelian-category source row, a module target row, an exact faithful functor row, finite exactness and faithfulness ledgers, naturality comparison rows, componentwise hsame transport, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FreydMitchellEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 6711.1 and Definition 6711.2 seed the finite BEDC certificate surface for an exact faithful embedding packet from an abelian-category carrier to a module carrier.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FreydMitchellEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not claim the Freyd–Mitchell embedding theorem, existence for arbitrary small abelian categories, target ring construction, or Lean verification.

Upgrade path: Formalization must introduce the displayed carrier and prove the NameCert obligation surface without adding an external embedding existence premise.

Chapter 6712

A Concrete Naming Certificate for $\mathsf{SequentialCauchyFilter}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SequentialCauchyFilter}^{\uparrow}$ packet records the finite route by which sequence-indexed Cauchy evidence becomes a displayed Cauchy-filter read before Real or Completion consumers inspect terminal data. It sits between the saturated filter surface of chapter 333, the finite basis generator of chapter 1501, the sequence-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The certificate names the sequential filter as finite BEDC rows; it does not turn a Cauchy sequence into a quotient stream, selected limit, countable-choice schedule, host equality proof, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6712.1 (Sequential Cauchy filter carrier)**.** *A* $\mathsf{SequentialCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F_{\mathrm{seq}} = (S, B, Q, D, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *sequence-window row, exposing exactly the finite index windows inspected by the sequential Cauchy request.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row generated from the displayed tail windows and their common-refinement witnesses.*
3. *Q is the* $\mathsf{CauchyFilter}^{\uparrow}$ *saturation row reached from B before any completion-facing consumer may read filter data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radius, tail comparison budget, and endpoint scale used by the displayed Cauchy test.*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same sequence windows and dyadic tolerances.*
6. *R is the sequential route ledger, ordering S, D, G, B, Q so the filter read is visibly generated from sequential evidence.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after the sequential route ledger and filter rows have been displayed.*

8. *H records componentwise* hsame *transport for sequence windows, filter bases, filter saturation, dyadic tolerances, regular readback, route ledger, terminal seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a sequential Cauchy request through S, D, G, B, Q, R, E.*
10. *P is the* Pkg *provenance over* $\mathsf{SequentialCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, Q, D, G, R, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credentials.*

Lean4 ✓ `BEDC.Derived.SequentialCauchyFilterUp.SequentialCauchyFilterTasteGate single carrier alignment`

Theorem 6712.2 (Sequential Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCauchyFilter}^{\uparrow}$ *carrier $F_{\mathrm{seq}} = (S, B, Q, D, G, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet; sequence-window exposure through S; filter-basis generation through B; Cauchy-filter saturation through Q; dyadic tolerance exposure through D; regular-rational readback through G; sequential route ordering through R; terminal Real-seal boundary through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6712.1. The analytic rows are exactly S, B, Q, D, G, R, E, and the structural rows are exactly H, C, P, N.

The sequence data are read first. The window row S exposes the inspected indices, the dyadic row D fixes the tolerance budget, and the regular readback row G records the rational evidence attached to those windows.

The filter rows are downstream of that route. The basis row B is generated from the displayed sequential data, and the saturation row Q is read only after the basis has been shown.

Finally, R, E, H, C, P, N order, seal, transport, replay, source, and name the same finite packet. Since quotient streams, selected limits, countable choice, host equality, trichotomy, ambient completeness, and bridge credentials are absent from the carrier, none is a local NameCert obligation. □

Theorem 6712.3 (Sequential Cauchy filter RegSeqRat route)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{SequentialCauchyFilter}^{\uparrow}$ *packet reaches the terminal seal only through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exports finite StreamName, RegSeqRat, DyadicRatCore, CauchyFilterBasis, CauchyFilter, and Real rows, together with BHist, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *support. It exports no quotient stream, selected limit, countable-choice function, host equality proof, trichotomy decision, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Start with the obligation surface of Definition 6712.2. It forces every accepted read to expose the finite sequence windows, dyadic tolerance ledger, and regular rational readback before a filter basis is available.

The filter handoff then passes through B and Q. A completion-facing consumer therefore receives the Cauchy-filter row as a saturation of the displayed sequential basis, not as an external filter or quotient stream.

The terminal seal E is downstream of the route ledger R. Transport, replay, provenance, and local naming preserve the same finite route, and no excluded coordinate is present from which a selected limit, countable-choice schedule, host equality proof, trichotomy decision, ambient completeness theorem, or bridge credential could be exported. □

Falsifiable prediction: An accepted $\mathsf{SequentialCauchyFilter}^{\uparrow}$ consumer that reaches a $\mathsf{CauchyFilter}^{\uparrow}$ row or terminal $\mathsf{Real}^{\uparrow}$ seal without first displaying the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: cauchyfilter, cauchy-filter-basis, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole sequential packet $F_{\mathrm{seq}} = (S, B, Q, D, G, R, E, H, C, P, N)$, because each sibling contributes only a saturated filter, basis generator, window row, regular readback, dyadic tolerance ledger, or terminal seal while this chapter binds them into one sequence-indexed Cauchy-filter certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCauchyFilter}^{\uparrow}$ packet is generated from StreamName sequence windows, CauchyFilterBasis generation rows, CauchyFilter saturation rows, DyadicRatCore tolerance ledgers, RegSeqRat readbacks, sequential route ledgers, terminal RealUp seal boundaries, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6712.1, Definition 6712.2, and Definition 6712.3 seed the finite sequential Cauchy-filter route over StreamName, RegSeqRat, DyadicRatCore, CauchyFilterBasis, CauchyFilter, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host equality, trichotomy, RealUp completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequence-window exposure, filter-basis generation, Cauchy-filter saturation, dyadic tolerance exactness, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SequentialCauchyFilterUp.

Chapter 6713

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$ packet records the finite tail-filter seal used when regular Cauchy sequence evidence from section 9238.1 is routed into the L10 Real and Completion corridor. It sits after the finite observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet turns the regular Cauchy tail discipline into a displayed filter seal, not into a quotient stream, selected limit, countable-choice schedule, host equality proof, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 6713.1 (Regular Cauchy filter seal carrier)**.** *A* $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, W, F, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row, recording the finite windows opened by the regular Cauchy tail request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic tail radius, comparison scale, and endpoint budget.*
4. *W is the tail-seal witness row, stating that the displayed windows and dyadic budget give the required regular Cauchy tail comparison.*
5. *F is the filter-facing seal row generated from S, R, D, W before any completion consumer may inspect the tail-filter route.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the StreamName, RegSeqRat, DyadicRatCore, and filter-facing rows have been displayed.*
7. *L is the ledger row connecting the carrier to the regular Cauchy diagonal and tail-seal markers of section 9238.1.*
8. *H records componentwise* hsame *transport for tail windows, regular readback, dyadic tolerance, tail witness, filter seal, terminal seal, ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a regular Cauchy tail request through S, R, D, W, F, E, L.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, W, F, E, L, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, host equality, trichotomy, ambient Real completeness, or bridge credentials.

Theorem 6713.2 (Regular Cauchy filter seal NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$ *carrier $T = (S, R, D, W, F, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet; tail-window exposure through S; regular-rational readback through R; dyadic tolerance exposure through D; tail-seal witnessing through W; filter-facing sealing through F; terminal Real sealing through E; vision-ledger routing through L; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6713.1. The analytic tail route is exactly S, R, D, W, F, E, L, and H, C, P, N are the structural rows.

The regular Cauchy evidence is read through finite windows and dyadic budgets. The row S opens the inspected tail windows, R supplies the regular rational readback, and D fixes the tolerance scale.

The seal rows are downstream. The witness row W records the tail comparison, the filter-facing row F packages that comparison as a seal, and the terminal row E is exposed only after the earlier rows are visible.

Finally, the ledger and structural rows bind the route to the regular Cauchy vision site and replay it for later consumers. Because no excluded object is a carrier coordinate, quotient streams, selected limits, countable choice, host equality, trichotomy, ambient completeness, and bridge credentials cannot become local obligations. □

Theorem 6713.3 (Regular Cauchy filter seal tail route)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$ *packet reads the tail-filter seal only through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyFilterSeal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route realizes the regular Cauchy diagonal and tail-seal rows of section 9238.1 as finite StreamName, RegSeqRat, DyadicRatCore, and Real seal data. It exports no quotient stream, selected limit, countable-choice schedule, host equality proof, trichotomy decision, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or bridge credential.*

Proof. Use the obligation surface of Definition 6713.2. It forces each accepted read to expose S, R, D before the tail witness or filter-facing seal can be consumed.

The row W records the regular Cauchy tail comparison inside the displayed dyadic budget, and F packages that comparison as the filter-facing seal. The terminal row E is therefore downstream of the finite tail route, not a selected limit.

The ledger row L ties this route to the regular Cauchy diagonal and tail-seal markers, while H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no excluded coordinate, the stated nonescape claims follow. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$ consumer that reaches a filter-facing seal or terminal $\mathsf{Real}^{\uparrow}$ row without first displaying the $\mathsf{StreamName}^{\uparrow}$ tail window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-vision: no listed sibling supplies the whole tail-filter seal packet $T = (S, R, D, W, F, E, L, H, C, P, N)$, because each sibling contributes only a window row, regular readback, tolerance ledger, terminal seal, or vision marker while this chapter binds them into one finite seal certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSeal}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyFilterSeal}^{\uparrow}$ packet is generated from StreamName tail windows, RegSeqRat readback rows, DyadicRatCore tolerance ledgers, tail-seal witness rows, filter-facing seal rows, terminal RealUp seal boundaries, vision ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSeal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6713.1, Definition 6713.2, and Definition 6713.3 seed the finite tail-filter seal route over StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSeal}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host equality, trichotomy, RealUp completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window exposure, RegSeqRat readback, dyadic tolerance exactness, tail-seal witnessing, filter-facing seal nonescape, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFilterSealUp.

Chapter 6714

A Concrete Naming Certificate for $\mathsf{DAlembertRatioTest}^{\uparrow}$

Following d'Alembert and Bishop–Bridges on constructive tests for real series, the $\mathsf{DAlembertRatioTest}^{\uparrow}$ packet records the classical ratio-test promise as a finite BEDC NameCert surface. It sits beside the real-series source of chapter 1581, the rational margin data of chapter 37, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It also refines the existing ratio-test corridor of chapter 2244 by naming the d'Alembert ratio-bound evidence as the explicit handoff from displayed adjacent terms to a Cauchy-facing convergence route.

Definition 6714.1 (d'Alembert ratio test carrier)**.** *A* $\mathsf{DAlembertRatioTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, Q, M, D, W, R, C, E, H, J, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing only the inspected term stream and finite partial-sum windows.*
2. *A is the adjacent-term row, listing the displayed pair windows a_n, a_{n+1} after the relevant source threshold.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *margin row, recording the rational witness $q < 1$ used by the d'Alembert comparison.*
4. *M is the ratio-bound row, displaying the tail comparison $|a_{n+1}| \leq q|a_n|$ only through the rows A, Q, W, R, D.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, translating the rational margin into the dyadic budgets consumed by later Cauchy requests.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the adjacent terms, margin checks, partial sums, and tail requests.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for all displayed adjacent-term, ratio-bound, and partial-sum observations.*
8. *C is the Cauchy handoff row, recording the finite route from the displayed ratio bound to a regular tail-control request.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, A, Q, M, D, W, R, C have all been displayed.*
10. *H records componentwise* hsame *transport for the source, adjacent-term, margin, dyadic, window, readback, handoff, seal, replay, provenance, and local-name rows.*
11. *J records displayed* Cont *replay from a convergence request through the same rows.*
12. *P is the* Pkg *provenance over* $\mathsf{DAlembertRatioTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DAlembertRatioTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, Q, M, D, W, R, C, E, H, J, P, N$. It has no coordinate for a host limit of ratios, quotient equality of real-name streams, a selected infinite sum, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) `BEDC.Derived.DAlembertRatioTestUp`

Theorem 6714.2 (d'Alembert ratio test NameCert obligations)**.** *For every accepted* $\mathsf{DAlembertRatioTest}^{\uparrow}$ *carrier $K = (S, A, Q, M, D, W, R, C, E, H, J, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DAlembertRatioTest}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{RealSeries}^{\uparrow}$ *source exposure, adjacent-term window exactness, rational margin exposure through* $\mathsf{Rat}^{\uparrow}$*, ratio-bound exactness,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance translation,* $\mathsf{StreamName}^{\uparrow}$ *window service,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, Cauchy handoff, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The row S supplies only the real-series source and the finite partial-sum windows already visible through the $\mathsf{RealSeries}^{\uparrow}$ packet.

The analytic ratio data are the adjacent-term row A, the rational margin row Q, and the displayed comparison row M. These rows name a bound below one after the chosen threshold, but they do not name a host ratio limit or a quotient of real-name streams.

The dyadic row D, window row W, and readback row R convert that comparison into finite observations at requested tolerances. The Cauchy handoff C is therefore downstream of the displayed ratio-bound evidence, not an independent convergence theorem.

Finally, the endpoint seal E and structural rows H, J, P, N preserve the same route. Since none of the refused objects appears among the carrier coordinates, the listed obligations exhaust the local certificate surface. □

Theorem 6714.3 (d'Alembert ratio test Cauchy handoff)**.** *Every Cauchy-facing consumer of an accepted* $\mathsf{DAlembertRatioTest}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through $S, A, Q, M, D, W, R, C, E, H, J, P, N$ before it can use the packet as convergence evidence. In particular, the handoff exports only displayed tail-control rows and never a selected infinite sum, a quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier route. The source and adjacent-term rows force every request to pass through the displayed $\mathsf{RealSeries}^{\uparrow}$ term windows before the ratio-bound row is visible.

The rational margin and dyadic rows then translate the bound below one into the finite tolerance language read by $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$. Thus the handoff row C is reached only after the displayed ratio evidence has been inspected at the requested scale.

The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of C and the structural rows. No carrier coordinate remains that could supply a selected sum or host completeness principle, so the stated route is the entire Cauchy-facing handoff. □

Theorem 6714.4 (d'Alembert ratio test Real seal boundary)**.** *For every accepted* $\mathsf{DAlembertRatioTest}^{\uparrow}$ *carrier* $K = (S, A, Q, M, D, W, R, C, E, H, J, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after the real-series source, adjacent-term windows, rational margin, displayed ratio bound, dyadic tolerance ledger, finite stream windows, regular readback, and Cauchy handoff have all been consumed. The seal cannot be read as an independent Real value, a host ratio-limit witness, or a completeness theorem.*

Proof. The definition places E after the analytic rows S, A, Q, M, the tolerance and observation rows D, W, R, and the handoff row C. A consumer that reads E must therefore preserve that displayed dependency route.

The transport, replay, provenance, and local-name rows do not add a new endpoint. They only carry the same packet through hsame, Cont, Pkg, and NameCert structure.

Since no coordinate stores a detached Real value, host limit, or completeness witness, the Real seal boundary is exactly the displayed downstream boundary. □

Theorem 6714.5 (d'Alembert ratio test RealSeries route)**.** *Every* $\mathsf{RealSeries}^{\uparrow}$ *convergence consumer of an accepted* $\mathsf{DAlembertRatioTest}^{\uparrow}$ *packet must read, in order, the source* $\mathsf{RealSeries}^{\uparrow}$ *windows, the adjacent quotient rows, the rational margin data, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route gives the consumer no host infinite sum, selected limit, quotient series equality, countable choice, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows $S, A, Q, M, D, W, R, C, E, H, J, P, N$. The source read begins at S, the adjacent quotient evidence is exposed only through A and M, and the rational margin is carried by Q before any tolerance ledger can be consumed.

Apply the Cauchy handoff of Definition 6714.3 and the Real seal boundary of Definition 6714.4. These force the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows to appear before the terminal seal E can serve a convergence consumer.

Finally read the structural rows H, J, P, N. Their provenance contains only the displayed BEDC rows, so the consumer has no coordinate for a host infinite sum, selected limit, quotient series equality, countable-choice schedule, trichotomy branch, or ambient completeness principle. □

Falsifiable prediction: An accepted $\mathsf{DAlembertRatioTest}^{\uparrow}$ endpoint read that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying a $\mathsf{Rat}^{\uparrow}$ margin below 1, adjacent $\mathsf{RealSeries}^{\uparrow}$ term windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance translation, $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback fails the carrier surface.

Independence witness: realseries, rat, dyadicratcore, streamname, regseqrat, real, real-series-ratio-test: the sibling packets separately expose series terms, rational margins, dyadic budgets, finite windows, regular readback, endpoint sealing, or a general ratio-test corridor. None by itself binds the d'Alembert margin, adjacent-term comparison, Cauchy handoff, Real seal, transport, replay, provenance, and local naming into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DAlembertRatioTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DAlembertRatioTest}^{\uparrow}$ packet is generated from a RealSeries source row, adjacent-term windows, a rational margin below one, displayed ratio-bound evidence, a DyadicRatCore tolerance ledger, finite StreamName windows, RegSeqRat readback, a Cauchy handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DAlembertRatioTest}^{\uparrow}}$, seed)

Scope closed: Definition 6714.1, Definition 6714.2, Definition 6714.3, and Definition 6714.4 seed the finite d'Alembert ratio-test route over RealSeries, Rat, DyadicRatCore, StreamName, RegSeqRat, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DAlembertRatioTest}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.DAlembertRatioTestUp`

Bridge status: none

Not claimed: This chapter does not claim a checked ratio-test theorem, host ratio limits, quotient stream equality, selected infinite sums, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ratio-bound exactness, dyadic tolerance translation, Cauchy handoff, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.DAlembertRatioTestUp.

Chapter 6715

A Concrete Naming Certificate for $\mathsf{BourbakiWitt}^{\uparrow}$

Following Bourbaki and Witt, the $\mathsf{BourbakiWitt}^{\uparrow}$ packet records the constructive order-theoretic fixed-point route for a progressive monotone self-map on a displayed chain-complete poset source. It sits after the separated order carrier of chapter 53, the certified-family bound surface of chapter 5155, and the complete-lattice monotone fixed-row route of chapter 5919. The packet names only finite chain rows, displayed upper-bound witnesses, approximation ledgers, transport, replay, provenance, and local naming; it does not assert Zorn's lemma, full choice, unrestricted chain completeness, quotient order equality, or an ambient maximal-chain theorem.

Definition 6715.1 (Bourbaki-Witt carrier)**.** *A* $\mathsf{BourbakiWitt}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (O, F, G, U, A, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Poset}^{\uparrow}$ *source row equipped with the displayed chain-completeness boundary accepted by this packet.*
2. *F is the progressive monotone self-map row, recording both monotonicity and the displayed comparison $x \leq F(x)$ for carried elements.*
3. *G is the finite chain ledger, listing the inspected chain windows and their inherited* $\mathsf{Poset}^{\uparrow}$ *comparison rows.*
4. *U is the displayed chain-bound witness row assigning an upper-bound name to each inspected chain window.*
5. *A is the finite approximation ledger, recording the iterated or successor-stage rows used by a fixed-point consumer before the bound row is read.*
6. *H records componentwise* hsame *transport for O, F, G, U, A, C, P, N.*
7. *C records displayed* Cont *replay from the poset source and progressive monotone map through chain windows, upper-bound witnesses, approximation rows, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{BourbakiWitt}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{CompleteLattice}^{\uparrow}$, $\mathsf{TarskiFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BourbakiWitt}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, F, G, U, A, H, C, P, N$. It has no coordinate for a choice-selected maximal chain, Zorn principle, unrestricted chain completeness, quotient order equality, host ordinal recursion, or ambient lattice semantics.

Theorem 6715.2 (Bourbaki-Witt NameCert obligations)**.** *For every accepted* $\mathsf{BourbakiWitt}^{\uparrow}$ *carrier* $B = (O, F, G, U, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BourbakiWitt}^{\uparrow}}$ *surface consists exactly of carrier admission for the chain-complete* $\mathsf{Poset}^{\uparrow}$ *source row, progressive monotone map exposure through* F*, chain-window exposure through* G*, displayed chain-bound witnesses through* U*, finite approximation coverage through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6715.1. The displayed rows are exactly $O, F, G, U, A, H, C, P, N$, so every local obligation must be read from one of those rows.

Read the order-theoretic rows first. The source row O supplies the separated partial-order carrier and the displayed chain-completeness boundary, while F supplies the progressive monotone self-map row consumed by the fixed-point route.

The chain rows G, U, A then account for the constructive content. Each inspected chain window is named before its upper-bound witness is used, and each approximation step is recorded before a consumer may read a fixed-row handoff.

Finally use H, C, P, N to transport, replay, source, and name the same route. Since no carrier coordinate stores a maximal-chain selector, Zorn principle, unrestricted chain-completeness theorem, quotient order equality, host ordinal recursion, or ambient complete-lattice semantics, the listed rows exhaust the local NameCert surface. □

Theorem 6715.3 (Bourbaki-Witt chain handoff)**.** *Every fixed-point consumer of an accepted* $\mathsf{BourbakiWitt}^{\uparrow}$ *packet must read the route*

$$\mathsf{Poset}^{\uparrow}(O), F, G, U, A, H, C, P, N$$

before it may use the exported fixed-row surface. The route hands finite chain windows and their displayed upper-bound witnesses to $\mathsf{CompleteLattice}^{\uparrow}$ *and* $\mathsf{TarskiFixedPoint}^{\uparrow}$ *consumers without selecting a maximal chain, invoking Zorn's lemma, asserting full choice, or claiming unrestricted chain completeness outside the displayed source row.*

Proof. Start from the $\mathsf{Poset}^{\uparrow}$ source row. It supplies the only order comparison surface visible to the packet, and the chain-completeness boundary is read as part of that displayed source rather than as an ambient theorem.

Apply the progressive monotone map row. The row F records both monotonicity over the carried order and the progressive comparison used to extend each inspected approximation window.

Use the chain ledger and bound rows next. The row G names the finite chain windows, U supplies their displayed upper-bound witnesses, and A records the approximation ledger that a fixed-point consumer may replay.

The handoff to $\mathsf{CompleteLattice}^{\uparrow}$ or $\mathsf{TarskiFixedPoint}^{\uparrow}$ is therefore mediated by H, C, P, N. Transport and replay preserve the same finite rows, while provenance and local naming prevent the endpoint from importing Zorn, full choice, unrestricted chain completeness, quotient order equality, or a detached maximal-chain construction. □

Falsifiable prediction: Every accepted $\mathsf{BourbakiWitt}^{\uparrow}$ fixed-row read factors through a chain-complete Poset source row, progressive monotone map row, finite chain ledger, displayed chain-bound witness row, finite approximation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: poset, complete-lattice, tarski-fixed-point: $\mathsf{BourbakiWitt}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries progressive monotone map data, finite chain windows, displayed chain-bound witnesses, approximation rows, transport, replay, provenance, and local naming without a maximal-chain selector.

Closure status for $\mathsf{NameCert}_{\mathsf{BourbakiWitt}^{\uparrow}}$.

Constructive story: A $\mathsf{BourbakiWitt}^{\uparrow}$ packet is generated from a chain-complete Poset source row, progressive monotone map row, finite chain ledger, displayed upper-bound witnesses, finite approximation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BourbakiWitt}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6715.1, Definition 6715.2, and Definition 6715.3 seed the finite chain-complete fixed-point route between Poset, CompleteLattice, and TarskiFixedPoint consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BourbakiWitt}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Zorn's lemma, full choice, unrestricted chain completeness, quotient order equality, host ordinal recursion, selected maximal chains, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, progressive monotone exactness, chain-window coverage, displayed upper-bound witnesses, approximation ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.BourbakiWittUp.

Chapter 6716

A Concrete Naming Certificate for $\mathsf{CompactChainUniformModulus}^{\uparrow}$

Following Heine and Cantor, the $\mathsf{CompactChainUniformModulus}^{\uparrow}$ packet records the finite cover-refinement chain by which a compact metric source and a continuous-map certificate yield a tolerance-only uniform-modulus handoff. It realizes the finite cover-refinement branch of chapter 9237, sitting between the compact carrier of chapter 60, the metric-distance rows of chapter 57, the continuous-map local-radius ledger of chapter 130, the rational lower-bound readback of chapter 37, the uniform-modulus consumer of chapter 369, and the terminal real-name seal of chapter 38. The packet names only a finite chain of compact cover cells, local-radius witnesses, lower-bound comparisons, handoff rows, transport, provenance, and local naming; it does not select a global modulus by choice, pass through quotient cover equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6716.1 (Compact chain uniform-modulus carrier)**.** *A* $\mathsf{CompactChainUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U_{\mathrm{cc}} = (K, M, F, C, L, Q, R, E, H, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-cover row, exposing the compact source only through a displayed finite cover or finite net ledger.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to compare source cells, centers, and refinement radii.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *local-modulus row, attaching a positive local radius to each displayed center and tolerance read.*
4. *C is the cover-chain row, ordering the finite refinement from compact cover cells to local-radius cells before any uniform-modulus handoff is exported.*
5. *L is the finite lower-bound row over the displayed positive rational radii.*
6. *Q is the* $\mathsf{Rat}^{\uparrow}$ *readback row for lower-bound comparisons, positivity, and finite minimum inspection.*
7. *R is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, available only after K, M, F, C, L, Q have been displayed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for real-valued consumers of the same modulus packet.*
9. *H records componentwise* hsame *transport for compact cover, metric, continuous-map, chain, lower-bound, rational readback, uniform-modulus, seal, provenance, and naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactChainUniformModulus}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactChainUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. There is no coordinate for selected subcovers outside K, quotient equality of covers, a choice-selected modulus function, hidden point witnesses, or ambient real completeness.

Theorem 6716.2 (Compact chain uniform-modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactChainUniformModulus}^{\uparrow}$ *carrier* $U_{\mathrm{cc}} = (K, M, F, C, L, Q, R, E, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactChainUniform}}$ *surface is exhausted by five finite obligation rows:*

1. *compact cover-chain admission for K and C;*
2. *metric and continuous-map local-radius compatibility for M and F;*
3. *finite lower-bound exactness for L and* $\mathsf{Rat}^{\uparrow}$ *readback Q;*
4. *uniform-modulus and real-seal handoff through R and E;*
5. *refusal, transport, provenance, and local naming through H, P, N.*

No obligation is discharged by choice-selected moduli, quotient cover equality, hidden subcover selection, external point equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier into the displayed rows. The compact and cover-chain rows K, C expose the only finite source cover inspected by the packet, while M, F attach the metric and local-radius data to that same chain.

The lower-bound rows are then read finitely. The row L records the finite positive-radius comparison, and Q supplies the rational readback used to keep the selected tolerance inside every displayed local radius.

Finally, the handoff rows R, E are downstream of those cover-chain and lower-bound rows. Componentwise transport, provenance, and local naming preserve the same packet, so the excluded choice, quotient, hidden-selection, point-equality, and completeness principles cannot enter the local certificate surface. □

Theorem 6716.3 (Finite cover-chain handoff)**.** *Every consumer that reads an accepted* CompactChainUniformModu *packet as a* $\mathsf{UniformModulus}^{\uparrow}$ *witness must first display the compact cover row K, metric row M, continuous local-radius row F, cover-chain row C, finite lower-bound row L, and* $\mathsf{Rat}^{\uparrow}$ *readback row Q. The exported object is the handoff row R together with the optional* $\mathsf{Real}^{\uparrow}$ *seal E; it is not a selected modulus function or a quotient class of covers.*

Proof. The carrier definition places R downstream of K, M, F, C, L, Q. A consumer cannot inspect the uniform-modulus row without first reading the finite compact cover, the metric comparisons, the local continuous-map radii, and the rational lower-bound ledger.

The structural rows H, P, N keep that read componentwise inside the same BHist packet. Since no carrier coordinate stores selected modulus functions or quotient cover classes, the handoff exports only the displayed finite cover-chain route. □

Falsifiable prediction: An accepted $\mathsf{CompactChainUniformModulus}^{\uparrow}$ consumer that reaches a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying the compact cover chain and finite $\mathsf{Rat}^{\uparrow}$ lower-bound ledger refutes the carrier surface.

Independence witness: compact, metric, continuousmap, rat, uniformmodulus, real: no listed sibling supplies the whole packet $U_{\mathrm{cc}} = (K, M, F, C, L, Q, R, E, H, P, N)$, because each sibling contributes only compact cover data, distance rows, local continuity radii, rational comparison, a uniform-modulus consumer, or a terminal seal while this chapter binds them into one finite cover-chain certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactChainUniformModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactChainUniformModulus}^{\uparrow}$ packet is generated from Compact finite-cover rows, MetricSpace distance rows, ContinuousMap local-radius rows, finite cover-chain rows, Rat lower-bound readback, UniformModulus handoff rows, RealUp seals, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactChainUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6716.1, Definition 6716.2, and Definition 6716.3 seed the finite compact cover-chain route from Compact, MetricSpace, ContinuousMap, Rat, UniformModulus, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactChainUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, selected global moduli, quotient cover equality, arbitrary subcover selection, point-choice principles, ambient RealUp completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, cover-chain exactness, local-radius compatibility, finite lower-bound readback, uniform-modulus handoff, Real-seal nonescape, transport, provenance, refusal, and local naming for BEDC.Derived.CompactChainUniformModulusUp.

Chapter 6717

A Concrete Naming Certificate for $\mathsf{RecursivePolishPresentation}^{\uparrow}$

Following Moschovakis and Weihrauch, the $\mathsf{RecursivePolishPresentation}^{\uparrow}$ packet records the finite naming surface of a recursively presented Polish space: a complete separable metric carrier, a scheduled dense sequence, and a decidable dyadic distance table exposed through BEDC histories. It sits over the complete-separable metric source of chapter 1735, the Polish-space synthesis of chapter 1490, the metric-distance rows of chapter 57, the finite stream-name windows of chapter 126, the regular rational readback of chapter 301, the represented-space boundary of chapter 1494, the effective Polish packet of chapter 1706, and the terminal real-name seal of chapter 38. The packet is a recursive presentation as finite NameCert data; it is not a quotient completion, a selected limit, a host equality principle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6717.1 (Recursive Polish presentation carrier)**.** *A* $\mathsf{RecursivePolishPresentation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P_{\mathrm{rec}} = (M, C, D, T, S, R, A, E, V, H, G, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row naming the metric carrier.*
2. *C is the* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *row over the same metric source.*
3. *D is the recursive dense-sequence row, exposing dense points only through scheduled finite indices.*
4. *T is the dyadic distance-table row for the displayed dense indices.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row controlling which dense names and table entries are opened.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational distance comparisons.*
7. *A is the* $\mathsf{PolishSpace}^{\uparrow}$ *handoff row, available only after M, C, D, T, S, R are displayed.*
8. *E is the effective-name row consumed by* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *and represented-space readers.*
9. *V is the* $\mathsf{Real}^{\uparrow}$ *seal row for terminal distance values.*
10. *H records componentwise* hsame *transport for metric, complete-separable, dense-sequence, table, stream, readback, Polish, effective, seal, provenance, and local naming rows.*

11. *G is the* Pkg *provenance over* $\mathsf{RecursivePolishPresentation}^{\uparrow}$, $\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RecursivePolishPresentation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for selected dense points outside D, quotient-completion representatives, equality of represented names, unscheduled table queries, countable-choice schedules, or ambient real completeness.

Theorem 6717.2 (Recursive Polish presentation NameCert obligations)**.** *For every accepted* $\mathsf{RecursivePolishPresentation}^{\uparrow}$ *carrier* $P_{\mathrm{rec}} = (M, C, D, T, S, R, A, E, V, H, G, N)$, *the local* $\mathsf{NameCert}_{\mathsf{RecursivePolishPresent}}$ *surface is exhausted by five finite obligation rows:*

1. *recursive dense-sequence admission through D over the common metric row M;*
2. *dyadic distance-table exactness through T, S, R;*
3. *dense coverage of the complete-separable and Polish rows C, A through the same scheduled names;*
4. *represented-space and effective-Polish handoff through E and the terminal* $\mathsf{Real}^{\uparrow}$ *seal V;*
5. *refusal, componentwise transport, provenance, replay, and local naming through H, G, N.*

No obligation is discharged by a selected limit, quotient completion equality, external dense-point choice, host equality of names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows. The metric and complete-separable rows M, C supply the analytic source, while the recursive dense row D and stream row S restrict all dense-name access to finite scheduled windows.

The table rows are read next. The dyadic table T and regular-rational readback R certify the inspected distance comparisons for the same dense indices, so no unscheduled table query or selected dense point is available.

Finally, A, E, V, H, G, N package the Polish, effective, represented-space, seal, transport, provenance, and local naming boundaries. Since the carrier excludes quotient completions, selected limits, host equality of names, countable-choice schedules, and ambient completeness coordinates, those objects cannot become local NameCert obligations. □

Theorem 6717.3 (Recursive dense-table handoff)**.** *Every* $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{CompleteSeparableMetric}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, *or* $\mathsf{RepresentedSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{RecursivePolishPresentation}^{\uparrow}$ *packet must first expose the common metric row M, complete-separable row C, recursive dense-sequence row D, dyadic distance-table row T, finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. The consumer receives only the displayed recursive dense-table route, not a quotient completion, selected dense sequence, selected limit, or host representation equality.*

Proof. The carrier orders the consumer-facing rows A, E, V after M, C, D, T, S, R. Thus a Polish, complete-separable, effective, or represented-space read cannot bypass the recursive dense sequence or the dyadic table ledger.

Componentwise transport and provenance preserve the same finite packet. Because no excluded coordinate is present in the carrier, the consumer receives the scheduled dense-table route and no quotient, selected, choice-like, or host-equality object. □

Falsifiable prediction: An accepted $\mathsf{RecursivePolishPresentation}^{\uparrow}$ consumer that opens a $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, or $\mathsf{RepresentedSpace}^{\uparrow}$ row without displaying the recursive dense sequence, dyadic distance table, finite $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: complete-separable-metric, polishspace, metric, streamname, regseqrat, representedspace, effective-polish-space, real: no listed sibling supplies the whole packet $P_{\mathrm{rec}} = (M, C, D, T, S, R, A, E, V, H, G, N)$, because each sibling contributes only a metric carrier, complete-separable synthesis, Polish handoff, finite window, rational readback, represented-space boundary, effective-name route, or terminal real seal while this chapter binds them into one recursive presentation certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RecursivePolishPresentation}^{\uparrow}}$.

Constructive story: A $\mathsf{RecursivePolishPresentation}^{\uparrow}$ packet is generated from MetricSpace rows, CompleteSeparableMetric rows, recursive dense-sequence schedules, dyadic distance-table rows, StreamName windows, RegSeqRat readback, PolishSpace handoffs, EffectivePolishSpace and RepresentedSpace handoffs, RealUp seals, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RecursivePolishPresentation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6717.1, Definition 6717.2, and Definition 6717.3 seed the recursive Polish presentation route over CompleteSeparableMetric, PolishSpace, MetricSpace, StreamName, RegSeqRat, represented-space, effective-Polish, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RecursivePolishPresentation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completions, selected limits, selected dense points, host equality of represented names, countable choice, ambient RealUp completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, recursive dense-sequence exactness, dyadic distance-table exactness, dense coverage, represented-space handoff, refusal ledger, transport, provenance, replay, and local naming for BEDC.Derived.RecursivePolishPresentationUp.

Chapter 6718

A Concrete Naming Certificate for $\mathsf{GrothendieckTopology}^{\uparrow}$

Following Grothendieck's SGA 4 site formalism, the $\mathsf{GrothendieckTopology}^{\uparrow}$ packet records a coverage sieve system on a certified category as finite BEDC rows. It sits after the category and functorial source surfaces of chapter 61 and chapter 62, before the restriction interface of chapter 150 and the gluing interface of chapter 151. The packet names maximal sieves, pullback-stable covering sieves, and local transitivity; it does not export a topos, a host powerset of arrows, an external saturation operator, a selected sheafification, or quotient equality of covering families.

Definition 6718.1 (Grothendieck topology carrier)**.** *A* $\mathsf{GrothendieckTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (C, S, M, P, T, H, R, Q, N)$$

with the following displayed rows:

1. *C is the source* $\mathsf{Cat}^{\uparrow}$ *row, carrying objects, hom rows, identity arrows, composition rows, and their classifier laws.*
2. *S is the sieve-family row, assigning to each displayed object U a finite ledger of sieves on U whose membership is read as arrows into U and is closed under precomposition in C.*
3. *M is the maximal-sieve row, recording that the sieve containing every displayed arrow into U is a covering sieve at U.*
4. *P is the pullback-stability row: for every covering sieve R on U and every displayed arrow $f : V \to U$, the pulled-back sieve*

   $$f^*R = \{g : W \to V \mid f \circ g \in R\}$$

   is a covering sieve on V.
5. *T is the transitivity row: if R covers U and Q is a sieve on U whose pullback along every displayed member of R covers the corresponding domain, then Q covers U.*
6. *H records componentwise* hsame *transport for category rows, sieve membership rows, maximal rows, pullback rows, transitivity rows, replay rows, provenance rows, and local naming rows.*
7. *R records displayed* Cont *replay from a site request through C, S, M, P, T.*
8. *Q is the* Pkg *provenance over* $\mathsf{GrothendieckTopology}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{PreSheaf}^{\uparrow}$, $\mathsf{Sheaf}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{GrothendieckTopology}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $C, S, M, P, T, H, R, Q, N$. It has no coordinate for host arrow powersets, quotient sieves, selected sheafification, topos objects, global choice of covers, or bridge credentials.

Theorem 6718.2 (Grothendieck topology NameCert obligations)**.** *For every accepted* $\mathsf{GrothendieckTopology}^{\uparrow}$ *carrier $J = (C, S, M, P, T, H, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{GrothendieckTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed nine-row packet; category-source exposure through C; sieve-family exposure through S; maximal-sieve coverage through M; pullback stability through P; transitivity and local character through T; componentwise* hsame *transport through H; displayed* Cont *replay through R; provenance through Q; and local naming through N.*

Proof. Project the carrier of Definition 6718.1. The site data are exactly C, S, M, P, T, and the structural rows are exactly H, R, Q, N.

The category row is read first. It supplies the object and hom rows on which sieve membership is meaningful, together with identities and composition so precomposition and pullback sieves are internal BEDC rows.

The coverage rows are then forced in their traditional order. The maximal row covers each object, the pullback row transports any covering sieve along a displayed arrow, and the transitivity row performs the local-character test using only the displayed pullback covers.

Finally, H, R, Q, N transport, replay, source, and name the same finite packet. Since no excluded coordinate is present in the carrier, host arrow powersets, quotient sieves, selected sheafification, topos objects, global cover choice, and bridge credentials are not local NameCert obligations. □

Theorem 6718.3 (Grothendieck topology sieve pullback stability)**.** *Let $J = (C, S, M, P, T, H, R, Q, N)$ be an accepted* $\mathsf{GrothendieckTopology}^{\uparrow}$ *packet. If R_U is a covering sieve on a displayed object U and $f : V \to U$ is a displayed arrow of the* $\mathsf{Cat}^{\uparrow}$ *row C, then the pulled-back sieve*

$$f^* R_U = \{g : W \to V \mid f \circ g \in R_U\}$$

is a covering sieve on V in the same packet. The read of this cover factors through C, S, P, H, R, Q, N and does not use host equality of arrows, a quotient of sieves, or a selected replacement cover.

Proof. Expose the accepted carrier and read the category row C. The source, target, and composition fields of C make the displayed expression $f \circ g$ a certified arrow into U whenever g is a displayed arrow into V.

Use the sieve-family row S to read membership of R_U as a finite BEDC predicate on arrows into U. The pullback row P is exactly the coverage clause that maps this displayed covering sieve and displayed arrow f to a covering sieve on V.

Transport and replay do not change the coverage decision. The rows H, R, Q, N keep the pulled-back sieve attached to the same packet, provenance, and local naming surface, so no host arrow equality, quotient sieve, or selected replacement cover is inserted. □

Theorem 6718.4 (Grothendieck topology nonescape)**.** *Every* $\mathsf{PreSheaf}^{\uparrow}$ *or* $\mathsf{Sheaf}^{\uparrow}$ *consumer of an accepted* $\mathsf{GrothendieckTopology}^{\uparrow}$ *packet reads coverage only through the finite route*

$$\mathsf{Cat}^{\uparrow} \longmapsto \mathsf{Functor}^{\uparrow} \longmapsto \mathsf{PreSheaf}^{\uparrow} \longmapsto \mathsf{Sheaf}^{\uparrow}$$

together with the displayed rows $C, S, M, P, T, H, R, Q, N$. No consumer can obtain a topos object, a host powerset of arrows, a quotient of covering families, a global choice of covers, an external sheafification, or a bridge credential from the packet.

Proof. Start with the obligation surface of Definition 6718.2. It exhausts the site-facing data through the category row, sieve-family row, maximal row, pullback-stability row, and transitivity row.

A presheaf consumer can only inspect the certified source category and restriction-facing sieve rows. The functorial source is therefore the displayed $\mathsf{Cat}^{\uparrow}$ and $\mathsf{Functor}^{\uparrow}$ corridor, not an ambient category of all arrows.

A sheaf consumer adds locality and gluing over the displayed covering sieves. The pullback-stability theorem Definition 6718.3 keeps every restricted cover inside the same finite packet, and the transitivity row supplies the local-character closure used by the gluing surface.

The structural rows H, R, Q, N transport, replay, source, and name only those displayed rows. Because the carrier has no excluded coordinate, none of the stated external objects can escape from the packet. □

Falsifiable prediction: An accepted $\mathsf{GrothendieckTopology}^{\uparrow}$ consumer that treats a pulled-back covering sieve as available without displaying the source $\mathsf{Cat}^{\uparrow}$ row, the sieve-family row, and the pullback-stability row refutes the carrier surface.

Independence witness: category, functor, presheaf, sheaf: no listed sibling supplies the whole site packet $J = (C, S, M, P, T, H, R, Q, N)$, because the siblings contribute category, functor, restriction, or gluing rows while this chapter binds maximal covers, sieve pullback stability, and local transitivity into one Grothendieck topology NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{GrothendieckTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{GrothendieckTopology}^{\uparrow}$ packet is generated from a CategoryUp source row, sieve-family rows, maximal-sieve cover rows, pullback-stability rows, transitivity and local-character rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GrothendieckTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6718.1, Definition 6718.2, Definition 6718.3, and Definition 6718.4 seed the finite site route over CategoryUp, FunctorUp, PreSheafUp, and SheafUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GrothendieckTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close topos objects, host arrow powersets, quotient sieves, global choice of covers, external sheafification, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sieve-family exposure, maximal-sieve coverage, pullback-stability exactness, transitivity exactness, presheaf and sheaf consumer nonescape, transport, replay, provenance, and local naming for BEDC.Derived.GrothendieckTopologyUp.

Chapter 6719

A Concrete Naming Certificate for $\mathsf{SobolevMorreyEmbedding}^{\uparrow}$

Following Morrey and Evans on Sobolev embeddings, the $\mathsf{SobolevMorreyEmbedding}^{\uparrow}$ packet records the finite BEDC surface by which a displayed Sobolev-energy row yields a Morrey modulus row when the exponent and dimension rows certify the supercritical inequality. It sits after the $\mathsf{Sobolev}^{\uparrow}$ carrier of chapter 440, the $\mathsf{MorreySpace}^{\uparrow}$ target surface of chapter 4004, the scalar readback of chapter 38, the regular rational tolerance route of chapter 301, the metric source of chapter 57, and the compact consumer surface of chapter 129. The packet names only displayed rows: Sobolev energy, exponent inequality, local ball windows, rational modulus readback, transport, provenance, and local $\mathsf{NameCert}$ data.

Definition 6719.1 (Sobolev–Morrey embedding carrier)**.** *A* $\mathsf{SobolevMorreyEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, Q, B, M, R, H, C, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, recording the displayed function, weak derivative budget, exponent row, and domain window.*
2. *Q is the supercritical exponent row, recording the dimension comparison and the rational witness for the Morrey exponent gap.*
3. *B is the local ball-window row, recording the finite metric balls on which oscillation estimates are requested.*
4. *M is the* $\mathsf{MorreySpace}^{\uparrow}$ *modulus row, recording the candidate Hölder-Morrey control produced from S, Q, B.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row for rational tolerances, energy bounds, and endpoint scalar values.*
6. *H stores componentwise* hsame *transport for S, Q, B, M, R, P, N.*
7. *C stores the displayed* Cont *routes from the Sobolev-energy row and exponent row to the Morrey modulus row.*
8. *P is the* Pkg *provenance over* $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{MorreySpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{SobolevMorreyEmbedding}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host-selected representative, quotient equality of functions, open-cover compactness, a global differentiability theorem, or an ambient real-completeness principle.

Theorem 6719.2 (Sobolev–Morrey modulus obligation)**.** *For every accepted* $\mathsf{SobolevMorreyEmbedding}^{\uparrow}$ *carrier $E = (S, Q, B, M, R, H, C, P, N)$, a consumer may read the Morrey modulus row M only after reading the Sobolev-energy row S, the supercritical exponent row Q, the local ball-window row B, and the rational scalar readback row R. Agreement on H, C, P, N preserves those rows but cannot synthesize a Morrey modulus without the displayed S, Q, B, R data.*

Proof. Project the carrier through Definition 6719.1. The definition lists M as a row produced from the displayed Sobolev energy, exponent gap, ball windows, and rational scalar readback rather than from a hidden host theorem.

The route row C records the finite passage from S, Q, B, R to M. Componentwise transport through H and package provenance through P preserve the same displayed rows, so the read of M remains tied to the visible energy and exponent obligations.

Since the carrier has no coordinate for a selected representative, quotient equality of functions, or ambient completeness, no structural row can fill the missing analytic input. Thus every accepted modulus read must consume the displayed S, Q, B, R rows first. □

Theorem 6719.3 (Sobolev–Morrey compact consumer surface)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{SobolevMorreyEmbedding}^{\uparrow}$ *packet must read the same finite route*

$$S, Q, B, M, R, H, C, P, N$$

before using the Morrey modulus as a compact-family control. The consumer may transport the modulus through hsame *and replay the displayed* Cont *route, but it cannot import Rellich–Kondrachov compactness, choose a subsequence, or identify functions by host quotient equality.*

Proof. Begin with the modulus obligation of Definition 6719.2. It forces the Morrey control row M to be read together with the Sobolev source, exponent gap, ball windows, and rational scalar readback.

The compact consumer then reads M only as a modulus row compatible with the $\mathsf{Met}^{\uparrow}$ and $\mathsf{CompactMetric}^{\uparrow}$ sibling surfaces. The transport and replay rows H, C preserve this finite route; they do not add subsequence selection or open-cover compactness.

The absence clauses in the carrier definition rule out host quotient equality and selected representatives. Hence the compact-facing use is a finite modulus-consumer surface, not a compactness theorem or a hidden Rellich–Kondrachov conclusion. □

Falsifiable prediction: An accepted $\mathsf{SobolevMorreyEmbedding}^{\uparrow}$ packet cannot export a Morrey modulus row unless the Sobolev-energy row, exponent-gap witness, local ball-window row, and rational scalar readback row are all displayed in the same carrier.

Independence witness: sobolev, morrey-space, real, regseqrat, metric, compactmetric: $\mathsf{SobolevMorreyEmbedding}$ joins the energy, exponent-gap, local-window, and modulus-consumer rows; the sibling packets do not by themselves expose the full embedding handoff surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevMorreyEmbedding}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SobolevMorreyEmbedding}^{\uparrow}$ packet is generated from Sobolev-energy, supercritical exponent, local ball-window, Morrey modulus, rational readback, hsame transport, continuation, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{SobolevMorreyEmbedding}\uparrow}$, seed)

Scope closed: Definition 6719.1, Definition 6719.2, and Definition 6719.3 bind the seed carrier and its compact-consumer handoff surface.

Formal verification: FormalStatus(NameCert$_{\text{SobolevMorreyEmbedding}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove the analytic Sobolev–Morrey inequality, Rellich–Kondrachov compactness, Lean verification, or a standard bridge.

Upgrade path: Scoped closure requires a checked obligation surface for the exponent-gap row, local ball-window row, and Morrey modulus readback route.

Chapter 6720

A Concrete Naming Certificate for $\mathsf{CantorCompleteMetricModulus}^{\uparrow}$

Following Cantor's nested intersection theorem and the Bishop–Bridges treatment of complete metric spaces by explicit Cauchy moduli, the $\mathsf{CantorCompleteMetricModulus}^{\uparrow}$ packet records the finite route by which a shrinking nested-ball schedule supplies a modulus before Real or Completion consumers read an endpoint. It sits beside the Cantor intersection route of chapter 4359, the complete-metric source of chapter 128, the nested closed-ball carrier of chapter 3526, and the L10 readback route through chapter 291, chapter 126, chapter 301, and chapter 38. The packet is a displayed modulus carrier, not a quotient completion, selected representative, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6720.1 (CantorCompleteMetricModulus carrier)**.** *A* $\mathsf{CantorCompleteMetricModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{ccm}} = (K, B, D, S, Q, E, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row for the metric source on which the nested schedule is read.*
2. *B is the* $\mathsf{NestedClosedBall}^{\uparrow}$ *row carrying the descending closed-ball spine and its containment witnesses.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *shrink ledger recording the positive radius bounds and requested tolerance comparisons.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing inspected centers, radii, and containment checks.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from the displayed center windows and dyadic shrink ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after K, B, D, S, Q have been displayed.*
7. *U is the modulus row: for each displayed dyadic tolerance it names a finite stage after which the nested-ball diameter and the regular readback are inside that tolerance.*
8. *H records componentwise* hsame *transport for complete-metric, nested-ball, dyadic, stream, regular-readback, Real-seal, modulus, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a completion request through* $K, B, D, S, Q, E, U, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{CantorCompleteMetricModulus}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorCompleteMetricModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, D, S, Q, E, U, H, C, P, N$. It has no coordinate for quotient completion equality, selected nested-point representatives, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6720.2 (CantorCompleteMetricModulus NameCert obligations)**.** *For every accepted* $\mathsf{CantorCompleteMetricModulus}^{\uparrow}$ *carrier* $M_{\mathrm{ccm}} = (K, B, D, S, Q, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CantorCompleteMet}}$ *surface consists exactly of carrier exposure for the complete-metric, nested-ball, dyadic, stream, regular-readback, Real-seal, modulus, transport, replay, provenance, and naming rows; shrink exactness for D; finite-window readback for S, Q; modulus exactness for U; Real-seal nonescape for E; and refusal of quotient completions, selected representatives, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6720.1. The visible rows are exactly $K, B, D, S, Q, E, U, H, C, P, N$, and every obligation must be attached to one of those rows.

The completion and nested-ball source is read through K and B. The shrink ledger D supplies the dyadic radius and tolerance comparisons used by the nested schedule.

The finite readback stage is S, Q, E. Windows in S expose only finitely many centers and containment checks, Q records the corresponding regular rational evidence, and E is reached only after that readback is displayed.

The modulus row U binds the schedule to each requested dyadic tolerance. Transport, replay, provenance, and naming through H, C, P, N preserve that same finite route, so no excluded quotient, selected point, choice, compactness, or ambient-completeness coordinate can be exported. □

Theorem 6720.3 (CantorCompleteMetricModulus Real-seal route)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{CantorCompleteMetricModulus}^{\uparrow}$ *packet must read the route*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{NestedClosedBall}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Name}$$

with the modulus row U displayed before the terminal $\mathsf{Real}^{\uparrow}$ *seal E is public. The route gives L10 consumers an explicit finite Cantor-completeness modulus and exports no quotient completion, selected representative, countable-choice schedule, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the source rows. The complete-metric service K and nested closed-ball spine B are the only rows from which a completion request may start.

Read the dyadic and finite-window data next. The shrink ledger D controls the requested tolerance, while S exposes the inspected center and containment windows and Q converts those windows into regular rational readback.

The modulus row U records the finite stage at which the requested tolerance is met. Only after U is displayed may the route reach the terminal Real seal E.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no quotient, selected representative, choice, open-cover, or ambient-completeness coordinate, the Real-seal route is exactly the displayed finite modulus route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorCompleteMetricModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorCompleteMetricModulus}^{\uparrow}$ packet is generated from CompleteMetric service, NestedClosedBall containment, DyadicRatCore shrink ledgers, StreamName finite windows, RegSeqRat readback, a RealUp seal, an explicit modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorCompleteMetricModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6720.1, Definition 6720.2, and Definition 6720.3 seed the finite Cantor complete-metric modulus route over complete-metric, nested-ball, dyadic, stream, regular-readback, Real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorCompleteMetricModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-ball shrink exactness, modulus exactness, finite-window readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CantorCompleteMetricModulusUp.

Chapter 6721

Real Archimedean Cutoff NameCert Construction

Following Bishop and Bridges constructive analysis, the $\mathsf{RealArchimedeanCutoff}^{\uparrow}$ packet records the finite Archimedean cutoff row for displayed $\mathsf{Real}^{\uparrow}$ names. It reads a real name only through finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and a $\mathsf{Nat}^{\uparrow}$ unary bound history, so the cutoff certificate stays inside displayed BEDC data and does not claim trichotomy, quotient reals, least upper bounds, choice, or ambient completeness.

Definition 6721.1 (RealArchimedeanCutoff carrier)**.** *A* $\mathsf{RealArchimedeanCutoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (R, S, G, D, U, L, H, T, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal whose displayed name is being cut off at a finite Archimedean scale.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened from R at the requested precisions.*
3. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, so every inspected rational value has a regular sequence source.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the inspected readback values with the displayed dyadic cutoff scale.*
5. *U is the* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{UnaryHistory}$ *bound row naming the finite number of window extensions used by the cutoff read.*
6. *L is the finite cutoff ledger pairing each requested precision with the displayed stream window, regular readback, dyadic tolerance, and unary bound row used for that precision.*
7. *H stores componentwise* hsame *transport for the Real seal, stream windows, regular readback, dyadic tolerance ledger, unary bound row, cutoff ledger, replay rows, provenance row, and local naming row.*
8. *T stores displayed* Cont *replay from a cutoff request through R, S, G, D, U, L, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RealArchimedeanCutoff}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{UnaryHistory}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanCutoff}^{\uparrow}}$ *row.*

The carrier contains only the displayed finite cutoff surface. It has no trichotomy row, no quotient equality of real names, no selected representative stream, no least-upper-bound object, no choice selector, and no completeness coordinate.

Theorem 6721.2 (RealArchimedeanCutoff NameCert obligations)**.** *For every accepted* $\mathsf{RealArchimedeanCutoff}^{\uparrow}$ *carrier* $C = (R, S, G, D, U, L, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanCutoff}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Real seal, stream windows, regular readback, dyadic tolerance ledger, unary bound row, cutoff ledger, componentwise transport, replay, provenance, and local naming rows;*
2. *classifier stability, requiring every classified cutoff read to transport* R, S, G, D, U, L *through the stored* hsame *and* Cont *routes;*
3. *finite bound readback, requiring the unary row* U *to expose the finite number of window extensions used before the cutoff ledger* L *is accepted;*
4. *Real seal nonescape, requiring every completion-facing consumer to read* $S, G, D, U, L, H, T, P, N$ *before it receives the* $\mathsf{Real}^{\uparrow}$ *seal row* R*;*
5. *ledger exactness, requiring each accepted cutoff comparison to be the displayed row in* L *that pairs the relevant* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance entry, and* $\mathsf{Nat}^{\uparrow}$ *or* $\mathsf{UnaryHistory}$ *bound.*

Proof. Carrier admission is projection from the tuple in Definition 6721.1. The Real seal, finite stream windows, regular readback, dyadic tolerance ledger, unary bound row, cutoff ledger, transport table, replay table, provenance row, and local naming row are all explicit coordinates of the accepted packet.

Classifier stability is componentwise. The stored hsame and Cont rows transport the Real seal together with the stream windows and regular readback, and they transport the dyadic tolerance and unary bound rows beside the same cutoff ledger.

Finite bound readback then uses only U and L. The unary row names how many window extensions are opened, while the ledger records which displayed window, readback, and dyadic tolerance entry is used at each requested precision.

Finally inspect the carrier inventory. Since the packet has no coordinate for trichotomy, quotient equality of real names, selected representatives, least-upper-bound machinery, choice, or ambient completeness, every completion-facing read remains inside the displayed finite cutoff surface. □

Theorem 6721.3 (RealArchimedeanCutoff sibling dependency)**.** *Every accepted* $\mathsf{RealArchimedeanCutoff}^{\uparrow}$ *read factors through the property-level Archimedean bound route of chapter 3372 and the Cauchy-real Archimedean witness route of chapter 3378 before the local cutoff ledger* L *can be exported. The cutoff certificate is a bounded finite read of the same Archimedean witness surface through* $R, S, G, D, U, L, H, T, P, N$*; it is not a least-bound principle, trichotomy principle, quotient-real equality route, or ambient completeness claim.*

Proof. Project the carrier of Definition 6721.1. The rows R, S, G, D, U, L expose the Real seal, finite stream windows, regular readback, dyadic tolerance, unary bound history, and cutoff ledger.

The property-level sibling supplies the Archimedean bound route used to interpret the unary bound row. The Cauchy-real sibling supplies the witness route that makes the same bound readable

from regular Cauchy real-name data. Thus the cutoff read cannot export L until the property route and the Cauchy-real witness route have both been displayed.

The structural rows H, T, P, N preserve that dependency through componentwise hsame transport, displayed Cont replay, provenance, and local naming. Since no row in $R, S, G, D, U, L, H, T, P, N$ is a least-bound object, trichotomy classifier, quotient-real selector, or Real-completeness witness, the dependency remains a finite bounded read of the Archimedean witness surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealArchimedeanCutoff}^{\uparrow}}$.

Constructive story: A $\mathsf{RealArchimedeanCutoff}^{\uparrow}$ packet is generated from a RealUp seal, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a NatUp unary bound history, a cutoff ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealArchimedeanCutoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6721.1 and Definition 6721.2 seed the finite Archimedean cutoff certificate for displayed Real names through StreamName, RegSeqRat, DyadicRatCore, Nat, and UnaryHistory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealArchimedeanCutoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient equality of real names, selected representatives, least upper bounds, choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, finite bound readback, Real seal nonescape, and ledger exactness for BEDC.Derived.RealArchimedeanCutoffUp.

Chapter 6722

A Concrete Naming Certificate for $\mathsf{CauchyMerge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyMerge}^{\uparrow}$ packet records the finite merge route used when two regular Cauchy source names must be compared or combined through a common tail schedule. It sits beside the StreamName windows of chapter 126, the RegSeqRat readback route of chapter 301, the DyadicRatCore tolerance ledger of chapter 291, the Real seal of chapter 38, and the reindexing discipline of chapter 1568. The packet gives the L10 regular-Cauchy merge route one finite naming surface; it does not form quotient streams, choose a limiting real, invoke countable choice, or appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6722.1 (Cauchy merge carrier)**.** *A* $\mathsf{CauchyMerge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R_0, R_1, W_0, W_1, D, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy source rows presented to the merge request.*
2. W_0 *and* W_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which the sources are read.*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the common precision scale, the two source budgets, and the merged tail budget.*
4. S *is the finite merge-schedule row. It names the alternating or cofinal inspection order used to serve both source rows from the shared ledger.*
5. A *is the* $\mathsf{CauchyReindexing}^{\uparrow}$ *alignment row, showing that the schedule reads each source through a permitted tail reindexing route.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after* $R_0, R_1, W_0, W_1, D, S, A$ *have been replayed.*
7. H *records componentwise* hsame *transport for the source, window, ledger, schedule, alignment, seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a merge request through* $R_0, R_1, W_0, W_1, D, S, A, E, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{CauchyMerge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyMerge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R_0, R_1, W_0, W_1, D, S, A, E, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected representative, a host limit, countable-choice data, host real equality, or ambient completeness.

Lean4 (definition) `BEDC.Derived.CauchyMergeUp`

Theorem 6722.2 (Cauchy merge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyMerge}^{\uparrow}$ *carrier*

$$M = (R_0, R_1, W_0, W_1, D, S, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyMerge}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular-Cauchy source rows, two StreamName window rows, the shared dyadic tolerance ledger, the finite merge schedule, the Cauchy reindexing alignment row, the terminal Real seal, componentwise transport, continuation replay, provenance, and local naming. No local obligation may read a quotient stream, chosen representative, selected host limit, countable-choice selector, host real equality proof, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier. The analytic rows are exactly $R_0, R_1, W_0, W_1, D, S, A, E$, and the structural rows are exactly H, C, P, N.

Carrier admission exposes the two regular-Cauchy sources only through their displayed StreamName windows. The shared DyadicRatCore ledger fixes the common tolerance scale, while the schedule row S supplies the finite order in which both source tails are inspected.

The alignment row A is the only route through which the schedule may reindex either source. Hence the terminal Real seal E is downstream of displayed regular-Cauchy readback, finite windows, a shared dyadic ledger, and permitted reindexing.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no additional row is present, quotient streams, selected representatives, host limits, countable choice, host equality, and ambient completeness cannot become local NameCert obligations. □

Theorem 6722.3 (Cauchy merge tail-equivalence route)**.** *Every accepted* $\mathsf{CauchyMerge}^{\uparrow}$ *packet turns the two regular-Cauchy sources into a Real-facing merge seal only through the finite route*

$$R_0, R_1 \longmapsto W_0, W_1 \longmapsto D \longmapsto S \longmapsto A \longmapsto E \longmapsto H, C, P, N.$$

If two merge consumers display the same two source rows, the same two window rows, the same dyadic ledger, the same merge schedule, and the same reindexing alignment row, then their tail-equivalence comparison is exhausted by this route and does not use quotient-stream equality or a selected limiting real.

Proof. Start from the two source rows R_0 and R_1. The window rows W_0 and W_1 specify the finite observations actually opened by the merge request, and the shared ledger D gives a single tolerance scale for both observations.

The schedule row S then determines how the two tails are interleaved or cofinally inspected. The alignment row A checks that each scheduled read is a Cauchy reindexing read, so the comparison cannot leave the displayed tail route.

Finally the Real seal E and the structural rows H, C, P, N repack the same finite route for downstream consumers. Equality of the displayed merge data therefore supplies tail-equivalence at the certificate boundary without adding quotient streams, chosen representatives, selected limits, countable choice, host real equality, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyMerge}^{\uparrow}$ merge read exposes two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, two $\mathsf{StreamName}^{\uparrow}$ window rows, a shared $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, a finite merge schedule, a $\mathsf{CauchyReindexing}^{\uparrow}$ alignment row, a $\mathsf{Real}^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and a NameCert row before any Real-facing seal can be consumed.

Independence witness: regularcauchymerge, cauchy-reindexing, real-completion-tail-route: $\mathsf{CauchyMerge}^{\uparrow}$ is not bijective to its listed siblings because it jointly carries two regular-Cauchy sources, two finite window rows, one shared dyadic tolerance ledger, one merge schedule, one reindexing alignment row, one Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMerge}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyMerge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6722.1, Definition 6722.2, and Definition 6722.3 seed the finite L10 route for merging two regular-Cauchy names through shared windows, a common dyadic ledger, a schedule, reindexing alignment, and a Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyMerge}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.CauchyMergeUp`

Bridge status: none

Not claimed: This chapter does not close quotient-stream equality, selected representatives, selected limits, countable choice, host real equality, ambient Real completeness, theorem checking, axiom-clean closure, or bridge checking.

Upgrade path: Theorem-checked closure requires checked carrier admission, classifier stability, hsame and Cont-compatible schedule transport, reindexing alignment exactness, and no-quotient/no-choice nonescape for BEDC.Derived.CauchyMergeUp.

Constructive story: A $\mathsf{CauchyMerge}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, two $\mathsf{StreamName}^{\uparrow}$ finite-window rows, one shared $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a finite merge schedule, a $\mathsf{CauchyReindexing}^{\uparrow}$ alignment row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6723

A Concrete Naming Certificate for $\mathsf{EventuallyConstantSequence}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on sequences, tails, and constructive real names, the $\mathsf{EventuallyConstantSequence}^{\uparrow}$ packet records the finite route by which an inspected sequence becomes constant after a displayed threshold. It sits beside the finite windows of chapter 126, the cofinite-tail interface of chapter 1564, the sequence-limit carrier of chapter 1413, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a tail certificate: it does not identify quotient streams, select a limiting value, invoke countable choice, assert host equality, or appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6723.1 (Eventually constant sequence carrier)**.** *An* $\mathsf{EventuallyConstantSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E_{\text{tail}} = (S, T, F, R, L, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *sequence-window row, exposing the inspected finite prefixes and tail windows of the source sequence.*
2. *T is the* $\mathsf{FrechetFilter}^{\uparrow}$ *cofinite-tail row, carrying the displayed threshold after which the sequence is read as constant.*
3. *F is the finite constant-value row, naming the value repeated on the admitted tail.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same tail windows and constant value.*
5. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *limit-handoff row, available only through the displayed tail threshold and constant readback.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the constant value and its sequence-limit handoff.*
7. *H records componentwise* hsame *transport for sequence windows, Frechet-tail threshold, constant-value row, regular readback, limit handoff, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an eventual-constant request through $S, T, F, R, L, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{EventuallyConstantSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{EventuallyConstantSequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, T, F, R, L, A, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected subsequence, an ambient convergence predicate, countable choice, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EventuallyConstantSequenceUp.EventuallyConstantSequenceTasteGate single carrier alignment`

Theorem 6723.2 (Eventually constant sequence NameCert obligations)**.** *For every accepted* $\mathsf{EventuallyConstantSequence}^{\uparrow}$ *carrier* $E_{\text{tail}} = (S, T, F, R, L, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EventuallyConstantSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed ten-row packet; StreamName window exposure through S; Frechet-tail threshold exposure through T; constant-value admission through F; regular-rational readback through R; RealSequenceLimit handoff through L; terminal Real seal through A; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.EventuallyConstantSequenceUp.EventuallyConstantSequenceNamecertObligations`

Proof. Project the carrier of Definition 6723.1. The analytic rows are exactly S, T, F, R, L, A, and the structural rows are exactly H, C, P, N.

The sequence is read first through finite windows. The row S exposes the inspected prefixes, while T supplies the cofinite-tail threshold that makes the eventuality claim visible as a finite Frechet-filter row.

The constant-value row F is then checked only on the displayed tail. The regular readback row R and limit handoff row L use that same tail threshold before the terminal Real seal A can be consumed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since quotient streams, selected subsequences, ambient convergence predicates, countable choice, host equality, and Real completeness are absent from these rows, none is a local NameCert obligation. □

Theorem 6723.3 (Eventually constant sequence tail-filter handoff)**.** *Every RealSequenceLimit-facing consumer of an accepted* $\mathsf{EventuallyConstantSequence}^{\uparrow}$ *packet reaches the limit handoff only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{FrechetFilter}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealSequenceLimit}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The Frechet tail row supplies the threshold, the StreamName row supplies the inspected windows, and the RegSeqRat row supplies the regular readback of the constant value. The handoff exports no quotient stream, selected limit, countable-choice tail selector, host equality proof, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.EventuallyConstantSequenceUp.EventuallyConstantSequenceTailFilterHandoff`

Proof. Start from the NameCert obligation surface of Definition 6723.2. It forces every accepted read to expose the sequence-window row S and the Frechet-tail threshold T before a limit-facing consumer reaches L.

Next read the constant-value and regular-rational rows. The row F identifies the repeated tail value inside the displayed threshold, and R records the same value through the regular-rational route used by Real-facing consumers.

The limit handoff L and Real seal A are downstream of those rows. Componentwise transport, continuation replay, provenance, and local naming preserve the same finite route, so no quotient

stream, selected limit, countable-choice selector, host equality proof, or ambient completeness theorem is exported. □

Theorem 6723.4 (Eventually constant sequence Real seal nonescape)**.** *Let* $E_{\text{tail}} = (S, T, F, R, L, A, H, C, P, N)$ *be an accepted* $\mathsf{EventuallyConstantSequence}^{\uparrow}$ *carrier. Any consumer that reads the terminal* $\mathsf{Real}^{\uparrow}$ *seal* A *must have already displayed* $S, T, F, R, L, H, C, P, N$*. Thus the Real seal is a finite tail certificate for an eventually constant sequence, not a hidden proof of arbitrary sequence convergence, quotient stream equality, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EventuallyConstantSequenceUp.EventuallyConstantSequenceRealSealNonescape`

Proof. Read the carrier projection. The terminal Real row A is listed only after the StreamName row, Frechet-tail threshold, constant-value row, regular readback, and RealSequenceLimit handoff.

Apply the tail-filter handoff theorem, Definition 6723.3. It places every limit-facing route through S, T, F, R, L before the Real seal can be consumed.

The structural rows H, C, P, N then transport, replay, source, and name the same displayed route. Because the packet has no coordinate for arbitrary convergence, quotient streams, selected limits, countable choice, host equality, or Real completeness, the seal cannot export any of those claims. □

Falsifiable prediction: Every accepted $\mathsf{EventuallyConstantSequence}^{\uparrow}$ consumer must display a $\mathsf{StreamName}^{\uparrow}$ window row, a $\mathsf{FrechetFilter}^{\uparrow}$ cofinite-tail threshold, a constant-value row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{RealSequenceLimit}^{\uparrow}$ handoff, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before the tail certificate can be consumed.

Independence witness: streamname, frechetfilter, real-sequence-limit, regseqrat, real: no listed sibling is bijective with $\mathsf{EventuallyConstantSequence}^{\uparrow}$, because this packet alone binds a displayed sequence-window row, a cofinite-tail threshold, a constant-value row, regular readback, RealSequenceLimit handoff, Real seal, transport, replay, provenance, and local naming into one finite eventually-constant certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{EventuallyConstantSequence}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EventuallyConstantSequence}^{\uparrow}$ packet is generated from StreamName sequence windows, a FrechetFilter cofinite-tail threshold, a constant-value row, RegSeqRat readback, a RealSequenceLimit handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EventuallyConstantSequence}^{\uparrow}}$, seed)

Scope closed: Definition 6723.1, Definition 6723.2, Definition 6723.3, and Definition 6723.4 seed the finite eventually-constant tail route over StreamName, FrechetFilter, RegSeqRat, RealSequenceLimit, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EventuallyConstantSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary sequence convergence, quotient stream equality, selected limits, countable choice, host real equality, RealUp completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-threshold exposure, constant-value exactness, RegSeqRat readback, RealSequenceLimit handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EventuallyConstantSequenceUp.

Chapter 6724

A Concrete Naming Certificate for SlowlyVaryingSequence$^{\uparrow}$

Following Karamata and Hardy, the SlowlyVaryingSequence$^{\uparrow}$ packet records the constructive finite-window surface of a positive sequence whose rescaled tails remain asymptotically unchanged. It sits beside the regular sequence readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal Real seal of chapter 38, and the asymptotic comparison surface of chapter 3400. The packet names only displayed finite tail evidence; it does not assert a uniform Tauberian theorem, selected subsequence, quotient class of sequences, choice principle, or ambient completeness.

Definition 6724.1 (SlowlyVaryingSequence carrier)**.** *A* SlowlyVaryingSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, E, A, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* StreamName$^{\uparrow}$ *row whose finite windows expose the inspected tail entries of the sequence.*
2. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to those windows, so every inspected value has a regular rational source.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used to compare rescaled tail windows.*
4. *E is the terminal* Real$^{\uparrow}$ *seal for the displayed values read from S, R, D.*
5. *A is the* AsymptoticEquivalence$^{\uparrow}$ *row comparing the original tail and each displayed rescaled tail through finite windows.*
6. *W is the finite rescaling-window ledger. It records the inspected scale, the starting tail bound, the stream window, the regular readback, the dyadic tolerance, and the accepted asymptotic-equivalence row for that scale.*
7. *H stores componentwise* hsame *transport for stream windows, regular readback, dyadic tolerances, Real seals, asymptotic-equivalence rows, window ledgers, replay rows, provenance rows, and local naming rows.*
8. *C stores displayed* Cont *replay from a slowly-varying request through S, R, D, E, A, W, H.*
9. *P is the* Pkg *provenance over* SlowlyVaryingSequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, AsymptoticEquivalence$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SlowlyVaryingSequence}^{\uparrow}}$ *row.*
The carrier contains no quotient sequence equality, selected asymptotic class representative, countable-choice tail selector, global convergence claim, or ambient Real completeness coordinate.

Theorem 6724.2 (SlowlyVaryingSequence NameCert obligations)**.** *For every accepted* $\mathsf{SlowlyVaryingSequence}^{\uparrow}$ *carrier* $L = (S, R, D, E, A, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SlowlyVaryingSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for those rows, finite-window exposure through* S*, regular rational readback through* R*, dyadic tolerance accounting through* D*, Real sealing through* E*, asymptotic-equivalence routing through* A*, rescaling-window exactness through* W*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6724.1. The stream, regular rational, dyadic tolerance, Real seal, asymptotic comparison, rescaling ledger, transport, replay, provenance, and local naming rows are all displayed coordinates of the finite packet.

The finite-window obligation is read through S, R, D, E. A consumer first opens a StreamName window, then reads the regular rational values and dyadic tolerances attached to that window, and only then receives the Real seal for the inspected values.

The slowly-varying obligation is read through A and W. Each rescaling request names its inspected scale and tail bound, and the window ledger records the exact asymptotic-equivalence row used for that request.

Componentwise transport and displayed replay preserve the same row order through H and C, while P and N name only this finite surface. Since the carrier has no quotient sequence equality, selected representative, choice selector, global convergence coordinate, or ambient completeness coordinate, the local NameCert obligations are exhausted by the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{SlowlyVaryingSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SlowlyVaryingSequence}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a Real seal, AsymptoticEquivalence rows, a finite rescaling-window ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SlowlyVaryingSequence}^{\uparrow}}$, seed)

Scope closed: Definition 6724.1 and Definition 6724.2 seed the finite slowly-varying sequence certificate over StreamName, RegSeqRat, DyadicRatCore, Real, and AsymptoticEquivalence rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SlowlyVaryingSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a Tauberian theorem, quotient sequence equality, selected representatives, countable-choice tail selection, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular rational readback, dyadic tolerance accounting, Real sealing, asymptotic-equivalence routing, and rescaling-window exactness for BEDC.Derived.SlowlyVaryingSequenceUp.

Chapter 6725

A Concrete Naming Certificate for $\mathsf{HaltingRefusalLedger}^{\uparrow}$

The $\mathsf{HaltingRefusalLedger}^{\uparrow}$ packet realizes the boundary of chapter 9369 as finite refusal data. It sits beside the fuel-indexed substrate bridge of chapter 960, the reduction fuel boundary of chapter 970, the step-indexed total host of chapter 964, the host trace surface of chapter 1050, and the closed-observation total-host packet of chapter 3706. The packet records how a local channel or bounded trace may terminate while a global halting classifier remains refused.

Falsifiable prediction: Every $\mathsf{HaltingRefusalLedger}^{\uparrow}$ read exposes finite fuel, trace, timeout-refusal, channel-termination, hsame, Cont, Pkg, and NameCert rows before refusing global halting.

Independence witness: fuel-indexed-substrate-bridge, reductionfuelboundary, step-indexed-total-host, hosttotaltrace, closed-observation-total-host: the ledger is not bijective to any listed sibling because it jointly stores local channel termination, finite fuel, trace readback, timeout refusal, and global-halting refusal in one packet.

Definition 6725.1 (HaltingRefusalLedger carrier)**.** *A* $\mathsf{HaltingRefusalLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, T, U, L, R, B, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite fuel row read through* $\mathsf{FuelIndexedSubstrateBridge}^{\uparrow}$ *and* $\mathsf{ReductionFuelBoundary}^{\uparrow}$*.*
2. *T is the finite trace row read through* $\mathsf{HostTotalTrace}^{\uparrow}$ *and the substrate-side bounded trace surface.*
3. *U is the timeout-refusal row recording that exhaustion of the displayed fuel is a local refusal, not a global nontermination proof.*
4. *L is the local channel-termination row supplied by the channel boundary of chapter 9369.*
5. *R is the total-host readback row routed through* $\mathsf{StepIndexedTotalHost}^{\uparrow}$ *and* $\mathsf{ClosedObservationTotalHost}^{\uparrow}$*.*
6. *B is the global-halting refusal row. It blocks any request to turn F, T, U, L, R into a total classifier for arbitrary certificate-level halting.*
7. *H stores componentwise* hsame *transport for fuel, trace, timeout refusal, channel termination, total-host readback, global-halting refusal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a halting-boundary request through F, T, U, L, R, B, H.*

9. *P is the* Pkg *provenance over* $\mathsf{HaltingRefusalLedger}^{\uparrow}$, $\mathsf{FuelIndexedSubstrateBridge}^{\uparrow}$, $\mathsf{ReductionFuelBoundary}^{\uparrow}$, $\mathsf{StepIndexedTotalHost}^{\uparrow}$, $\mathsf{HostTotalTrace}^{\uparrow}$, $\mathsf{ClosedObservationTotalHost}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HaltingRefusalLedger}^{\uparrow}}$ *row.*

The carrier contains no global halting oracle, no selected nontermination witness, no total classifier for arbitrary certificate continuations, and no collapse of local channel termination into certificate-level halting.

Theorem 6725.2 (HaltingRefusalLedger NameCert obligations)**.** *For every accepted* $\mathsf{HaltingRefusalLedger}^{\uparrow}$ *carrier $G = (F, T, U, L, R, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HaltingRefusalLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite fuel, trace, timeout-refusal, channel-termination, total-host readback, global-halting refusal, transport, replay, provenance, and naming rows; fuel-trace exposure through F, T; timeout exactness through U; channel-local termination exposure through L; total-host readback through R; and global-halting refusal through B.*

Proof. Project the carrier of Definition 6725.1. The rows $F, T, U, L, R, B, H, C, P, N$ are the complete finite packet exposed to a halting-boundary consumer.

The local positive rows are F, T, L, R. Fuel and trace are read through the fuel-indexed substrate and host-trace siblings, while L records only channel-local event termination and R records only total-host readback under displayed observations.

The refusal rows are U and B. A timeout row refuses to treat fuel exhaustion as a completed unbounded computation, and the global-halting row refuses to turn local termination or finite trace evidence into a total classifier for arbitrary certificate continuations.

Transport, replay, provenance, and naming preserve this separation through H, C, P, N. Since no carrier coordinate stores a global halting oracle, selected nontermination witness, or total certificate-level classifier, the NameCert obligations are exhausted by the displayed ledger rows. □

The Lean TasteGate surface for $\mathsf{HaltingRefusalLedger}^{\uparrow}$ must provide explicit Nontrivial $\mathsf{HaltingRefusalLedger}^{\uparrow}$ and FieldFaithful $\mathsf{HaltingRefusalLedger}^{\uparrow}$ instances preserving finite fuel, trace, timeout-refusal, channel-termination, total-host readback, global-halting refusal, componentwise transport, displayed replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HaltingRefusalLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HaltingRefusalLedger}^{\uparrow}$ packet is generated from finite fuel, finite trace, timeout-refusal, channel-termination, total-host readback, global-halting refusal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HaltingRefusalLedger}^{\uparrow}}$, seed)

Scope closed: Definition 6725.1 and Definition 6725.2 seed the finite refusal ledger separating local channel termination and bounded trace evidence from global certificate-level halting.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HaltingRefusalLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a global halting classifier, selected nontermination witness, total classifier for arbitrary certificate continuations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fuel-trace exposure, timeout exactness, channel-local termination exposure, total-host readback, and global-halting refusal for BEDC.Derived.HaltingRefusalLedgerUp.

Chapter 6726

A Concrete Naming Certificate for $\mathsf{CauchyNetTailFilter}^{\uparrow}$

Following Moore and Smith, Kelley, and Bishop–Bridges on nets, filters, and constructive completion, the $\mathsf{CauchyNetTailFilter}^{\uparrow}$ packet records the finite handoff from displayed Cauchy-net evidence to displayed tail-filter evidence. It sits beside the completion route of chapter 3794, the finite filter-base surface of chapter 1601, the cofinite sequence-tail specialization of chapter 1564, the finite schedule interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a BEDC-native bridge from Cauchy-net windows to tail-filter windows; it does not choose a limit, quotient nets, assume countable choice, decide trichotomy, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6726.1 (CauchyNetTailFilter carrier)**.** *A* $\mathsf{CauchyNetTailFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (J, W, K, B, F, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the* $\mathsf{CauchyNet}^{\uparrow}$ *index-window row, naming the directed indices and inspected pairs used by the net-side Cauchy request.*
2. *W is the finite tail-threshold row, recording the displayed index after which the inspected net windows are admitted.*
3. *K is the Cauchy-net tolerance ledger attached to J and W, so every tail request keeps the original Cauchy evidence visible.*
4. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *meet row generated from finite tails and finite intersections of tail events.*
5. *F is the* $\mathsf{FrechetFilter}^{\uparrow}$ *cofinite handoff row used when the directed tail is narrowed to a sequence-tail read.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row exposing the finite observation windows passed to downstream Real or completion consumers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same schedule and tolerance ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, readable only after J, W, K, B, F, S, R have been displayed.*
9. *H records componentwise* hsame *transport for the Cauchy-net, threshold, filter-base, cofinite handoff, schedule, readback, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a tail-filter request through $J, W, K, B, F, S, R, E, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyNetTailFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetTailFilter}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. It has no coordinate for selected limits, quotient nets, quotient filters, countable-choice schedules, trichotomy, host equality of tails, or ambient Real completeness.

Theorem 6726.2 (CauchyNetTailFilter NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNetTailFilter}^{\uparrow}$ *carrier $T = (J, W, K, B, F, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyNetTailFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy-net index windows J, finite tail threshold W, Cauchy tolerance ledger K,* $\mathsf{FilterBase}^{\uparrow}$ *meet row B,* $\mathsf{FrechetFilter}^{\uparrow}$ *cofinite handoff F,* $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming N.*

Proof. Project the carrier of Definition 6726.1. The net-side evidence is exactly J, W, K: displayed index windows, a finite threshold, and the Cauchy tolerance ledger attached to those windows.

The filter-facing handoff is then B, F. The $\mathsf{FilterBase}^{\uparrow}$ row records finite meets of tail events, while the $\mathsf{FrechetFilter}^{\uparrow}$ row records the cofinite sequence-tail specialization available to sequential consumers.

Downstream Real and completion reads must pass through S, R, E. The $\mathsf{StreamName}^{\uparrow}$ schedule exposes only finite windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row records regular rational readback for those windows, and the $\mathsf{Real}^{\uparrow}$ seal is reached only after the schedule and readback have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since there is no additional coordinate, the local NameCert surface cannot export selected limits, quotient nets, countable choice, trichotomy, or Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyNetTailFilter}^{\uparrow}$ completion-facing read exposes CauchyNet index windows, a finite tail threshold, a Cauchy tolerance ledger, a FilterBase meet row, a FrechetFilter cofinite handoff, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert naming before it can serve a completion or Real consumer.

Independence witness: cauchynetcompletion, filterbase, frechetfilter, streamname, regseqrat, real: $\mathsf{CauchyNetTailFilter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries net index windows, tail thresholds, filter-base meets, cofinite sequence-tail handoff, finite schedules, regular readback, Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetTailFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyNetTailFilter}^{\uparrow}$ packet is generated from CauchyNet index windows, finite tail thresholds, a Cauchy tolerance ledger, a FilterBase meet row, a FrechetFilter cofinite handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyNetTailFilter}^{\uparrow}}$, seed)

Scope closed: Definition 6726.1 and Definition 6726.2 seed the finite Cauchy-net tail-filter bridge over CauchyNet, CauchyNetCompletion, FilterBase, FrechetFilter, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyNetTailFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient nets, quotient filters, countable choice, trichotomy, host equality of tails, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-net index-window exposure, finite tail-threshold exactness, FilterBase meet generation, FrechetFilter cofinite handoff, StreamName scheduling, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyNetTailFilterUp.

Chapter 6727

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyRealizer}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers by regular Cauchy sequences, the $\mathsf{BishopRegularCauchyRealizer}^{\uparrow}$ packet records the finite route by which dyadic tolerances, stream observations, regular rational readback, an explicit Cauchy modulus, and the terminal real-name seal are assembled into one choice-free realizer. It sits over the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational sequence route of chapter 301, the Cauchy-modulus carrier of chapter 292, and the displayed $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a realizer surface for regular Cauchy real names; it is not a quotient of streams, not a selected host limit, not countable choice, and not ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 6727.1 (BishopRegularCauchyRealizer carrier)**.** *A* $\mathsf{BishopRegularCauchyRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, S, Q, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including dyadic scale, comparison, and refinement rows used by the regularity bound.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, carrying the finite windows at which the rational name is inspected.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the rational values attached to those windows.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row that binds a precision request to a displayed window budget before any Real-facing seal is read.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal row receiving the regular Cauchy name only after D, S, Q, M have been displayed.*
6. *H records componentwise* hsame *transport for dyadic tolerance, stream window, rational readback, modulus, endpoint seal, provenance, and local naming rows.*
7. *C records displayed* Cont *replay along the same route.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyRealizer}^{\uparrow}}$ *row.*

The classifier on such packets is componentwise transport through H together with replay through C. No coordinate exports a quotient stream, a selected limit, an unrestricted choice schedule, host real equality, or a detached completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 6727.2 (BishopRegularCauchyRealizer NameCert obligations)**.** *For every accepted* BishopRegularCauchy *carrier $R = (D, S, Q, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyRealizer}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed dyadic tolerance ledger, stream-window row, regular-rational readback row, Cauchy-modulus row, Real seal, componentwise transport, replay, provenance, and local naming. Every Real-facing read of the packet must expose the route*

$$D, S, Q, M \longmapsto E \longmapsto H, C, P, N.$$

It cannot replace the route by quotient equality of streams, a host-selected limit, countable choice, or an ambient completeness theorem.

Proof. Project the carrier. The accepted packet displays only the rows $D, S, Q, M, E, H, C, P, N$, and the local naming row has no coordinate outside that list.

The dyadic tolerance row D supplies the precision scale, the stream row S supplies the finite inspection windows, and the regular rational row Q supplies the rational values at those windows. The modulus row M is the only admitted route from a precision request to a window budget.

The endpoint seal E is downstream from those four rows. Componentwise transport through H, displayed replay through C, and provenance through P preserve the same route before the local NameCert row N names it.

The excluded objects are absent from the carrier. Therefore the NameCert obligations expose the finite regular Cauchy realizer route and do not create quotient stream equality, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 6727.3 (BishopRegularCauchyRealizer Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{BishopRegularCauchyRealizer}^{\uparrow}$ *carrier factors through the displayed dyadic, stream, regular-rational, and Cauchy-modulus rows*

$$D, S, Q, M, E, H, C, P, N.$$

In particular, the seal cannot be read as a selected limit of a host sequence, a quotient class of Cauchy streams, a countable-choice construction, or a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Open the exported seal row E. By Definition 6727.1, that row is part of the same finite packet as D, S, Q, M, H, C, P, N and has no independent source.

Apply Definition 6727.2. It forces each Real-facing read to pass first through dyadic tolerance, stream-window, regular-rational, and Cauchy-modulus rows, and then through transport, replay, provenance, and local naming.

Since the carrier contains no quotient stream coordinate, no selected host limit, no countable-choice schedule, and no ambient completeness row, the exported seal remains inside the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyRealizer}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyRealizer}^{\uparrow}$ packet is generated from a dyadic tolerance ledger, finite stream-window observations, regular rational readback, an explicit Cauchy modulus, a Real endpoint seal, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyRealizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6727.1, Definition 6727.2, and Definition 6727.3 seed the choice-free regular Cauchy realizer route over dyadic, stream, rational, modulus, and Real-seal rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopRegularCauchyRealizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient real equality, selected limits, countable choice, host real equality, or ambient completeness for Real$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, modulus-window handoff, Real-seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyRealizerUp.

Chapter 6728

A Concrete Naming Certificate for $\mathsf{RiemannStieltjesIntegral}^{\uparrow}$

Following Riemann and Stieltjes, and the Bishop-style use of tagged partitions, the $\mathsf{RiemannStieltjesIntegral}^{\uparrow}$ packet records a finite integral carrier for a regulated real integrand against a bounded-variation integrator. It presents the integral value only through displayed partition sums, variation control, regular-rational readback, finite stream windows, and the terminal real-name seal; it does not import a measure space, a selected limiting partition, a quotient of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

This chapter is a bounded-variation consumer over the Real and Completion route. It reads the tagged-partition surface of chapter 1526, the variation ledger of chapter 398, the regulated real function surface of chapter 1554, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The existing $\mathsf{RiemannStieltjes}^{\uparrow}$ chapter supplies a neighboring handoff surface, while this packet isolates the integral carrier consumed by later bounded-variation arguments.

Definition 6728.1 (Riemann–Stieltjes integral carrier)**.** *A* $\mathsf{RiemannStieltjesIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, G, V, T, S, Q, W, R, E, H, C, P, N)$$

with displayed rows: F *is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *integrand row;* G *is the regulated real integrator row;* V *is the* $\mathsf{BoundedVariation}^{\uparrow}$ *ledger for* G*;* T *is the tagged-partition row inherited from the* $\mathsf{RiemannIntegral}^{\uparrow}$ *surface;* S *is the finite Stieltjes-sum row;* Q *is the mesh and refinement request row;* W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row;* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the accepted sums;* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value; and* H, C, P, N *are the componentwise* hsame*, displayed* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegral}^{\uparrow}}$ *rows.*

Theorem 6728.2 (Riemann–Stieltjes integral NameCert obligations)**.** *For every accepted carrier* $I = (F, G, V, T, S, Q, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission; regulated real integrand and integrator exposure through* F, G*; bounded-variation control through* V*; tagged-partition and Stieltjes-sum exposure through* T, S, Q*; finite-window and regular-rational readback through* W, R*; terminal real sealing through* E*; componentwise transport, replay, provenance, and local naming through* H, C, P, N*; and non-escape from measure spaces, quotient functions, selected partition limits, countable choice, and ambient completion.*

Proof. Project the displayed carrier. The rows F, G, V expose the regulated real function data and the bounded-variation control before any Stieltjes sum can be inspected.

The tagged-partition rows T, S, Q then describe only finite sums and refinement requests. They inherit the finite partition discipline from the Riemann integral surface but attach the integrator step differences through the displayed variation ledger rather than through a measure.

The completion-facing read is forced through W, R, E. The finite windows are read as $\mathsf{StreamName}^{\uparrow}$ rows, the accepted sums as $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, and the endpoint value only after the $\mathsf{Real}^{\uparrow}$ seal is displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate names a measure space, quotient function, selected limiting partition, countable-choice schedule, or ambient completion theorem, the listed obligations exhaust the NameCert surface. □

Theorem 6728.3 (Riemann–Stieltjes integral bounded-variation handoff)**.** *Every downstream bounded-variation consumer of an accepted* $\mathsf{RiemannStieltjesIntegral}^{\uparrow}$ *packet must factor its integral read through*

$$F, G, V, T, S, Q, W, R, E, H, C, P, N.$$

In particular, the consumer receives the $\mathsf{BoundedVariation}^{\uparrow}$ *ledger for the integrator before it may read the Stieltjes-sum row, and it receives the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before it may treat the integral as a Real-facing value.*

Proof. Start with a bounded-variation-facing consumer. The packet has no integral-value coordinate except the terminal seal E, and E is downstream of the finite-window and regular-rational readback rows W, R.

The Stieltjes-sum row S is also downstream of V. Thus the consumer cannot inspect integrator step differences without first displaying the bounded-variation ledger that controls those differences.

Now apply the Real and Completion route discipline. The finite window W and regular readback R are the only rows that connect finite sums to the terminal $\mathsf{Real}^{\uparrow}$ seal, so the consumer must pass through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ before reading E.

Transport, replay, provenance, and local naming preserve the same route. Hence any accepted bounded-variation handoff factors through the displayed rows and cannot replace them by a measure-completion, quotient-function, selected-limit, or ambient-completeness assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannStieltjesIntegral}^{\uparrow}$ packet is generated from regulated real function rows, a bounded-variation ledger, tagged finite partitions, Stieltjes sums, finite stream windows, regular rational readback, a terminal real seal, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6728.1, Definition 6728.2, and Definition 6728.3 seed the finite Riemann–Stieltjes integral packet over bounded-variation, tagged-partition, finite-window, regular-rational, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic integration, Lebesgue–Stieltjes completion, quotient function equality, selected limiting partitions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, tagged-partition stability, bounded-variation control, finite-window readback, regular-rational exactness, terminal real sealing, transport, replay, provenance, and local naming for the same packet.

Chapter 6729

A Concrete Naming Certificate for $\mathsf{PrecompactFunctionFamily}^{\uparrow}$

Following Arzela–Ascoli and Bourbaki compact-open function-family theory, the $\mathsf{PrecompactFunctionFamily}^{\uparrow}$ packet records a family-level precompactness carrier as finite BEDC data. It sits between the precompact uniform route of chapter 4068, the compact-open topology surface of chapter 4138, the compact-open function-space carrier of chapter 2221, the bounded-function-family ledger of chapter 3522, and the finite-net equicontinuity selector of chapter 3358. The packet names the reusable family precompactness surface; it does not assert host compactness of a function space, choose a convergent subnet, quotient functions, or import open-cover compactness.

Definition 6729.1 (Precompact function family carrier)**.** *A* $\mathsf{PrecompactFunctionFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, T, U, B, E, N, W, H, C, P, L)$$

with the following displayed rows:

1. *X is the compact-domain source row read through the compact-metric or compact-window surface used by compact-open consumers.*
2. *Y is the target metric or uniform row whose bounded images are inspected by the family ledger.*
3. *T is the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *row recording the finite compact-window requests imposed on the family.*
4. *U is the* $\mathsf{PrecompactUniform}^{\uparrow}$ *handoff row for the induced uniform family surface.*
5. *B is the* $\mathsf{BoundedFunctionFamily}^{\uparrow}$ *row, exposing pointwise and sup-bound ledgers only as displayed finite data.*
6. *E is the equicontinuity row consumed through the finite-net selector and uniform-modulus route.*
7. *N is the finite net row that records the inspected family approximants at the requested tolerances.*
8. *W is the compact-open window ledger binding T, U, B, E, N to the same source and target rows.*
9. *H records componentwise* hsame *transport for X, Y, T, U, B, E, N, W and the local certificate rows.*
10. *C records displayed* Cont *replay from compact-open family requests through precompact uniform, bounded-family, equicontinuity, finite-net, and window rows.*

11. *P is the* Pkg *provenance over* $\mathsf{PrecompactFunctionFamily}^{\uparrow}$, $\mathsf{PrecompactUniform}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$, $\mathsf{BoundedFunctionFamily}^{\uparrow}$, $\mathsf{EquicontinuityFiniteNetSelector}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *L is the local* $\mathsf{NameCert}_{\mathsf{PrecompactFunctionFamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host function-space topology, arbitrary open cover, selected subnet, quotient equality of maps, countable choice, or ambient compactness theorem.

Theorem 6729.2 (Precompact function family NameCert obligations)**.** *For every accepted* PrecompactFunctionFam *carrier*

$$F = (X, Y, T, U, B, E, N, W, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{PrecompactFunctionFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for the source row X, target row Y, compact-open topology row T, precompact uniform handoff U, bounded-family row B, equicontinuity row E, finite-net row N, compact-open window ledger W, componentwise transport H, displayed replay C, provenance P, and local naming L.*

Proof. Project the carrier of Definition 6729.1. The compact-open read starts from X, Y, T, so every family request is already tied to displayed source, target, and compact-window rows.

The precompactness data are then forced through U, B, E, N, W. The precompact uniform handoff supplies the total-bounded family surface, the bounded-family and equicontinuity rows provide the Arzela–Ascoli side conditions, and the finite-net row records the inspected approximants at the requested tolerances.

Finally attach H, C, P, L. These rows transport, replay, source, and name the same packet, so the local certificate has no remaining coordinate from which to extract host function-space compactness, selected subnets, quotient maps, countable choice, or an open-cover compactness principle. □

Theorem 6729.3 (Precompact function family finite-net handoff)**.** *Every finite-net consumer of an accepted* $\mathsf{PrecompactFunctionFamily}^{\uparrow}$ *carrier must read the route*

$$\mathsf{CompactOpenTopology}^{\uparrow} \longrightarrow \mathsf{PrecompactUniform}^{\uparrow} \longrightarrow \mathsf{BoundedFunctionFamily}^{\uparrow} \longrightarrow \mathsf{EquicontinuityFiniteNetSelector}$$

through the carrier rows T, U, B, E, N before it reaches W, H, C, P, L. The handoff is a displayed compact-open family net surface, not a selected convergent subnet, host compactness theorem, quotient equality of functions, or ambient open-cover argument.

Proof. Begin with Definition 6729.2. It places the compact-open row T and the precompact uniform row U inside the same local certificate before any finite-net consumer can read N.

Next read the family hypotheses through B and E. The bounded-family row and equicontinuity selector provide the displayed Arzela–Ascoli inputs that make the finite net meaningful over the fixed source and target rows.

The remaining rows W, H, C, P, L preserve the handoff. Since the packet has no host topology, selected subnet, quotient-function equality, countable-choice schedule, or open-cover compactness coordinate, the finite-net consumer receives exactly the displayed family-level precompactness surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrecompactFunctionFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{PrecompactFunctionFamily}^{\uparrow}$ packet is generated from compact-domain and target rows, compact-open topology windows, a precompact uniform handoff, bounded-family and equicontinuity rows, finite-net approximants, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{PrecompactFunctionFamily}\uparrow}$, seed)

Scope closed: Definition 6729.1, Definition 6729.2, and Definition 6729.3 seed the finite family-level precompactness carrier for compact-open and Arzela–Ascoli consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{PrecompactFunctionFamily}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host function-space compactness, selected subnets, quotient equality of maps, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-open window exactness, precompact uniform handoff, bounded-family and equicontinuity rows, finite-net readback, transport, replay, provenance, and local naming for BEDC.Derived.PrecompactFunctionFamilyUp.

Chapter 6730

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ packet records located apartness between regular Cauchy real names as finite NameCert data before any completed real object is consulted. It reads the regular rational source rows of chapter 301, the positive dyadic separation witnesses of chapter 291, the finite window schedules of chapter 126, the terminal real-name seal of chapter 38, and the separated completion boundary of chapter 1567. The carrier names a constructive apartness route for later Real and Completion consumers; it does not assert trichotomy, Dedekind cuts, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6730.1 (Regular-Cauchy located-apartness carrier)**.** *A* $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows naming the regular Cauchy rational streams under comparison.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the two sources at the same requested precisions.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive separation witness row; it displays a dyadic radius and a finite window at which the two regular Cauchy reads are separated by that positive tolerance.*
4. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from A, B, W, D, recording the inspected rational values and their dyadic separation ledger.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular sources, shared windows, positive dyadic witness, and readback row have been displayed.*
6. *H records componentwise* hsame *transport for the two source rows, the shared window, the positive dyadic witness, the readback row, the real seal, the replay row, the provenance row, and the local name row.*
7. *C records displayed* Cont *replay from the two regular Cauchy source rows through the common finite window, the positive dyadic witness, the regular readback, and then the real seal.*

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealApartnessCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedApartness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W, D, R, E, H, C, P, N$. It has no coordinate for real trichotomy, Dedekind cuts, quotient equality of real names, selected limits, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6730.2 (Regular-Cauchy located-apartness NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ *carrier $L = (A, B, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedApa}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive separation witness, paired readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*

2. *located positivity, requiring the witness row D to display a positive dyadic separation before any apartness consumer can inspect the seal row E;*

3. *regular readback exactness, requiring the values compared by D to be the values exposed by A, B through the shared window W and repacked in R;*

4. *componentwise stability, requiring H and C to transport and replay only the displayed rows A, B, W, D, R, E, P, N;*

5. *ledger exhaustion, requiring the packet to export no trichotomy decision, Dedekind cut, quotient real equality, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No local obligation is stored outside these rows.

Proof. Carrier admission is obtained by projecting the tuple of Definition 6730.1. The displayed rows are precisely the two regular Cauchy sources, common finite window, dyadic positivity witness, paired readback, Real seal, transport, replay, provenance, and local name.

Located positivity is the role of D. The row stores a positive dyadic separation witness together with the finite window on which the two source reads are inspected, so apartness is exposed as positive data rather than as a trichotomy branch.

Regular readback exactness follows from the order of A, B, W, D, R. The readback row R is downstream of the two sources, the common window, and the dyadic witness; hence it cannot compare host representatives or quotient classes.

Componentwise stability and ledger exhaustion are supplied by H, C, P, N. These rows transport, replay, source, and name the same finite packet, and no row remains that could introduce Dedekind cuts, quotient real equality, selected limits, countable choice, or ambient completeness. □

Theorem 6730.3 (Regular-Cauchy located-apartness Real-seal boundary)**.** *Let $L = (A, B, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ *packet. Every Real-facing apartness consumer of L factors through the finite route*

$$A, B, W, D, R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the $\mathsf{Real}^{\uparrow}$ *seal exposes only a regular-Cauchy located-apartness read through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealApartnessCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. It cannot be reinterpreted as trichotomy, a Dedekind cut, quotient real equality, a selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted Real-facing apartness read. Carrier admission gives the two regular Cauchy source rows A, B and the shared finite window row W before any separation data can be inspected.

Next read the positive witness and regular readback. The dyadic row D supplies the positive separation, while R records that the compared values are exactly the regular rational reads exposed through A, B, W.

Finally expose the seal row and structural rows. Since E is downstream of A, B, W, D, R, and since H, C, P, N transport, replay, source, and name only that packet, every consumer remains inside the displayed finite route and cannot escape to trichotomy, Dedekind cuts, quotient real equality, selected limits, countable choice, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ consumer that reads apartness without two $\mathsf{RegSeqRat}^{\uparrow}$ sources, a shared $\mathsf{StreamName}^{\uparrow}$ finite window, a positive $\mathsf{DyadicRatCore}^{\uparrow}$ separation witness, paired readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row refutes the carrier surface.

Independence witness: regseqrat, dyadicratcore, streamname, real, realapartnesscompletion: no listed sibling alone carries the two regular Cauchy source rows, shared finite window, positive dyadic separation witness, paired readback, terminal Real seal, transport, replay, provenance, and local naming rows of $L = (A, B, W, D, R, E, H, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a shared StreamName finite window, a positive DyadicRatCore separation witness, paired RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6730.1, Definition 6730.2, and Definition 6730.3 seed the finite located-apartness carrier over regular Cauchy names, dyadic positive witnesses, shared stream windows, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close real trichotomy, Dedekind cuts, quotient real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive dyadic witness exactness, RegSeqRat readback exposure, StreamName window sharing, Real-seal nonescape, structural transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedApartnessUp.

Chapter 6731

A Concrete Naming Certificate for $\mathsf{OpenCover}^{\uparrow}$

Following Bourbaki and Bishop–Bridges, the $\mathsf{OpenCover}^{\uparrow}$ packet records the finite interface by which an open cover is displayed before a compactness, finite-subcover, Lebesgue-number, or compact-uniform-continuity consumer may read it. It sits between the open-set rows of $\mathsf{Topology}^{\uparrow}$, the radius and ball rows of $\mathsf{Met}^{\uparrow}$, the compact source row of $\mathsf{Compact}^{\uparrow}$, the finite-subcover extraction route of $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$, and the compact-uniform-continuity construction of chapter 9237. The packet names an indexed family only through finite BHist rows; it does not import host powersets, arbitrary choice of subcovers, or open-cover compactness as a primitive.

The finite cover ledger is consumed by chapter 129 and the finite extraction row of chapter 3503 before compact-uniform-continuity arguments inspect it.

The finite index, open-set, membership, refinement, and finite-subcover rows are read through chapter 88, chapter 57, chapter 60, and chapter 3503 before compact-uniform-continuity consumers inspect them.

Definition 6731.1 (Open-cover carrier)**.** *An* $\mathsf{OpenCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (I, U, M, R, F, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index-window row, naming the cover indices visible to the current consumer request.*
2. *U is the open-set predicate row over* $\mathsf{Topology}^{\uparrow}$*, recording for each displayed index the local open-set certificate used by the cover.*
3. *M is the membership and coverage row: each covered point read is tied to one displayed index of I and one open row of U.*
4. *R is the refinement row, comparing two displayed cover windows only by finite index maps and inclusion witnesses between their open-set rows.*
5. *F is the finite-subcover ledger, exposed only when a* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *consumer has supplied the compact source and the finite extraction route.*
6. *H records componentwise* hsame *transport for index, open-set, membership, coverage, refinement, finite-subcover, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a cover request through I, U, M, R, F, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{OpenCover}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{OpenCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. There is no coordinate for a host powerset of all opens, an arbitrary subcover selector, a quotient of covers, countable choice, or open-cover compactness as an ambient principle.

Theorem 6731.2 (Open-cover finite ledger obligations)**.** *For every accepted* $\mathsf{OpenCover}^{\uparrow}$ *carrier $O = (I, U, M, R, F, H, C, P, N)$, the local cover ledger visible to any compactness-facing consumer is exhausted by finite index admission, open-set predicate admission, membership and coverage exactness, refinement exactness, finite-subcover handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. A* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *consumer may inspect F only after I, U, M, R have been displayed, and no consumer may replace those rows by a host powerset, arbitrary subcover choice, or primitive open-cover compactness theorem.*

Proof. Project the carrier of Definition 6731.1. The rows I, U, M, R expose the only index, open-set, membership, coverage, and refinement data available to the packet.

The finite-subcover row F is downstream of those rows. It is read only as a handoff to the compact or finite-subcover-criterion consumer, so it cannot select a hidden subfamily or quantify over an ambient powerset of opens.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores a host powerset, arbitrary selector, quotient cover equality, countable-choice schedule, or primitive open-cover compactness principle, none of those objects can become a local ledger obligation. □

Theorem 6731.3 (Open-cover NameCert surface)**.** *The seed* $\mathsf{NameCert}_{\mathsf{OpenCover}^{\uparrow}}$ *surface consists exactly of the carrier rows in Definition 6731.1: finite index windows,* $\mathsf{Topology}^{\uparrow}$ *open-set predicates, membership and coverage witnesses, refinement rows, a finite-subcover ledger for* $\mathsf{Compact}^{\uparrow}$ *and* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *consumers, componentwise transport, displayed replay, provenance, and local naming. When the same cover is used in a metric argument, the* $\mathsf{Met}^{\uparrow}$ *contribution is read only through the displayed ball or radius rows named by U, M, R, not through a separate open-cover compactness principle.*

Proof. The NameCert surface first reads I, U, M, R. These rows determine the displayed cover window, the open predicates, and the finite coverage and refinement evidence.

The compact handoff is then represented by F. It is a finite ledger row over the same displayed cover window, so the compact-uniform-continuity route of chapter 9237 receives a finite cover interface rather than an ambient cover-selection principle.

The remaining rows H, C, P, N are structural. They preserve the same finite route under transport, replay it for downstream consumers, record its provenance, and name it locally. Thus the surface is exactly the stated finite open-cover interface. □

Theorem 6731.4 (Open-cover constructive boundary)**.** *Every* $\mathsf{OpenCover}^{\uparrow}$ *read used by compact, finite-subcover, Lebesgue-number, or compact-uniform-continuity arguments must pass through the finite route*

$$I, U, M, R, F, H, C, P, N.$$

The route may cite Topology$^{\uparrow}$ *for open-set predicates,* Met$^{\uparrow}$ *for ball and radius witnesses,* Compact$^{\uparrow}$ *for the compact source, and* FiniteSubcoverCriterion$^{\uparrow}$ *for finite extraction, but it exports no host powerset of opens, arbitrary choice of subcovers, quotient cover equality, countable-choice schedule, or primitive open-cover compactness theorem.*

Proof. Read the cover rows in order. The index window I bounds the visible family, U supplies the open predicates, and M, R account for coverage and refinement using only displayed rows.

The finite-subcover ledger F is available only after the compact source or finite-subcover criterion has supplied its own finite extraction data. This keeps compactness-facing arguments on the same finite ledger used by the cover.

Transport, replay, provenance, and local naming do not add new cover data. Therefore every downstream consumer receives the finite route named in the statement and none of the excluded host or choice principles. □

Closure status for NameCert$_{\text{OpenCover}^{\uparrow}}$.

Constructive story: An OpenCover$^{\uparrow}$ packet is generated from finite index windows, Topology open-set predicate rows, membership and coverage rows, refinement rows, finite-subcover ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{OpenCover}^{\uparrow}}$, seed)

Scope closed: Definition 6731.1, Definition 6731.2, Definition 6731.3, and Definition 6731.4 seed the finite open-cover interface for compactness and compact-uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\text{OpenCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, host powersets of opens, arbitrary subcover choice, quotient cover equality, countable choice, primitive open-cover compactness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, open-set predicate exactness, membership and coverage exactness, refinement stability, finite-subcover handoff, transport, replay, provenance, and local naming for BEDC.Derived.OpenCoverUp.

Chapter 6732

A Concrete Naming Certificate for $\mathsf{CompleteProductMetric}^{\uparrow}$

Following Bishop and Bridges and Kelley on constructive metric completion and product metrics, the $\mathsf{CompleteProductMetric}^{\uparrow}$ packet records the finite BEDC surface where a binary product metric is already displayed and the completion-facing Cauchy windows are accepted as complete-product data. It sits after the product-distance packet of chapter 424, the metric-completion carrier of chapter 1506, the separated-completion boundary of chapter 1612, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Banach, Polish, compact, and completion routes a complete product-metric certificate without adding host product metrics, quotient completion equality, selected product limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6732.1 (Complete product-metric carrier)**.** *A* $\mathsf{CompleteProductMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, \Pi, \Delta, M, S, W_X, W_Y, R_X, R_Y, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted component metric-completion source rows.*
2. *Π is the accepted* $\mathsf{ProductMetric}^{\uparrow}$ *product-distance row, including the displayed product carrier, projection reads, and product-distance ledger.*
3. *Δ is the completion-facing metric row read from Π rather than from a host product metric.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route that accepts paired Cauchy windows as completion-facing data.*
5. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *comparison boundary for identifying completed product reads only through displayed separated data.*
6. *W_X and W_Y are the paired* $\mathsf{StreamName}^{\uparrow}$ *window rows inspected on the component Cauchy names.*
7. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed product-distance estimate.*
9. *H records componentwise* hsame *transport for the component rows, product metric, completion route, separated boundary, stream windows, regular readbacks, Real seal, continuation, provenance, and local naming.*

10. *C records displayed* Cont *replay from a complete-product request through* $X, Y, \Pi, \Delta, M, S, W_X, W_Y, R_X, R_Y, E$.
11. *P is the* Pkg *provenance over* $\mathsf{CompleteProductMetric}^{\uparrow}$, $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteProductMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host product metrics, quotient completion classes, selected representatives, countable choice, trichotomy, detached real carriers, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6732.2 (Complete product-metric NameCert obligations)**.** *For every accepted* $\mathsf{CompleteProductMetric}^{\uparrow}$ *carrier* $Q = (X, Y, \Pi, \Delta, M, S, W_X, W_Y, R_X, R_Y, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompleteProductMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the component completion sources, the* $\mathsf{ProductMetric}^{\uparrow}$ *product-distance row, the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion route, the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *comparison boundary, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, local naming, and refusal of host product metrics, quotient completion equality, selected product limits, countable choice, trichotomy, detached real carriers, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 6732.1. The displayed packet exposes exactly the two component source rows, the product-distance row Π, the completion route M, the separated boundary S, paired windows, regular readbacks, the Real seal, and the structural rows.

The product metric is read before the completion route. Thus Δ and M can consume only the $\mathsf{ProductMetric}^{\uparrow}$ ledger carried by Π, together with the finite windows and regular readbacks, and cannot import a host product metric.

The separated-completion boundary is then forced through S. It compares completed product reads only after the paired Cauchy windows and product-distance estimate have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient completion equality, selected representatives, countable choice, trichotomy, detached real carriers, ambient completeness, or bridge checking, the listed obligations exhaust the local certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteProductMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteProductMetric}^{\uparrow}$ packet is generated from two component completion sources, a $\mathsf{ProductMetric}^{\uparrow}$ product-distance row, a $\mathsf{MetricCompletion}^{\uparrow}$ route, a $\mathsf{SeparatedCompletion}^{\uparrow}$ comparison boundary, paired $\mathsf{StreamName}^{\uparrow}$ windows, paired $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompleteProductMetric}^{\uparrow}}$, seed)

Scope closed: Definition 6732.1 and Definition 6732.2 seed the finite complete product-metric route from displayed product-distance and completion rows to separated completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompleteProductMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host product metrics, quotient completion equality, selected representatives, countable choice, trichotomy, detached real carriers, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-distance exactness, completion-route stability, separated-boundary stability, transport, replay, provenance, and local naming for BEDC.Derived.CompleteProductMetricUp.

Chapter 6733

A Concrete Naming Certificate for RegularCauchyProductMetric$^{\uparrow}$

Following Bishop–Bridges product-metric and regular-Cauchy sequence mathematics, the RegularCauchyProductMe
packet realizes the paired finite-window product-distance route used by the compact-uniform-continuity construction of chapter 9237. It sits after the product-distance packet of chapter 3551, the regular product route of chapter 461, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet gives finite-net and uniform-modulus consumers a paired regular-Cauchy product metric surface without host product metrics, quotient stream equality, selected product limits, countable choice, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 6733.1 (Regular Cauchy product-metric carrier)**.** *A* RegularCauchyProductMetric$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, K, W_A, W_B, R_A, R_B, D, \Delta, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two accepted regular Cauchy source rows.*
2. *K is the accepted* RegularCauchyProduct$^{\uparrow}$ *row joining the two source names by displayed product windows.*
3. *W_A and W_B are the synchronized* StreamName$^{\uparrow}$ *finite-window rows inspected by finite-net consumers.*
4. *R_A and R_B are the* RegSeqRat$^{\uparrow}$ *readback rows attached to the two displayed window streams.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *product-distance ledger recording coordinate tolerances, product radius, and comparison budget.*
6. *Δ is the* CauchyProductMetric$^{\uparrow}$ *metric row read from K, W_A, W_B, R_A, R_B, D.*
7. *E is the terminal* Real$^{\uparrow}$ *seal for the product-distance read.*
8. *H records componentwise* hsame *transport for the source rows, product row, windows, readbacks, dyadic ledger, metric row, Real seal, continuation, provenance, and local naming.*
9. *C records displayed* Cont *replay from a finite-net product-distance request through $A, B, K, W_A, W_B, R_A, R_B, D, \Delta$*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyProductMetric}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{CauchyProductMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, K, W_A, W_B, R_A, R_B, D, \Delta, E, H, C, P, N$. It has no coordinate for host product metrics, quotient stream equality, selected limits, compactness, trichotomy, detached real carriers, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6733.2 (Regular Cauchy product-metric NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyProductMetric}^{\uparrow}$ *carrier $M = (A, B, K, W_A, W_B, R_A, R_B, D, \Delta, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular Cauchy sources, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *product row, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-distance ledger, the* $\mathsf{CauchyProductMetric}^{\uparrow}$ *metric row, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, local naming, and refusal of host product metrics, quotient stream equality, selected limits, compactness, trichotomy, detached real carriers, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 6733.1. The accepted packet exposes exactly the two source rows, the regular product row, synchronized windows, regular readbacks, dyadic ledger, metric row, Real seal, and structural rows.

The finite-net route reads the windows before it reads the product-distance ledger. Hence D is tied to W_A, W_B, R_A, R_B and cannot be replaced by a host product metric.

The metric row Δ is then forced through the sibling $\mathsf{CauchyProductMetric}^{\uparrow}$ route. It consumes the regular product and dyadic ledger as displayed rows, so compact-uniform consumers receive a product-distance certificate rather than quotient stream equality or selected limits.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no coordinate stores compactness, host product metrics, quotient streams, selected representatives, detached real carriers, ambient completeness, or bridge checking, the listed obligations exhaust the local certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyProductMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyProductMetric}^{\uparrow}$ packet is generated from two regular Cauchy source rows, a $\mathsf{RegularCauchyProduct}^{\uparrow}$ row, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, paired $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{DyadicRatCore}^{\uparrow}$ product-distance ledger, a $\mathsf{CauchyProductMetric}^{\uparrow}$ metric row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyProductMetric}^{\uparrow}}$, seed)

Scope closed: Definition 6733.1 and Definition 6733.2 seed the finite regular-Cauchy product-distance route consumed by compact-uniform-continuity finite-net and uniform-modulus consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyProductMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim compactness, host product metrics, quotient stream equality, selected limits, trichotomy, detached real carriers, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-window exactness, dyadic product-distance ledger stability, CauchyProductMetric handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyProd

Chapter 6734

A Concrete Naming Certificate for $\mathsf{HadamardSpace}^{\uparrow}$

Following Hadamard and Bridson–Haefliger on complete CAT(0) geometry, the $\mathsf{HadamardSpace}^{\uparrow}$ packet records the finite NameCert surface for a complete geodesic metric carrier with the displayed nonpositive-curvature comparison row that convexity-facing consumers may read. It sits over the metric carrier of chapter 57, the complete-metric boundary of chapter 128, the geodesic metric route of chapter 2213, the convex-set rows of chapter 208, the CAT(0) metric comparison surface of chapter 6336, and the terminal real-name seal of chapter 38. The packet names the traditional Hadamard-space interface as finite BEDC rows; it does not assert global choice of geodesics, quotient point equality, selected projections, local compactness, differentiable manifold structure, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6734.1 (Hadamard space carrier)**.** *A* $\mathsf{HadamardSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, C, G, V, K, R, A, T, D, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *carrier row, exposing the named point classifier, distance readbacks, ball observations, and metric-law ledger.*
2. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row, recording the displayed Cauchy-thread or completion-facing service available over the same metric source.*
3. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *row, exposing only the finite geodesic incidence and endpoint-distance observations inspected by the packet.*
4. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row for the geodesic convex subsets and segment-closure reads that downstream projection or fixed-point consumers may inspect.*
5. *K is the* $\mathsf{CATZeroMetric}^{\uparrow}$ *comparison row, carrying the finite CAT(0) quadrilateral or comparison-triangle obligations used by the Hadamard read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback row for the metric, geodesic, convexity, and CAT(0) distance budgets.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *distance and radius seal reached only after M, C, G, V, K, R have been displayed.*

8. *T records componentwise* hsame *transport for the metric, completeness, geodesic, convexity, comparison, rational-readback, and real-seal rows.*
9. *D records displayed* Cont *replay from Hadamard-space requests through the same finite rows.*
10. *P is the* Pkg *provenance over* $\mathsf{HadamardSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HadamardSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for selected geodesics, quotient points, ambient Hilbert spaces, choice-selected projections, differentiable structure, local compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6734.2 (Hadamard space NameCert obligations)**.** *For every accepted* $\mathsf{HadamardSpace}^{\uparrow}$ *carrier*

$$H = (M, C, G, V, K, R, A, T, D, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HadamardSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Met}^{\uparrow}$ *row M,* $\mathsf{CompleteMetric}^{\uparrow}$ *row C,* $\mathsf{GeodesicMetric}^{\uparrow}$ *row G,* $\mathsf{ConvexSet}^{\uparrow}$ *row V,* $\mathsf{CATZeroMetric}^{\uparrow}$ *row K,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal A, componentwise* hsame *transport T, displayed* Cont *replay D, provenance P, and local naming N. Every Hadamard-space consumer must read the complete geodesic CAT(0) surface through those rows and cannot import selected geodesics, quotient equality, projection selectors, Hilbert-space embeddings, local compactness, differentiable structure, or ambient real completeness.*

Proof. Project the carrier of Definition 6734.1. The metric source M, complete-metric row C, geodesic row G, convexity row V, and CAT(0) comparison row K are the only geometric data available to the packet.

The tolerance and real-valued distance reads are then forced through R and A. These rows attach the regular rational readback and terminal Real seal to the same displayed metric, geodesic, convexity, and comparison surface.

Finally use the structural rows T, D, P, N. They transport, replay, source, and name only the displayed rows, so there is no route from the accepted packet to selected geodesics, quotient point equality, projection selectors, Hilbert-space embeddings, local compactness, differentiable structure, or ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{HadamardSpace}^{\uparrow}$ read factors through displayed $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before any complete CAT(0) consumer output is visible.

Independence witness: metric, complete-metric, geodesic-metric, convex-set, cat-zero-metric, regseqrat, real: none of the listed siblings alone is bijective with $\mathsf{HadamardSpace}^{\uparrow}$ because the packet jointly carries a complete metric source, geodesic incidence, convexity reads, CAT(0) comparison, regular rational budgets, a terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HadamardSpace}^{\uparrow}$ packet is generated from MetricSpace carrier rows, CompleteMetric completion rows, GeodesicMetric segment rows, ConvexSet geodesic-convex rows, CatZeroMetric comparison rows, RegSeqRat tolerance readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HadamardSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6734.1 and Definition 6734.2 seed the finite complete geodesic CAT(0) NameCert surface over displayed metric, completeness, geodesic, convexity, comparison, tolerance, real-seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HadamardSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected geodesics, quotient point equality, projection selectors, Hilbert-space embeddings, local compactness, differentiable structure, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric exposure, geodesic incidence, convexity routing, CAT(0) comparison, rational readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HadamardSpaceUp.

Chapter 6735

A Concrete Naming Certificate for $\mathsf{MarkovKernel}^{\uparrow}$

Following Doob and Kallenberg on transition kernels, the $\mathsf{MarkovKernel}^{\uparrow}$ packet names the probability-theory interface that sends each displayed source state to a probability distribution on a displayed target event family. It sits between the event-and-measure surface of chapter 184, the measurable-preimage surface of chapter 185, the pushforward-law surface of chapter 186, and the finite transition-row surface of chapter 189. The chapter records the kernel row as its own NameCert object rather than reading it only as a Markov-chain transition coordinate.

Definition 6735.1 (Markov-kernel carrier)**.** *A* $\mathsf{MarkovKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, \mathcal{A}_T, k, N, E, H, C, P, L)$$

with the following displayed rows:

1. *S is the source-state row, carried as a measurable state surface compatible with a* $\mathsf{ProbSpace}^{\uparrow}$ *source when one is present;*
2. *T is the target-state row, equipped with the target measurable-event family $\mathcal{A}_T$;*
3. *k is the endpoint assignment sending each displayed source state s and target event $B \in \mathcal{A}_T$ to a* $\mathsf{Real}^{\uparrow}$ *endpoint $k(s, B)$;*
4. *N records normalization, requiring the row $B = T$ to read as the probability unit for each displayed source state;*
5. *E records empty-event and finite-disjoint-union readback for the target event family at each displayed source state;*
6. *H records componentwise* hsame *transport for source states, target events, and real endpoints;*
7. *C records displayed* Cont *replay from source state and target event rows through endpoint, normalization, finite-additivity, and naming rows;*
8. *P is the* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{MarkovChain}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{MarkovKernel}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host conditional probability object, filtration, selected stochastic process, quotient event algebra, or off-packet measurability theorem.

Theorem 6735.2 (Markov-kernel NameCert obligations)**.** *For the carrier of Definition 6735.1, the local* $\mathsf{NameCert}_{\mathsf{MarkovKernel}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$K = (S, T, \mathcal{A}_T, k, N, E, H, C, P, L),$$

source-state exposure through S*, target-event exposure through* $T, \mathcal{A}_T$*, endpoint readback through* k*, probability normalization through* N*, empty-event and finite-disjoint-union readback through* E*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* L*.*

Consequently an accepted $\mathsf{MarkovKernel}^{\uparrow}$ *packet is a finite state-to-distribution interface. It is not a host conditional distribution, not a filtration, and not a Markov-chain process.*

Lean4 ✓ `BEDC.Derived.MarkovKernelUp.MarkovKernelCarrier namecert obligations`

Proof. Project the displayed carrier. Its rows expose the source state, target event family, real-valued endpoint assignment, normalization row, finite-additivity row, transport, replay, provenance, and local name.

Read N and E as the distribution discipline at a fixed source state. The normalization row supplies the total target event as probability unit, while the empty-event and finite-disjoint-union rows make each displayed source fiber behave as a probability-distribution row over $\mathcal{A}_T$.

Use H, C, P, L to bind the same rows under classifier transport and replay. Since no coordinate contains a conditional-probability object, filtration, stochastic process, or quotient event algebra, the NameCert obligations are exhausted by the displayed finite rows. □

Theorem 6735.3 (Markov-kernel transition-distribution handoff)**.** *Every* $\mathsf{MarkovChain}^{\uparrow}$ *transition row that is accepted as a* $\mathsf{MarkovKernel}^{\uparrow}$ *packet hands its current-state input to a* $\mathsf{Distribution}^{\uparrow}$ *row on the next-state event family. The handoff first displays the* $\mathsf{ProbSpace}^{\uparrow}$ *source boundary and the adjacent* $\mathsf{RandomVar}^{\uparrow}$ *rows, then reads the current-state coordinate through the kernel row* k*, and only then exposes the next-law endpoint as a* $\mathsf{Distribution}^{\uparrow}$ *target distribution. It exports no host stochastic process, filtration, conditional-expectation primitive, or selected path law.*

Proof. Start with the Markov-chain carrier of Definition 189.1. Its transition row already records a current-state to next-law datum between adjacent $\mathsf{RandomVar}^{\uparrow}$ rows over a $\mathsf{ProbSpace}^{\uparrow}$ source.

Apply the Markov-kernel carrier above to that transition row. The source state is the current-state coordinate, the target event family is the next-state measurable family, and the endpoint assignment $k(s, B)$ is the displayed next-law readback.

Now read the target law through Definition 186.1. The $\mathsf{Distribution}^{\uparrow}$ surface receives a target event and a real endpoint, while the $\mathsf{RandomVar}^{\uparrow}$ and $\mathsf{ProbSpace}^{\uparrow}$ rows provide the measurable source boundary. The handoff therefore factors through the finite kernel packet rather than through any host stochastic-process structure. □

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkovKernel}^{\uparrow}$ packet is generated from source-state rows, target-event rows, state-indexed real endpoints, normalization, finite-disjoint-union readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MarkovKernel}^{\uparrow}}$, seed)

Scope closed: Definition 6735.1, Definition 6735.2, and Definition 6735.3 seed the state-to-distribution kernel packet and its Markov-chain transition handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MarkovKernel}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host conditional-probability object, filtration, selected stochastic process, quotient event algebra, full measurability theorem, or standard kernel bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint normalization, finite-additivity readback, classifier stability, distribution handoff, provenance, and local NameCert for the same packet.

Chapter 6736

A Concrete Naming Certificate for $\mathsf{ToeplitzSummability}^{\uparrow}$

Following Toeplitz's theorem on regular summability matrices, as presented in Hardy's summability theory, the $\mathsf{ToeplitzSummability}^{\uparrow}$ packet records the finite BEDC certificate by which a row-window matrix transform preserves an already displayed real sequence limit. It sits beside the Cesaro route of chapter 1827, the Abel summation surface of chapter 1763, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the local carrier and handoff obligations for regular matrix summability; it does not import Banach limits, quotient sequence equality, selected representatives, host infinite matrices, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6736.1 (Toeplitz summability carrier)**.** *A* $\mathsf{ToeplitzSummability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, M, B, Z, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Real}^{\uparrow}$ *sequence source row, exposing only the finite source observations and the already displayed real-name limit requested by the summability packet.*
2. *M is the finite row-window matrix ledger, listing the inspected coefficients $a_{n,k}$, row indices, column windows, truncation bounds, and dyadic coefficient approximants currently visible.*
3. *B is the row-sum boundedness ledger, recording the finite dyadic bounds that keep the displayed row sums uniformly controlled before any transformed read is exposed.*
4. *Z is the column-limit-zero ledger, recording for each displayed column and tolerance the finite evidence that sufficiently late matrix rows make that column small.*
5. *U is the row-sum-one limit ledger, recording the finite evidence that the inspected row sums approach the unit row over the displayed tolerance schedule.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the transformed sequence obtained from S, M, B, Z, U.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source row, matrix ledger, three regularity ledgers, and regular rational readback have been displayed.*
8. *H stores componentwise* hsame *transport for the source row, matrix ledger, row-sum bound, column-limit-zero data, row-sum-one data, regular readback, real seal, continuation row, provenance, and local naming.*

9. *C stores displayed* Cont *replay from matrix-row inspection to source-window selection, from the regularity ledgers to transformed-row construction, from transformed rows to regular readback, and from regular readback to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{ToeplitzSummability}^{\uparrow}$, $\mathsf{CesaroConvergence}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ToeplitzSummability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, B, Z, U, R, E, H, C, P, N$. It has no coordinate for Banach limits, choice-selected subsequences, quotient sequence equality, host infinite matrices, detached summability methods, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6736.2 (Toeplitz summability NameCert obligations)**.** *For every accepted* $\mathsf{ToeplitzSummability}^{\uparrow}$ *carrier $T = (S, M, B, Z, U, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ToeplitzSummability}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed real sequence source, finite row-window matrix ledger, row-sum boundedness ledger, column-limit-zero ledger, row-sum-one ledger, regular readback, real seal, transport, continuation, provenance, and naming rows;*

2. *matrix-window exactness, requiring every coefficient used by the transform to be read from M over an inspected finite row and column window;*

3. *regularity exactness, requiring bounded row sums, vanishing columns, and row sums approaching one to be read respectively from B, Z, U before the transformed row reaches R;*

4. *source-to-transform handoff, requiring every transformed finite row to be constructed from the same displayed source row S and matrix ledger M;*

5. *regular readback and real sealing, requiring completion-facing output to pass through R and then E;*

6. *transport, continuation, provenance, and local naming, requiring H, C, P, N to preserve the same finite route without adding Banach limits, choice, quotient equality, host infinite matrices, or ambient completeness.*

Proof. Project the carrier of Definition 6736.1. Carrier admission is exactly the displayed inventory $S, M, B, Z, U, R, E, H, C, P, N$, so the certificate surface has no detached coordinate for a completed matrix or a host summability method.

The matrix-window clause is read from M. The three regularity ledgers are independent rows: bounded row sums are supplied by B, column-limit-zero evidence by Z, and row-sum-one evidence by U.

The source sequence is inspected only through S, and every transformed finite row is downstream of S, M, B, Z, U. Hence no transformed read can reach $\mathsf{RegSeqRat}^{\uparrow}$ before those rows have been displayed.

The endpoint-facing route then continues through R and the terminal $\mathsf{Real}^{\uparrow}$ seal E. The structural rows H, C, P, N transport, replay, source, and name this same route, so the six listed obligations exhaust the local NameCert surface. □

Theorem 6736.3 (Toeplitz summability regular-matrix handoff)**.** *Every accepted* $\mathsf{ToeplitzSummability}^{\uparrow}$ *read that exposes a regular matrix transform factors through the finite route*

$$S \longmapsto M \longmapsto (B, Z, U) \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

The $\mathsf{CesaroConvergence}^{\uparrow}$ *and* $\mathsf{AbelSummation}^{\uparrow}$ *sibling rows may appear as provenance anchors for familiar summability subroutes, but no consumer can bypass the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or the* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with an accepted transform read. The only source data visible to the classifier are the displayed observations in S, and the only coefficient data are the finite row windows in M.

The matrix is regular only through the three ledgers B, Z, U. Thus the transform has no accepted route unless row-sum boundedness, column-limit-zero evidence, and row-sum-one evidence have all been displayed for the inspected windows.

The transformed sequence reaches a regular rational consumer through R, and the real endpoint is visible only through E. The Cesaro and Abel sibling references live in provenance row P and do not create a second path around S, M, B, Z, U, R, E.

Finally H, C, P, N preserve and name the same finite route. Since the carrier contains no Banach-limit field, quotient sequence equality field, host infinite matrix, choice selector, or ambient completeness witness, the displayed route exhausts the regular-matrix handoff. □

Theorem 6736.4 (Toeplitz summability Real limit preservation)**.** *Let* $T = (S, M, B, Z, U, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ToeplitzSummability}^{\uparrow}$ *carrier. If the source row* S *exposes a* $\mathsf{Real}^{\uparrow}$ *sequence name with a displayed real limit, and* M, B, Z, U *expose the finite regularity rows required by Toeplitz's theorem, then the transformed sequence may be read by a completion-facing consumer only as the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R *followed by the* $\mathsf{Real}^{\uparrow}$ *seal* E*. The exported real endpoint is the endpoint carried by the displayed source route, not a Banach limit, a selected external limit, a quotient sequence equality class, a host infinite matrix calculation, or an ambient completeness theorem.*

Proof. Use Definition 6736.2 to read the source and matrix data. The displayed source row S supplies the real sequence name and its limit row, while M supplies only finite coefficient windows.

The Toeplitz regularity evidence is then exactly B, Z, U. Row-sum boundedness controls the finite row transform, column-limit-zero evidence prevents any fixed source coordinate from escaping the displayed tail discipline, and row-sum-one evidence preserves the constant-limit row.

Apply Definition 6736.3. The transformed sequence cannot be exposed directly as a host limit; it first reaches the $\mathsf{RegSeqRat}^{\uparrow}$ row R and then the $\mathsf{Real}^{\uparrow}$ seal E.

The remaining rows H, C, P, N transport, replay, source, and name this route. Therefore the exported endpoint is the displayed BEDC real-limit preservation route, with no additional field for Banach limits, choice, quotient equality, host infinite matrices, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{ToeplitzSummability}^{\uparrow}$ completion-facing read factors through a Real sequence source row, a finite row-window matrix ledger, row-sum boundedness, column-limit-zero rows, row-sum-one limit rows, RegSeqRat readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: cesaroconvergence, abelsummation, regseqrat, real: $\mathsf{ToeplitzSummability}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source real-sequence data, finite matrix row windows, all three Toeplitz regularity ledgers, regular readback, real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ToeplitzSummability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ToeplitzSummability}^{\uparrow}$ packet is generated from a Real sequence source row, a finite row-window matrix ledger, row-sum boundedness, column-limit-zero rows, row-sum-one limit rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ToeplitzSummability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6736.1, Definition 6736.2, Definition 6736.3, and Definition 6736.4 seed the finite regular matrix summability route from displayed Real sequence data to Real-facing seals.

Formal verification: FormalStatus(NameCert$_{\mathsf{ToeplitzSummability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach limits, choice, quotient sequence equality, host infinite matrices, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking for ToeplitzSummability$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, matrix-window exactness, row-sum boundedness, column-limit-zero exactness, row-sum-one exactness, RegSeqRat readback, Real-seal preservation, transport, provenance, and TasteGate field faithfulness for BEDC.Derived.ToeplitzSummabilityUp.

Chapter 6737

A Concrete Naming Certificate for $\mathsf{DoobDecomposition}^{\uparrow}$

Following Doob and Meyer, the $\mathsf{DoobDecomposition}^{\uparrow}$ packet records the finite row surface by which a displayed submartingale window is split into a martingale residual row and a predictable increasing compensator row. It sits beside the submartingale and martingale packets of chapter 6556 and chapter 190, consumes the conditional-expectation surface of chapter 188, and feeds the bounded stopping and crossing consumers of chapter 383 and chapter 1629. The chapter names only the finite decomposition carrier; it does not import measure completion, almost-sure quotient equality, optional projection, or a host predictable sigma-algebra.

Definition 6737.1 (Doob decomposition carrier)**.** *A* $\mathsf{DoobDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\Omega, S, M, A, C, F, X, E, R, I, T, H, K, P, N)$$

with the following displayed rows:

1. Ω *is the consumed probability-context row shared with the input stochastic process.*
2. S *is the accepted* $\mathsf{Submartingale}^{\uparrow}$ *row being decomposed.*
3. M *is the* $\mathsf{Martingale}^{\uparrow}$ *residual row over the same finite filtration window.*
4. A *is the predictable increasing compensator row, displayed as finite step differences visible at the previous filtration stage.*
5. C *is the* $\mathsf{CondExp}^{\uparrow}$ *row used to read the successor conditional-expectation faces.*
6. F *is the finite filtration and adaptedness ledger shared by* S, M, A.
7. X *is the input submartingale endpoint family.*
8. E *is the finite conditional-expectation family read from* X *through* C.
9. R *is the residual endpoint family obtained by subtracting the predictable step differences displayed in* A *from the input endpoints* X.
10. I *is the increasing-row ledger recording nonnegative displayed step differences of* A.
11. T *is the bounded stopping-window handoff row consumed by* $\mathsf{OptionalStopping}^{\uparrow}$ *and crossing consumers.*
12. H *records componentwise* hsame *transport for all displayed rows.*

13. *K records displayed* Cont *replay for input exposure, conditional-expectation exposure, residual readback, predictable step-difference readback, stopping-window routing, and crossing handoff.*
14. *P is the* Pkg *provenance row naming exactly* $\mathsf{Submartingale}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert, *and the local decomposition rows.*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{DoobDecomposition}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through these displayed finite rows. It has no coordinate for completed filtrations, almost-sure quotient classes, optional projection, selected path representatives, or a host predictable sigma-algebra.

Theorem 6737.2 (Doob decomposition NameCert obligations)**.** *For the carrier of Definition 6737.1, the local* $\mathsf{NameCert}_{\mathsf{DoobDecomposition}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$\Omega, S, M, A, C, F, X, E, R, I, T, H, K, P, N,$$

submartingale input exposure through S, residual martingale exposure through M, successor conditional-expectation exposure through C, E, predictable increasing exposure through A, I, shared finite filtration exposure through F, endpoint and residual readback through X, R, bounded stopping and crossing handoff through T, componentwise hsame *transport through H, displayed* Cont *replay through K, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6737.1. Its row list fixes the input submartingale, residual martingale, predictable increasing compensator, conditional-expectation faces, common filtration window, endpoint families, stopping handoff, and structural rows.

The decomposition rows are $S, M, A, C, F, X, E, R, I$. The input row S supplies the one-sided conditional-expectation comparison, C, E display the successor faces, A, I display the predictable nonnegative step differences, and M, R record the residual martingale readback on the same finite filtration window.

The consumer rows remain bounded. The row T exposes only the finite stopped-window route needed by $\mathsf{OptionalStopping}^{\uparrow}$ and $\mathsf{Upcrossing}^{\uparrow}$, so downstream crossing consumers read the decomposition through displayed finite windows.

The structural rows H, K, P, N transport, replay, source, and name the same finite packet. Since no row names measure completion, almost-sure quotient equality, optional projection, selected path representatives, or a host predictable sigma-algebra, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{DoobDecomposition}^{\uparrow}$ consumer that reads a martingale residual or predictable increasing row without first displaying the $\mathsf{Submartingale}^{\uparrow}$ input row, the $\mathsf{CondExp}^{\uparrow}$ successor faces, and the shared finite filtration ledger is outside the carrier.

Independence witness: submartingale, martingale, condexp, optionalstopping, upcrossing: no listed sibling supplies the whole decomposition packet $D = (\Omega, S, M, A, C, F, X, E, R, I, T, H, K, P, N)$, because $\mathsf{Submartingale}^{\uparrow}$ names the one-sided input law, $\mathsf{Martingale}^{\uparrow}$ names equality-direction residual rows, $\mathsf{CondExp}^{\uparrow}$ names successor faces, and $\mathsf{OptionalStopping}^{\uparrow}$ and $\mathsf{Upcrossing}^{\uparrow}$ consume bounded windows without carrying the predictable increasing split.

Closure status for $\mathsf{NameCert}_{\mathsf{DoobDecomposition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DoobDecomposition}^{\uparrow}$ packet is generated from a displayed probability context, a submartingale input row, a martingale residual row, a predictable increasing compensator row, conditional-expectation faces, a finite filtration ledger, endpoint and residual readback rows, bounded stopping handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{DoobDecomposition}\uparrow}$, seed)

Scope closed: Definition 6737.1 and Definition 6737.2 seed the finite Doob decomposition NameCert boundary between submartingale input rows, martingale residual rows, predictable increasing rows, conditional-expectation faces, and bounded stopping or crossing consumers.

Formal verification: FormalStatus(NameCert$_{\text{DoobDecomposition}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim uniqueness up to almost-sure equality, measure completion, optional projection, completed filtrations, selected path representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, decomposition-row exactness, predictable increasing exposure, martingale residual exposure, bounded consumer handoff, and local NameCert accountability for BEDC.Derived.DoobDecompositionUp.

Chapter 6738

A Concrete Naming Certificate for $\mathsf{ContinuedFractionReal}^{\uparrow}$

Following Lagrange and Hardy–Wright on continued fractions, the $\mathsf{ContinuedFractionReal}^{\uparrow}$ packet records the real-facing finite-prefix route from continued-fraction data through convergent rows, dyadic tolerance ledgers, regular rational readback, and a terminal real-name seal. It sits after the partial-quotient source of chapter 342, the convergent table of chapter 1777, the dyadic tolerance ledger of chapter 291, the finite-window surface of chapter 126, the regular rational handoff of chapter 301, and the terminal seal of chapter 38. The packet names a finite readback route for continued-fraction real representations; it is not an infinite continued-fraction selector, quotient real equality, trichotomy, countable choice, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 6738.1 (ContinuedFractionReal carrier)**.** *A* $\mathsf{ContinuedFractionReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, C, D, W, R, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ContinuedFraction}^{\uparrow}$ *finite-prefix row, recording the inspected partial quotients and the local recurrence source used by the real-facing read.*
2. *C is the* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *convergent-table row, recording numerator, denominator, normalized rational, and displayed finite-index data for the prefix in A.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, endpoint enclosures, and precision budgets attached to the displayed convergent windows.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording exactly which prefix windows and convergent indices a downstream consumer may inspect.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from C, D, W after the source prefix in A has been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the finite-prefix, convergent-table, dyadic-ledger, finite-window, and regular-rational rows have been read.*
7. *H records componentwise* hsame *transport for the source prefix, convergent table, dyadic ledger, finite windows, regular handoff, Real seal, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from a real-facing continued-fraction request through A, C, D, W, R, E, H.*

9. *P is the* Pkg *provenance over* ContinuedFractionReal$^{\uparrow}$, ContinuedFraction$^{\uparrow}$, ContinuedFractionConvergents$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuedFractionReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, C, D, W, R, E, H, K, P, N$. It has no coordinate for an infinite continued-fraction selector, quotient real equality, trichotomy, countable choice, a selected limit, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6738.2 (ContinuedFractionReal NameCert obligations)**.** *For every accepted* ContinuedFractionReal$^{\uparrow}$ *carrier $F = (A, C, D, W, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContinuedFractionReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed continued-fraction prefix, convergent table, dyadic tolerance ledger, finite windows, regular rational handoff, Real seal, transport, replay, provenance, and local naming rows;*
2. *convergent-window exactness, requiring the row C to expose only the convergents indexed by W and sourced by the prefix row A;*
3. *dyadic tolerance compatibility, requiring the ledger D to attach the same finite windows to the same convergent rows before R is available;*
4. *RegSeqRat handoff, requiring every regular rational read to pass through A, C, D, W before reaching R;*
5. *Real seal nonescape, requiring E to remain terminal with respect to A, C, D, W, R and to expose no detached real object;*
6. *transport, replay, provenance, and local-name stability through H, K, P, N.*

No local obligation is stored outside these six rows.

Proof. Carrier admission is projection from Definition 6738.1. The accepted packet displays exactly the finite continued-fraction prefix, convergent table, dyadic tolerance ledger, finite windows, regular handoff, terminal Real seal, and structural rows.

Convergent-window exactness reads A, C, W together. The convergent table is not a separate infinite expansion; it lists only the numerator, denominator, normalized rational, and finite-index rows selected by the displayed window.

Dyadic tolerance compatibility then reads D over the same finite windows. The dyadic ledger supplies the radius and endpoint budget consumed by the regular rational row R, so no uninspected convergent tail or hidden precision source is available.

The handoff and seal are ordered by the carrier. The row R is downstream of A, C, D, W, and the row E is downstream of R.

Finally H, K, P, N transport, replay, source, and name only this displayed route. Since the carrier has no coordinate for quotient real equality, trichotomy, countable choice, selected limits, infinite selectors, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6738.3 (ContinuedFractionReal convergent handoff)**.** *Every real-facing read of an accepted* ContinuedFractionReal$^{\uparrow}$ *carrier passes through the finite continued-fraction prefix and convergent table before it reaches* RegSeqRat$^{\uparrow}$*. In particular, the displayed route is*

$$A \longmapsto C \longmapsto D, W \longmapsto R \longmapsto E.$$

The consumer receives finite partial-quotient data, convergent numerator and denominator rows, dyadic tolerance rows, finite windows, regular rational readback, and a terminal Real seal; it receives no selected infinite expansion or quotient-real representative.

Proof. Start from an accepted carrier $F = (A, C, D, W, R, E, H, K, P, N)$. The only continued-fraction source row is A, and the only convergent-table row is C.

The handoff row R is downstream of C, D, W. Thus a real-facing consumer must first read the finite prefix and its convergent table, then the dyadic tolerance and window rows that license the regular rational readback.

The terminal row E is available only after R. The structural rows preserve the same route under hsame, Cont, Pkg, and local naming, so the read cannot bypass the finite-prefix and convergent-table boundary. □

Theorem 6738.4 (ContinuedFractionReal seal nonescape)**.** *An accepted* ContinuedFractionReal$^{\uparrow}$ *packet exports no infinite continued-fraction selector, quotient real equality, trichotomy, countable choice, selected limit, or ambient* Real$^{\uparrow}$ *completeness. Every exported read factors through* $A, C, D, W, R, E, H, K, P, N$.

Proof. Project the carrier rows. The visible surface is exactly $A, C, D, W, R, E, H, K, P, N$, and each row is finite BEDC data.

The excluded principles require an off-packet coordinate: an infinite selector, an equality quotient, a trichotomy branch, a choice schedule, a chosen limiting object, or an ambient completeness theorem. None is present in the classifier or the provenance row.

Therefore transport and replay preserve only the displayed finite route. The terminal Real seal can expose the regular rational readback boundary, but it cannot export any of the excluded completed-real or choice-theoretic data. □

Lean4 (statement) `BEDC.Derived.ContinuedFractionRealUp`

Closure status for NameCert$_{\text{ContinuedFractionReal}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{ContinuedFractionReal}^{\uparrow}}$, seed)

Scope closed: Definition 6738.1, Definition 6738.2, Definition 6738.3, and Definition 6738.4 seed the finite continued-fraction real route through ContinuedFraction, convergent-table, DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{ContinuedFractionReal}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.ContinuedFractionRealUp`

Bridge status: none

Not claimed: This chapter does not close infinite continued-fraction selectors, quotient real equality, trichotomy, countable choice, selected limits, ambient Real$^{\uparrow}$ completeness, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convergent-window exactness, dyadic tolerance compatibility, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContinuedFractionRealUp.

Constructive story: A ContinuedFractionReal$^{\uparrow}$ packet is generated from a ContinuedFraction finite-prefix row, a convergent-table row, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat handoff, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6739

A Concrete Naming Certificate for $\mathsf{LatinSquare}^{\uparrow}$

Following Euler and standard design theory, the $\mathsf{LatinSquare}^{\uparrow}$ packet records the finite carrier for a Latin square by naming the row, column, and symbol incidences rather than by importing a host array object. It sits beside the finite permutation surface of chapter 116 and the row-column readback surface of chapter 49: permutations certify the row and column symbol ledgers, while matrix rows supply the finite rectangular inspection window.

Definition 6739.1 (Latin-square carrier)**.** *A* $\mathsf{LatinSquare}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, C, S, A, P_r, P_c, H, T, G, N)$$

with the following displayed rows:

1. *R is the finite row-index window.*
2. *C is the finite column-index window.*
3. *S is the finite symbol row, with one displayed symbol entry for each visible row-column coordinate.*
4. *A is the matrix readback row over* $\mathsf{Mat}^{\uparrow}$*, recording that the visible entries are read only through the displayed row and column windows.*
5. *P_r is the row-permutation ledger: for each displayed row, the symbols across the visible columns are certified by a* $\mathsf{Permutation}^{\uparrow}$ *row.*
6. *P_c is the column-permutation ledger: for each displayed column, the symbols across the visible rows are certified by a* $\mathsf{Permutation}^{\uparrow}$ *row.*
7. *H records componentwise* hsame *transport for row indices, column indices, symbol entries, matrix readback, row permutations, column permutations, replay, provenance, and local naming.*
8. *T records displayed* Cont *replay from a Latin-square inspection request through $R, C, S, A, P_r, P_c, H, G, N$.*
9. *G is the* Pkg *provenance over* $\mathsf{LatinSquare}^{\uparrow}$*,* $\mathsf{Permutation}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LatinSquare}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for an infinite design, an ambient quasigroup law, an arbitrary relabeling choice, or a host matrix equality principle.

Theorem 6739.2 (Latin-square NameCert obligations)**.** *For every accepted* $\mathsf{LatinSquare}^{\uparrow}$ *carrier* $L = (R, C, S, A, P_r, P_c, H, T, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LatinSquare}^{\uparrow}}$ *surface is exhausted by finite row-index admission, finite column-index admission, symbol-entry admission, matrix readback through* $\mathsf{Mat}^{\uparrow}$*, row-permutation ledgers, column-permutation ledgers, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The packet exports no ambient quasigroup operation, no infinite design axiom, no selected relabeling outside the displayed permutation rows, and no host matrix equality theorem.*

Proof. Project the carrier of Definition 6739.1. The rows R, C, S, A provide the finite inspection window and the displayed symbol entries.

Next read the two permutation ledgers. The row ledger P_r certifies that each displayed row sees the symbol row as a permutation, and the column ledger P_c certifies the same condition columnwise. Both ledgers are finite $\mathsf{Permutation}^{\uparrow}$ rows attached to the visible $\mathsf{Mat}^{\uparrow}$ readback.

Finally use H, T, G, N. These rows transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for a host quasigroup law, infinite design principle, arbitrary relabeling, or ambient matrix equality, the listed obligations exhaust the NameCert surface. □

Theorem 6739.3 (Latin-square row-column-symbol route)**.** *Every consumer of an accepted* $\mathsf{LatinSquare}^{\uparrow}$ *packet must read the finite route*

$$R, C, S, A, P_r, P_c, H, T, G, N$$

before using any Latin-square incidence. The row and column windows are inspected through the $\mathsf{Mat}^{\uparrow}$ *row* A*, the symbol uniqueness reads are inspected through the* $\mathsf{Permutation}^{\uparrow}$ *ledgers* P_r *and* P_c*, and the exported result is only the finite row-column-symbol route named by the local* $\mathsf{NameCert}_{\mathsf{LatinSquare}^{\uparrow}}$ *surface.*

Proof. Start from Definition 6739.2. It makes the row, column, symbol, matrix, and permutation rows the visible surface of every accepted carrier.

The sibling dependencies then fix the two read directions. The $\mathsf{Mat}^{\uparrow}$ row supplies the finite rectangular address space, while the two $\mathsf{Permutation}^{\uparrow}$ ledgers certify that rows and columns each display the same finite symbol row without repetition.

Transport and replay preserve exactly this route. Thus a downstream design-theory or finite-combinatorics consumer receives the displayed finite packet and cannot replace it by an ambient quasigroup law, a hidden relabeling, or a host matrix equality theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LatinSquare}^{\uparrow}}$.

Constructive story: A $\mathsf{LatinSquare}^{\uparrow}$ packet is generated from finite row-index windows, finite column-index windows, symbol-entry rows, MatrixUp readback, row and column PermutationUp ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LatinSquare}^{\uparrow}}$, seed)

Scope closed: Definition 6739.1, Definition 6739.2, and Definition 6739.3 seed the finite row-column-symbol carrier over displayed $\mathsf{Permutation}^{\uparrow}$ and $\mathsf{Mat}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LatinSquare}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close orthogonal arrays, block designs, quasigroup isotopy, completion of partial Latin squares, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row-index and column-index exactness, symbol-entry exactness, row-permutation and column-permutation ledger coverage, matrix readback, transport, replay, provenance, and local naming for BEDC.Derived.LatinSquareUp.

Chapter 6740

A Concrete Naming Certificate for $\mathsf{MayerVietorisSequence}^{\uparrow}$

Following Mayer–Vietoris and the Eilenberg–Steenrod exactness discipline, the $\mathsf{MayerVietorisSequence}^{\uparrow}$ packet records the finite boundary-route surface needed to read the classical decomposition sequence as BEDC NameCert data. It sits beside the homology carrier of chapter 98, the cohomology substrate of chapter 99, and the simplicial-complex rows of chapter 238. The packet names cover, intersection, inclusion, boundary, connecting-map, transport, replay, provenance, and local naming rows; it does not assert full exactness beyond the displayed finite rows, excision as a global theorem, selected chain representatives, quotient homology equality, or ambient topological choice.

Definition 6740.1 (Mayer–Vietoris sequence carrier)**.** *A* $\mathsf{MayerVietorisSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, U, V, I, A, B, C, D, \Delta, S, H, R, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{SimplicialComplex}^{\uparrow}$ *or homology-facing source row.*
2. *U, V are the two named subcomplex or subspace rows whose union is read only as a displayed cover ledger.*
3. *I is the intersection row $U \cap V$ with its own finite carrier and membership ledger.*
4. *A, B, C are the* $\mathsf{Homology}^{\uparrow}$ *rows for I, $U \oplus V$, and X at the inspected degree window.*
5. *D records the inclusion-induced maps from I into U and V, with the sign convention exposed as finite boundary data.*
6. *Δ is the connecting-boundary row from the inspected X-homology window to the preceding intersection window.*
7. *S is the finite sequence ledger listing the displayed row order*

$$A \longmapsto B \longmapsto C \longmapsto \Delta.$$

8. *H records componentwise* hsame *transport for cover, intersection, homology, inclusion, boundary, sequence, provenance, and local naming rows.*
9. *R records displayed* Cont *replay for consumers that ask for the same finite boundary route.*

10. *P is the* Pkg *provenance over* $\mathsf{MayerVietorisSequence}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MayerVietorisSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for unrestricted exactness, excision outside the displayed cover, selected cycles, quotient homology representatives, host set equality, or ambient topological choice.

Lean4 ✓ `BEDC.Derived.MayerVietorisSequenceUp.MayerVietorisSequenceTasteGate single carrier alignment`

Theorem 6740.2 (Mayer–Vietoris sequence NameCert obligations)**.** *For every accepted* $\mathsf{MayerVietorisSequence}^{\uparrow}$ *carrier $M = (X, U, V, I, A, B, C, D, \Delta, S, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MayerVietorisSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the ambient source X, cover rows U, V, intersection row I, homology rows A, B, C, inclusion-boundary row D, connecting row Δ, sequence ledger S, componentwise transport H, displayed replay R, provenance P, and local naming N. A consumer may read finite boundary-route obligations from these rows, but it receives no full long exact sequence principle beyond the displayed inspected window.*

Proof. Project the carrier of Definition 6740.1. The cover, intersection, homology, inclusion, connecting, sequence, transport, replay, provenance, and naming rows are the only coordinates available to the packet.

The finite boundary route is then read through A, B, C, D, Δ, S. The ledger S fixes the inspected order, while D and Δ expose only the inclusion and connecting-boundary data displayed for that window.

Finally use the structural rows H, R, P, N. They preserve, replay, source, and name the same finite packet, so the local certificate cannot export unrestricted exactness, global excision, selected representatives, quotient equality, host set equality, or ambient topological choice. □

Theorem 6740.3 (Mayer–Vietoris boundary handoff)**.** *Every downstream exact-sequence, homology, or cohomology consumer of an accepted* $\mathsf{MayerVietorisSequence}^{\uparrow}$ *packet must read the displayed boundary route*

$$I, U, V, X \longmapsto A, B, C, D, \Delta, S$$

before it may consume the structural rows H, R, P, N. The handoff supplies finite inclusion and connecting-boundary obligations for the inspected row window, not full exactness of all degrees, excision outside the named cover, selected chain representatives, quotient homology equality, or an ambient topological model.

Proof. Begin with the NameCert obligations of Definition 6740.2. They force every consumer to read the cover rows U, V, the intersection row I, and the ambient row X before the homology sequence ledger is inspected.

The boundary data are then exposed by D, Δ, S. These rows record the inclusion maps, sign convention, connecting boundary, and finite sequence order for the displayed window only.

It remains to pass the route to downstream consumers. The transport and replay rows H, R preserve the displayed boundary route, while P, N source and name it. Since no other coordinate is present, the handoff cannot provide full long exactness, global excision, selected representatives, quotient equality, or host topological data. □

Closure status for $\mathsf{NameCert}_{\mathsf{MayerVietorisSequence}^{\uparrow}}$.

Constructive story: A MayerVietorisSequence$^{\uparrow}$ packet is generated from an ambient simplicial or homology source row, two cover rows, an intersection row, homology rows, inclusion-boundary rows, a connecting-boundary row, a finite sequence ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MayerVietorisSequence}^{\uparrow}}$, seed)

Scope closed: Definition 6740.1, Definition 6740.2, and Definition 6740.3 seed the finite boundary-route NameCert surface for Mayer–Vietoris sequence packets over homology and simplicial-complex rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MayerVietorisSequence}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.MayerVietorisSequenceUp.MayerVietorisSequenceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim full exactness beyond displayed rows, global excision, selected cycles, quotient homology equality, host set equality, or bridge checking.

Upgrade path: Obligation closure requires checked cover, intersection, homology, inclusion, connecting-boundary, sequence-ledger, transport, replay, provenance, and local naming rows for BEDC.Derived.MayerVietorisSequenceUp.

Chapter 6741

A Concrete Naming Certificate for $\mathsf{RealLineOrderTopology}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{RealLineOrderTopology}^{\uparrow}$ packet names the finite open-interval topology surface induced by the displayed $\mathsf{Real}^{\uparrow}$ order classifier. It consumes the endpoint and seal rows of chapter 38, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the endpoint-cell boundary of chapter 394. The chapter records only a finite open-interval basis boundary; it does not assert trichotomy, open-cover compactness, quotient real equality, selected points, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6741.1 (Real line order-topology carrier)**.** *A* $\mathsf{RealLineOrderTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T_{\mathsf{Real}} = (E, O, S, Q, D, A, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite endpoint row. Each endpoint is read as a* $\mathsf{Real}^{\uparrow}$ *order-classifier boundary together with the adjacent* $\mathsf{LocatedInterval}^{\uparrow}$ *cell in which the endpoint is inspected.*
2. *O is the open-interval probe row. A probe records a finite request of the form (a, b, w), where a and b are displayed endpoint names and w is the inspected finite window.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row attached to every endpoint and interval probe.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained endpoint windows and probe windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare endpoint windows and to bound the open-interval probe.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after E, O, S, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for endpoint rows, open-interval probes, windows, readbacks, dyadic tolerances, the Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an endpoint request through the finite open-interval probe, the window row, the readback row, the dyadic tolerance row, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrderTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrderTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, O, S, Q, D, A, H, C, P, N$. The carrier has no coordinate for trichotomy, open-cover compactness, quotient real equality, selected points, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6741.2 (Real line order-topology NameCert obligations)**.** *For an accepted* $\mathsf{RealLineOrderTopology}^{\uparrow}$ *carrier* $T_{\mathsf{Real}} = (E, O, S, Q, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLineOrderTopology}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *endpoint admission for the displayed* $\mathsf{Real}^{\uparrow}$ *order-classifier endpoints and the adjacent* $\mathsf{LocatedInterval}^{\uparrow}$ *cells;*
2. *open-interval probe admission for the finite requests in O;*
3. *finite-window and readback admission through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*;*
4. *dyadic tolerance admission through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before any endpoint comparison is replayed;*
5. *Real-seal admission through A after the endpoint, probe, window, readback, and tolerance rows have been displayed;*
6. *structural preservation by H, C, P, N;*
7. *non-escape for trichotomy, open-cover compactness, quotient real equality, selected points, host real equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6741.1. The finite packet displays exactly the endpoint row, open-interval probe row, window row, readback row, dyadic tolerance row, Real seal, and structural rows.

The interval-topology part is read next. An open-interval probe in O is admitted only with endpoint data from E, and those endpoint rows are the same Real and located-interval rows cited in the carrier. Thus the topology surface is generated by displayed open intervals rather than by an ambient open-set lattice.

The numerical part is finite. The rows S, Q, D provide inspected windows, regular rational readback, and dyadic tolerance bounds before A can be read as a Real seal.

Finally H, C, P, N preserve, replay, source, and name the same route. Since the excluded principles have no carrier coordinate, the local certificate cannot export them as obligations. □

Theorem 6741.3 (Real line open-interval basis)**.** *Every accepted* $\mathsf{RealLineOrderTopology}^{\uparrow}$ *packet presents its topology-facing read as a finite open-interval basis generated from the rows*

$$E, O, S, Q, D, A, H, C, P, N.$$

A downstream $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer may inspect the basis only by first reading the displayed* $\mathsf{Real}^{\uparrow}$ *endpoints,* $\mathsf{LocatedInterval}^{\uparrow}$ *cell boundary,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances. The basis exports no trichotomy, open-cover compactness, quotient real equality, selected point, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 6741.1. The only topology-facing row is O, and it is a finite list of open-interval probes attached to endpoint rows E.

Read the endpoint route. The endpoints are sealed as $\mathsf{Real}^{\uparrow}$ rows and inspected through the located interval cells already named by chapter 394. They do not arrive as host real points or quotient classes.

Read the finite numerical route. The rows S, Q, D supply windows, regular rational readbacks, and dyadic tolerances for the interval probes before the Real seal A is available.

The structural rows H, C, P, N keep the same finite route under transport, replay, provenance, and local naming. Therefore any metric-space or continuous-map consumer receives a finite open-interval basis, not a classical topology with the excluded principles attached. □

Theorem 6741.4 (Real line order-topology Real-seal nonescape)**.** *In every accepted* $\mathsf{RealLineOrderTopology}^{\uparrow}$ *carrier* $T_{\mathsf{Real}} = (E, O, S, Q, D, A, H, C, P, N)$*, the Real seal* A *is downstream of the endpoint row* E*, the open-interval probe row* O*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*. Reading* A *cannot produce trichotomy, open-cover compactness, quotient real equality, selected points, host real equality, or completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with the carrier definition. The row A is listed as the terminal $\mathsf{Real}^{\uparrow}$ seal reached only after E, O, S, Q, D have been displayed.

Apply the NameCert obligations of Definition 6741.2. They force endpoint admission, open-interval probe admission, finite-window readback, and dyadic tolerance admission before the Real-seal row is inspected.

The open-interval basis theorem, Definition 6741.3, keeps every topology-facing consumer on that same displayed route. Thus a read of A remains attached to finite endpoint, interval, window, readback, and tolerance data.

The carrier has no row for the excluded principles. Consequently the terminal Real seal cannot be used to export trichotomy, open-cover compactness, quotient real equality, selected points, host equality, or $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: If a Real-line topology consumer reads an open set without displaying endpoint rows, finite open-interval probes, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, and the Real seal, it is not a $\mathsf{RealLineOrderTopology}^{\uparrow}$ packet.

Independence witness: real, streamname, regseqrat, dyadicratcore, locatedinterval: the packet is not bijective to any sibling because it binds endpoint rows, finite open-interval probes, window-readback tolerances, the Real seal, transport, replay, provenance, and local naming as one topology-facing boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrderTopology}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealLineOrderTopology}^{\uparrow}$ packet is generated from finite Real endpoint rows, open-interval probes, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, a terminal Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrderTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6741.1, Definition 6741.2, and Definition 6741.3 seed the finite order-topology boundary for Real-line consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrderTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, open-cover compactness, quotient real equality, selected points, host real equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-interval probe admission, finite-window readback, dyadic tolerance admission, Real-seal nonescape, and structural preservation for BEDC.Derived.RealLineOrderTopologyUp.

Chapter 6742

A Concrete Naming Certificate for $\mathsf{UltrametricBaireTheorem}^{\uparrow}$

Following Baire and Oxtoby, the $\mathsf{UltrametricBaireTheorem}^{\uparrow}$ packet records the complete-ultrametric Baire theorem as finite BEDC NameCert data. It sits over the complete-ultrametric carrier of chapter 3879, the dense-open schedule of chapter 1542, the common-prefix ultrametric route of chapter 3485, the complete-metric service of chapter 128, the finite observation windows of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite route by which a complete ultrametric dense-open construction is exposed to theorem consumers; it does not assert a host intersection object, a selected branch, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness outside the displayed route.

Definition 6742.1 (Ultrametric Baire theorem carrier)**.** *An* $\mathsf{UltrametricBaireTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, U, V, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open schedule row, listing the finite dense-open requests and predecessor-ball refinements visible to the theorem route.*
2. *U is the* $\mathsf{CompleteUltrametric}^{\uparrow}$ *source row, exposing the complete non-Archimedean Cauchy service consumed by the construction.*
3. *V is the* $\mathsf{BaireUltrametric}^{\uparrow}$ *finite common-prefix ultrametric row, binding the displayed cylinders to the ultrametric comparison route.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row, recording the complete-metric service read by consumers that only know the metric interface.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected centers, radii, and dense-open requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed rational tolerances.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal for the radius and limit-name reads exposed by the route.*
8. *H records componentwise* hsame *transport for all displayed rows.*
9. *C records displayed* Cont *replay from the dense-open request through the complete-ultrametric and finite-window rows.*

10. *P is the* Pkg *provenance over* $\mathsf{UltrametricBaireTheorem}^{\uparrow}$, $\mathsf{CompleteUltrametric}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{BaireUltrametric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UltrametricBaireTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for countable choice, a selected generic point, quotient equality of streams, host intersection of dense opens, spherical completeness, or open-cover compactness.

Theorem 6742.2 (Ultrametric Baire theorem NameCert obligations)**.** *For every accepted* UltrametricBaireTheorem *carrier $T = (B, U, V, M, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UltrametricBaireTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed dense-open schedule, complete-ultrametric source, common-prefix ultrametric route, complete-metric handoff, finite stream windows, regular-rational readback, terminal real seal, componentwise transport, displayed replay, package provenance, and local naming. Every theorem-level consumer must read the route through those rows before treating the complete-ultrametric Baire argument as public.*

Proof. Project the carrier of Definition 6742.1. The dense-open schedule is read from B, the complete-ultrametric source from U, the common-prefix ultrametric route from V, and the complete-metric interface from M.

The finite observation and tolerance data are then read through S, R, E. These rows expose the stream windows, regular-rational tolerances, and real-name seal without adding a selected branch or a host intersection object.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier lists no coordinate for countable choice, quotient stream equality, spherical completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the NameCert surface is exhausted by the displayed rows. □

Lean4 (statement) `BEDC.Derived.UltrametricBaireTheoremUp`

Falsifiable prediction: Every accepted $\mathsf{UltrametricBaireTheorem}^{\uparrow}$ read factors through $\mathsf{CompleteUltrametric}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{BaireUltrametric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows before any theorem-level complete-ultrametric Baire consumer receives the route.

Independence witness: complete-ultrametric, bairecategory, baire-ultrametric, completemetric, streamname, regseqrat, real: $\mathsf{UltrametricBaireTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the dense-open schedule, complete-ultrametric source, common-prefix ultrametric route, complete-metric handoff, finite windows, rational readback, real seal, transport, replay, provenance, and local naming as one theorem packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UltrametricBaireTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{UltrametricBaireTheorem}^{\uparrow}$ packet is generated from a BaireCategory dense-open schedule, a CompleteUltrametric source row, a BaireUltrametric common-prefix route, a CompleteMetric handoff, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UltrametricBaireTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 6742.1 and Definition 6742.2 seed the complete-ultrametric Baire theorem carrier and its finite NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UltrametricBaireTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, countable choice, a selected generic point, quotient stream equality, host dense-open intersection, spherical completeness, open-cover compactness, ambient Real completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exactness, complete-ultrametric source exposure, common-prefix route stability, finite-window readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.UltrametricBaireTheoremUp.

Chapter 6743

A Concrete Naming Certificate for $\mathsf{AsplundSpace}^{\uparrow}$

Following Asplund and the standard Banach-space theory of separable dual restrictions, the $\mathsf{AsplundSpace}^{\uparrow}$ packet records the finite BEDC surface by which a Banach carrier exposes separable-subspace dual witnesses without importing a host dual-space theorem. It sits over the Banach-space surface of **??**, the norm row of chapter 89, the vector-space source of chapter 47, the functional-analysis handoff of chapter 94, and the terminal real-name seal of chapter 38. The packet names a finite Asplund interface for downstream weak compactness, differentiability, and dual-separability consumers; it does not choose all separable subspaces, construct a global dual object, quotient functionals, assert Radon–Nikodym differentiability, or import a host weak topology.

Definition 6743.1 (Asplund space carrier)**.** *An* $\mathsf{AsplundSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, V, N, F, S, D, R, T, C, P, L)$$

with the following displayed rows:

1. *B is the* $\mathsf{BanachSpace}^{\uparrow}$ *carrier row, exposing the accepted complete normed vector-space source inspected by the packet.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row for the vector operations visible inside the accepted Banach carrier.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row recording the norm observations and comparison ledgers used by separable-subspace reads.*
4. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *route row binding bounded-linear-functional requests to the same Banach, vector, and norm source.*
5. *S is the separable-subspace window row, carrying only the finite named subspace probes and dense-window requests currently under inspection.*
6. *D is the separable-dual witness row, recording the finite dual-probe windows read from S through F.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for norm and functional-value comparisons reached after B, V, N, F, S, D have been displayed.*
8. *T records componentwise* hsame *transport for Banach, vector, norm, functional-analysis, separable-window, dual-witness, Real-seal, and local certificate rows.*

9. *C records displayed* Cont *replay from Asplund-space requests through the same finite rows.*
10. *P is the* Pkg *provenance over* $\mathsf{AsplundSpace}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{AsplundSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host dual Banach space, quotient functionals, all separable subspaces, weak-star compactness, differentiability theorems, selected dense sequences, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6743.2 (Asplund space NameCert obligations)**.** *For every accepted* $\mathsf{AsplundSpace}^{\uparrow}$ *carrier*

$$A = (B, V, N, F, S, D, R, T, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{AsplundSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{BanachSpace}^{\uparrow}$ *row B,* $\mathsf{VecSpace}^{\uparrow}$ *row V,* $\mathsf{Norm}^{\uparrow}$ *row N,* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *route F, separable-subspace window S, separable-dual witness row D, terminal* $\mathsf{Real}^{\uparrow}$ *seal R, componentwise transport T, displayed replay C, provenance P, and local naming L. Every Asplund consumer must read separable-dual data through those rows and cannot import a host dual space, a quotient functional universe, a selected dense sequence, a global weak topology, Radon–Nikodym differentiability, or ambient real completeness.*

Proof. Project the carrier of Definition 6743.1. The accepted Banach, vector, and norm source is exactly B, V, N, so the packet has no independent host-space coordinate.

Next read the functional-analysis and separable-dual surface through F, S, D. These rows bind every dual-facing request to the displayed separable-subspace window before the terminal Real seal can be consumed.

Finally attach R, T, C, P, L. They seal, transport, replay, source, and name only the displayed rows, which leaves no route to a host dual Banach space, quotient functionals, selected dense sequences, weak-star compactness, differentiability theorems, or ambient real completeness. □

Theorem 6743.3 (Asplund separable dual route)**.** *Every separable-dual consumer of an accepted* $\mathsf{AsplundSpace}^{\uparrow}$ *carrier must first expose the finite route*

$$\mathsf{BanachSpace}^{\uparrow} \longrightarrow \mathsf{VecSpace}^{\uparrow} \longrightarrow \mathsf{Norm}^{\uparrow} \longrightarrow \mathsf{FunctionalAnalysis}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the rows $B, V, N, F, S, D, R, T, C, P, L$ of Definition 6743.1. The route is a displayed separable-subspace dual witness surface, not a global dual-space construction, quotient-functional equality, selected dense sequence, weak compactness theorem, differentiability theorem, or host Banach-space theorem.

Proof. Start from Definition 6743.2. It places B, V, N, F before the separable-subspace window and dual-witness rows can be inspected.

The rows S and D then localize the dual read to the named finite subspace window. The terminal Real seal R records only norm and functional-value comparisons coming from that window.

The structural rows T, C, P, L preserve this same route. Since no carrier coordinate names all separable subspaces, a host dual object, quotient equality of functionals, selected dense sequences, weak compactness, or differentiability, the separable-dual route exports only the displayed NameCert packet. □

Falsifiable prediction: Every accepted $\mathsf{AsplundSpace}^{\uparrow}$ separable-dual read factors through displayed $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, separable-window, separable-dual witness, $\mathsf{Real}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before any downstream weak-compactness or differentiability consumer output is visible.

Independence witness: banachspace, vecspace, norm, functionalanalysis, real: none of the listed siblings alone is bijective with $\mathsf{AsplundSpace}^{\uparrow}$ because the packet jointly carries a Banach source, vector operations, norm reads, functional-analysis routing, separable-subspace windows, separable-dual witnesses, a terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AsplundSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{AsplundSpace}^{\uparrow}$ packet is generated from BanachSpace carrier rows, VecSpace operation rows, Norm comparison rows, FunctionalAnalysis handoff rows, finite separable-subspace windows, separable-dual witness rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AsplundSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6743.1, Definition 6743.2, and Definition 6743.3 seed the finite Asplund-space NameCert surface over displayed Banach, vector, norm, functional-analysis, separable-window, dual-witness, real-seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AsplundSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host dual Banach space, quotient functionals, all separable subspaces, selected dense sequences, weak compactness, differentiability, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Banach-space exposure, vector and norm routing, functional-analysis handoff, separable-subspace window exactness, separable-dual witness readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.AsplundSpaceUp.

Chapter 6744

A Concrete Naming Certificate for CompactUniformEquicontinuityImage$^{\uparrow}$

Following Heine–Cantor and Arzela–Ascoli finite-net arguments, the CompactUniformEquicontinuityImage$^{\uparrow}$ packet records the image-side NameCert surface for compact metric sources whose continuous or equicontinuous family rows transport finite nets into uniformly controlled image windows. It realizes the compact-uniform-continuity vision of chapter 9237 through the compact-metric source of chapter 129, the total-boundedness finite-net row of chapter 127, the uniform-continuity handoff of chapter 391, the continuous-map rows of chapter 130, the equicontinuity surface of chapter 4076, and the terminal real-name seal of chapter 38. The packet names finite-net image transport; it does not assert open-cover compactness, selected image covers outside the displayed net, quotient equality of maps, a host compact-image theorem, or ambient Real$^{\uparrow}$ completeness.

Definition 6744.1 (Compact uniform equicontinuity image carrier)**.** *A* CompactUniformEquicontinuityImage$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, T, U, M, E, I, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing the compact metric finite-net data under inspection.*
2. *T is the* TotallyBounded$^{\uparrow}$ *finite-net row read from the same compact source.*
3. *U is the* UniformContinuity$^{\uparrow}$ *modulus row for the image request.*
4. *M is the* ContinuousMap$^{\uparrow}$ *graph row whose values are transported along the finite net.*
5. *E is the* Equicontinuity$^{\uparrow}$ *family row when the image request is family-level rather than single-map.*
6. *I is the image-window row, recording the finite list of target values and radius ledgers obtained from K, T, U, M, E.*
7. *R is the terminal* Real$^{\uparrow}$ *seal for source radii, target radii, and image-window comparisons.*
8. *H records componentwise* hsame *transport for compact source, total-bounded finite net, uniform-continuity, continuous-map, equicontinuity, image-window, Real-seal, and local certificate rows.*
9. *C records displayed* Cont *replay from image requests through the same finite rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an open-cover compactness proof, a selected external image cover, quotient equality of maps, a host Arzela–Ascoli theorem, global compact-image closure, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6744.2 (Compact uniform equicontinuity image NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}$ *carrier*

$$Q = (K, T, U, M, E, I, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{CompactMetric}^{\uparrow}$ *source row K,* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row T,* $\mathsf{UniformContinuity}^{\uparrow}$ *modulus row U,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row M,* $\mathsf{Equicontinuity}^{\uparrow}$ *family row E, image-window row I, terminal* $\mathsf{Real}^{\uparrow}$ *seal R, componentwise transport H, displayed replay C, provenance P, and local naming N. Every image consumer must read finite-net transport through those rows and cannot import open-cover compactness, selected image covers, quotient equality of maps, host compact-image closure, Arzela–Ascoli compactness, or ambient real completeness.*

Proof. Project the carrier of Definition 6744.1. The compact source and finite net are exactly K, T, so image transport starts from displayed compact-metric and total-bounded rows.

Next read the map control through U, M, E. The uniform-continuity row, continuous-map graph row, and optional family equicontinuity row are the only routes by which source-net radii become image-window radii.

Finally attach I, R, H, C, P, N. These rows record, seal, transport, replay, source, and name the finite image window, leaving no route to open-cover compactness, selected external image covers, quotient map equality, host compact-image closure, Arzela–Ascoli compactness, or ambient real completeness. □

Theorem 6744.3 (Compact finite-net image handoff)**.** *Every image-window consumer of an accepted* $\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}$ *carrier must first expose the sibling route*

$$\mathsf{CompactMetric}^{\uparrow} \longrightarrow \mathsf{TotallyBounded}^{\uparrow} \longrightarrow \mathsf{UniformContinuity}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

and, for family requests, the $\mathsf{Equicontinuity}^{\uparrow}$ *row as well. The handoff is a finite-net image packet over $K, T, U, M, E, I, R, H, C, P, N$, not an open-cover compactness proof, selected image cover, quotient-map equality, host compact-image theorem, or ambient Arzela–Ascoli closure.*

Proof. Start from Definition 6744.2. It places compact metric data K and total-bounded finite-net data T before any image-window row can be read.

The control rows U, M, E then transport finite source nets into target image windows. The row I records the displayed image centers and radius ledgers, and R supplies only the terminal Real comparisons attached to those ledgers.

The structural rows H, C, P, N preserve the same handoff. Since the carrier contains no open-cover proof, external image-cover selector, quotient equality of maps, host compact-image theorem, or Arzela–Ascoli compactness coordinate, the consumer receives exactly the finite-net image NameCert packet. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}$ image read factors through displayed $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, image-window, $\mathsf{Real}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before a downstream compact-image or Arzela–Ascoli consumer output is visible.

Independence witness: compactmetric, totallybounded, uniformcontinuity, continuousmap, equicontinuity, real: none of the listed siblings alone is bijective with $\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}$ because the packet jointly carries a compact metric source, finite-net schedule, uniform-continuity modulus, continuous-map graph row, family equicontinuity row, image-window ledger, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}$ packet is generated from CompactMetric finite-net source rows, TotallyBounded schedules, UniformContinuity modulus rows, ContinuousMap graph rows, Equicontinuity family rows, finite image-window ledgers, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6744.1, Definition 6744.2, and Definition 6744.3 seed the finite-net image transport surface over compact source, total-bounded, uniform-continuity, continuous-map, equicontinuity, image-window, real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected image covers, quotient equality of maps, host compact-image closure, Arzela–Ascoli compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, total-bounded finite-net routing, uniform-continuity and continuous-map handoff, equicontinuity family routing, image-window exactness, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformEquicontinuityImageUp.

Chapter 6745

A Concrete Naming Certificate for $\mathsf{MoscoRecoverySequence}^{\uparrow}$

Following Mosco and Attouch on variational convergence and recovery sequences, the $\mathsf{MoscoRecoverySequence}^{\uparrow}$ packet records the finite completion-facing witness object that supplies explicit strong recovery data after a Mosco or Gamma convergence surface has exposed its lower-bound side. It sits beside the Mosco convergence certificate of chapter 5938, the Gamma-convergence recovery-window carrier of chapter 5957, the terminal value readback of chapter 38, and the completion handoff of chapter 1506. The packet is a witness ledger for recovery requests; it is not a selected minimizer, a quotient equality of functionals, a global compactness theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6745.1 (Mosco recovery sequence carrier)**.** *A* $\mathsf{MoscoRecoverySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, F, W, A, G, Q, E, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric or completion-facing source row on which the recovery witnesses are inspected.*
2. *F is the variational functional-window row inherited from a Mosco or Gamma convergence read.*
3. *W is the weak-liminf context row that fixes which lower-bound request the recovery witness answers.*
4. *A is the finite approximation schedule row, listing the inspected recovery candidates and their convergence windows.*
5. *G is the strong recovery goal row, recording the target point, admissible support, and upper-bound comparison demanded by the consumer.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *value-readback row for the displayed functional values and tolerance budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the recovery value rows have been exposed.*
8. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row that lets completion-facing consumers read convergence of the displayed approximants without selecting a quotient representative.*
9. *H records componentwise* hsame *transport for X, F, W, A, G, Q, E, M and the local certificate rows.*

10. *C records displayed* Cont *replay from recovery requests through approximation windows, value readback, Real sealing, and completion handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{MoscoRecoverySequence}^{\uparrow}$, $\mathsf{MoscoConvergence}^{\uparrow}$, $\mathsf{GammaConvergence}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MoscoRecoverySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, W, A, G, Q, E, M, H, C, P, N$. It has no coordinate for a host-selected recovery sequence, minimizer existence, quotient equality of functionals, compactness by choice, or ambient completeness of the Real or completion carriers.

Lean4 ✓ `BEDC.Derived.MoscoRecoverySequenceUp.MoscoRecoverySequenceTasteGate single carrier alignment`

Theorem 6745.2 (Mosco recovery sequence NameCert obligations)**.** *For every accepted* $\mathsf{MoscoRecoverySequence}^{\uparrow}$ *carrier*

$$R = (X, F, W, A, G, Q, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MoscoRecoverySequence}^{\uparrow}}$ *surface consists exactly of carrier admission, source exposure through X, functional-window exposure through F, lower-bound context exposure through W, finite approximation scheduling through A, recovery-goal exposure through G, regular rational value readback through Q, terminal real sealing through E, metric-completion handoff through M, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier. The rows X, F, W, A, G, Q, E, M are the only coordinates from which a recovery consumer can read source data, variational windows, the lower-bound context, finite approximants, value budgets, real seals, and completion handoff.

The approximation row A and goal row G provide the explicit witness surface. They are read after the Mosco or Gamma convergence context has been displayed and before completion-facing consumers use M.

Finally attach H, C, P, N. These rows transport, replay, source, and name the same finite packet, so the local NameCert obligations cannot be widened to a selected host recovery sequence, minimizer, quotient functional equality, choice schedule, or ambient completeness theorem. □

Lean4 ✓ `BEDC.Derived.MoscoRecoverySequenceUp.MoscoRecoverySequenceCarrier namecert obligations`

Theorem 6745.3 (Mosco recovery sequence real-metric boundary)**.** *Every completion-facing consumer of an accepted* $\mathsf{MoscoRecoverySequence}^{\uparrow}$ *carrier must read the finite route*

$\mathsf{MoscoConvergence}^{\uparrow}$, $\mathsf{GammaConvergence}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, Nam

through $X, F, W, A, G, Q, E, M, H, C, P, N$ before it treats the recovery witness as a real-valued metric approximation. The boundary supplies explicit recovery witnesses for the convergence surface; it does not assert selected minimizers, quotient equality of functionals, global compactness, countable choice, host equality of completion points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations. They place the finite recovery schedule A and goal row G between the convergence context F, W and the readback rows Q, E, M.

The Real-facing side is read through Q and E. A consumer sees only regular rational value windows and their terminal seal, not an ambient Real completeness theorem or a selected limiting value.

The metric side is read through M after the displayed approximants have been exposed. Transport, replay, provenance, and local naming keep the same rows attached to the packet, so the recovery witness remains an explicit finite object rather than a host-selected sequence or quotient-completion representative. □

Lean4 ✓ `BEDC.Derived.MoscoRecoverySequenceUp.MoscoRecoverySequenceRealMetricBoundary`

Falsifiable prediction: An accepted $\mathsf{MoscoRecoverySequence}^{\uparrow}$ consumer that reaches a real-valued completion approximation without reading $A, G, Q, E, M, H, C, P, N$ refutes the carrier surface.

Independence witness: mosco-convergence, gamma-convergence, metriccompletion, regseqrat, real: $\mathsf{MoscoRecoverySequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a convergence context, explicit finite recovery schedules, recovery goals, rational value readback, Real sealing, metric-completion handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MoscoRecoverySequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MoscoRecoverySequence}^{\uparrow}$ packet is generated from convergence-context rows, finite recovery schedules, recovery-goal rows, RegSeqRat value readback, Real seals, metric-completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MoscoRecoverySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6745.1, Definition 6745.2, and Definition 6745.3 seed the finite recovery-witness route over convergence context, approximation schedule, value readback, Real seal, completion handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MoscoRecoverySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected minimizer existence, quotient equality of functionals, countable choice, global compactness, host equality of completion points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Formalization requires BEDC.Derived.MoscoRecoverySequenceUp carrier admission together with checked recovery scheduling, value readback, completion handoff, transport, replay, provenance, and local naming obligations.

Chapter 6746

A Concrete Naming Certificate for $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$ packet records the unit map that sends a displayed $\mathsf{Real}^{\uparrow}$ point into the Cauchy-filter completion interface as finite BEDC NameCert data. It sits over the real-name seal of chapter 38, the Cauchy-filter carrier of chapter 333, the filter-base rows of chapter 1601, the metric-completion boundary of chapter 1506, the completion universal-property packet of chapter 397, the regular-rational readback of chapter 301, and the finite stream windows of chapter 126. The packet names the monad unit as a displayed point-to-filter route; it does not choose quotient representatives, select limits, import countable choice, assert ambient $\mathsf{Real}^{\uparrow}$ completeness, or identify host filters.

Definition 6746.1 (Real Cauchy-filter monad-unit carrier)**.** *A* $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, F, B, M, E, R, S, H, C, P, N)$$

with the following displayed rows:

1. *A is the source* $\mathsf{Real}^{\uparrow}$ *row, already sealed by displayed regular-rational and stream-window data.*
2. *F is the principal* $\mathsf{CauchyFilter}^{\uparrow}$ *row generated from A through finite neighbourhood observations.*
3. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row exposing the finite neighbourhood base used by the principal filter.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row that receives the Cauchy-filter point as completion-facing data.*
5. *E is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *unit-and-extension row naming the universal-property consumer of the same point.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the real-name source is inspected by rational windows.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the finite windows consumed by R.*
8. *H records componentwise* hsame *transport for $A, F, B, M, E, R, S, C, P, N$.*
9. *C records displayed* Cont *replay from the real point through filter-base, Cauchy-filter, completion, universal-property, readback, and stream-window rows.*

10. *P is the* Pkg *provenance over* $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, F, B, M, E, R, S, H, C, P, N$. It has no coordinate for quotient representatives, selected filter limits, host filter equality, countable choice, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.RealCauchyFilterMonadUnitUp`

Theorem 6746.2 (Real Cauchy-filter monad-unit obligations)**.** *For every accepted* $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$ *carrier*

$$U = (A, F, B, M, E, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Real source, Cauchy-filter row, filter-base row, completion handoff, universal-property row, rational readback, stream schedule, transport, replay, provenance, and local naming;*
2. *principal-filter exposure, requiring the Cauchy-filter row F to be read only through the finite filter-base row B generated from the real point A;*
3. *completion compatibility, requiring the metric-completion row M and universal-property row E to consume the same displayed Cauchy-filter route;*
4. *readback stability, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and* $\mathsf{StreamName}^{\uparrow}$ *row S to remain attached to the source* $\mathsf{Real}^{\uparrow}$ *row before the filter row is exposed;*
5. *structural preservation by H, C, P, N;*
6. *nonescape for quotient representatives, selected limits, host filter equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean theorem verification, and bridge checking.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 6746.1. The Real source is A, the filter-facing rows are F, B, the completion-facing rows are M, E, and the finite readback rows are R, S.

The principal-filter obligation is forced because the carrier has no second filter generator. A consumer reaches F only after the filter-base row B has displayed the finite neighbourhood observations generated from A.

Completion compatibility is rowwise. The metric-completion handoff M and the universal-property row E both consume the same F, B route, so neither can introduce a quotient representative or a selected completion point.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the excluded objects have no carrier coordinate, they cannot become NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RealCauchyFilterMonadUnitUp.RealCauchyFilterMonadUnitTasteGate single carrier alignment`

Theorem 6746.3 (Real Cauchy-filter monad-unit law)**.** *Every accepted* $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$ *packet presents the monad-unit law as the finite route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}, \mathsf{CompletionUniversalProperty}^{\uparrow}.$$

The route sends a displayed real point to its principal Cauchy-filter row and then to the completion interface, while the $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *rows keep the real-name readback visible. It exports no quotient representative, selected limit, host filter equality, countable choice, or ambient completeness principle.*

Proof. Read the carrier coordinates. The source row A is the only Real input, and R, S are the only rational and stream readback rows attached to it.

The filter-base row B generates the principal filter row F. Thus the map from A to F is a displayed unit route rather than a choice of a filter representative.

The completion rows M, E then consume F and B as the same Cauchy-filter handoff. Transport, replay, provenance, and local naming preserve this route, so the monad-unit law is exactly the finite BEDC packet named in the statement. □

Falsifiable prediction: Any claimed $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$ unit that reaches a completion row without displaying the Real source, filter-base row, Cauchy-filter row, regular-rational readback, stream schedule, transport, replay, provenance, and local NameCert rows is rejected by the carrier of Definition 6746.1.

Independence witness: real, cauchyfilter, filterbase, metriccompletion, completionuniversalproperty, regseqrat, streamname: none is bijective with $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$ because only this packet jointly records a Real source, principal filter-base generation, Cauchy-filter handoff, completion-unit consumption, rational readback, finite stream schedule, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}$ packet is generated from a RealUp source row, a principal FilterBaseUp row, a CauchyFilterUp row, MetricCompletionUp and CompletionUniversalPropertyUp handoff rows, RegSeqRatUp readback, StreamNameUp windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6746.1, Definition 6746.2, and Definition 6746.3 seed the finite monad-unit packet from displayed Real points to Cauchy-filter completion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyFilterMonadUnit}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RealCauchyFilterMonadUnitUp`

Bridge status: none

Not claimed: This chapter does not close quotient representatives, selected filter limits, host filter equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, principal-filter exposure, completion compatibility, readback stability, structural preservation, and nonescape for BEDC.Derived.RealCauchyFilterMonadUnitUp.

Chapter 6747

A Concrete Naming Certificate for $\mathsf{ClosedObservationProofTrace}^{\uparrow}$

The $\mathsf{ClosedObservationProofTrace}^{\uparrow}$ packet realizes the finite-observation branch of chapter 9370 as a MetaCIC-facing NameCert object. It records a proof trace only when finite observation rows, termination rows, transport, replay, provenance, local naming, refusal rows, kernel-acceptance rows, and proof-trace rows are displayed together. The packet is not a quotient of proof terms, not a host equality of derivations, not an erasure theorem, and not a divergent computation hidden behind a proof record.

The proof-trace row consumes the finite evaluator of chapter 818 and the kernel acceptance boundary of chapter 6007 before it is replayed. The finite evaluator supplies the closed observation and totality surface, while the kernel acceptance boundary supplies the accepted proof-record row; no closurestatus or TasteGate promotion is made at this dependency handoff.

Definition 6747.1 (Closed observation proof-trace carrier)**.** *A* $\mathsf{ClosedObservationProofTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (O, Q, H, C, P, N, R, K, D)$$

with the following displayed rows:

1. *O is the closed finite-observation row, recording the observed proof-facing object as finite data.*
2. *Q is the termination row, displaying the normal-form or totality evidence required before the trace is accepted.*
3. *H records componentwise* hsame *transport for observation, termination, refusal, kernel, trace, replay, provenance, and local naming rows.*
4. *C records displayed* Cont *replay from observation through termination, kernel acceptance, trace replay, refusal checks, provenance, and local naming.*
5. *P is the* Pkg *provenance over* $\mathsf{ClosedObservationProofTrace}^{\uparrow}$*, closed observation rows, total proof records, kernel acceptance witnesses,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
6. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedObservationProofTrace}^{\uparrow}}$ *row.*
7. *R is the divergence-refusal row, rejecting any reduction row that is not displayed as terminating.*
8. *K is the kernel-acceptance witness row for the total proof record.*
9. *D is the proof-trace row, recording the finite derivation trace that is replayed by C.*

The classifier compares accepted packets only through $O, Q, H, C, P, N, R, K, D$. It has no coordinate for divergent reduction, quotient proof equality, erased proof-term identity, host derivation equality, or an unbounded computation trace.

Lean4 (definition) `BEDC.Derived.ClosedObservationProofTraceUp`

Theorem 6747.2 (Closed observation proof-trace obligations)**.** *For every accepted* $\mathsf{ClosedObservationProofTrace}^{\uparrow}$ *carrier*

$$T = (O, Q, H, C, P, N, R, K, D),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedObservationProofTrace}^{\uparrow}}$ *surface consists exactly of carrier admission for finite observation, termination, componentwise transport, displayed replay, provenance, local naming, divergence refusal, kernel acceptance, and proof-trace rows. The packet admits no proof trace unless Q and R jointly display totality and refusal of divergent reduction before the kernel row K and trace row D are replayed.*

Proof. Project the carrier of Definition 6747.1. The observation row is O, the termination row is Q, the refusal row is R, the kernel row is K, and the trace row is D.

The totality condition is local. A trace can be replayed only after Q displays termination and R rejects the divergent alternative, so a nonterminating reduction row has no route into K or D.

The structural rows H, C, P, N transport, replay, source, and name this finite surface. Since no carrier coordinate stores quotient proof equality, erased proof identity, host derivation equality, or an unbounded computation trace, none becomes a NameCert obligation. □

Theorem 6747.3 (Closed observation proof-trace totality route)**.** *Every accepted* $\mathsf{ClosedObservationProofTrace}^{\uparrow}$ *proof record factors through*

$$O \longmapsto Q, R \longmapsto K, D \longmapsto H, C, P, N.$$

The route exposes finite observation, termination, divergent-row refusal, kernel acceptance, proof-trace replay, transport, provenance, and local naming before a proof record is accepted. It exports no divergent reduction row, quotient proof identity, proof-term erasure equivalence, host derivation equality, or unbounded trace.

Proof. Read the carrier rows. The finite observation row O is the only source row, and Q, R are the only totality and refusal gates.

The kernel row K and proof-trace row D are downstream of those gates. Thus the accepted trace is a total proof record with displayed termination and refusal data, not an erased or quotient proof object.

Finally H, C, P, N preserve the same route. A consumer that asks for an unbounded trace or a divergent reduction row leaves the accepted carrier. □

Falsifiable prediction: Any accepted $\mathsf{ClosedObservationProofTrace}^{\uparrow}$ proof trace with a divergent reduction row is rejected by Definition 6747.1, because the refusal row R and termination row Q must be displayed before kernel acceptance and proof-trace replay.

Independence witness: curryhoward, typecheckingderivationtrace, prooftermerasuretrace, kernelacceptancewitness: the packet is not bijective with any sibling because the obligation rows jointly require finite observation, termination, divergence refusal, kernel acceptance, trace replay, transport, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedObservationProofTrace}^{\uparrow}}$.

Constructive story: A ClosedObservationProofTrace$^{\uparrow}$ packet is generated from finite observation rows, termination rows, divergent-row refusal, kernel acceptance, proof-trace replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ClosedObservationProofTrace}^{\uparrow}}$, seed)

Scope closed: Definition 6747.1, Definition 6747.2, and Definition 6747.3 seed the finite proof-trace packet over total observation records and divergence refusal.

Formal verification: FormalStatus(NameCert$_{\text{ClosedObservationProofTrace}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.ClosedObservationProofTraceUp`

Bridge status: none

Not claimed: This chapter does not close quotient proof equality, proof-term erasure equivalence, host derivation equality, divergent computation rows, Lean theorem verification, or bridge checking.

Upgrade path: The Lean follow-up must provide Nontrivial and FieldFaithful TasteGate instances after carrier admission, totality routing, divergence refusal, kernel acceptance, trace replay, transport, provenance, and local naming are formalized for BEDC.Derived.ClosedObservationProofTraceUp.

Chapter 6748

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailShift}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyTailShift}^{\uparrow}$ packet records the finite tail-window evidence needed to read a regular Cauchy rational sequence after discarding an initial segment. It sits between the regular-rational certificate of chapter 301, the stream-window naming surface of chapter 126, and the terminal real seal of chapter 38. The packet is only a finite means object: it names shifted windows, tolerance rows, transport, replay, provenance, and local naming, and it does not identify quotient real representatives, selected limits, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6748.1 (Regular Cauchy tail-shift carrier)**.** *A* $\mathsf{RegularCauchyTailShift}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, L, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the source stream name, the discarded prefix length, the shifted request window, and the finite overlap witnesses that compare the original and shifted reads.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail row, recording the regular Cauchy rational data visible on both sides of the shift and the tail index from which the two windows are read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the original window, shifted window, overlap comparison, and tail-index budget.*
4. *L is the* $\mathsf{Real}^{\uparrow}$ *seal available only after W, Q, D have all been displayed.*
5. *H records componentwise* hsame *transport for the stream window, regular-rational tail data, dyadic tolerance ledger, real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a shifted-tail request through W, Q, D and then to L, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailShift}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailShift}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through W, Q, D, L, H, C, P, N. It has no coordinate for a selected limit, quotient representative equality, a host sequence equality proof, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailShiftUp.RegularCauchyTailShiftTasteGate single carrier alignment`

Theorem 6748.2 (Regular Cauchy tail-shift NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailShift}^{\uparrow}$ *carrier* $T = (W, Q, D, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailShift}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail data,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It also requires overlap exactness for the original and shifted windows, tail-index stability for the regular rational rows, dyadic tolerance accounting for the finite overlap comparison, and Real seal nonescape for the terminal read.*

Proof. Project the carrier of Definition 6748.1. The rows W, Q, D, L, H, C, P, N are the whole accepted inventory, so every local certificate obligation must read from those rows.

The window and tail obligations are finite. The row W displays the original and shifted stream windows, while Q displays the regular Cauchy rational tail data that both windows consume.

The numerical comparison is read through D. Its dyadic tolerance rows account for the original window, shifted window, overlap comparison, and tail-index budget before the seal L is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier row names selected limits, quotient equality, host sequence equality, or ambient completeness, the certificate cannot export any of those claims. □

Theorem 6748.3 (Regular Cauchy tail-shift RegSeqRat stability)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read that is consumed through an accepted* $\mathsf{RegularCauchyTailShift}^{\uparrow}$ *carrier is stable under the displayed tail shift. For a carrier*

$$T = (W, Q, D, L, H, C, P, N),$$

the consumer must first expose the $\mathsf{StreamName}^{\uparrow}$ *source and shifted windows in* W*, the regular rational tail row* Q*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*. Only then may it read the* $\mathsf{Real}^{\uparrow}$ *seal* L *and the structural rows* H, C, P, N*. Thus the shifted read reaches the same finite Real-facing route as the original tail read, without using selected limits, quotient representative equality, host sequence equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier definition. The window row W records both the original and shifted StreamName windows, and the tail row Q is the only regular rational data available to either read.

Apply the NameCert obligations of Definition 6748.2. Overlap exactness and tail-index stability force the two visible reads to share the same finite tail surface before any Real-facing endpoint is inspected.

The dyadic row D supplies the requested tolerance comparison for the shifted window. Once that comparison is displayed, the seal L and the transport, replay, provenance, and naming rows H, C, P, N preserve the same route.

Because the packet contains no coordinate for selected limits, quotient equality, host sequence equality, or ambient Real completeness, the stability conclusion is only the finite $\mathsf{RegSeqRat}^{\uparrow}$ tail-window stability just described. □

Theorem 6748.4 (Regular Cauchy tail-shift window composition)**.** *Let* $T_0 = (W_0, Q_0, D_0, L_0, H_0, C_0, P_0, N_0)$ *and* $T_1 = (W_1, Q_1, D_1, L_1, H_1, C_1, P_1, N_1)$ *be accepted* $\mathsf{RegularCauchyTailShift}^{\uparrow}$ *packets whose shifted window of* T_0 *is the source window consumed by* T_1*. Then the composed tail-shift read still exposes only the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transports, displayed* Cont *replays,* Pkg *provenance, and local*

NameCert *rows of the two packets. The combined discard length is represented by the finite window row*

$$W_{01} = \mathsf{composeTailWindow}(W_0, W_1).$$

Thus the composite exports a finite shifted-window route and not a selected limit, quotient representative, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project both accepted carriers. The only data available for composition are the source and shifted $\mathsf{StreamName}^{\uparrow}$ rows, the regular rational tail rows, the dyadic tolerance ledgers, and the structural rows displayed by the two packets.

Apply Definition 6748.2 to both packets. The first certificate exposes the shifted window used as the source for the second, and the second certificate exposes the next shifted window over the same finite inventory.

Use Definition 6748.3 on the first shifted read and then again on the second shifted read. The composed window row W_{01} records only the finite discard-length calculation and the visible overlap witnesses.

The Real seals remain downstream of their corresponding W, Q, D rows, and the transport, replay, provenance, and naming rows only preserve the displayed route. Since neither packet contains a selected limit, quotient representative, host sequence equality, or ambient completeness coordinate, the composed route cannot export one. □

Falsifiable prediction: Every $\mathsf{RegularCauchyTailShift}^{\uparrow}$ read factors through StreamName windows, RegSeqRat tail data, a DyadicRatCore tolerance ledger, a Real seal, hsame transport, Cont replay, Pkg provenance, and local naming before a shifted regular-Cauchy tail can be consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyTailShift}^{\uparrow}$ is not bijective to any listed sibling because it binds a discarded-prefix window, regular-rational tail data, dyadic overlap tolerances, Real sealing, transport, replay, provenance, and local naming as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailShift}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailShift}^{\uparrow}$ packet is generated from StreamName source and shifted windows, RegSeqRat tail data, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailShift}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6748.1, Definition 6748.2, and Definition 6748.3 seed the finite tail-shift route used by Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailShift}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyTailShiftUp.RegularCauchyTailShiftTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient representative equality, host sequence equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked window overlap exactness, tail-index stability, dyadic tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailShiftUp.

Chapter 6749

A Concrete Naming Certificate for $\mathsf{BishopCauchyNameSeal}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy reals, the $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ packet records the finite seal object that ties the L10 route from dyadic tolerances to StreamName observations, RegSeqRat readback, and the terminal Real seal. It sits over the dyadic endpoint and tolerance rows of chapter 291, the finite observation interface of chapter 126, the regular rational sequence route of chapter 301, the Real naming boundary of chapter 38, and the Bishop regular Cauchy completion surface of chapter 1639. The packet names the four-object route as a local NameCert seal; it does not assert completeness of $\mathsf{Real}^{\uparrow}$, quotient Cauchy streams, selected limits, countable choice, or host equality of real names.

Definition 6749.1 (Bishop Cauchy name-seal carrier)**.** *A* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger, recording the requested precision rows before any stream observation is read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row whose entries are inspected at the displayed dyadic tolerances.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from D and W.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular readback has been displayed.*
5. *H records componentwise* hsame *transport for D, W, R, E and the local certificate rows.*
6. *C records displayed* Cont *replay of the route from dyadic tolerances through stream observations, regular readback, and the Real seal.*
7. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyNameSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, W, R, E, H, C, P, N. It has no coordinate for quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6749.2 (Bishop Cauchy name-seal four-input visibility)**.** *For every accepted* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *carrier* $S = (D, W, R, E, H, C, P, N)$*, a Real or Completion consumer must expose the four L10 rows*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as D, W, R, E *before the local seal can be read. The packet admits no shortcut from dyadic tolerance requests directly to a Real name, and no StreamName or RegSeqRat read is detached from the same displayed dyadic ledger.*

Proof. Project the carrier coordinates from Definition 6749.1. The only data rows before transport and replay are D, W, R, E.

The tuple order records the dependency route. The finite observation row W reads the dyadic ledger D, the regular readback row R reads D and W, and the terminal seal E is downstream of all three rows.

The structural rows H, C, P, N preserve that route. Since no additional carrier coordinate names a direct Real constructor, a detached stream, or a quotient representative, the four input rows are exactly the visible L10 surface. □

Theorem 6749.3 (Bishop Cauchy name-seal regularity handoff)**.** *Every accepted* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *packet hands finite StreamName observations to the regular rational sequence route only through*

$$D \longmapsto W \longmapsto R.$$

The handoff consumes the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is available.*

Proof. Start with four-input visibility. It fixes D and W as the only rows from which a regular readback can be formed.

Read the regular row R. By the carrier definition, R is attached to the same dyadic tolerance ledger and finite observation window, so a consumer cannot replace W by a host stream or replace D by an unrecorded tolerance schedule.

Transport and replay through H and C move only the displayed rows. The regularity handoff is therefore the finite route $D \longmapsto W \longmapsto R$. □

Theorem 6749.4 (Bishop Cauchy name-seal Real nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *carrier factors through*

$$D \longmapsto W \longmapsto R \longmapsto E.$$

The terminal row E *is a seal for the displayed regular Cauchy route, not a proof of* $\mathsf{Real}^{\uparrow}$ *completeness, host equality, selected limits, quotient streams, or countable choice.*

Proof. Use the regularity handoff to expose D, W, R in order. No Real-facing row is visible before the regular rational readback is displayed.

The terminal row E is the only Real seal coordinate in the carrier. It is read after R and is replayed by C with provenance and local naming supplied by P, N.

Because the carrier has no coordinate for completeness, quotient stream equality, selected limits, countable choice, or host real equality, any consumer that reaches $\mathsf{Real}^{\uparrow}$ must remain inside the displayed route. □

Theorem 6749.5 (Bishop Cauchy name-seal classifier transport)**.** *Let $S = (D, W, R, E, H, C, P, N)$ and $S' = (D', W', R', E', H', C', P', N')$ be accepted* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *carriers. If H records componentwise* hsame *transport from D, W, R, E to D', W', R', E' and C replays the displayed route, then acceptance transports from S to S' only through the rows*

$$D, W, R, E, H, C, P, N.$$

Proof. Inspect the classifier in Definition 6749.1. Its admissible inputs are the displayed data rows and the structural certificate rows.

Componentwise hsame transport compares the dyadic ledger, stream window, regular readback, Real seal, provenance, and local naming rows. Displayed Cont replay preserves the same dependency order.

No host equality or quotient relation is part of the packet. The transported acceptance therefore uses only the listed rows and cannot be widened to an external equality of real names. □

Theorem 6749.6 (Bishop Cauchy name-seal provenance exhaustion)**.** *For every accepted* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *carrier $S = (D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyNameSeal}^{\uparrow}}$ *obligations are exhausted by carrier admission, four-input visibility, regularity handoff, Real-seal nonescape, classifier transport, displayed replay, package provenance, and local naming for D, W, R, E, H, C, P, N.*

Proof. Carrier admission projects the tuple $S = (D, W, R, E, H, C, P, N)$. The preceding obligations account for visibility of D, W, R, E, the regularity handoff, Real nonescape, and classifier transport.

The remaining structural rows are C, P, N. They replay, source, and name the same finite packet and do not add mathematical data beyond the displayed route.

Thus every NameCert obligation is read from the listed rows. Nothing remains from which a consumer could infer quotient streams, selected limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ Real-facing read factors through one DyadicRatCore endpoint and tolerance ledger, one StreamName finite observation row, one RegSeqRat regular readback row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-regular-cauchy-completion: $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the four L10 rows as one local seal with transport, replay, provenance, and naming before any Real or Completion consumer may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyNameSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ packet is generated from DyadicRatCore endpoint and tolerance rows, StreamName finite observations, RegSeqRat regular readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyNameSeal}^{\uparrow}}$, seed)

Scope closed: Definition 6749.1, Definition 6749.2, Definition 6749.3, Definition 6749.4, Definition 6749.5, and Definition 6749.6 seed the finite four-object L10 name-seal route over dyadic, stream, regular, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyNameSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy streams, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{BishopCauchyNameSeal}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, four-input visibility, regularity handoff, Real-seal nonescape, classifier transport, displayed replay, provenance, and local naming for BEDC.Derived.BishopCauchyNameSealUp.

Chapter 6750

A Concrete Naming Certificate for $\mathsf{CompactModulusExtraction}^{\uparrow}$

Following Bishop and Bridges on compact metric continuity, the $\mathsf{CompactModulusExtraction}^{\uparrow}$ packet records the finite extraction route by which pointwise moduli over a compact finite net are folded into a displayed uniform modulus. It sits over the compact source rows of chapter 60, the continuous-map pointwise-modulus surface of chapter 130, the metric triangle rows of chapter 57, the rational lower-bound fold of chapter 37, and the output interface of chapter 369. The packet names the constructive Heine–Cantor finite-net handoff as local NameCert data; it does not add open-cover compactness, selected subcovers, host function equality, real completeness, or an external continuity theorem.

Definition 6750.1 (Compact modulus extraction carrier)**.** *A* $\mathsf{CompactModulusExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, Q, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row, listing the inspected centers, coverage radius, and finite adjacency ledger.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to each displayed net center.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *finite lower-bound fold row, computing the positive rational tolerance budget over the displayed pointwise moduli.*
4. *T is the* $\mathsf{Met}^{\uparrow}$ *triangle row that routes nearby source points through a chosen net center and then through the target comparison.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row obtained from K, F, Q, T.*
6. *H records componentwise* hsame *transport for K, F, Q, T, U and the local certificate rows.*
7. *C records displayed* Cont *replay from finite-net coverage through pointwise moduli, rational fold, metric triangle comparison, and uniform-modulus output.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactModulusExtraction}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, Q, T, U, H, C, P, N$. It has no coordinate for a selected open subcover, host continuity theorem, quotient function equality, arbitrary supremum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6750.2 (Compact modulus extraction NameCert obligations)**.** *For every accepted* CompactModulusExtra *carrier $M = (K, F, Q, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactModulusExtraction}^{\uparrow}}$ *surface consists exactly of carrier admission, compact finite-net exposure through K, pointwise-modulus exposure through F, rational lower-bound fold exposure through Q, metric triangle exposure through T, UniformModulus handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier. The rows K, F, Q, T, U are the only mathematical data coordinates available to a compact-uniform-continuity consumer.

The compact row supplies finite centers, the continuous-map row supplies pointwise moduli at those centers, the rational row folds the displayed positive bounds, and the metric row supplies the triangle comparison that lets the folded bound apply to a nearby source point.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. No selected subcover, host theorem, quotient function equality, arbitrary supremum, or ambient completeness row remains outside the listed obligations. □

Theorem 6750.3 (Compact modulus extraction finite-net fold)**.** *Every accepted* $\mathsf{CompactModulusExtraction}^{\uparrow}$ *packet extracts its uniform modulus only through*

$$K, F \longmapsto Q \longmapsto T \longmapsto U.$$

The rational fold Q is computed over the finite centers displayed by K and the pointwise moduli displayed by F, and the metric triangle row T is consumed before the $\mathsf{UniformModulus}^{\uparrow}$ *output row U is public.*

Proof. Start from the compact finite-net row K. It displays the finite list of centers and coverage data, so the fold is over a finite BHist ledger rather than over an ambient compactness principle.

Read F at each displayed center and then fold the resulting rational lower bounds through Q. Since Q is a $\mathsf{Rat}^{\uparrow}$ row, the consumer sees the finite rational computation rather than a selected infimum.

Finally apply the metric triangle row T and expose U. The output uniform modulus is therefore downstream of the finite net, pointwise moduli, rational fold, and triangle comparison. □

Theorem 6750.4 (Compact modulus extraction transport nonescape)**.** *Let $M = (K, F, Q, T, U, H, C, P, N)$ and $M' = (K', F', Q', T', U', H', C', P', N')$ be accepted* $\mathsf{CompactModulusExtraction}^{\uparrow}$ *carriers. If H transports the compact, pointwise-modulus, rational-fold, metric-triangle, and uniform-modulus rows componentwise, then the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row transports only through $K, F, Q, T, U, H, C, P, N$.*

Proof. Inspect the classifier of Definition 6750.1. It names only the finite-net, pointwise-modulus, rational-fold, metric-triangle, output, and structural rows.

Componentwise hsame transport moves each of those rows to its displayed counterpart, while Cont replay preserves the route from K, F through Q, T to U.

No carrier coordinate supplies host function equality, selected open covers, arbitrary suprema, or ambient completeness. The transported output is therefore the same finite extraction route and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{CompactModulusExtraction}^{\uparrow}$ uniform-modulus read factors through one compact finite-net row, one ContinuousMap pointwise-modulus row, one RatUp finite lower-bound fold row, one MetricSpace triangle row, one UniformModulus handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compact, continuousmap, metric, rat, uniformmodulus: $\mathsf{CompactModulusExtraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite compact-net rows, pointwise-modulus rows, rational lower-bound folds, metric triangle rows, and a UniformModulus handoff as one extraction packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusExtraction}^{\uparrow}$ packet is generated from compact finite-net rows, ContinuousMap pointwise-modulus rows, RatUp lower-bound folds, MetricSpace triangle rows, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6750.1, Definition 6750.2, Definition 6750.3, and Definition 6750.4 seed the finite compact-modulus extraction route over compact, continuous-map, rational-fold, metric-triangle, UniformModulus, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host function equality, arbitrary suprema, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CompactModulusExtraction}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, pointwise-modulus exposure, rational lower-bound fold, metric triangle handoff, UniformModulus output, transport, replay, provenance, and local naming for BEDC.Derived.CompactModulusExtractionUp.

Chapter 6751

A Concrete Naming Certificate for $\mathsf{AlexandroffDuplicate}^{\uparrow}$

Following Alexandroff's duplicate-space construction, the $\mathsf{AlexandroffDuplicate}^{\uparrow}$ packet records the finite observable-open face of a duplicated point-set topology. It is anchored by the topology carrier of chapter 88 and the observable truth boundary of chapter 1860; the optional order-topology source is read through chapter 1890 when that row is present. The chapter names only the finite rows required for duplicate-tagged observable opens, not a host separation theorem, a completed real line, or an unrestricted lattice of open sets.

Definition 6751.1 (Alexandroff duplicate carrier)**.** *An* $\mathsf{AlexandroffDuplicate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, B, O, W, R, H, C, P, N)$$

with the following displayed rows:

1. T *is the* $\mathsf{Topology}^{\uparrow}$ *source row naming the finite open data currently under inspection.*
2. B *is the* $\mathsf{Bool}^{\uparrow}$ *duplicate-tag row; each inspected point is tagged by one of the two duplicate faces.*
3. O *is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth row for the inspected tagged points.*
4. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the tagged observations actually read by the packet.*
5. R *is an optional* $\mathsf{RealOrderTopology}^{\uparrow}$ *source anchor; when absent, the carrier still records the topology row* T *and duplicate tag row* B *without importing order-completeness data.*
6. H *records componentwise* hsame *transport for topology rows, duplicate tags, observable-open truth rows, finite windows, the optional order source, continuation rows, provenance rows, and local naming rows.*
7. C *records displayed* Cont *replay from* T, B *to* O*, from* O *to* W*, and from any present order-topology anchor* R *back to the same finite topology source row.*
8. P *is the* Pkg *provenance over* $\mathsf{AlexandroffDuplicate}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{SierpinskiSpace}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RealOrderTopology}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{AlexandroffDuplicate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, O, W, R, H, C, P, N$*. It has no coordinate for all open subsets of a host duplicate space, a separation axiom, quotient point equality, order completeness, countable choice, or a global topological representation.*

Theorem 6751.2 (Alexandroff duplicate NameCert obligations)**.** *For every accepted* $\mathsf{AlexandroffDuplicate}^{\uparrow}$ *packet* $A = (T, B, O, W, R, H, C, P, N)$*, the local NameCert surface consists exactly of carrier admission for the* $\mathsf{Topology}^{\uparrow}$ *source row,* $\mathsf{Bool}^{\uparrow}$ *duplicate tags,* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth values,* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows, the optional* $\mathsf{RealOrderTopology}^{\uparrow}$ *source anchor, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. A consumer may read an observable duplicate-open only after those finite rows are displayed; it cannot replace them by a host duplicate-space topology, a hidden open-set lattice, a separation theorem, or ambient real-order completeness.*

Proof. Project the carrier of Definition 6751.1. The rows $T, B, O, W, R, H, C, P, N$ are the whole accepted packet, so the duplicate-open consumer cannot detach the observable truth row from the topology source or from the duplicate tag row.

Read the finite route in order. The $\mathsf{Topology}^{\uparrow}$ row supplies the source open data, the $\mathsf{Bool}^{\uparrow}$ row supplies the duplicate face, the $\mathsf{SierpinskiSpace}^{\uparrow}$ row records the observable truth value, and the $\mathsf{StreamName}^{\uparrow}$ row bounds the inspected window.

The optional $\mathsf{RealOrderTopology}^{\uparrow}$ row only anchors the source topology when it is present. The transport, continuation, provenance, and local naming rows replay the same displayed packet, so no hidden open-set lattice, separation axiom, countable-choice schedule, or real-order completeness datum is exported. □

Falsifiable prediction: Every $\mathsf{AlexandroffDuplicate}^{\uparrow}$ observable-open read factors through $\mathsf{Topology}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ rows before any optional $\mathsf{RealOrderTopology}^{\uparrow}$ source anchor is consumed.

Independence witness: topology, bool, sierpinski-space, streamname, real-order-topology: $\mathsf{AlexandroffDuplicate}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries topology source data, duplicate tags, observable-open truth values, finite observation windows, an optional order-topology source anchor, transports, continuations, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AlexandroffDuplicate}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AlexandroffDuplicate}^{\uparrow}$ packet is generated from a Topology source row, Bool duplicate tags, SierpinskiSpace observable-open truth rows, StreamName finite windows, an optional RealOrderTopology source anchor, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlexandroffDuplicate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6751.1 and Definition 6751.2 bind the finite duplicate carrier and its observable-open NameCert obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlexandroffDuplicate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim a host duplicate-space topology, separation axioms, a global open-set lattice, quotient point equality, real-order completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, duplicate-tag stability, observable-open replay, finite-window readback, optional order-anchor routing, and local NameCert exactness for BEDC.Derived.AlexandroffDuplicateUp.

Chapter 6752

A Concrete Naming Certificate for $\mathsf{FormalBallSpace}^{\uparrow}$

Following Edalat and Heckmann formal-ball presentations of metric completion, the $\mathsf{FormalBallSpace}^{\uparrow}$ packet records the finite center-radius space read used by constructive completion consumers. It sits after the metric source of chapter 57, the separated-metric boundary of chapter 1411, the formal-ball domain of chapter 5723, the formal-ball completion route of chapter 2012, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite NameCert carrier for rounded formal balls over a displayed metric source; it is not a quotient completion, a selected limit, a host basis of all balls, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6752.1 (FormalBallSpace carrier)**.** *A* $\mathsf{FormalBallSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, X, R, B, O, S, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the displayed distance witness and its finite replay surface.*
2. *X is the center carrier row read over the same metric source.*
3. *R is the positive radius read, supplied through* $\mathsf{RegSeqRat}^{\uparrow}$ *or an equivalent positive rational tolerance row.*
4. *B is the formal-ball pair row, recording center-radius pairs (x, r) with x read from X and r read from R.*
5. *O is the ball-order and refinement row, displaying the accepted comparison between formal balls.*
6. *S is the rounded-shrink schedule row, recording finite radius shrinkage requests before completion consumers inspect the packet.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for finite window addresses of centers, radii, comparisons, and shrink steps.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the positive-radius and shrink tolerances to real-facing consumers.*
9. *H records componentwise* hsame *transport for metric sources, centers, positive radii, formal-ball pairs, refinement rows, shrink schedules, readback windows, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from metric requests through center-radius reads, order and refinement checks, rounded shrinkage, stream windows, regular rational readback, and completion-facing handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{FormalBallSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{FormalBallDomain}^{\uparrow}$, $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBallSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, X, R, B, O, S, W, Q, H, C, P, N$. It has no coordinate for quotient equality of completions, selected Cauchy representatives, a host family of all balls, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6752.2 (FormalBallSpace NameCert obligations)**.** *For every accepted* $\mathsf{FormalBallSpace}^{\uparrow}$ *carrier*

$$F = (M, X, R, B, O, S, W, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FormalBallSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, center carrier, positive radius read, formal-ball pair row, ball-order and refinement row, rounded-shrink schedule, finite StreamName window, RegSeqRat readback, componentwise transport, displayed replay, provenance, and local naming. Positive-radius stability is read from R and Q; order and refinement stability is read from O under H, C; roundedness is read from S; completion readback passes through W, Q before any* $\mathsf{FormalBallCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer is served; and ledger nonescape keeps quotient completion equality, selected limits, host all-ball bases, countable choice, and ambient completeness outside the packet.*

Proof. Project the carrier of Definition 6752.1. Carrier admission exposes the rows $M, X, R, B, O, S, W, Q, H, C, P, N$ and no further coordinate.

Use finite row induction over the displayed packet. The center and radius rows give the formal-ball pair B; the order and refinement row O compares only those displayed pairs; and the rounded-shrink schedule S consumes finite positive-radius data before a completion-facing read is available.

Transport and replay are componentwise. The rows H and C preserve the metric source, center, positive radius, order, shrink schedule, StreamName window, and RegSeqRat readback together, while P and N source and name the same finite surface.

Finally read completion consumers through W and Q. Since the accepted carrier has no row for quotient completion equality, selected representatives, a host basis of all balls, countable choice, or ambient completeness, those objects cannot become local NameCert obligations. □

Falsifiable prediction: Any accepted $\mathsf{FormalBallSpace}^{\uparrow}$ completion-facing read that bypasses the positive-radius row R, the rounded-shrink schedule S, or the readback rows W, Q is rejected by Definition 6752.1, because the carrier exposes completion data only through the finite center-radius packet.

Independence witness: metric, separatedmetric, formal-ball-domain, formal-ball-completion, streamname, regseqrat, real: the packet is not bijective with any listed sibling because it jointly records metric source, center carrier, positive radius, formal-ball pair, refinement order, rounded shrinkage, finite windows, regular rational readback, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBallSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FormalBallSpace}^{\uparrow}$ packet is generated from a displayed MetricSpaceUp source, center carrier rows, positive radius reads, formal-ball pairs, ball-order and refinement rows, rounded-shrink schedules, StreamName finite

windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FormalBallSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6752.1 and Definition 6752.2 seed the finite formal-ball space carrier over positive radii, rounded refinement, completion readback, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{FormalBallSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, a host all-ball basis, countable choice, ambient Real$^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius stability, order and refinement stability, rounded-shrink schedule replay, completion readback, ledger nonescape, and TasteGate field faithfulness for BEDC.Derived.FormalBallSpaceUp.

Chapter 6753

A Concrete Naming Certificate for $\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}$

Following Bishop and Bridges on totally bounded metric spaces and constructive completion, the $\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}$ packet records the finite-net surface that a completion consumer may read before any completed point is sealed. It sits after the broad completion route of chapter 1573, the finite-net carrier of chapter 127, the Cauchy-filter basis of chapter 1501, the dense embedding row of chapter 1512, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The certificate is a finite NameCert surface between total-bounded finite nets and completion readback; it is not open-cover compactness, quotient completion, selected limit construction, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6753.1 (Bishop totally bounded completion net carrier)**.** *A* $\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, T, N, F, E, R, Q, H, C, P, L)$$

with the following visible rows:

1. *X is the source metric row whose distance witnesses are accepted by the total-bounded and completion-facing ledgers.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, recording for each displayed positive tolerance a closed* ProbeBundle *of centers, membership rows, and rational distance bounds.*
3. *N is the Bishop refinement row. It relates a finer tolerance request to a previously displayed finite net without replacing the packet by an open cover or a selected subnet.*
4. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row generated from T and N.*
5. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that inserts source observations into the completion boundary.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when completion names are inspected by finite rational windows.*
7. *Q records the completion-readback seal that lets a downstream* $\mathsf{Real}^{\uparrow}$ *consumer read only after F, E, R have been displayed.*
8. *H, C, P, L are, respectively, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance over the cited sibling chapters, and the local* $\mathsf{NameCert}_{\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by replaying these rows. No coordinate exports open-cover compactness, quotient representatives, selected limits, countable choice, or an ambient completeness theorem.

Theorem 6753.2 (Bishop totally bounded completion net NameCert obligations)**.** *For every accepted* $\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}$ *carrier* $B = (X, T, N, F, E, R, Q, H, C, P, L)$*, the local* NameCert *surface consists exactly of carrier admission for those rows, finite-net persistence through* T, N*, Cauchy-filter-basis generation through* F*, dense completion insertion through* E*, rational readback through* R*, completion-to-Real sealing through* Q*, and componentwise transport, replay, provenance, and local naming through* H, C, P, L*.*

Proof. Carrier admission is projection from Definition 6753.1. The listed rows are the whole visible packet, so every obligation must be read from them.

Finite-net persistence is forced by T and N. A tolerance request first reads the finite centers, membership constructors, distance witnesses, and rational bounds of T; refinement then follows the displayed Bishop row N.

The completion readback is downstream of that finite-net data. The row F builds the Cauchy-filter basis, E embeds source observations into the completion boundary, R supplies regular rational windows, and Q seals the readback for Real-facing consumers. The remaining rows only transport, replay, source, and name the same route. □

Theorem 6753.3 (Bishop totally bounded completion net Real-seal handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}$ *packet receives the displayed route*

$$X, T, N \longmapsto F \longmapsto E \longmapsto R \longmapsto Q \longmapsto H, C, P, L.$$

Thus the consumer reads the original total-bounded finite-net ledger before the completion and Real seal rows, and it cannot substitute open-cover compactness, quotient completion, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness for that route.*

Proof. Start with the finite-net side. The source row X supplies the metric witnesses, while T and N display the finite centers and refinement requests in Bishop style.

Next pass to completion readback. The basis row F is generated from the finite-net ledger, the embedding row E places source observations at the completion boundary, and the regular readback row R is the only rational-window route available before the terminal seal Q.

Finally use the transport and provenance rows. Since H, C, P, L only preserve and name the displayed packet, the Real-facing consumer has no coordinate from which to read an open cover, quotient representative, selected limit, choice schedule, or ambient completeness claim. □

Independence witness: totallyboundedcompletion, totallybounded, cauchy-filter-basis, completionembedding, regseqrat, real: $\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the source metric, finite-net ledger, Bishop refinement row, Cauchy-filter basis, dense embedding, rational readback, terminal seal, transport, replay, provenance, and local naming as one completion-net packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}$ packet starts from a displayed metric source, records total-bounded finite nets and Bishop refinement rows, generates a Cauchy-filter basis, embeds source observations into a completion boundary, reads regular rational windows, seals the route for Real-facing consumers, and preserves the same finite surface by transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6753.1, Definition 6753.2, and Definition 6753.3 seed the finite Bishop completion-net route from total-bounded ledgers to completion and Real readback.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopTotallyBoundedCompletionNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient completion, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net persistence, Cauchy-filter-basis generation, dense embedding handoff, regular readback, Real-seal handoff, and ledger nonescape for the same packet.

Chapter 6754

A Concrete Naming Certificate for $\mathsf{DicksonLemma}^{\uparrow}$

Following Dickson and standard constructive finite-combinatorics, the $\mathsf{DicksonLemma}^{\uparrow}$ packet records the finite-product order induction surface used to route bad-sequence obstructions through named finite data. It sits after the unary finite-spine carrier of chapter 28, the product and list ledgers of chapter 34 and chapter 36, the ordered comparison rows of chapter 53 and chapter 54, and the algebra-facing chain rows of chapter 3637 and chapter 3472. The packet is a finite NameCert surface for product-order induction; it is not a classical selected subsequence theorem, not a quotient of infinite streams, and not a hidden Hilbert-basis proof.

Definition 6754.1 (Dickson lemma carrier)**.** *A* $\mathsf{DicksonLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{Dickson}(N, P, L, O, T, B, H, C, Q, D)$$

with the following visible rows.

- *N is the* $\mathsf{Nat}^{\uparrow}$ *coordinate row. It supplies unary finite-spine witnesses for every displayed coordinate height.*
- *P is the* $\mathsf{Prod}^{\uparrow}$ *finite-product row. It binds the displayed coordinates as one product-order packet rather than as detached projections.*
- *L is the* $\mathsf{List}^{\uparrow}$ *window row. It records the finite prefix of the candidate bad sequence inspected by the induction.*
- *O is the* $\mathsf{Poset}^{\uparrow}$ *product-order row, with coordinatewise comparison over the same natural-number classifier.*
- *T is the* $\mathsf{TotalOrder}^{\uparrow}$ *coordinate-comparison row used only inside the natural coordinate reads.*
- *B is the bounded-bad-prefix row. It records that every obstruction is witnessed by a finite list window, a coordinate, and a product-order comparison failure inside that window.*
- *H, C, Q, D are, respectively, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{DicksonLemma}^{\uparrow}}$ *naming row.*

The classifier compares accepted packets by replaying exactly these rows. No coordinate exports a selected infinite subsequence, excluded-middle search over streams, quotient sequence equality, or an ambient algebraic Noetherian theorem.

Theorem 6754.2 (Dickson lemma NameCert obligations)**.** *For every accepted* $\mathsf{DicksonLemma}^{\uparrow}$ *carrier* $\mathsf{Dickson}(N, P, L, O, T, B, H, C, Q, D)$*, the local* $\mathsf{NameCert}_{\mathsf{DicksonLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, natural-coordinate access through* N*, finite-product assembly through* P*, finite-window readback through* L*, product-order comparison through* O*, coordinate total-order comparison through* T*, bounded-bad-prefix induction through* B*, componentwise transport through* H*, continuation replay through* C*, provenance nonescape through* Q*, and local naming through* D*.*

Proof. Project the carrier of Definition 6754.1. The accepted packet exposes only the rows $N, P, L, O, T, B, H, C, Q$, so the local certificate cannot read an outside stream object or an algebra theorem as an extra coordinate.

The finite-order part is read first. The row N supplies the natural-number coordinate surfaces, P binds those surfaces into a displayed product, and L records the finite list window on which the induction is performed.

The comparison part is then forced by O, T, B. The product-order row O reads comparisons coordinatewise, T supplies the natural coordinate comparison used by that read, and B records the finite obstruction window consumed by the induction. Transport, continuation replay, provenance, and local naming preserve that same finite inventory. □

Theorem 6754.3 (Dickson lemma finite-product order handoff)**.** *Every downstream consumer of an accepted* $\mathsf{DicksonLemma}^{\uparrow}$ *packet that asks for a finite-product order induction route must read the displayed handoff*

$$\mathsf{Nat}^{\uparrow} \longrightarrow \mathsf{Prod}^{\uparrow} \longrightarrow \mathsf{List}^{\uparrow} \longrightarrow \mathsf{Poset}^{\uparrow} \longrightarrow \mathsf{TotalOrder}^{\uparrow} \longrightarrow \mathsf{NameCert}_{\mathsf{DicksonLemma}^{\uparrow}}.$$

Consequently a $\mathsf{NoetherianRing}^{\uparrow}$ *or* $\mathsf{HilbertBasis}^{\uparrow}$ *consumer may cite* $\mathsf{DicksonLemma}^{\uparrow}$ *only as a finite product-order induction packet over displayed natural coordinates, finite list windows, and product-order comparisons. It cannot substitute selected infinite subsequence extraction, quotient stream equality, maximal ideal choice, or a complete Hilbert-basis proof for that route.*

Proof. Start with the natural-coordinate and finite-product rows. The row N supplies the unary natural surfaces, and P records how the displayed coordinates are assembled as one product packet.

Next read the finite window. The row L exposes only a finite list prefix, so the induction sees a bounded bad-prefix surface rather than an infinite stream or a selected subsequence.

Finally apply the order rows and the local certificate. The rows O, T, B turn the finite window into a product-order induction witness, while H, C, Q, D transport, replay, source, and name the same packet. Algebra-facing consumers may reuse this handoff as finite combinatorics, but the packet does not contain Noetherian-ring stabilization, a Hilbert-basis construction, or any choice-based extraction principle. □

Independence witness: nat, prod, list, poset, total-order, noetherian-ring, hilbert-basis: $\mathsf{DicksonLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds natural coordinates, finite product assembly, finite list windows, product-order comparison, coordinate total-order comparison, bounded bad-prefix induction, transport, replay, provenance, and local naming as one finite-product order packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DicksonLemma}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DicksonLemma}^{\uparrow}$ packet is generated from NatUp coordinate rows, a ProdUp finite-product row, a ListUp finite-window row, PosetUp product-order comparison, TotalOrderUp coordinate comparison, a bounded-bad-prefix induction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DicksonLemma}\uparrow}$, seed)

Scope closed: Definition 6754.1, Definition 6754.2, and Definition 6754.3 seed the finite-product order induction interface over NatUp, ProdUp, ListUp, PosetUp, TotalOrderUp, and downstream NoetherianRingUp or HilbertBasisUp consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{DicksonLemma}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, maximal ideal choice, Hilbert-basis proof, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, natural-coordinate access, finite-product assembly, finite-window readback, product-order comparison, bounded-bad-prefix induction, componentwise transport, provenance nonescape, and local NameCert exactness for BEDC.Derived.DicksonLemmaUp.

Chapter 6755

A Concrete Naming Certificate for $\mathsf{CechNerve}^{\uparrow}$

Following Cech, Leray, and the classical cover-nerve construction, the $\mathsf{CechNerve}^{\uparrow}$ packet records the finite simplicial object determined by a displayed finite topological cover. It sits after the topology carrier of chapter 88, the finite-radius cover ledger of chapter 452, and the finite face inventory of chapter 238. The packet names cover members, intersection witnesses, nerve faces, stability, ledger, transport, provenance, and local naming rows; it does not assert the nerve theorem, selected points in arbitrary intersections, open-cover compactness, quotient realization equality, or ambient homology computation.

Definition 6755.1 (Cech nerve carrier)**.** *A* $\mathsf{CechNerve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, L, U, F, I, S, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the indexed-open membership classifier used by the cover.*
2. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *or finite-cover radius row, recording the finite cover scale when the cover is served by compact or metric data.*
3. *U is the finite cover-member row, listing the displayed cover indices and their topology-open witnesses.*
4. *F is the nerve-face classifier row: a finite subset of cover indices is accepted exactly when its displayed intersection witness is present.*
5. *I is the intersection-witness ledger, recording the finite meet or overlap data consumed by F.*
6. *S is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *row whose faces are the accepted finite nerve faces.*
7. *G is the stability row, carrying componentwise* hsame *transport for the topology, cover, intersection, nerve-face, simplicial-complex, ledger, replay, provenance, and local naming rows.*
8. *H is the nonescape ledger, refusing selected intersection points, arbitrary subcovers, host nerve realizations, quotient simplicial equality, and ambient homology computation.*
9. *C records displayed* Cont *replay from a cover request through T, L, U, I, F, S, G, H.*

10. *P is the* Pkg *provenance over* $\mathsf{CechNerve}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CechNerve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed cover members, intersection witnesses, nerve-face classifier, simplicial-complex row, stability row, ledger row, replay, provenance, and local naming data.

Theorem 6755.2 (Cech nerve NameCert obligations)**.** *For every accepted* $\mathsf{CechNerve}^{\uparrow}$ *carrier* $K = (T, L, U, F, I, S, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CechNerve}^{\uparrow}}$ *surface consists exactly of carrier admission through* $T, L, U, F, I, S, G, H, C, P, N$*; classifier admission for the finite nerve-face row* F*; stability under componentwise transport through* G*; ledger exposure through* I, H*; replay through* C*; provenance through* P*; local naming through* N*; and nonescape for selected intersection points, arbitrary subcover choice, host nerve realizations, quotient simplicial equality, and ambient homology computation.*

Proof. Project the carrier of Definition 6755.1. The topology row T, finite-radius or finite-cover row L, cover-member row U, intersection ledger I, nerve-face classifier F, and simplicial-complex row S are the only geometric coordinates in the packet.

The classifier is finite. A face is accepted only through F, and F reads the displayed intersection witnesses in I over the listed cover members U. Thus the nerve is the finite face inventory delivered to $\mathsf{SimplicialComplex}^{\uparrow}$, not a host simplicial realization.

Stability is componentwise. The row G transports topology, cover, intersection, face, and simplicial-complex data together, while C replays the same route and P, N source and name the packet.

Finally read the ledger row H. Since the carrier has no coordinate for selected intersection points, arbitrary subcover choice, quotient realization equality, or ambient homology computation, those objects cannot be exported by an accepted $\mathsf{CechNerve}^{\uparrow}$ read. □

Falsifiable prediction: Every accepted $\mathsf{CechNerve}^{\uparrow}$ read exposes a topology row, finite cover or radius row, cover-member row, intersection-witness ledger, finite nerve-face classifier, simplicial-complex row, componentwise hsame stability, nonescape ledger, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: topology, finitelebesguenumber, simplicialcomplex, compact-cover-nerve, support-nerve-census: none is bijective to $\mathsf{CechNerve}^{\uparrow}$ because this packet jointly carries cover members, finite intersection witnesses, nerve-face classification, a simplicial-complex export row, stability, ledger, replay, provenance, and local naming as one cover-to-simplicial-object certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CechNerve}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CechNerve}^{\uparrow}}$, seed)

Scope closed: Definition 6755.1 and Definition 6755.2 seed the finite cover-to-simplicial-object certificate over TopologyUp, FiniteLebesgueNumberUp, SimplicialComplexUp, transport, ledger, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CechNerve}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the nerve theorem, selected intersection points, arbitrary subcover choice, open-cover compactness, quotient realization equality, ambient homology computation, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked cover-member admission, finite intersection-witness exposure, nerve-face classification, SimplicialComplex handoff, transport stability, ledger nonescape, replay, provenance, and local naming for BEDC.Derived.CechNerveUp.

Constructive story: A CechNerve$^{\uparrow}$ packet is generated from a TopologyUp source row, a finite cover or FiniteLebesgueNumberUp radius row, cover-member rows, intersection-witness rows, a finite nerve-face classifier, a SimplicialComplexUp export row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 6756

A Concrete Naming Certificate for $\mathsf{CompactOpenExhaustion}^{\uparrow}$

Following Bishop and Bridges on constructive compactness and finite approximation, the $\mathsf{CompactOpenExhaustion}^{\uparrow}$ packet names the displayed finite-subcover exhaustion route used by the L10 completion corridor. It sits after the compact metric rows of chapter 129, the topology rows of chapter 88, the finite epsilon-net rows of chapter 1767, the stream-name rows of chapter 126, the regular rational readback rows of chapter 301, and the terminal real seal of chapter 38. The chapter records a finite exhaustion packet; it does not assert arbitrary open-cover compactness.

Definition 6756.1 (CompactOpenExhaustion carrier)**.** *A* $\mathsf{CompactOpenExhaustion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, O, F, S, W, R, E_{\mathsf{Real}^{\uparrow}}, H, C, P, N).$$

Here K *is the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* O *is the* $\mathsf{Topology}^{\uparrow}$ *open-membership ledger,* F *is the finite* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *cover row,* S *is the finite subcover schedule,* W *is the* $\mathsf{StreamName}^{\uparrow}$ *inspection window,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row,* $E_{\mathsf{Real}^{\uparrow}}$ *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached through the displayed windows,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay,* P *is* Pkg *provenance over the listed rows, and* N *is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenExhaustion}^{\uparrow}}$ *row.*

The carrier predicate says that every accepted read exposes the finite rows $K, O, F, S, W, R, E_{\mathsf{Real}^{\uparrow}}, H, C, P, N$ *before any exhaustion consumer may inspect a subcover claim. The packet has no coordinate for an arbitrary open cover, an infinite cover selection rule, ambient compactness, or a host completeness theorem.*

Lean4 ✓ `BEDC.Derived.CompactOpenExhaustionUp.TasteGate.CompactOpenExhaustionTasteGate single carrier alignment`

Theorem 6756.2 (CompactOpenExhaustion NameCert obligations)**.** *For every accepted* $\mathsf{CompactOpenExhaustion}^{\uparrow}$ *carrier* $E = (K, O, F, S, W, R, E_{\mathsf{Real}^{\uparrow}}, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactOpenExhaustion}^{\uparrow}}$ *surface consists exactly of compactmetric source exposure, topology open-membership exposure, finite-net cover exposure, finite subcover scheduling, stream-window inspection, regular rational readback, terminal Real seal discipline, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6756.1. The rows $K, O, F, S, W, R, E_{\mathsf{Real}^{\uparrow}}$ display the compact metric source, open-membership ledger, finite net, finite subcover schedule, inspection windows, rational readback, and terminal Real seal.

The structural rows H, C, P, N do not add a new cover principle. They only transport the displayed rows, replay the accepted read, record provenance, and name the same local packet.

Thus the NameCert surface is the finite exhaustion packet itself, with no hidden open-cover compactness, selected infinite subcover, host topological compactness, or ambient completeness coordinate. □

Theorem 6756.3 (CompactOpenExhaustion finite-subcover route)**.** *Every* $\mathsf{CompactOpenExhaustion}^{\uparrow}$ *finite-subcover exhaustion read factors through the displayed route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{Topology}^{\uparrow}, \mathsf{FiniteEpsilonNet}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, H, C, P, N.$$

The route reads K before O, reads the finite-net cover row F before the subcover schedule S, and reads the finite windows $W, R, E_{\mathsf{Real}^{\uparrow}}$ before the exhaustion claim is exported to an L10 completion consumer.

Proof. Start with Definition 6756.2. It fixes the local NameCert surface as the rows displayed by the carrier.

The finite-net row F is downstream of the compactmetric and topology rows K, O, so the subcover schedule S is read only after the finite cover entries are visible. The stream, rational readback, and Real seal rows then provide the finite inspection boundary consumed by completion-facing routes.

Finally, the transport, replay, provenance, and naming rows preserve the same packet. Therefore the exhaustion export is a finite route through the displayed BEDC rows rather than a general open-cover compactness theorem. □

Falsifiable prediction: Every accepted $\mathsf{CompactOpenExhaustion}^{\uparrow}$ read factors through displayed CompactMetricUp, TopologyUp, FiniteEpsilonNetUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and local NameCert rows before exporting a finite subcover exhaustion.

Independence witness: A purported $\mathsf{CompactOpenExhaustion}^{\uparrow}$ read that exports a subcover without the finite $\mathsf{FiniteEpsilonNet}^{\uparrow}$ row F, the finite schedule S, or the window rows $W, R, E_{\mathsf{Real}^{\uparrow}}$ is outside this certificate, even if an external topology library proves compactness by open covers.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenExhaustion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenExhaustion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6756.1, Definition 6756.2, and Definition 6756.3 seed the finite subcover exhaustion route over CompactMetricUp, TopologyUp, FiniteEpsilonNetUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOpenExhaustion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, infinite subcover selection, host topological compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: The next paper-side step is a scoped root-obligation theorem tying this finite exhaustion packet to its L10 completion consumer.

Constructive story: A $\mathsf{CompactOpenExhaustion}^{\uparrow}$ packet is generated from compactmetric source data, topology open-membership rows, finite-net cover entries, a finite subcover schedule, stream windows, regular rational readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6757

A Concrete Naming Certificate for $\mathsf{AubinNitsche}^{\uparrow}$

Following Aubin and Nitsche on finite-element duality estimates, the $\mathsf{AubinNitsche}^{\uparrow}$ packet records the finite BEDC route by which an L^2-style error read is obtained from Galerkin orthogonality, a displayed dual solve, Sobolev regularity, projection comparison, and a terminal Real error-bound row. It sits over the Galerkin projection surface of chapter 5169, the variational dual row of chapter 3419, the regularity source of chapter 440, and the scalar seal of chapter 38. The packet names only the displayed duality-error route; it does not import host Hilbert-space quotients, selected minimizers, ambient completeness, or an unrestricted PDE solution operator.

Definition 6757.1 (Aubin-Nitsche carrier)**.** *An* $\mathsf{AubinNitsche}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, L, S, H, R, D, E, T, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{GalerkinProjection}^{\uparrow}$ *row, exposing the finite trial space, projection residual, and Galerkin orthogonality surface used by the error read.*
2. *L is the* $\mathsf{LaxMilgram}^{\uparrow}$ *dual row, displaying the variational dual solve available for the residual functional.*
3. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *regularity row, recording the finite regularity budget that allows the dual solution to be compared with projected test data.*
4. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *or norm-comparison row, carrying the displayed pairing and norm ledger without quotienting the ambient function space.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *error-bound row, sealing constants, radii, and tolerances used by the final scalar estimate.*
6. *D is the duality comparison row, relating the primal error read to the dual residual route through G, L, S, H.*
7. *E is the projection-error row, exposing the approximation term that bounds the dual test error before R is read.*
8. *T records componentwise* hsame *transport for G, L, S, H, R, D, E and for the replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an L^2-error request through*

$$G, L, S, H, D, E \longmapsto R \longmapsto T, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{AubinNitsche}^{\uparrow}$, $\mathsf{GalerkinProjection}^{\uparrow}$, $\mathsf{LaxMilgram}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AubinNitsche}^{\uparrow}}$ *row.*

The carrier contains no host Hilbert-space quotient, selected minimizer, ambient completeness theorem, unrestricted PDE solution operator, Lean verification row, or bridge credential.

Lean4 ✓ `BEDC.Derived.AubinNitscheUp.AubinNitscheTasteGate single carrier alignment`

Theorem 6757.2 (Aubin-Nitsche NameCert obligations)**.** *For every accepted* $\mathsf{AubinNitsche}^{\uparrow}$ *carrier*

$$A = (G, L, S, H, R, D, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AubinNitsche}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, Galerkin orthogonality exposure through G, dual-solve exposure through L, Sobolev regularity exposure through S, norm or Hilbert comparison through H, projection-error comparison through E, duality comparison through D, Real-bound sealing through R, componentwise transport through T, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6757.1. The analytic rows are the Galerkin row G, dual Lax–Milgram row L, Sobolev regularity row S, norm or Hilbert comparison row H, duality comparison row D, projection-error row E, and Real-bound row R.

The Galerkin and dual rows expose the two variational inputs. The row G supplies the displayed residual-orthogonality surface, while L supplies only the dual solve named by the variational certificate.

The regularity and comparison rows then bound the dual test error. The row S records the finite Sobolev budget, H records the pairing and norm ledger, and E records the projection-error comparison before any scalar estimate is sealed.

Finally D composes the displayed duality comparison and R seals the scalar error data. The structural rows T, C, P, N transport, replay, source, and name the same route, so no hidden quotient, selected minimizer, ambient completeness theorem, unrestricted PDE solution operator, Lean verification row, or bridge credential remains available. □

Theorem 6757.3 (Aubin-Nitsche duality-error route)**.** *Every public L^2-error read exported by an accepted* $\mathsf{AubinNitsche}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{GalerkinProjection}^{\uparrow} \longmapsto \mathsf{LaxMilgram}^{\uparrow} \longmapsto \mathsf{Sobolev}^{\uparrow} \longmapsto \mathsf{Hilbert}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and through the packet rows for duality comparison, projection error, transport, replay, provenance, and local naming. The exported estimate is a finite duality-error certificate; it exports no host Hilbert-space quotient, selected minimizer, ambient completeness theorem, unrestricted PDE solution operator, quotient real equality, or countable-choice selector.

Proof. Start with a public L^2-error request. By Definition 6757.2, the request first reads the Galerkin projection row G and its residual-orthogonality surface.

The dual route is then forced through L. The dual solve is available only as the displayed Lax–Milgram row, so the consumer cannot replace it by a host solution operator or selected minimizer.

Next read S, H, E, D in order. These rows supply the Sobolev regularity budget, norm or Hilbert pairing ledger, projection-error comparison, and duality comparison needed before the scalar bound is exposed.

The Real row R is the only scalar seal in the carrier. Since T, C, P, N preserve the same rows and no forbidden coordinate appears in the carrier, the public error read remains inside the displayed finite route. □

Falsifiable prediction: Every $\mathsf{AubinNitsche}^{\uparrow}$ error read factors through displayed GalerkinProjectionUp, LaxMilgramUp, SobolevUp, HilbertUp, RealUp, duality comparison, projection-error, BHist, hsame, Cont, Pkg, and NameCert rows before any public estimate is exported.

Independence witness: galerkin-projection, lax-milgram, sobolev, hilbert, real: $\mathsf{AubinNitsche}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Galerkin orthogonality, a variational dual solve, Sobolev regularity, norm or Hilbert comparison, projection-error comparison, Real scalar sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AubinNitsche}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AubinNitsche}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6757.1, Definition 6757.2, and Definition 6757.3 seed the finite duality-error route over Galerkin, Lax–Milgram, Sobolev, norm or Hilbert, projection, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AubinNitsche}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hilbert-space quotients, selected minimizers, ambient completeness, unrestricted PDE solution operators, quotient real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Galerkin orthogonality exposure, dual-solve exposure, Sobolev regularity exposure, projection-error comparison, Real-bound sealing, componentwise transport, replay, provenance, and local naming for BEDC.Derived.AubinNitscheUp.

Constructive story: An $\mathsf{AubinNitsche}^{\uparrow}$ packet is generated from a Galerkin projection row, LaxMilgram dual row, Sobolev regularity row, norm or Hilbert comparison row, Real error-bound row, duality comparison row, projection-error row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6758

A Concrete Naming Certificate for $\mathsf{CantorTernaryExpansion}^{\uparrow}$

Following Cantor's middle-third construction and the Bishop–Bridges discipline for real names, the $\mathsf{CantorTernaryExpansion}^{\uparrow}$ packet records a finite ternary-prefix presentation of Cantor-set membership before any downstream real consumer reads it as a $\mathsf{Real}^{\uparrow}$ name. It sits beside the retained-set surface of chapter 1530, the nested-interval route of chapter 320, the dyadic interval arithmetic of chapter 306, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only a displayed finite-window route from ternary digits to a real seal; it does not import quotient real equality, choice of an infinite branch, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6758.1 (Cantor ternary expansion carrier)**.** *A* $\mathsf{CantorTernaryExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, D, I, K, W, R, E, H, C, P, L)$$

with the following rows:

1. *A is the finite ternary prefix row, listing the inspected digits and their prefix length.*
2. *D is the digit-compatibility row requiring every displayed digit to be 0 or 2 and recording the excluded middle-third alternative.*
3. *I is the retained interval row read through* $\mathsf{CantorSet}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*, and* $\mathsf{DyadicInterval}^{\uparrow}$ *siblings.*
4. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row comparing ternary prefix intervals with dyadic observation budgets.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite digit stream segment consumed by the real-name read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same prefix window and tolerance budget.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the prefix, tolerance, stream, and rational readback rows have been displayed.*
8. *H records componentwise* hsame *transport for A, D, I, K, W, R, E and the local certificate rows.*
9. *C records displayed* Cont *replay from ternary-prefix requests through interval, tolerance, stream, rational, and Real-seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorTernaryExpansion}^{\uparrow}$, $\mathsf{CantorSet}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{CantorTernaryExpansion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a completed infinite ternary choice sequence, host subset equality, quotient real equality, selected branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6758.2 (Cantor ternary expansion NameCert obligations)**.** *For every accepted* $\mathsf{CantorTernaryExpansion}^{\uparrow}$ *carrier*

$$T = (A, D, I, K, W, R, E, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CantorTernaryExpansion}^{\uparrow}}$ *surface consists exactly of ternary prefix data A, digit compatibility D, retained interval data I,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance K,* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, provenance P, and local naming L.*

Proof. Project the carrier of Definition 6758.1. The only digit data are the finite prefix row A and the compatibility row D, so the packet cannot read an unbounded ternary branch before the displayed window has been named.

The retained interval row I is then read through the Cantor-set, nested-interval, and dyadic-interval siblings. The dyadic tolerance row K, stream window W, regular rational readback R, and terminal Real seal E turn that interval route into a finite real-name observation.

Finally H, C, P, L transport, replay, source, and name the same rows. Since the carrier contains no branch selector, quotient real equality, host closed-set equality, or ambient completeness row, the NameCert surface is exhausted by the displayed finite-window route. □

Theorem 6758.3 (Cantor ternary expansion Real seal route)**.** *Every Real-facing read of an accepted* $\mathsf{CantorTernaryExpansion}^{\uparrow}$ *carrier must factor in order through the ternary prefix row A, digit-compatibility row D, retained interval row I, dyadic tolerance row K, stream window W, regular rational readback R, and terminal Real seal E before the structural rows H, C, P, L are consumed. The route strengthens the* $\mathsf{CantorSet}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *frontier without importing quotient real equality or choice.*

Proof. Use Definition 6758.2. It places the prefix and digit rows before the interval, tolerance, stream, rational, and Real rows.

The interval row reads the Cantor-set and nested-interval siblings as finite retained intervals, while the dyadic interval and dyadic rational rows provide the tolerance comparison needed by the stream and rational readback.

The Real seal is therefore available only after A, D, I, K, W, R have been displayed. The structural rows H, C, P, L preserve and name that route, so a Real-facing consumer receives a finite NameCert path rather than a selected infinite ternary branch or a quotient real equality proof. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorTernaryExpansion}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorTernaryExpansion}^{\uparrow}$ packet is generated from ternary prefix data, digit-compatibility rows, retained interval rows, DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorTernaryExpansion}^{\uparrow}}$, seed)

Scope closed: Definition 6758.1, Definition 6758.2, and Definition 6758.3 seed the finite ternary-prefix real-name route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorTernaryExpansion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, selected infinite ternary branches, Cantor-set compactness, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked prefix, digit, interval, tolerance, stream, rational readback, Real-seal, transport, replay, provenance, and local naming rows for BEDC.Derived.CantorTernaryExpansionUp.

Chapter 6759

A Concrete Naming Certificate for $\mathsf{DyadicWindowReflector}^{\uparrow}$

Following Bishop–Bridges real-name completeness arguments, the $\mathsf{DyadicWindowReflector}^{\uparrow}$ packet records the finite-window reflector that turns displayed dyadic tolerance requests into the StreamName, RegSeqRat, and Real rows consumed by Real-completeness proofs. It realizes the finite-window classifier route of the Real-completeness vision through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows. The reflector consumes the dyadic tolerance, StreamName observation-window, RegSeqRat readback, and terminal Real seal surfaces through chapter 291, chapter 126, chapter 301, and chapter 38 before any completion-facing read is admitted. The packet names only the finite reflector surface; it does not assert selected limits, quotient Cauchy equality, open-ended choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6759.1 (Dyadic window reflector carrier)**.** *A* $\mathsf{DyadicWindowReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, W, R, E, Q, H, C, P, L)$$

with the following rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget row, including the inspected dyadic radius and comparison window.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row addressed by the same dyadic budget.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from W under the displayed dyadic tolerance.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the reflected finite window.*
5. *Q is the classifier row recording that the Real-completeness query reads only the displayed dyadic, stream, rational, and Real coordinates.*
6. *H records componentwise* hsame *transport for D, W, R, E, Q and the local certificate rows.*
7. *C records displayed* Cont *replay from a finite-window completeness request through the dyadic, stream, rational, and Real-seal route.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicWindowReflector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{DyadicWindowReflector}^{\uparrow}}$ *row.*

The classifier has no coordinate for a selected limiting real, quotient stream equality, hidden Cauchy class, or unrestricted completeness theorem.

Theorem 6759.2 (Dyadic window reflector NameCert obligations)**.** *For every accepted* $\mathsf{DyadicWindowReflector}^{\uparrow}$ *carrier*

$$F = (D, W, R, E, Q, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicWindowReflector}^{\uparrow}}$ *surface consists exactly of the dyadic tolerance budget* D*, stream window* W*, regular rational readback* R*, terminal Real seal* E*, finite-window classifier row* Q*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming* L*.*

Proof. Project the carrier of Definition 6759.1. The dyadic tolerance row D is the only numerical budget available to the reflector, and the stream row W is the only window on which that budget acts.

The rational readback R and Real seal E are downstream of the same displayed window. The classifier row Q records that Real-completeness consumers see exactly this finite-window route rather than a hidden limiting object.

The structural rows H, C, P, L preserve, replay, source, and name the route. Thus the local certificate cannot export selected limits, quotient stream equality, hidden Cauchy classes, or ambient Real completeness beyond the displayed rows. □

Theorem 6759.3 (Dyadic window reflector vision route)**.** *Every finite-window classifier read used by the Real-completeness route factors through* $D, W, R, E, Q, H, C, P, L$ *in an accepted* $\mathsf{DyadicWindowReflector}^{\uparrow}$ *carrier. In particular, the vision-side* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *passages are realized as a concrete NameCert packet over dyadic budgets, stream windows, rational readback, Real seal rows, transport, replay, provenance, and local naming.*

Proof. Apply Definition 6759.2. It fixes the reflector surface as the rows $D, W, R, E, Q, H, C, P, L$.

The dyadic budget row D addresses the observation window W, and the readback row R converts that window into the rational tolerance data required by the terminal Real seal E. The classifier row Q is therefore the finite-window classifier seen by the Real-completeness route.

Finally H, C, P, L keep the classifier stable under componentwise transport and displayed replay. The reflector is consequently a concrete NameCert route for later diagonal-limit formalization, not a selected-limit or quotient-completion principle. □

Theorem 6759.4 (Dyadic window reflector DyadicRatCore route)**.** *Every* $\mathsf{DyadicWindowReflector}^{\uparrow}$ *read first consumes its numerical tolerance budget through chapter 291 before it can open the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows. Thus the sibling route factors through chapter 291, chapter 126, chapter 301, and chapter 38.*

Proof. Project the carrier rows $D, W, R, E, Q, H, C, P, L$ of Definition 6759.1. The row D is the $\mathsf{DyadicRatCore}^{\uparrow}$ source of the inspected radius and comparison window, so it is the only numerical budget available to the reflector.

Only after D is fixed can the stream row W be addressed, the rational readback row R be computed, and the Real seal row E be exposed. The structural rows Q, H, C, P, L preserve this order: the classifier sees the dyadic, stream, rational, and Real coordinates; transport and replay keep those coordinates componentwise; provenance and local naming record the same route.

Without the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row supplied by chapter 291, the reflector has no displayed numerical budget with which to select or compare StreamName windows. Hence its sibling dependency route must pass through DyadicRatCore before the StreamName, RegSeqRat, and Real rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicWindowReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicWindowReflector}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance budget, StreamName windows, RegSeqRat readback, a Real seal, a finite-window classifier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicWindowReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6759.1, Definition 6759.2, Definition 6759.3, and Definition 6759.4 seed the Real-completeness finite-window reflector route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicWindowReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient Cauchy equality, unrestricted Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic-budget, stream-window, rational-readback, Real-seal, classifier, transport, replay, provenance, and local naming rows for BEDC.Derived.DyadicWindowReflectorUp.

Chapter 6760

A Concrete Naming Certificate for $\mathsf{FanBarInduction}^{\uparrow}$

Following Brouwer and Heyting, the $\mathsf{FanBarInduction}^{\uparrow}$ packet records the finite induction surface available for bars on the binary fan before any open-cover compactness, branch selection, quotient stream equality, countable choice, or ambient Real-completeness claim is read. It sits after the finite fan certificate of chapter 400, the Cantor-space prefix carrier of chapter 1475, the barred-spread replay of chapter 1675, and the Bool/List prefix carriers of chapter 32 and chapter 36. The packet names a finite bar-induction handoff for downstream compact fan-modulus and total-bounded routes; it is not an unrestricted induction principle over arbitrary spreads.

Definition 6760.1 (Fan bar induction carrier)**.** *A* $\mathsf{FanBarInduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, B, I, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CantorSpace}^{\uparrow}$ *binary-prefix tree row, retaining exactly the visible* $\mathsf{Bool}^{\uparrow}$ *endpoint rows and* $\mathsf{List}^{\uparrow}$ *prefix spines under inspection;*
2. *B is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar row, recording decidable bar decisions and the unary depth ledger for the retained fan window;*
3. *I is the* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *local backwards-replay row, restricted to displayed children of T and barred prefixes of B;*
4. *W is the finite witness window listing the prefixes where the replay reads bar data, successor rows, and terminal decisions;*
5. *Q is the prefix-closure ledger, asserting that every prefix of a displayed witness prefix is again a displayed* $\mathsf{List}^{\uparrow}$ *row with its* $\mathsf{Bool}^{\uparrow}$ *endpoint data still visible;*
6. *H stores componentwise* hsame *transport for the tree, bar, induction replay, witness-window, prefix-closure, continuation, provenance, and local naming rows;*
7. *C records displayed* Cont *replay for root inspection, left and right successor inspection, prefix restriction, and induction replay;*
8. *P is the* Pkg *provenance over* $\mathsf{FanBarInduction}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{FanBarInduction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these finite rows. It has no coordinate for selected infinite branches, open-cover compactness, quotient stream equality, countable choice, arbitrary spread induction, or ambient Real completeness.

Theorem 6760.2 (Fan bar induction NameCert obligations)**.** *For every accepted* $\mathsf{FanBarInduction}^{\uparrow}$ *carrier* $F = (T, B, I, W, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FanBarInduction}^{\uparrow}}$ *surface consists exactly of carrier admission for the binary-prefix tree, finite-bar row, local backwards-replay row, witness window, prefix-closure ledger, componentwise transport, displayed replay, package provenance, and local name; finite fan-bar exactness requiring B and W to expose the same retained prefixes; induction-replay exactness requiring I to use only displayed successors of T; prefix-closure exactness requiring Q to keep every inspected prefix inside the Bool/List carrier surface; and non-escape of open-cover compactness, branch selection, quotient stream equality, countable choice, arbitrary spread induction, or ambient Real completeness.*

Proof. Project the carrier of Definition 6760.1. Carrier admission exposes exactly $T, B, I, W, Q, H, C, P, N$, so every certificate read starts with the finite binary-prefix, bar, replay, window, closure, transport, continuation, provenance, and naming rows.

Read finite fan-bar exactness through chapter 400. The row B supplies the decidable bar decisions and depth ledger, while W lists the prefixes actually inspected.

Read the backwards-replay row through chapter 1675. Because I is restricted to the displayed children of T, the replay remains local to the retained Cantor-space prefix tree and does not select an infinite branch.

Finally use the Bool/List carrier route of chapter 32 and chapter 36 for Q. Prefix closure keeps endpoint and spine data inside finite carriers, and the structural rows H, C, P, N preserve the same route without adding compactness, quotient, choice, arbitrary induction, or Real-completeness coordinates. □

Theorem 6760.3 (Fan bar induction finite prefix closure)**.** *Let $F = (T, B, I, W, Q, H, C, P, N)$ be an accepted* $\mathsf{FanBarInduction}^{\uparrow}$ *carrier. Every accepted replay of the fan-bar induction row is prefix-closed in the displayed window: if a replay reads a barred prefix from W, then each earlier prefix of that same* $\mathsf{List}^{\uparrow}$ *spine is read through Q, with its* $\mathsf{Bool}^{\uparrow}$ *endpoint rows and its* $\mathsf{CantorSpace}^{\uparrow}$ *tree coordinate still visible. Thus a downstream compact fan-modulus or total-bounded consumer may consume a finite prefix-closed induction handoff, but it receives no selected branch, open-cover compactness theorem, quotient stream equality, countable-choice functional, arbitrary spread-induction rule, or ambient Real-completeness claim.*

Proof. Start with the NameCert obligations of Definition 6760.2. They require every induction replay to expose T, B, I, W, Q before the structural rows are consumed.

The window row W identifies the displayed barred prefixes. The prefix-closure ledger Q then reads each earlier prefix through the same $\mathsf{List}^{\uparrow}$ spine and the same $\mathsf{Bool}^{\uparrow}$ endpoint discipline, so the replay never leaves the finite Cantor-space tree row T.

Transport and replay through H and C preserve those displayed prefix rows, while P and N source and name the same finite packet. Since the accepted carrier has no coordinate for branch selection, open covers, quotient streams, countable choice, arbitrary spread induction, or Real completeness, the finite prefix-closed handoff exports none of those objects. □

Falsifiable prediction: An accepted $\mathsf{FanBarInduction}^{\uparrow}$ read is refuted if a consumer reaches a fan-bar induction replay without first displaying the finite fan-bar row, Cantor-space prefix tree, barred-

spread replay, Bool/List prefix rows, prefix-closure ledger, transport row, replay row, provenance row, and local naming row.

Independence witness: fan theorem, Cantor space, Brouwer bar induction, Bool endpoints, and List prefixes: none is bijective with $\mathsf{FanBarInduction}^{\uparrow}$ because the packet jointly carries finite fan-bar decisions, binary-prefix rows, local backwards replay, prefix-closure data, structural transport, displayed continuation, package provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FanBarInduction}^{\uparrow}}$.

Constructive story: A $\mathsf{FanBarInduction}^{\uparrow}$ packet is generated from a finite FanTheorem bar row, a CantorSpace prefix tree, a BrouwerBarInduction local backwards replay, Bool endpoint rows, List prefix spines, a prefix-closure ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FanBarInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6760.1, Definition 6760.2, and Definition 6760.3 seed the finite fan-bar induction carrier over finite fan bars, Cantor-space prefixes, barred-spread replay, Bool/List prefix rows, prefix closure, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FanBarInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, selected infinite branches, quotient stream equality, countable choice, arbitrary spread induction, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite fan-bar exactness, local backwards-replay exactness, prefix-closure exactness, structural transport, displayed replay, provenance, local naming, and non-escape for BEDC.Derived.FanBarInductionUp.

Chapter 6761

A Concrete Naming Certificate for $\mathsf{CauchyApproximationModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyApproximationModulus}^{\uparrow}$ packet records the finite modulus surface that tells a constructive Cauchy approximation route which tail window answers a requested dyadic tolerance. It sits between the dyadic tolerance ledger of chapter 291, the finite observation route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies downstream Real and Completion consumers with explicit request-to-tail data only; it does not identify quotient streams, choose a limit representative, use host real equality, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6761.1 (Cauchy approximation modulus carrier)**.** *A* $\mathsf{CauchyApproximationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, D, W, R, S, T, C, P, N)$$

with the following displayed rows:

1. *Q is the requested dyadic tolerance row.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger that reads the tolerance as a finite rational budget.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row naming the first finite observation window accepted for that budget.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window and dyadic budget.*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after Q, D, W, R have been exposed.*
6. *T records componentwise* hsame *transport for tolerance, dyadic ledger, tail window, regular readback, seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tolerance request through D, W, R, S, T.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, W, R, S, T, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6761.2 (Cauchy approximation modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyApproximationModulus}^{\uparrow}$ *carrier* $M = (Q, D, W, R, S, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, dyadic tolerance exactness, tail-window exactness, regular readback handoff, Real seal nonescape, componentwise transport, continuation replay, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 6761.1. The tolerance row Q is read first, and the dyadic ledger D is the only row allowed to translate that request into a finite rational comparison budget.

The tail-window row W then supplies the finite $\mathsf{StreamName}^{\uparrow}$ observations used by the request. The regular readback row R and the terminal seal row S are downstream of that displayed window, so the route cannot skip directly to a host real value or selected limit.

The structural rows T, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate is available, the local certificate has exactly the stated obligations and no quotient, choice, trichotomy, or ambient-completeness row. □

Theorem 6761.3 (Cauchy approximation modulus window stability)**.** *Let* $M = (Q, D, W, R, S, T, C, P, N)$ *be an accepted* $\mathsf{CauchyApproximationModulus}^{\uparrow}$ *packet. Any transported read of the same dyadic tolerance must return through the displayed* hsame *row* T *to the same tail-window, regular-readback, and Real-seal route. Thus downstream regular-Cauchy and* $\mathsf{Real}^{\uparrow}$ *consumers receive a stable finite window basis for that tolerance, not a quotient stream equality or host completeness claim.*

Proof. Project the accepted carrier. A tolerance read exposes Q, and the dyadic comparison budget is fixed by D before any stream window can be used.

Transported reads move componentwise through T. The continuation row C replays the route from Q through D, W, R, S, so the consumer returns to the same displayed tail window and regular readback before seeing the terminal seal.

The packet has no coordinate for a second stream representative, a selected limit, a host equality proof, or a completeness theorem. Stability is therefore the stability of the finite displayed window route itself. □

Falsifiable prediction: Every $\mathsf{CauchyApproximationModulus}^{\uparrow}$ read used by a Real or Completion consumer factors through one displayed dyadic tolerance, one DyadicRatCore comparison budget, one StreamName tail-window row, one RegSeqRat readback row, one RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{CauchyApproximationModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a tolerance request, dyadic comparison budget, accepted tail window, regular readback, terminal Real seal, transport, replay, provenance, and local naming in one modulus packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyApproximationModulus}^{\uparrow}$ packet is generated from a dyadic tolerance request, DyadicRatCore comparison budget, StreamName tail window, RegSeqRat readback, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyApproximationModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6761.1, Definition 6761.2, and Definition 6761.3 seed the finite request-to-tail modulus route for the L10 Real and Completion spine.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyApproximationModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, selected limits, host real equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, tail-window exactness, regular readback handoff, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.CauchyApproximationModulusUp.

Chapter 6762

A Concrete Naming Certificate for $\mathsf{RegularCauchyBallBasis}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ packet records the finite tail-ball basis used to inspect a regular Cauchy name before it is handed to a Real-completion seal. It combines the dyadic radius rows of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal boundary of chapter 38. The packet is a finite basis of tail thresholds and dyadic balls; it is not a quotient completion, a selected limit, a host metric completeness theorem, or an ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 6762.1 (Regular Cauchy ball basis carrier)**.** *A* $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, D, O, R, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite tail-threshold row naming the indices after which the regular Cauchy read is inspected.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ball-radius ledger attached to those thresholds.*
3. *O is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row opened for the threshold and radius data.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from T, D, O.*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed tail-ball basis has been read.*
6. *H records componentwise* hsame *transport for thresholds, dyadic balls, observation windows, regular readbacks, seals, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tail request through T, D, O, R, S, H.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBallBasis}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBallBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, D, O, R, S, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, selected representatives, host metric completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6762.2 (Regular Cauchy ball basis NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ *carrier* $B = (T, D, O, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBallBasis}^{\uparrow}}$ *surface consists exactly of carrier admission, threshold exactness, dyadic ball exactness, finite observation-window exposure, regular readback handoff, Real seal nonescape, componentwise transport, continuation replay, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 6762.1. The threshold row T names the tail being inspected, and the dyadic ledger D names the finite ball radius attached to that tail.

The observation row O opens only the finite $\mathsf{StreamName}^{\uparrow}$ windows demanded by T and D. The regular readback R and terminal seal S remain downstream of those windows.

The structural rows H, C, P, N preserve, replay, source, and name the same packet. Since the classifier has no coordinate beyond these rows, the local NameCert surface has exactly the stated obligations and no quotient, selected-limit, choice, metric-completeness, or ambient-completeness row. □

Theorem 6762.3 (Regular Cauchy ball basis tail extraction)**.** *Every downstream Real-completeness consumer of an accepted* $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ *carrier extracts its finite tail-ball basis through the route*

$$T, D, O \longmapsto R, S \longmapsto H, C, P, N.$$

The extracted basis supplies tail thresholds, dyadic balls, finite stream windows, regular readback, and a terminal Real seal, but it supplies no quotient completion, selected representative, host metric limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Proof. Project the accepted carrier. The only rows that can serve as a basis are the threshold row T, the dyadic ball ledger D, and the finite observation row O.

The regular readback R consumes that finite basis before the terminal seal S is visible. Componentwise transport and replay through H and C return the consumer to the same threshold, ball, window, readback, and seal rows.

The provenance and local naming rows P, N name exactly that route. Because the carrier contains no quotient, selected representative, host metric limit, choice schedule, or ambient completeness coordinate, the extracted object is the displayed finite basis and nothing stronger. □

Falsifiable prediction: Every $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ Real-completeness read factors through finite tail thresholds, a DyadicRatCore ball-radius ledger, StreamName observation windows, RegSeqRat readback, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries tail thresholds, dyadic ball radii, finite observation windows, regular readback, a terminal Real seal, transport, replay, provenance, and local naming as one basis packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBallBasis}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ packet is generated from finite tail thresholds, a DyadicRatCore ball-radius ledger, StreamName observation windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBallBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6762.1, Definition 6762.2, and Definition 6762.3 seed the finite tail-ball basis consumed by Real-completeness routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBallBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, selected limits, host metric completeness, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold exactness, dyadic ball exactness, finite observation-window exposure, regular readback handoff, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyBallBasisUp.

Chapter 6763

A Concrete Naming Certificate for $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$

Following Cauchy and the constructive calculus tradition, the $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$ packet records the finite comparison route behind the Cauchy mean value theorem. It sits beside the calculus root of chapter 3632, the derivative packet of chapter 122, and the real-name seal of chapter 38. The packet packages endpoint rows, an interior witness row, derivative comparison data, dyadic tolerance control, regular rational readback, and the terminal Real seal without importing a host Rolle theorem, a quotient function space, or an ambient completeness principle.

Definition 6763.1 (Cauchy mean value theorem carrier)**.** *A* $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (E, I, D, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the endpoint row, naming the two endpoint evaluations and the finite interval certificate read by the calculus packet.*
2. *I is the interior witness row, naming the displayed interior point at which the comparison is read.*
3. *D is the* $\mathsf{Derivative}^{\uparrow}$ *comparison row for the two derivative-facing reads.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the finite-difference comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that interprets the endpoint and derivative comparison through regular rational windows.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after E, I, D, Q, R have been exposed.*
7. *H records componentwise* hsame *transport for endpoints, the interior witness, derivative comparison, tolerance ledger, readback, seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from endpoint rows through the interior witness, derivative comparison, tolerance ledger, readback, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyMeanValueTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, I, D, Q, R, S, H, C, P, N$. It has no coordinate for host differentiability, quotient equality of functions, a selected global extremum, classical choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6763.2 (Cauchy mean value theorem NameCert obligations)**.** *For every accepted* CauchyMeanValueTheo *carrier*

$$M = (E, I, D, Q, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyMeanValueTheorem}^{\uparrow}}$ *surface consists exactly of endpoint exposure, interior witness exposure, derivative comparison exposure, dyadic tolerance exactness, regular rational readback, Real seal nonescape, componentwise transport, continuation replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6763.1. The endpoint row E, interior witness row I, derivative comparison row D, tolerance ledger Q, regular readback row R, and Real seal S are the complete analytic inventory.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. A consumer can therefore move the packet and replay the comparison, but it returns to the displayed endpoint, witness, derivative, tolerance, readback, and seal rows.

Since the packet has no additional coordinate, the local NameCert cannot export a host differentiability theorem, quotient function equality, selected global extremum, classical-choice step, or ambient Real-completeness claim. □

Theorem 6763.3 (Cauchy mean value finite-difference route)**.** *Every downstream calculus consumer of an accepted* $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$ *packet reads the comparison route through*

$$E, I, D, Q \longmapsto R, S \longmapsto H, C, P, N.$$

Thus the Cauchy mean value conclusion is exposed as finite endpoint data, an interior witness row, derivative comparison data, dyadic tolerance control, regular rational readback, and a Real seal; it is not exposed as a host Rolle theorem, quotient-function equality, selected extremum principle, or ambient completeness theorem.

Proof. Read the endpoint row E and the interior witness row I. These rows name the finite interval endpoints and the displayed interior point before any derivative comparison is visible.

Next read the derivative comparison row D together with the dyadic tolerance ledger Q. The regular rational readback R and terminal Real seal S consume those finite rows, so the calculus conclusion is reached through displayed finite-difference data.

Finally use H, C, P, N for transport, replay, provenance, and local naming. Because the carrier contains no row for a host Rolle theorem, quotient-function equality, selected extremum principle, or ambient completeness theorem, every downstream read remains inside the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMeanValueTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$ packet is generated from endpoint rows, an interior witness row, a derivative comparison row, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyMeanValueTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 6763.1, Definition 6763.2, and Definition 6763.3 seed the finite L10 Cauchy mean value route over endpoint, interior-witness, derivative-comparison, dyadic-tolerance, regular-readback, and Real-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyMeanValueTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host Rolle theorem, quotient equality of functions, a selected extremum principle, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, interior witness exposure, derivative comparison exposure, tolerance exactness, readback handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyMeanValueTheoremUp.

Chapter 6764

A Concrete Naming Certificate for $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$

Following Runge and Kutta on finite-stage ordinary differential equation methods and Bishop–Bridges constructive real analysis, the $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$ packet records the finite stage data needed to inspect one displayed ODE step. It sits beside the ODE carrier of chapter 193, the Picard–Lindelof finite-approximation discipline of chapter 1888, the dyadic arithmetic rows of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names finite stage equations over displayed data; it does not assert host ODE existence, selected global solutions, quotient equality of names, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6764.1 (Runge–Kutta finite-step carrier)**.** *A* $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, F, A, S, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the displayed ODE row read from chapter 193, including the state, time, and right-hand-side interface inspected by the step.*
2. *F is the finite stage-function row naming the stage evaluation scheme used by the Runge–Kutta tableau.*
3. *A is the tableau row containing the finitely many stage coefficients, weights, and nodes.*
4. *S is the dyadic step-size row read through chapter 291.*
5. *D is the dyadic arithmetic ledger for coefficient products, stage update terms, and final weighted sums.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened for the source state, time, and stage arguments.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row naming the computed step as regular rational data.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the ODE, stage, tableau, dyadic, window, and readback rows have been displayed.*
9. *H records componentwise* hsame *transport for the ODE row, stage row, tableau row, step-size row, dyadic ledger, stream window, readback row, Real seal, replay, provenance, and local name.*

10. *C records the displayed* Cont *replay for finite stage evaluation, dyadic accumulation, stream-window inspection, regular readback, and Real seal handoff.*
11. *P is the* Pkg *provenance over the ODE, Picard–Lindelof, dyadic, stream, regular rational, Real, transport, replay, and NameCert rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RungeKuttaFiniteStep}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the rows $O, F, A, S, D, W, R, E, H, C, P, N$.

Theorem 6764.2 (Runge–Kutta finite-step NameCert obligations)**.** *For the carrier of Definition 6764.1, the local* $\mathsf{NameCert}_{\mathsf{RungeKuttaFiniteStep}^{\uparrow}}$ *obligation surface consists exactly of ODE-row exposure through O, finite stage-function exposure through F, tableau exposure through A, dyadic step-size exposure through S, dyadic arithmetic through D, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier $K = (O, F, A, S, D, W, R, E, H, C, P, N)$. The analytic rows are displayed before the structural rows, and the classifier reads no coordinate outside this finite list.

Use the ODE and Picard–Lindelof neighbor chapters only as source rows for a displayed finite step. The stage-function and tableau rows record a finite evaluation scheme, while S, D, W provide the dyadic and stream-window data needed to compute the inspected step.

The readback and seal rows are downstream of those finite rows. Since H, C, P, N transport, replay, source, and name the same packet, they do not add a host existence theorem, selected solution, quotient equality, or Real completeness principle. □

Theorem 6764.3 (Runge–Kutta finite-step RegSeqRat handoff)**.** *Every accepted* $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$ *carrier that exposes the readback row R must first display the ODE row O, stage-function row F, tableau row A, dyadic step-size row S, dyadic arithmetic ledger D, and finite* $\mathsf{StreamName}^{\uparrow}$ *window W. Thus the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff is a finite step readback over displayed stage data, not a selected solution operator.*

Proof. Read the carrier definition. The row R is the first regular rational output row, and it is placed after the ODE, stage, tableau, dyadic, and stream-window rows.

The dyadic ledger D is where coefficient products, stage update terms, and weighted sums are displayed. The stream window W supplies the finite source data read by those dyadic calculations.

Therefore a consumer cannot read R as a free-standing regular rational name. It is available only as the handoff of the finite Runge–Kutta stage calculation over O, F, A, S, D, W. □

Theorem 6764.4 (Runge–Kutta finite-step Real-seal nonescape)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal row E of an accepted* $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$ *carrier cannot be reread as an ambient ODE solution, a selected flow map, quotient equality of solution names, or completeness of* $\mathsf{Real}^{\uparrow}$*. Any route to E still factors through the displayed rows O, F, A, S, D, W, R.*

Proof. Project the carrier. The seal row E is terminal for one finite-step packet and is reached only after the readback row R.

Apply the RegSeqRat handoff theorem. It forces R to factor through the ODE, stage, tableau, dyadic step-size, dyadic arithmetic, and stream-window rows before any Real-facing seal is exposed.

The structural rows H, C, P, N preserve that route under componentwise transport and replay. They do not contain data for a global solution, a selected flow, quotient equality, or a completeness principle, so the seal cannot escape the finite-step boundary. □

Falsifiable prediction: A $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$ consumer that reaches R or E without displaying the ODE row, finite stage-function row, tableau row, dyadic step-size row, dyadic arithmetic ledger, and finite $\mathsf{StreamName}^{\uparrow}$ window refutes the carrier surface.

Independence witness: ode, picard-lindelof, dyadicratcore, streamname, regseqrat, real: no listed sibling supplies the whole packet $K = (O, F, A, S, D, W, R, E, H, C, P, N)$, because this chapter binds finite ODE stage data, a Runge–Kutta tableau, dyadic step arithmetic, stream windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming in one NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RungeKuttaFiniteStep}^{\uparrow}}$.

Constructive story: A $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$ packet is generated from a displayed ODE row, finite stage-function row, tableau row, dyadic step-size row, dyadic arithmetic ledger, finite stream window, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RungeKuttaFiniteStep}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6764.1, Definition 6764.2, Definition 6764.3, and Definition 6764.4 seed the finite-stage ODE computation packet over ODE, Picard–Lindelof, DyadicRatCore, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RungeKuttaFiniteStep}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host ODE existence, selected global solutions, quotient equality of names, ambient Real completeness, or a Lean theorem.

Upgrade path: A formal route can encode the twelve-row carrier and prove the NameCert-obligation, RegSeqRat-handoff, and Real-seal nonescape theorems.

Chapter 6765

A Concrete Naming Certificate for $\mathsf{ClassifierChannelShiftLedger}^{\uparrow}$

The $\mathsf{ClassifierChannelShiftLedger}^{\uparrow}$ packet realizes the classifier-level information distinction of chapter 9366 as finite before-and-after channel data. It separates record growth from classifier shift by displaying the before classifier row, after classifier row, record-growth row, shift witness, transport, replay, provenance, and local naming in one NameCert surface. The classifier-shift witness row is consumed after the gap-closure boundary of chapter 1006, because a classifier channel only counts as moved once the source gap has a displayed closure boundary rather than mere record growth. The packet is a BEDC-native ledger for classifier-channel movement, not a longer continuation trace and not a host semantic comparison.

The before and after classifier rows consume the classifier-membership surface of chapter 3911: a channel comparison reads B and A only after membership has been exposed as a finite type-checking classifier row. The refusal row for record-growth-as-discovery is routed through chapter 1006, so the ledger distinguishes classifier-row consumption from refusal-row consumption before W is allowed to witness movement.

Definition 6765.1 (Classifier-channel shift ledger carrier)**.** *A* $\mathsf{ClassifierChannelShiftLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, A, R, W, H, C, P, N)$$

with the following displayed rows:

1. *B is the before-classifier row, naming the certified classifier state before the audited transition.*
2. *A is the after-classifier row, naming the certified classifier state after the audited transition.*
3. *R is the record-growth row, naming the displayed histories added by mechanical unfolding or continuation replay.*
4. *W is the classifier-shift witness row, empty exactly when B and A have identical classifier readings on the displayed source scope and nonempty when the channel changes.*
5. *H records componentwise* hsame *transport for before classifier, after classifier, record growth, shift witness, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from the before classifier and record-growth rows to the after classifier and shift witness rows.*

7. *P is the* Pkg *provenance over classifier-level information, computation as continuation, type checking as classifier membership, gap-closure boundary,* BHist, hsame, Cont, *and* NameCert.

8. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassifierChannelShiftLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, A, R, W, H, C, P, N. It has no coordinate that identifies record growth with classifier shift, no hidden semantic oracle, and no permission to read a longer record as discovery without the displayed shift witness.

Theorem 6765.2 (Classifier-channel shift ledger NameCert obligations)**.** *For every accepted* ClassifierChannelShiftL *carrier*

$$L = (B, A, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClassifierChannelShiftLedger}^{\uparrow}}$ *surface consists exactly of before-classifier exposure, after-classifier exposure, record-growth exposure, shift-witness exactness, componentwise transport, continuation replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6765.1. The analytic rows are B, A, R, W: the two classifier states, the record-growth row, and the witness that says whether the classifier channel moved.

The structural rows H, C, P, N transport, replay, source, and name the same finite tuple. They can carry the classifier-channel packet through a consumer, but they cannot replace the shift witness by the existence of a longer record.

Since the carrier has no further coordinate, the local NameCert surface has exactly the stated obligations and no hidden semantic oracle, host classifier comparison, or record-growth-as-discovery rule. □

Theorem 6765.3 (Classifier-channel shift ledger record-growth separation)**.** *An accepted* ClassifierChannelShiftLedg *packet with identical before and after classifier rows has an empty classifier-shift witness row even when the record-growth row is nonempty. Conversely, a nonempty shift witness must be read from W and cannot be inferred from R alone.*

Proof. Read the before and after classifier rows B and A. When they are identical on the displayed source scope, the carrier definition fixes W as the empty shift witness row.

The record-growth row R is separate. It may record added histories from continuation replay, but no clause of the carrier turns that growth into classifier movement.

For the converse reading, a consumer must project W directly. Transport, replay, provenance, and local naming through H, C, P, N preserve the displayed tuple, so a nonempty classifier shift is witnessed by W and not by R alone. □

Falsifiable prediction: A packet with identical before/after classifier rows has zero classifier-shift witness even when the record-growth row is nonempty.

Independence witness: Compare `classifier_level_information`, `computation_as_continuation`, `type_checking_as_classifier_membership`, and gapclosureboundary: the packet has before/after classifier rows and a shift witness that none of those siblings carry, so no bijection preserves all fields.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierChannelShiftLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassifierChannelShiftLedger}^{\uparrow}$ packet is generated from before-classifier, after-classifier, record-growth, shift-witness, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClassifierChannelShiftLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6765.1, Definition 6765.2, and Definition 6765.3 seed the finite classifier-channel ledger separating record growth from classifier shift.

Formal verification: FormalStatus(NameCert$_{\text{ClassifierChannelShiftLedger}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close positive discovery certification, a global semantic classifier oracle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shift-witness exactness, record-growth separation, Nontrivial ClassifierChannelShiftLedgerUp, and FieldFaithful ClassifierChannelShiftLedgerUp in TasteGate.lean.

Chapter 6766

A Concrete Naming Certificate for $\mathsf{ModulatedCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ModulatedCauchyCompletion}^{\uparrow}$ packet records the finite modulus-bearing completion route by which regular rational observations become a Real-facing seal. It sits beside the stream window packet of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the explicit modulus surface of chapter 292, and the terminal real-name seal of chapter 38. The chapter isolates the finite rows a completion consumer may inspect before any completed object is claimed.

Definition 6766.1 (Modulated Cauchy completion carrier)**.** *A* $\mathsf{ModulatedCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, M, W, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *stream row whose finite requests are the only observations admitted by the packet.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row; for each displayed precision request it names the finite threshold after which the source stream must be read.*
3. *W is the finite window ledger pairing each request with the threshold supplied by M.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same window ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S, W, D after the thresholded window has been displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the source stream, modulus, window, dyadic tolerance, and regular readback rows have been consumed.*
7. *H records componentwise* hsame *transport for S, M, W, D, R, E and for the structural rows.*
8. *C records displayed* Cont *replay from source requests to modulus thresholds, from thresholds to windows, from windows to dyadic tolerances, from tolerances to regular readback, and from readback to the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{ModulatedCauchyCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulatedCauchyCompletion}^{\uparrow}}$ *row.*

The carrier exports only this finite modulus-controlled completion surface. It contains no quotient-completion coordinate, selected limit, countable-choice scheduler, host real equality, or ambient completeness row for $\mathsf{Real}^{\uparrow}$.

Theorem 6766.2 (Modulated Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{ModulatedCauchyCompletion}^{\uparrow}$ *carrier* $T = (S, M, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ModulatedCauchyCompletion}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission exposes precisely the rows $S, M, W, D, R, E, H, C, P, N$ before a completion-facing read is exported;*
2. *modulus coverage requires every displayed precision request in W to be served by a threshold row in M over the same source stream S;*
3. *regular-window readback factors each admitted read through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *before the Real seal is visible;*
4. *Real-seal nonescape makes E downstream of S, M, W, D, R and excludes quotient completions, selected limits, countable choice, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*
5. *provenance and transport require H, C, P, N to preserve the same displayed route under* hsame *transport,* Cont *replay, package sourcing, and local naming.*

Proof. Carrier admission is projection from Definition 6766.1. The packet lists exactly the source stream, modulus, window ledger, dyadic tolerance row, regular readback, Real seal, and structural rows as its public surface.

For modulus coverage, inspect M and W together. Each window row is admitted only with the threshold supplied by the displayed $\mathsf{CauchyModulus}^{\uparrow}$ row, so no precision request can be served by an external schedule or by countable choice.

The regular-window readback then reads S, W, D, R in order. The sibling chapters chapter 126, chapter 292, chapter 291, and chapter 301 provide the stream, modulus, dyadic, and regular rational surfaces named by the carrier.

Finally the seal row E is downstream of that finite route, and H, C, P, N only transport, replay, source, and name the same packet. Since the carrier has no quotient, selected-limit, choice, host-equality, or ambient-completeness coordinate, a Real-facing consumer receives only the displayed $\mathsf{Real}^{\uparrow}$ seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulatedCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulatedCauchyCompletion}^{\uparrow}$ packet is generated from a source StreamName row, an explicit CauchyModulus threshold row, finite window rows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ModulatedCauchyCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 6766.1 and Definition 6766.2 seed the finite modulus-controlled completion route for Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ModulatedCauchyCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, full RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus coverage, regular-window readback, Real-seal nonescape, and transport-provenance preservation for BEDC.Derived.ModulatedCauchyCompletionUp.

Chapter 6767

A Concrete Naming Certificate for $\mathsf{LogicalRelation}^{\uparrow}$

Following Tait, Girard, and Reynolds, the $\mathsf{LogicalRelation}^{\uparrow}$ packet records the finite proof-theoretic surface used by reducibility candidates, Kripke logical relations, and parametricity-style typed-term arguments. It sits beside the MetaCIC critical-path ledger of chapter 765, the readback discipline of chapter 6305, and the lambda-calculus syntax carrier of chapter 200. The packet names typed-term rows, world-extension rows, reducibility evidence, substitution-stability rows, componentwise transport, replay, provenance, and local naming; it does not assert global normalization, subject reduction, full confluence, quotient syntax equality, or a completed semantic model.

Definition 6767.1 (LogicalRelation carrier)**.** *A* $\mathsf{LogicalRelation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, W, E, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-term row, carrying the term, type, binder context, and source syntax route read from* $\mathsf{LambdaCalc}^{\uparrow}$ *or the represented MetaCIC term surface.*
2. *W is the world-extension row, recording context growth, environment extension, step-index windows, or Kripke monotonicity data as finite packet entries.*
3. *E is the reducibility-evidence row, naming the candidate, logical predicate membership, closed-candidate witness, or parametric relation evidence consumed by the proof route.*
4. *S is the substitution-stability row, recording how typed substitution, environment extension, and binder transport preserve the same relation under the world extension.*
5. *H records componentwise* hsame *transport for T, W, E, S, C, P, N.*
6. *C records displayed* Cont *replay from typed-term inspection through world extension, reducibility evidence, substitution stability, transport, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{LogicalRelation}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{NormalizationByEvaluation}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LogicalRelation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an unbounded semantic universe, proof-irrelevant candidate quotient, host evaluator, global normalization theorem, or external syntax equality.

Theorem 6767.2 (LogicalRelation NameCert obligations)**.** *For an accepted* $\mathsf{LogicalRelation}^{\uparrow}$ *carrier* $R = (T, W, E, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LogicalRelation}^{\uparrow}}$ *surface consists exactly of carrier admission for typed-term rows, world-extension rows, reducibility evidence, substitution-stability rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any candidate-mediated strong-normalization, parametricity, or MetaCIC normalization consumer must read the typed term through* T*, extend only through* W*, consume reducibility evidence through* E*, preserve substitution through* S*, and then pass through* H, C, P, N*. The packet exports no global strong normalization theorem, no full subject reduction theorem, no global confluence theorem, no beta-conversion decidability result, and no quotient equality of syntax.*

Proof. Carrier admission is projection from Definition 6767.1. The tuple lists exactly the typed-term, world-extension, reducibility-evidence, substitution-stability, transport, replay, provenance, and local naming rows.

The proof-theoretic route is finite. A consumer may inspect typed terms through T, extend contexts through W, and use candidate or logical-predicate evidence through E only while the substitution row S remains attached to the same displayed packet.

The structural rows then preserve the route. Componentwise transport H and replay C move the typed-term, world, evidence, and substitution rows together, while P, N record the source chapters and local naming. Since the carrier lacks rows for global normalization, full subject reduction, global confluence, beta-conversion decidability, quotient syntax equality, or completed semantic universes, those conclusions cannot be exported by the local certificate. □

Falsifiable prediction: Every accepted $\mathsf{LogicalRelation}^{\uparrow}$ consumer that claims candidate-mediated normalisation, parametricity, or MetaCIC normalization must expose the typed-term row, world-extension row, reducibility-evidence row, substitution-stability row, componentwise transport, continuation replay, provenance, and local NameCert before citing the result.

Independence witness: metaciccriticalpath, normalization-by-evaluation, lambdacalc: $\mathsf{LogicalRelation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries typed-term rows, world-extension rows, reducibility evidence, and substitution stability as one proof-theoretic packet. $\mathsf{MetaCICCriticalPath}^{\uparrow}$ carries residual and candidate budgets without the relation carrier, $\mathsf{NormalizationByEvaluation}^{\uparrow}$ carries evaluation and readback without the candidate relation, and $\mathsf{LambdaCalc}^{\uparrow}$ carries syntax and beta ledgers without world-indexed reducibility evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{LogicalRelation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LogicalRelation}^{\uparrow}$ packet is generated from typed-term rows, world-extension rows, reducibility evidence, substitution-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LogicalRelation}^{\uparrow}}$, seed)

Scope closed: Definition 6767.1 and Definition 6767.2 seed the finite proof-theoretic packet for candidate-mediated MetaCIC and typed-term arguments.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LogicalRelation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global normalization, full subject reduction, global confluence, beta-conversion decidability, quotient syntax equality, completed semantic models, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, world extension, reducibility evidence, substitution stability, transport replay, provenance, and local naming for BEDC.Derived.LogicalRelationUp.

Chapter 6768

A Concrete Naming Certificate for $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$

Following Bishop and Bridges and Bourbaki/Kelley completion terminology, the $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$ packet records the finite boundary where two displayed reads of a Cauchy completion are compared before any quotient completion equality is invoked. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the public completion reflector route of chapter 1585. The packet names an equalizer surface for two completion reads; it does not identify quotient classes, select representatives, import host equality, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6768.1 (Cauchy completion equalizer carrier)**.** *A* $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, Q, D, R, A, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row listing the finite observation windows used by both completion reads.*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row through which the two reads are compared at each requested window.*
3. *D is the displayed source regularity row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *and carrying the rational Cauchy data common to both sides.*
4. *R is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row exposing the completion-facing handoff without presenting a quotient carrier or selected host limit.*
5. *A is the first displayed completion read, obtained only after S, Q, D, R have been exposed.*
6. *B is the second displayed completion read over the same S, Q, D, R boundary.*
7. *H records componentwise* hsame *transport for the stream, dyadic, regular-rational, reflector, two read, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a comparison request through $S, Q, D, R, A, B, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionEqualizer}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $S, Q, D, R, A, B, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Theorem 6768.2 (Cauchy completion equalizer NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionEqua}$ *carrier $E = (S, Q, D, R, A, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionEqualizer}^{\uparrow}}$ *surface consists exactly of carrier admission, shared stream-window exposure through S, shared dyadic tolerance exposure through Q, regular-rational source exposure through D, reflector handoff through R, the two displayed completion reads A, B, componentwise transport through H, displayed replay through C, provenance through P, local naming through N, and non-escape from quotient completion equality, selected representatives, countable choice, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Carrier admission is projection from Definition 6768.1. The accepted packet exposes exactly the stream, dyadic, regular-rational, reflector, two read, transport, replay, provenance, and naming rows.

The equalizer read is shared before it is compared. Both A and B are downstream of the same finite windows S, tolerance row Q, regular-rational source row D, and reflector row R.

The comparison is therefore a displayed BHist and $\mathsf{NameCert}$ route, not a quotient-completion equation. Since the carrier contains no row for selected representatives, host equality, countable choice, ambient completeness, or bridge checking, the listed rows exhaust the local obligation surface. □

Theorem 6768.3 (Cauchy completion equalizer reflector kernel)**.** *Every* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$ *carrier receives the two completion reads only through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyCompletionReflector}^{\uparrow} \longmapsto A, B.$$

Consequently the equalizer kernel available to the consumer is the displayed agreement boundary over $S, Q, D, R, A, B, H, C, P, N$, not quotient completion equality, selected representatives, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Open an accepted carrier $E = (S, Q, D, R, A, B, H, C, P, N)$. The only completion-facing handoff row is R, and both displayed reads A and B are stored after the shared stream, dyadic, and regular-rational rows.

The reflector-facing consumer must therefore inspect S, Q, D, R before either read is available. Transport through H and replay through C preserve the same boundary, while P and N source and name only that boundary.

No further kernel data can be read from the packet. The missing quotient, representative-selection, host-equality, choice, completeness, and bridge coordinates cannot be reconstructed from the displayed rows, so the consumer receives exactly the finite equalizer surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionEqualizer}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$ packet is generated from shared StreamName windows, a DyadicRatCore tolerance row, a RegSeqRat source row, a CauchyCompletionReflector handoff, two displayed completion reads, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionEqualizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6768.1, Definition 6768.2, and Definition 6768.3 seed the finite equalizer boundary for two displayed completion reads over StreamName, DyadicRatCore, RegSeqRat, CauchyCompletionReflector, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyCompletionEqualizer}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window exposure, dyadic tolerance exposure, regular-rational source exposure, reflector handoff, displayed-read comparison, transport and replay stability, provenance non-escape, and local NameCert faithfulness for BEDC.Derived.CauchyCompletionEqualizerUp.

Chapter 6769

A Concrete Naming Certificate for $\mathsf{HeineCantorFiniteNet}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Heine–Cantor theorem, the $\mathsf{HeineCantorFiniteNet}^{\uparrow}$ packet isolates the finite-net route from compact metric continuity to a uniform modulus. It reads the metric source of chapter 57, the compact finite-net surface of chapter 129, the pointwise continuity rows of chapter 130, and the uniform-modulus consumer interface of chapter 369. The packet names the finite lower-bound fold and coverage ledger used by the compact continuity argument; it does not import open-cover compactness, selected Lebesgue numbers, host modulus functions, sequential compactness, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6769.1 (Heine-Cantor finite-net carrier)**.** *A* $\mathsf{HeineCantorFiniteNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, K, F, L, Q, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the distance and comparison reads used by the compact finite-net and continuity rows.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, displaying a finite center bundle and the coverage ledger over X.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, including the pointwise modulus rows attached to the centers listed by K.*
4. *L is the local finite-net ledger pairing each center of K with its pointwise modulus row from F and its source-radius comparison.*
5. *Q is the rational lower-bound fold over the finitely many source-radius comparisons in L.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row consumed only after K, F, L, Q have been displayed.*
7. *H records componentwise* hsame *transport for the metric source, compact finite-net row, continuous-map row, local ledger, rational fold, uniform-modulus row, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a target-tolerance request through $X, K, F, L, Q, U, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{HeineCantorFiniteNet}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HeineCantorFiniteNet}^{\uparrow}}$ *row.*
The carrier exposes only the compact finite-net coverage route, pointwise modulus inventory, finite lower-bound fold, uniform-modulus output, componentwise transport, replay, provenance, and local naming.

Theorem 6769.2 (Heine-Cantor finite-net modulus extraction)**.** *Let $G = (X, K, F, L, Q, U, H, C, P, N)$ be an accepted* $\mathsf{HeineCantorFiniteNet}^{\uparrow}$ *carrier. Every* $\mathsf{UniformModulus}^{\uparrow}$ *read exported by G factors through compact finite-net coverage and pointwise modulus rows before the row U is visible:*

$$X, K, F, L, Q \longmapsto U \longmapsto H, C, P, N.$$

Thus the modulus extraction is a finite NameCert route through the metric source, compact finite-net row, continuous-map pointwise rows, local ledger, and rational lower-bound fold, not a selected host modulus function or an open-cover compactness principle.

Proof. Project the carrier of Definition 6769.1. The output row U is downstream of the source metric row X, the compact finite-net row K, and the continuous-map row F.

Read the finite ledger L. It pairs only the centers already displayed by K with pointwise modulus rows already displayed by F, so the extraction has no independent source of compactness data.

Fold the displayed source-radius comparisons through Q. Because the fold ranges over the finite center bundle in K, the resulting lower bound is a finite ledger row rather than a selected Lebesgue number or host minimum.

Finally replay the route through H, C, P, N. These structural rows transport, continue, package, and name the same displayed packet, so every uniform-modulus consumer reaches U only through X, K, F, L, Q. □

Theorem 6769.3 (Heine-Cantor finite-net ledger exhaustion)**.** *The local* $\mathsf{NameCert}_{\mathsf{HeineCantorFiniteNet}^{\uparrow}}$ *ledger for Definition 6769.1 is exhausted by carrier admission for $X, K, F, L, Q, U, H, C, P, N$, compact finite-net coverage, pointwise modulus pairing, finite rational lower-bound folding, uniform-modulus output admission, componentwise transport, continuation replay, package provenance, and local naming. The packet exports no selected Lebesgue number, host modulus function, sequential compactness principle, countable choice, quotient equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission supplies exactly the displayed tuple. The analytic rows are X, K, F, L, Q, U, and the structural rows are H, C, P, N.

The extraction theorem, Definition 6769.2, accounts for every modulus-facing read. It forces the consumer through compact finite-net coverage, pointwise modulus rows, and the finite rational fold before the uniform-modulus output is consumed.

The absent principles are not coordinates of the carrier and are not generated by the structural rows. Therefore the local NameCert ledger is exhausted by the finite route named above. □

Closure status for $\mathsf{NameCert}_{\mathsf{HeineCantorFiniteNet}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HeineCantorFiniteNet}^{\uparrow}}$, seed)

Scope closed: Definition 6769.1, Definition 6769.2, and Definition 6769.3 seed the finite-net route from compact metric continuity to a uniform modulus.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HeineCantorFiniteNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close general Heine-Borel compactness, open-cover compactness, selected Lebesgue numbers, host modulus functions, sequential compactness, quotient equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, pointwise modulus pairing, rational lower-bound folding, uniform-modulus output admission, transport, replay, provenance, and local naming for BEDC.Derived.HeineCantorFiniteNetUp.

Constructive story: A HeineCantorFiniteNet$^{\uparrow}$ packet is generated from a Metric source row, CompactMetric finite-net coverage, ContinuousMap pointwise modulus rows, a local finite-net ledger, a rational lower-bound fold, a UniformModulus output row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6770

A Concrete Naming Certificate for $\mathsf{BishopLocatedMaximum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedMaximum}^{\uparrow}$ packet records maximum-location data as a finite BEDC NameCert route through compact finite nets, displayed value windows, and located comparisons. It sits over the compact-metric source of chapter 129, the uniformly continuous map row of chapter 130, the finite-net handoff of chapter 6769, the stream schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the stronger attained-extreme surface of chapter 3984. The packet exposes the finite comparison route needed by optimization consumers without selecting an argmax, importing open-cover compactness, identifying quotient real names, invoking countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6770.1 (Bishop located maximum carrier)**.** *A* $\mathsf{BishopLocatedMaximum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, N, W, R, E, M, H, C, P, L)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, carrying the compact metric inspection surface and the finite center coverage consumed by maximum-location reads.*
2. *F is the uniformly continuous* $\mathsf{ContinuousMap}^{\uparrow}$ *row, exposing only displayed value requests over the compact source row K.*
3. *N is the finite-net cover row, recording the finite list of centers, radii, and coverage witnesses through which every maximum-facing request enters.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the finite value windows attached to the centers of N.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *value readback row for the rational windows exposed by W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, admitting the displayed value readbacks as Real-facing names before comparisons are consumed.*
7. *M is the located maximum comparison row, comparing each displayed candidate value with the finite net family through located upper and lower comparison windows.*
8. *H records componentwise* hsame *transport for the compact source, uniformly continuous map row, finite-net cover, stream schedule, regular rational readback, Real seal, located comparison row, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from a maximum-facing request through $K, F, N, W, R, E, M, H, P, L$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedMaximum}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, HeineCantorFiniteNet $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedMaximum}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed compact source, uniformly continuous map row, finite-net cover, stream windows, regular rational readbacks, Real seals, located maximum comparisons, transport, replay, provenance, and local naming. It has no coordinate for a selected argmax, open-cover compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedMaximumUp.BishopLocatedMaximumTasteGate single carrier alignment`

Theorem 6770.2 (Bishop located maximum NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedMaximum}^{\uparrow}$ *carrier $B = (K, F, N, W, R, E, M, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedMaximum}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed compact source, uniformly continuous map row, finite-net cover, value windows, regular rational readbacks, Real seal, located comparison row, transport, replay, provenance, and local naming;*

2. *finite-net exposure, requiring every maximum-facing source request to pass through the centers and coverage witnesses named by N;*

3. *value readback through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *requiring W, R, E to be visible before any comparison row is consumed;*

4. *located maximum comparison, requiring M to compare only displayed Real-sealed value windows over the finite net;*

5. *ledger refusal for selected argmax data, open-cover compactness, quotient real equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6770.1. The rows K, F, N expose the compact source, map row, and finite-net coverage surface that every later value read must use.

Read the value rows next. The stream schedule W supplies finite windows, R reads those windows as regular rational data, and E seals the displayed readbacks as $\mathsf{Real}^{\uparrow}$ names before a comparison can be used.

The comparison row M has access only to the Real-sealed finite-net values already displayed by N, W, R, E. The structural rows H, C, P, L transport, replay, source, and name the same finite route, so the five listed obligations exhaust the local NameCert surface. □

Theorem 6770.3 (Bishop located maximum finite-net handoff)**.** *Every maximum-facing read exported by an accepted* $\mathsf{BishopLocatedMaximum}^{\uparrow}$ *carrier factors through the displayed finite route*

$$K, F, N \longmapsto W, R, E \longmapsto M \longmapsto H, C, P, L.$$

Thus an optimization consumer can inspect only the compact source, uniformly continuous map row, finite net, value windows, located comparison, and Real seal before reaching the local naming row. It cannot bypass the finite-net handoff to obtain a selected argmax, open-cover compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source and map rows. The compact metric source K and uniformly continuous map row F become visible to a maximum-facing read only through the finite-net cover N.

The value route is then fixed. The stream schedule W records the finite observation windows attached to the net, the regular rational row R reads those windows, and the terminal seal E is reached before any optimization-facing comparison is available.

Use the located comparison row M only after the sealed value windows are displayed. Since M compares the finite family exposed by N, W, R, E, it supplies a located maximum comparison surface rather than a selected maximizing point.

Finally replay the same route through H and C, while P and L provide provenance and local naming. The carrier has no coordinate for the excluded principles, so every consumer reaches maximum-location data only through the finite handoff shown above. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedMaximum}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedMaximum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6770.1, Definition 6770.2, and Definition 6770.3 seed the finite-net maximum-location route over compact-source, uniformly continuous map, value-window, located-comparison, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedMaximum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected maximizers, full open-cover compactness, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{BishopLocatedMaximum}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, StreamName-RegSeqRat-Real value readback, located maximum comparison, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedMaximum

Constructive story: A $\mathsf{BishopLocatedMaximum}^{\uparrow}$ packet is generated from a CompactMetric source row, a uniformly continuous ContinuousMap row, a finite-net cover, StreamName value windows, RegSeqRat readbacks, a Real seal, a located maximum comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6771

A Concrete Naming Certificate for $\mathsf{FiniteMetricCompactness}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{FiniteMetricCompactness}^{\uparrow}$ packet records the elementary compactness certificate for a finite metric carrier. It sits between the distance rows of chapter 57, the finite-net compactness surface of chapter 129, the total-boundedness ledger of chapter 127, the dyadic tolerance reads of chapter 38, and the finite-net Heine–Cantor route of chapter 6769. The packet names only finite point rows, explicit distance comparisons, dyadic tolerance rows, finite-net coverage, transport, replay, provenance, and local naming; it does not import open-cover compactness, sequential compactness, choice-selected subsequences, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6771.1 (Finite metric compactness carrier)**.** *A* $\mathsf{FiniteMetricCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F_{\mathrm{mc}} = (X, D, E, R, T, K, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the finite point-row bundle, listing every admitted point of the carrier before any compactness read is exported.*
2. *D is the* $\mathsf{Met}^{\uparrow}$ *distance row over X, displaying symmetry, diagonal, and triangle-comparison reads only for the finite point inventory.*
3. *E is the finite equality and* hsame*-stability row for point names, distance cells, tolerance cells, coverage rows, and local naming rows.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *dyadic tolerance row, exposing positive dyadic requests and comparison readback for the metric inequalities used by the net ledger.*
5. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, assigning to each displayed tolerance in R a finite center subrow drawn from X.*
6. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *ledger row that records the same finite-net coverage as a compact-metric certificate and nothing stronger.*
7. *L is the local coverage ledger: for each point row of X and each tolerance row of R, it displays a center from the finite center subrow of T and the corresponding D-comparison.*

8. *H records componentwise* hsame *transport for point rows, metric rows, dyadic tolerance rows, finite-net coverage, compact-metric ledger rows, replay rows, provenance rows, and local naming rows.*
9. *C records* Cont *replay from a tolerance request through $X, D, E, R, T, K, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteMetricCompactness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{HeineCantorFiniteNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. There is no coordinate for open covers, infinite subsequences, countable choice, quotient metric equality, or a completeness argument over ambient real names.

Theorem 6771.2 (Finite metric compactness NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMetricCompactness}^{\uparrow}$ *carrier $F_{\mathrm{mc}} = (X, D, E, R, T, K, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricCompactness}^{\uparrow}}$ *surface is exhausted by six finite obligation rows:*

1. *finite point-row admission for X;*
2. $\mathsf{Met}^{\uparrow}$ *distance-row exactness for D over the listed points;*
3. $\mathsf{Real}^{\uparrow}$ *dyadic tolerance admission and comparison readback for R;*
4. $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net coverage and* $\mathsf{CompactMetric}^{\uparrow}$ *ledger agreement through T, K, L;*
5. *componentwise* hsame *transport and* Cont *replay through E, H, C;*
6. *provenance and local naming through P, N.*

No obligation is discharged by open-cover compactness, selected subsequences, countable choice, quotient equality of metric presentations, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6771.1. The point inventory X is finite, and every distance comparison consumed by the certificate is displayed by D over that same inventory.

Read the tolerance and coverage rows. The row R supplies only dyadic tolerance requests and comparisons, while T and L answer each such request with finitely many centers drawn from X and displayed distance inequalities. The compact-metric ledger K records this finite-net evidence as its compactness surface.

Finally replay the structural rows. The rows E, H, C, P, N transport, continue, package, and name the displayed packet, so the excluded open-cover, subsequence, choice, quotient, and completeness principles have no carrier coordinate from which to enter the local NameCert surface. □

Theorem 6771.3 (Finite metric compactness finite-net sequential bridge)**.** *Every consumer that reads an accepted* $\mathsf{FiniteMetricCompactness}^{\uparrow}$ *packet as a sequential compactness witness must factor that read through the explicit finite-net coverage rows*

$$X, D, R, T, L \longmapsto K \longmapsto H, C, P, N.$$

The bridge therefore exports a finite-center repetition route: an infinite sequence over the finite point-row inventory yields a recurrent center only because the carrier exposes the finite inventory and the finite-net coverage ledger. It does not export a Bolzano–Weierstrass theorem, a choice-selected subsequence operator, an open-cover compactness principle, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. The carrier contains no sequential object as primitive data. A sequential consumer must first read the finite point-row inventory X and the metric comparisons D.

The finite-net rows then supply the only compactness route. For each dyadic tolerance request in R, the rows T and L display finitely many centers and the distance comparisons that cover all listed points. The ledger K repackages precisely that evidence as a $\mathsf{CompactMetric}^{\uparrow}$ row.

Any sequential reading is therefore downstream of a finite-center repetition argument over the displayed inventory. Since the structural rows H, C, P, N preserve only the same packet, the bridge cannot introduce open covers, choice-selected subsequences, Bolzano–Weierstrass data, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{FiniteMetricCompactness}^{\uparrow}$ consumer that reaches a $\mathsf{CompactMetric}^{\uparrow}$ row without displaying finite point rows, dyadic tolerance rows, and finite-net coverage refutes the carrier surface.

Independence witness: metric, compactmetric, totallybounded, real, heine-cantor-finite-net: no listed sibling supplies the whole packet $F_{\mathrm{mc}} = (X, D, E, R, T, K, L, H, C, P, N)$, because each sibling contributes only distance rows, compact-metric ledger form, finite-net coverage, dyadic tolerance reads, or a downstream Heine–Cantor route while this chapter binds them into one finite metric compactness certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMetricCompactness}^{\uparrow}$ packet is generated from finite point rows, Metric distance rows, Real dyadic tolerance rows, TotallyBounded finite-net coverage, CompactMetric ledger rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetricCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6771.1, Definition 6771.2, and Definition 6771.3 seed the finite metric compactness route through explicit finite-net coverage.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMetricCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, Bolzano–Weierstrass compactness, choice-selected subsequences, quotient equality, ambient RealUp completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, metric distance exactness, dyadic tolerance readback, finite-net coverage, compact-metric ledger agreement, sequential bridge nonescape, transport, replay, provenance, refusal, and local naming for BEDC.Derived.FiniteMetricCompactnessUp.

Chapter 6772

A Concrete Naming Certificate for $\mathsf{FortissimoSpace}^{\uparrow}$

Following Steen–Seebach and Kelley on classical point-set examples, the $\mathsf{FortissimoSpace}^{\uparrow}$ packet records the fortissimo topology by finite observable-open rows rather than by an unrestricted host topology. It sits after the topology carrier of chapter 88, the Sierpinski observable truth surface of chapter 1860, the finite schedule discipline of chapter 126, and the set-like membership boundary of chapter 3668. The certificate names a distinguished point, isolated-point rows, and countable-exception neighbourhood schedules; it does not assert a host separation theorem, a completed power set of opens, a selected enumeration of every exception set, or an ambient real line.

Definition 6772.1 (FortissimoSpace carrier)**.** *A* $\mathsf{FortissimoSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, \omega, I, Q, O, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted point carrier row, read as a* $\mathsf{SetLike}^{\uparrow}$ *membership surface for the displayed finite public points.*
2. *ω is the distinguished-point row. It names the unique non-isolated point whose neighbourhoods are inspected by countable-exception schedules.*
3. *I is the isolated-point ledger. For every displayed point row apart from ω, it stores the singleton-open read used by topology and Sierpinski consumers.*
4. *Q is the countable-exception* $\mathsf{StreamName}^{\uparrow}$ *schedule. Each finite prefix lists the points excluded from the current neighbourhood of ω and records that later prefixes may only refine the visible exception ledger.*
5. *O is the observable-open row. It exposes the truth of membership in an inspected open only through the isolated singleton rows in I or the distinguished-point neighbourhood schedule in Q.*
6. *T is the* $\mathsf{Topology}^{\uparrow}$ *provenance row, recording finite union and intersection reads only for the opens generated by I, Q, O.*
7. *H records componentwise* hsame *transport for the point carrier, distinguished point, isolated rows, exception schedule, observable-open row, topology provenance, replay, package, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$X, \omega, I, Q \longmapsto O \longmapsto T.$$

9. *P is the* Pkg *provenance over* $\mathsf{FortissimoSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FortissimoSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, \omega, I, Q, O, T, H, C, P, N$. It has no coordinate for a host set of all open subsets, a global choice of countable exception enumerations, a separation theorem, compactness, metrizability, or ambient real-line structure.

Theorem 6772.2 (FortissimoSpace NameCert obligations)**.** *For every accepted* $\mathsf{FortissimoSpace}^{\uparrow}$ *carrier*

$$F = (X, \omega, I, Q, O, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FortissimoSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, distinguished-point admission, isolated singleton-open admission, countable-exception schedule exactness, observable-open truth through* $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$ *open-row provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming over the rows of Definition 6772.1. No obligation row asserts a host topology, a completed lattice of opens, a selected global enumeration of all countable exception sets, separation axioms, compactness, metrizability, or real-line structure.*

Proof. Carrier admission is projection from Definition 6772.1. The accepted packet first displays the point carrier X, the distinguished point ω, the isolated-point ledger I, and the countable-exception schedule Q.

The observable-open row O is then forced to read membership in only two ways. Away from ω it uses the isolated singleton rows in I; at ω it uses the finite prefix of the exception schedule in Q.

The topology row T records only the finite open-row provenance generated by those reads. The structural rows H, C, P, N transport, replay, source, and name the same finite route without adding any host open-set coordinate.

Because the carrier inventory contains no completed open lattice, selected global exception enumeration, separation theorem, compactness row, metrizability row, or ambient real-line row, none of those objects can be exported as a local NameCert obligation. □

Theorem 6772.3 (FortissimoSpace Sierpinski topology handoff)**.** *Every* $\mathsf{Topology}^{\uparrow}$*-facing,* $\mathsf{SierpinskiSpace}^{\uparrow}$*-facing, or observable-open consumer of an accepted* $\mathsf{FortissimoSpace}^{\uparrow}$ *packet must read the route*

$$X, \omega, I, Q, O, T, H, C, P, N.$$

The row O exposes only observable-open truth from isolated singleton rows and countable-exception neighbourhood prefixes, while T exposes only the corresponding $\mathsf{Topology}^{\uparrow}$ *open-row provenance. The handoff does not import host open sets, selected exception enumerations, separation axioms, compactness, metrizability, or ambient real-line data.*

Proof. Project the accepted carrier. The point source is X, the distinguished point is ω, the isolated singleton evidence is I, and the only neighbourhood schedule at ω is the finite $\mathsf{StreamName}^{\uparrow}$ row Q.

The observable-open consumer then reads O. This row converts the isolated and distinguished-point routes into $\mathsf{SierpinskiSpace}^{\uparrow}$ truth values without exposing an ambient predicate on all subsets.

The topology consumer reads T only after that observable route has been replayed. The rows H, C, P, N preserve and name the same carrier coordinates, so no later consumer can replace the certificate by a host topology or selected family of exception sets. □

Closure status for $\mathsf{NameCert}_{\mathsf{FortissimoSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FortissimoSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6772.1, Definition 6772.2, and Definition 6772.3 seed the distinguished-point, isolated-row, countable-exception, observable-open, and topology-provenance surface for $\mathsf{FortissimoSpace}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FortissimoSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host topology, completed open lattices, selected global exception enumerations, separation axioms, compactness, metrizability, real-line structure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, distinguished-point admission, isolated singleton-open admission, countable-exception schedule exactness, observable-open truth, topology provenance, transport stability, replay stability, provenance exhaustion, and local NameCert rows for BEDC.Derived.FortissimoSpaceUp.

Constructive story: A $\mathsf{FortissimoSpace}^{\uparrow}$ packet is generated from a SetLikeUp point row, a distinguished point row, isolated singleton-open rows, a countable-exception StreamName schedule, observable-open Sierpinski truth, TopologyUp open-row provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6773

A Concrete Naming Certificate for $\mathsf{FiniteSignedMeasure}^{\uparrow}$

Following Hahn and standard signed-measure theory, the $\mathsf{FiniteSignedMeasure}^{\uparrow}$ packet names the finite signed event-value surface that Hahn decomposition and variation-measure consumers need before reading positive and negative mass rows. It sits after the base measure carrier of chapter 92, the finite nonnegative event-value packet of chapter 6127, the finite-partition variation ledger of chapter 3593, the decomposition route of chapter 5952, the regular-measure handoff of chapter 2263, and the terminal scalar seal of chapter 38. The packet records finite signed values, variation bounds, polarity ledgers, and their displayed transport rows.

Definition 6773.1 (Finite signed measure carrier)**.** *A* $\mathsf{FiniteSignedMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, E, V, Pm, Nm, T, U, R, H, C, L, Q)$$

with the following displayed rows:

1. *S is the* $\mathsf{Measure}^{\uparrow}$ *event-family row, exposing the admitted measurable events and their classifier.*
2. *E is the finite event ledger whose signed values are visible to the packet.*
3. *V is the signed event-value ledger, assigning each event in E a displayed* $\mathsf{Real}^{\uparrow}$ *scalar value.*
4. *Pm is the positive-variation finite measure row, read through* $\mathsf{FiniteMeasure}^{\uparrow}$ *on the same event ledger.*
5. *Nm is the negative-variation finite measure row, also read through* $\mathsf{FiniteMeasure}^{\uparrow}$ *on the same event ledger.*
6. *T is the total-variation bound row, naming a displayed* $\mathsf{Real}^{\uparrow}$ *bound for $Pm + Nm$ over the admitted finite event family.*
7. *U is the polarity and cancellation ledger, recording how the signed value row V is read as the difference of the displayed positive and negative finite-measure rows.*
8. *R is the regularity and scalar readback row, routing optional* $\mathsf{RadonMeasure}^{\uparrow}$ *requests and every terminal* $\mathsf{Real}^{\uparrow}$ *scalar through the same finite signed surface.*
9. *H records componentwise* hsame *transport for $S, E, V, Pm, Nm, T, U, R, C, L, Q$.*
10. *C records displayed* Cont *replay from an event request through signed value, positive variation, negative variation, total variation, polarity, and scalar readback rows.*

11. *L is the* Pkg *provenance over* FiniteSignedMeasure$^{\uparrow}$, Measure$^{\uparrow}$, FiniteMeasure$^{\uparrow}$, VariationMeasure$^{\uparrow}$, HahnDecomposition$^{\uparrow}$, RadonMeasure$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *Q is the local* $\mathsf{NameCert}_{\mathsf{FiniteSignedMeasure}^{\uparrow}}$ *row.*

The carrier has no coordinate for host signed-measure equality, a completed measure algebra, quotient event equality, selected Jordan decomposition, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6773.2 (FiniteSignedMeasure NameCert obligations)**.** *For every accepted* FiniteSignedMeasure$^{\uparrow}$ *carrier*

$$G = (S, E, V, Pm, Nm, T, U, R, H, C, L, Q),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSignedMeasure}^{\uparrow}}$ *surface consists exactly of event-family admission through S, finite event visibility through E, signed scalar values through V, positive and negative variation reads through Pm and Nm, total-variation boundedness through T, polarity and cancellation through U, Radon and real readback through R, componentwise transport through H, displayed replay through C, provenance through L, and local naming through Q.*

Proof. Project the carrier of Definition 6773.1. The rows S, E, V are the only event and signed-value data exposed before the variation rows appear.

Read Pm and Nm as finite nonnegative measure rows over the same finite event ledger. The total-variation row T bounds their displayed finite sum, while U records the signed-value read as the difference of those two finite nonnegative rows.

The readback row R is the only route to optional RadonMeasure or terminal Real consumers. Transport and replay are componentwise through H and C, so a consumer cannot replace the finite ledger by a host signed measure or by quotient event equality.

Finally L and Q source and name the packet. Since the carrier contains no completed measure algebra, selected Jordan decomposition, countable-choice selector, host signed-measure equality, or ambient Real-completeness coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 6773.3 (FiniteSignedMeasure Hahn consumer route)**.** *Every* HahnDecomposition$^{\uparrow}$ *consumer of a finite signed measure must read an accepted* FiniteSignedMeasure$^{\uparrow}$ *carrier through the displayed rows $S, E, V, Pm, Nm, T, U, R, H, C, L, Q$ before exposing positive-region, negative-region, or null-boundary data. The same route supplies* VariationMeasure$^{\uparrow}$, RadonMeasure$^{\uparrow}$, *and* Real$^{\uparrow}$ *consumers with finite signed values, finite variation bounds, and scalar readback without exporting host signed-measure equality, quotient event equality, selected partitions, or ambient measure completion.*

Proof. Begin with the Hahn decomposition carrier. Its signed-measure input row can be supplied by a finite signed surface only after the event ledger, signed values, variation rows, total-variation bound, and polarity ledger have been displayed.

Use the obligation theorem above. The rows Pm, Nm, T, U expose exactly the positive-variation, negative-variation, total-variation, and cancellation data that a Hahn-facing consumer needs before it reads positive and negative regions.

VariationMeasure and RadonMeasure consumers use the same packet boundary. The finite-partition variation read sees the signed value and variation rows, while the regular-measure read can pass through R only after the finite signed ledger has been displayed.

The remaining rows H, C, L, Q transport, replay, source, and name that route. No coordinate in the carrier can yield a host signed measure, quotient equality of events, a selected measurable partition, a completed measure algebra, countable choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSignedMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSignedMeasure}^{\uparrow}$ packet is generated from a MeasureUp event-family row, a finite event ledger, signed RealUp event values, positive and negative FiniteMeasureUp variation rows, total-variation bound, polarity and cancellation ledger, optional RadonMeasureUp and RealUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSignedMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6773.1, Definition 6773.2, and Definition 6773.3 seed the finite signed event-value carrier consumed by HahnDecompositionUp, VariationMeasureUp, RadonMeasureUp, MeasureUp, FiniteMeasureUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSignedMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host signed-measure equality, completed measure algebras, quotient event equality, selected Jordan or Hahn decompositions, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signed event-value transport, positive and negative finite-measure variation reads, total-variation boundedness, polarity cancellation, Hahn consumer routing, Radon and Real readback, replay, provenance, and local naming for BEDC.Derived.FiniteSignedMeasureUp.

Chapter 6774

A Concrete Naming Certificate for $\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}$

Following Goebel and Kirk, the $\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}$ packet records the finite naming surface for an asymptotic-center read along a displayed regular Cauchy completion path. It sits over the regular rational rows of chapter 301, the common stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the real-name seal of chapter 38, the generic metric surface of chapter 57, and the complete-metric witness row of chapter 3687. The packet names the center candidate by finite readback and metric-radius comparison, not by quotienting Cauchy names, selecting a limit, or importing compactness.

Definition 6774.1 (Regular Cauchy asymptotic-center carrier)**.** *A* $\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, K, A, W, D, R, E, T, H, C, P, S, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose distance classifier is used for every radius comparison.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *witness row supplying the completion-facing limit discipline for the ambient metric carrier.*
3. *A is the displayed regular Cauchy source family whose tail distances are being inspected.*
4. *W is the common* $\mathsf{StreamName}^{\uparrow}$ *window through which all tail and center-candidate reads are exposed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the metric-radius budget read through W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational approximants of the tail-radius data.*
7. *E is the candidate-center row. It is presented only through the same finite window and the same metric source as the tail reads.*
8. *T is the finite asymptotic-radius comparison row, recording that every inspected tail request factors through M, K, A, W, D, R, E before a center claim is visible.*
9. *H records componentwise* hsame *transport for the metric source, complete-metric witness, Cauchy source family, common window, dyadic tolerance ledger, regular rational readback, candidate row, comparison row, package provenance, real seal, and local naming row.*

10. *C records displayed* Cont *replay from an asymptotic-center request through the same rows.*
11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite radius ledger and regular rational readback have been displayed.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, a selected ambient limit, compactness, uniform convexity, excluded middle, countable choice, or a global minimizer principle outside the displayed packet.

Theorem 6774.2 (Regular Cauchy asymptotic-center NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}$ *carrier* $Q = (M, K, A, W, D, R, E, T, H, C, P, S, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}}$ *surface consists exactly of carrier admission, common-window exposure, dyadic tolerance budgeting, regular rational readback, metric-radius comparison, complete-metric limit-discipline handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, and local naming over the rows displayed in Definition 6774.1. No obligation row exports quotient equality of Cauchy names, selected limits, compactness, uniform convexity, countable choice, trichotomy, or an external minimization oracle.*

Proof. Project the accepted carrier. The analytic data visible to a center consumer are precisely the metric source M, the complete-metric witness K, the regular Cauchy source family A, the common finite window W, the dyadic tolerance ledger D, the regular rational readback row R, the candidate row E, and the comparison row T.

The NameCert rows H, C, P, S, N add transport, replay, provenance, terminal sealing, and local naming for that same finite packet. They do not add an independent equality coordinate, because every transported read is componentwise and every replay follows the displayed route through W, D, R, T.

It remains to exclude hidden completion principles. The carrier lists no quotient-completion row, no selected limit row, no compactness or convexity row, and no external minimizer oracle. Thus the local certificate exhausts exactly the finite asymptotic-radius route displayed in the carrier. □

Theorem 6774.3 (Regular Cauchy asymptotic-center Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}$ *carrier factors through*

$$\mathsf{Met}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$$

along the rows $M, K, W, D, R, S, H, C, P, N$ before the candidate-center row E or comparison row T may be consumed. Consequently the terminal seal reports only the displayed regular Cauchy asymptotic-radius packet and cannot be used to derive quotient equality of names, selected completion limits, compactness, uniform convexity, countable choice, trichotomy, or a global minimizer principle.

Proof. Read the carrier order in Definition 6774.1. The terminal seal row S is downstream of the common stream window, dyadic tolerance ledger, regular rational readback, metric source, and complete-metric witness.

The comparison row T is also downstream of those finite rows. A consumer therefore cannot ask the $\mathsf{Real}^{\uparrow}$ seal for an asymptotic-radius statement until the shared window W, tolerance ledger D, readback row R, and metric/complete-metric handoff M, K have already been displayed.

The omitted principles are absent from the packet. Since H and C only transport and replay the listed rows, the seal cannot escape the finite route by manufacturing quotient equality, a selected limit, compactness, convexity, choice, trichotomy, or a minimizer outside the displayed data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6774.1, Definition 6774.2, and Definition 6774.3 seed the finite asymptotic-center route over displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, compactness, uniform convexity, countable choice, trichotomy, or global minimizer existence.

Upgrade path: Obligation closure requires checked carrier admission, common-window exposure, dyadic tolerance budgeting, regular rational readback, metric-radius comparison, complete-metric handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyAsymptoticCenterUp.

Constructive story: A $\mathsf{RegularCauchyAsymptoticCenter}^{\uparrow}$ packet is generated from a Metric source row, a CompleteMetric witness row, a regular Cauchy source family, one common StreamName window, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a candidate-center row, a finite asymptotic-radius comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, a RealUp seal, and a local NameCert row.

Chapter 6775

A Concrete Naming Certificate for $\mathsf{FiniteOpenIntervalCover}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of compact intervals, the $\mathsf{FiniteOpenIntervalCover}^{\uparrow}$ packet records the finite interval-cover data visible before any Heine–Borel, compactness, or completion-facing consumer may use it. It sits after the dyadic arithmetic of chapter 291, the stream windows of chapter 126, the regular rational rows of chapter 301, the real-name seal of chapter 38, and the interval-domain source of chapter 1543. The packet names only a displayed finite cover route; it does not assert open-cover compactness, select a subcover, identify quotient real names, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6775.1 (Finite open interval cover carrier)**.** *A* $\mathsf{FiniteOpenIntervalCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, O, L, R, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{IntervalDomain}^{\uparrow}$ *source row, naming the closed or bounded interval window whose cover is being inspected.*
2. *O is the finite open-interval row, listing the displayed interval members by rational endpoint names and local openness witnesses.*
3. *L is the located-overlap row, recording which displayed interval-domain cells meet which cover members.*
4. *R is the finite refinement row, comparing two displayed cover windows by finite parent maps and endpoint-containment witnesses.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for endpoint names, overlap probes, and retained finite members.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational observation row used to compare endpoint windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row for dyadic endpoint, radius, and containment checks.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after I, O, L, R, S, Q, D have been displayed.*
9. *H records componentwise* hsame *transport for source, cover, overlap, refinement, stream, regular-rational, dyadic, and seal rows.*

10. *C records displayed* Cont *replay for finite cover admission, endpoint containment, overlap inspection, and Real-facing seal reads.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteOpenIntervalCover}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenIntervalCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary open cover, a hidden finite-subcover selector, quotient equality of real names, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6775.2 (Finite open interval cover NameCert obligations)**.** *For the carrier of Definition 6775.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenIntervalCover}^{\uparrow}}$ *surface consists exactly of interval-domain source admission through I, finite open-interval admission through O, located-overlap exactness through L, finite refinement exactness through R, stream and regular-rational readback through S, Q, dyadic containment arithmetic through D, Real seal non-escape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier row by row. The source row I fixes the interval-domain window, while O and L expose the only cover members and overlap witnesses visible to a downstream consumer.

The refinement row R compares cover windows by finite parent maps and displayed containment checks. The readback rows S, Q, D then inspect endpoint names, regular-rational windows, and dyadic inequalities without leaving the finite packet surface.

Finally E, H, C, P, N seal, transport, replay, source, and name the same displayed route. Since no carrier coordinate stores an arbitrary open cover, a selected subcover, quotient real equality, countable choice, selected limits, or ambient completeness, those objects cannot become NameCert obligations for $\mathsf{FiniteOpenIntervalCover}^{\uparrow}$. □

Theorem 6775.3 (Finite open interval cover constructive boundary)**.** *Every completion-facing or compactness-facing read of an accepted* $\mathsf{FiniteOpenIntervalCover}^{\uparrow}$ *packet must pass through the finite route*

$$I, O, L, R, S, Q, D, E, H, C, P, N.$$

The route may expose interval-domain cells, finite open interval members, stream-name windows, regular-rational observations, dyadic endpoint comparisons, and the terminal $\mathsf{Real}^{\uparrow}$ *seal, but it exports no open-cover compactness theorem, choice-selected subcover, quotient real equality, countable-choice schedule, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The consumer first reads I, O, L, R. These rows determine the source interval window, the finite cover members, the located overlap evidence, and the finite refinement comparison.

It then reads S, Q, D to inspect endpoint names and dyadic containment data. These observations are finite rows over the already displayed cover window, so they cannot quantify over a host family of all open intervals.

The remaining rows E, H, C, P, N preserve the same route under Real-seal inspection, transport, replay, provenance, and local naming. Therefore every downstream consumer receives exactly the finite packet named in the statement and none of the excluded compactness, choice, quotient, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOpenIntervalCover}^{\uparrow}}$.

Constructive story: A FiniteOpenIntervalCover$^{\uparrow}$ packet is generated from an IntervalDomainUp source row, finite open-interval rows, located-overlap witnesses, finite refinement rows, StreamName windows, RegSeqRat observations, DyadicRatCore comparisons, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteOpenIntervalCover}^{\uparrow}}$, seed)

Scope closed: Definition 6775.1, Definition 6775.2, and Definition 6775.3 seed the finite interval-cover interface over displayed interval-domain, stream, regular-rational, dyadic, and Real-seal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteOpenIntervalCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, finite-subcover selection, quotient real equality, countable choice, selected limits, ambient Real$^{\uparrow}$ completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite open-interval admission, located-overlap exactness, finite refinement stability, stream and regular-rational readback, dyadic containment arithmetic, Real seal non-escape, transport, replay, provenance, and local naming.

Chapter 6776

A Concrete Naming Certificate for $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$

Following Ahlfors and Beardon on disk automorphisms, the $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ packet records the finite disk-map and inverse rows by which a Poincare disk self-map is read as an automorphism before hyperbolic metric, boundary, Schwarz–Pick, or composition consumers inspect it. It sits after the disk metric packet of chapter 6209, the fractional linear carrier of chapter 5110, the hyperbolic metric surface of chapter 3474, and the boundary transport packet of chapter 6595. The certificate names only displayed disk-map, boundary-transport, hyperbolic-metric-preservation, inverse, composition, provenance, and NameCert rows; it does not import host complex analysis, a completed automorphism group, quotient boundary equality, or an unrecorded analytic classification theorem.

Definition 6776.1 (Poincare disk automorphism carrier)**.** *A* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, M, U, V, B, K, I, J, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-metric source row for the finite domain and codomain observations.*
2. *M is the* $\mathsf{MobiusTransform}^{\uparrow}$ *coefficient and disk-action row whose determinant guard and disk-local action are visible in the packet.*
3. *U is the disk-self-map row, recording that the displayed action sends admitted disk rows to admitted disk rows.*
4. *V is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *preservation row, exposing equality of the displayed hyperbolic metric reads only through the finite disk-metric and Real-facing rows.*
5. *B is the* $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$ *row, carrying the boundary readback induced by the same displayed disk map.*
6. *K is the inverse row. It displays a second disk-map packet whose two composites replay to the identity rows visible on the admitted disk observations.*
7. *I is the composition row, recording finite replay for composing two admitted automorphism packets before any group-style consumer may read the result.*

8. *J is the refusal ledger excluding host analytic continuation, completed automorphism groups, quotient boundary equality, selected global normal forms, and unrecorded Schwarz–Pick equality.*
9. *H records componentwise* hsame *transport for disk-metric, Mobius, disk-map, hyperbolic-metric, boundary-transport, inverse, composition, refusal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a disk-map request through Mobius coefficient inspection, disk admission, metric preservation, boundary transport, inverse and composition checks, refusal, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{MobiusTransform}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphism}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, U, V, B, K, I, J, H, C, P, N$. It has no coordinate for a host analytic automorphism group, quotient boundary equality, selected normal form, unbounded complex-analysis theorem, or off-packet inverse.

Theorem 6776.2 (Poincare disk automorphism NameCert obligations)**.** *For every accepted* PoincareDiskAutomorph *carrier*

$$A = (D, M, U, V, B, K, I, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphism}^{\uparrow}}$ *surface consists exactly of Poincare disk metric admission through D, Mobius coefficient and disk-action admission through M, disk self-map admission through U, hyperbolic metric preservation through V, boundary transport through B, inverse replay through K, composition replay through I, refusal exposure through J, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming over the rows of Definition 6776.1. No obligation row asserts a host automorphism group, analytic classification theorem, quotient boundary equality, selected normal form, or arbitrary complex-analysis principle.*

Proof. Project the carrier of Definition 6776.1. The visible map data are the disk-metric source D, the Mobius coefficient row M, and the disk self-map row U.

The metric and boundary obligations are then read from the same displayed map. The row V compares only finite $\mathsf{HyperbolicMetric}^{\uparrow}$ reads, while B records the induced boundary transport without exposing a quotient boundary object.

The inverse and composition rows K, I are replay obligations over displayed disk observations. They make the automorphism surface reusable by downstream consumers, but they do not construct a completed automorphism group or select a global normal form.

Finally, J, H, C, P, N attach refusal, transport, replay, provenance, and local naming to the same finite rows. Since no carrier coordinate stores host complex analysis, quotient boundary equality, selected normal forms, or an off-packet inverse, none of those objects can become a NameCert obligation. □

Theorem 6776.3 (Poincare disk automorphism metric-boundary route)**.** *Every* $\mathsf{HyperbolicMetric}^{\uparrow}$*-facing,* $\mathsf{HyperbolicBoundaryTransport}^{\uparrow}$*-facing, or composition-facing consumer of an accepted* PoincareDiskAutomorph *packet must read the finite route*

$$\mathsf{PoincareDiskMetric}^{\uparrow},\ \mathsf{MobiusTransform}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{HyperbolicBoundaryTransport}^{\uparrow}.$$

The metric-preservation row and the boundary-transport row are downstream of the displayed disk-map row and upstream of inverse and composition replay. The route exports no host automorphism group, quotient ideal-boundary equality, selected disk automorphism normal form, or analytic classification outside the packet.

Proof. Start with the disk-map request. The packet first exposes the $\mathsf{PoincareDiskMetric}^{\uparrow}$ disk observations and the $\mathsf{MobiusTransform}^{\uparrow}$ coefficient action, then records disk self-map admission through U.

The hyperbolic metric and boundary rows are read next. The row V can compare metric values only after the disk self-map is visible, and the row B carries only the boundary transport induced by that same displayed map.

The inverse and composition rows are therefore downstream replay data. Rows K and I can be consumed only after the metric-preservation and boundary-transport surface has been named, and the structural rows keep the same finite carrier under transport and provenance. Thus the consumer route remains internal to BEDC NameCert data rather than to host complex analysis. □

Falsifiable prediction: An accepted $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ consumer is refuted if it reads hyperbolic metric preservation, boundary transport, inverse replay, or composition replay without displaying PoincareDiskMetric, MobiusTransform, HyperbolicMetric, HyperbolicBoundaryTransport, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: poincare-disk-metric, mobius-transform, hyperbolic-metric, hyperbolic-boundary-transport: $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk-map, metric-preservation, boundary-transport, inverse, composition, refusal, transport, replay, provenance, and local naming as one automorphism packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphism}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphism}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6776.1, Definition 6776.2, and Definition 6776.3 seed the finite disk-map, Mobius, hyperbolic-metric, boundary-transport, inverse, composition, refusal, transport, replay, provenance, and local NameCert surface for $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphism}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host complex analysis, completed automorphism groups, quotient ideal-boundary equality, selected disk automorphism normal forms, analytic classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-map admission, Mobius coefficient transport, hyperbolic metric preservation, boundary transport, inverse replay, composition replay, refusal exposure, provenance exhaustion, and local naming for BEDC.Derived.PoincareDiskAutomorphismUp.

Constructive story: A $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ packet is generated from PoincareDiskMetric rows, MobiusTransform rows, disk self-map admission, HyperbolicMetric preservation, HyperbolicBoundaryTransport rows, inverse and composition replay, refusal data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6777

A Concrete Naming Certificate for $\mathsf{HedgehogSpace}^{\uparrow}$

Following Kelley and Engelking on hedgehog spaces, the $\mathsf{HedgehogSpace}^{\uparrow}$ packet names a finite-spine point-set topology surface rather than an arbitrary-cardinal wedge. It sits after the metric carrier of chapter 57, the topology carrier of chapter 88, the finite real-distance readback of chapter 38, and the visible basepoint discipline already used by finite point-set packets. The packet records a common basepoint, finitely displayed spines, branch coordinates, metric and topology source rows, real distance rows, transport, replay, provenance, and local naming; it does not claim arbitrary-cardinal hedgehogs, choice-selected spine families, or a host topology of all wedges.

Definition 6777.1 (Hedgehog space carrier)**.** *A* $\mathsf{HedgehogSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, b, X, Q, M, T, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite spine-label ledger. Each accepted spine label names one visible branch and no off-packet branch may be read.*
2. *b is the common basepoint row shared by all displayed spines.*
3. *X is the branch-coordinate row, recording for each displayed point either the basepoint or a visible spine label together with a finite interval coordinate.*
4. *Q is the branch-equality and basepoint-collapse ledger. It identifies points from different spines only at b and otherwise compares coordinates inside the same visible spine.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *source row for the finite wedge metric read.*
6. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row generated by the same finite branch and basepoint data.*
7. *D is the* $\mathsf{Real}^{\uparrow}$ *distance row, exposing basepoint distance, same-spine coordinate distance, and different-spine wedge distance only through finite Real-facing readback.*
8. *H records componentwise* hsame *transport for spine labels, basepoint rows, branch coordinates, equality collapse, metric source, topology source, Real distance, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a point request through finite spine inspection, basepoint collapse, metric and topology reads, Real distance readback, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{HedgehogSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HedgehogSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, b, X, Q, M, T, D, H, C, P, N$. It has no coordinate for an arbitrary set of spines, a choice-selected family of branches, a completed host wedge topology, or an unrecorded quotient equality.

Theorem 6777.2 (Hedgehog space NameCert obligations)**.** *For every accepted* $\mathsf{HedgehogSpace}^{\uparrow}$ *carrier*

$$J = (S, b, X, Q, M, T, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HedgehogSpace}^{\uparrow}}$ *surface consists exactly of finite spine-label admission, common-basepoint admission, branch-coordinate admission, basepoint-collapse exactness,* $\mathsf{Met}^{\uparrow}$ *wedge-metric source admission,* $\mathsf{Topology}^{\uparrow}$ *generated-open source admission,* $\mathsf{Real}^{\uparrow}$ *distance readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming over the rows of Definition 6777.1. No obligation row asserts an arbitrary-cardinal hedgehog, choice-selected spine family, host quotient topology, or completed collection of all open neighbourhoods.*

Proof. Project the carrier of Definition 6777.1. The accepted surface first displays the finite spine labels S, the common basepoint b, the branch coordinates X, and the basepoint-collapse ledger Q.

The metric and topology rows are then read from the same visible data. The row M supplies only the finite wedge-metric source, while T supplies only the open-row provenance generated from the displayed branches and their shared basepoint.

The distance row D is terminal Real-facing readback for that same wedge route. Transport and replay through H and C preserve the displayed rows componentwise, and P, N source and name them locally. Since no row stores an arbitrary spine family, selected branch choice, host quotient topology, or completed open lattice, none of those objects can become a NameCert obligation. □

Theorem 6777.3 (Hedgehog metric wedge route)**.** *Every* $\mathsf{Met}^{\uparrow}$*-facing,* $\mathsf{Topology}^{\uparrow}$*-facing, or* $\mathsf{Real}^{\uparrow}$*-distance consumer of an accepted* $\mathsf{HedgehogSpace}^{\uparrow}$ *packet must read the finite route*

$$S, b, X, Q \to M, T, D \to H, C, P, N.$$

Same-spine reads compare branch coordinates inside one visible spine; different-spine reads pass through the common basepoint row b before reaching the $\mathsf{Real}^{\uparrow}$ *distance row. The route exports no arbitrary-cardinal spine family, choice-selected branch set, host wedge topology, or quotient space external to the packet.*

Proof. Begin with the visible point request. The classifier admits a point only when the finite spine ledger, basepoint row, and branch-coordinate row display its spine and coordinate data.

Use the collapse ledger Q to separate the two metric cases. Same-spine requests remain inside a single displayed branch, while different-spine requests are forced through the common basepoint row before any distance readback is exposed.

The rows M, T, D then give the metric source, topology source, and Real-facing distance for exactly that finite wedge route. The structural rows H, C, P, N transport, replay, source, and name the same packet, so a consumer cannot replace it by a host hedgehog with an arbitrary spine set or by a selected family of branches. □

Falsifiable prediction: An accepted $\mathsf{HedgehogSpace}^{\uparrow}$ consumer is refuted if it reads a non-displayed spine, a choice-selected branch family, a host quotient topology, or a Real distance not routed through the finite spine labels, common basepoint, branch coordinates, MetricUp source, TopologyUp source, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: metric, topology, real, wedge: $\mathsf{HedgehogSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite spine labels, a common basepoint, branch-coordinate rows, basepoint-collapse exactness, MetricUp and TopologyUp source rows, RealUp distance rows, transport, replay, provenance, and local naming as one point-set topology packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HedgehogSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HedgehogSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6777.1, Definition 6777.2, and Definition 6777.3 seed the finite-spine basepoint, branch-coordinate, metric, topology, Real-distance, transport, replay, provenance, and local NameCert surface for $\mathsf{HedgehogSpace}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HedgehogSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary-cardinal hedgehogs, choice-selected spine families, host wedge topologies, completed open lattices, quotient-space equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-spine admission, basepoint-collapse exactness, branch-coordinate transport, MetricUp and TopologyUp source replay, RealUp distance readback, provenance exhaustion, and local naming for BEDC.Derived.HedgehogSpaceUp.

Constructive story: A $\mathsf{HedgehogSpace}^{\uparrow}$ packet is generated from finite spine labels, a common basepoint row, branch-coordinate rows, basepoint-collapse exactness, MetricUp and TopologyUp sources, RealUp distance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6778

A Concrete Naming Certificate for $\mathsf{BishopGraphCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completions, the $\mathsf{BishopGraphCompletion}^{\uparrow}$ packet records the finite graph-read surface by which a metric or real-facing completion consumer may inspect vertices, approximation edges, and regular rational labels before any completed point is exposed. It sits after the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the metric carrier of chapter 57, and the continuous-map handoff of chapter 130. The packet is a finite NameCert carrier for graph-shaped completion reads; it is not a host graph-completion oracle, quotient stream equality, selected limit, countable choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 6778.1 (Bishop graph-completion carrier)**.** *A* $\mathsf{BishopGraphCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (V, E, W, Q, R, M, F, L, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite vertex row, listing the named approximation states available to the completion consumer.*
2. *E is the directed edge row, recording the admissible refinement arrows between vertices.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which vertex and edge reads are requested.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational-readback row attached to the same finite windows.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after V, E, W, Q have been consumed.*
6. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose displayed distance comparisons govern accepted refinement edges.*
7. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff row, recording graph-compatible maps that preserve displayed refinement and metric reads.*
8. *L is the local graph-completion ledger, pairing each accepted consumer request with a finite path in E and a terminal Real-facing seal in R.*
9. *H records componentwise* hsame *transport for vertices, edges, windows, rational readbacks, metric comparisons, continuous-map handoffs, ledger rows, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a completion request through the finite vertex-edge path, StreamName windows, RegSeqRat readback, metric source, continuous-map handoff, Real seal, and local ledger.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopGraphCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopGraphCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $V, E, W, Q, R, M, F, L, H, C, P, N$. It has no coordinate for host graph-completion oracles, quotient streams, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Theorem 6778.2 (Bishop graph-completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopGraphCompletion}^{\uparrow}$ *carrier*

$$G = (V, E, W, Q, R, M, F, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopGraphCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed vertex row, directed edge row, finite StreamName windows, RegSeqRat readback, Real seal, MetricSpace source, ContinuousMap handoff, graph-completion ledger, componentwise transport, displayed replay, package provenance, and local naming. Edge stability is read from E together with M; readback stability is read from W, Q, R; map stability is read from F under H, C; and ledger nonescape keeps host graph-completion oracles, quotient streams, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge checking outside the packet.*

Proof. Project the carrier of Definition 6778.1. Carrier admission exposes exactly the rows $V, E, W, Q, R, M, F, L, H$ and no further completion coordinate.

The graph read is finite before it is completion-facing. A consumer request first names windows in W, then reads the vertex and edge rows V, E, and then obtains rational labels through Q over the same finite requests.

Metric and map stability are displayed rows, not ambient facts. The metric source M governs which refinement arrows are admissible, while the continuous-map row F records preservation of those displayed arrows under the same transport and replay rows H, C.

Finally the local ledger L pairs each accepted request with the finite path and Real seal already displayed by the packet. Since the carrier contains no host oracle, quotient-stream coordinate, selected-limit coordinate, countable-choice scheduler, ambient-completeness row, or bridge-checking row, the listed rows exhaust the local NameCert obligations. □

Theorem 6778.3 (Bishop graph-completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopGraphCompletion}^{\uparrow}$ *carrier receives completion-facing data only through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Consequently the consumer may inspect the displayed vertex-edge path, rational readback, metric comparison, map handoff, transport, replay, provenance, and local naming rows, but it cannot read a host graph-completion oracle, quotient stream, selected limit, countable choice witness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness proof from the packet.*

Proof. Open an accepted carrier $G = (V, E, W, Q, R, M, F, L, H, C, P, N)$. The completion-facing seal R is downstream of the finite windows W, the graph rows V, E, the rational readback Q, the metric source M, and the continuous-map handoff F.

A Real-facing consumer must therefore consume the same displayed route before R is available. The ledger L records the finite edge path used by the request, while H and C preserve the route under componentwise transport and replay.

The packet has no other completion field. In particular, it stores neither quotient-stream equality nor a selected host limit, and it supplies no countable-choice scheduler, host graph-completion oracle, or ambient completeness proof. The available handoff is exactly the finite route displayed in the statement. □

Falsifiable prediction: Any accepted $\mathsf{BishopGraphCompletion}^{\uparrow}$ completion-facing read that bypasses the finite edge row E, the readback row Q, or the ledger row L is rejected by Definition 6778.1, because the packet exposes Real-facing completion data only through the displayed vertex-edge route.

Independence witness: streamname, regseqrat, real, metric, continuousmap: the packet is not bijective with any listed sibling because it jointly records finite vertices, refinement edges, stream windows, regular rational readback, Real seals, metric comparisons, continuous-map handoffs, graph-completion ledgers, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopGraphCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopGraphCompletion}^{\uparrow}$ packet is generated from finite vertex rows, directed refinement-edge rows, StreamName windows, RegSeqRat readback, a RealUp seal, MetricSpace comparisons, ContinuousMap handoff rows, a graph-completion ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopGraphCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6778.1, Definition 6778.2, and Definition 6778.3 seed the finite graph-completion route for StreamName, RegSeqRat, RealUp, MetricSpace, ContinuousMap, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopGraphCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host graph-completion oracles, quotient streams, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, vertex-edge path exposure, rational readback, metric-edge stability, continuous-map preservation, Real-seal nonescape, transport and replay preservation, provenance faithfulness, and local NameCert coverage for BEDC.Derived.BishopGraphCompletionUp.

Chapter 6779

A Concrete Naming Certificate for $\mathsf{CompletionExactness}^{\uparrow}$

Following Bishop-style completion exactness, the $\mathsf{CompletionExactness}^{\uparrow}$ packet records the finite boundary where a completion-facing route is accepted only when its displayed coverage, soundness, completeness, and classifier equivalence rows agree. It sits over the dyadic tolerance core of chapter 291, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the two-read comparison boundary of chapter 6768. The packet names an exactness predicate for the L10 completion route; it does not select limits, quotient Cauchy names, identify host reals, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6779.1 (Completion exactness carrier)**.** *A* $\mathsf{CompletionExactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, W, R, S, V, K, T, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance coverage row, recording the dyadic budgets through which completion reads are inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row scheduled by D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed windows.*
4. *S is the soundness row, asserting that each accepted completion read is backed by the displayed dyadic, stream, regular-rational, and terminal* $\mathsf{Real}^{\uparrow}$ *seal data.*
5. *V is the completeness row, asserting that every displayed dyadic-window and regular-rational route admitted by the classifier reaches an accepted completion read.*
6. *K is the classification-iff row, recording that the public classifier accepts exactly the reads satisfying the coverage, soundness, and completeness rows.*
7. *T records componentwise* hsame *transport and displayed* Cont *replay for D, W, R, S, V, K.*
8. *P is the provenance row over* $\mathsf{CompletionExactness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionExactness}^{\uparrow}}$ *row.*

The classifier has no coordinate for a chosen limit, quotient representative, host equality of real names, countable-choice schedule, or unrestricted completion theorem.

Theorem 6779.2 (Completion exactness NameCert obligations)**.** *For every accepted* $\mathsf{CompletionExactness}^{\uparrow}$ *carrier*

$$E = (D, W, R, S, V, K, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompletionExactness}^{\uparrow}}$ *surface consists exactly of dyadic coverage through* D*, StreamName observation through* W*, regular-rational readback through* R*, soundness through* S*, completeness through* V*, classifier equivalence through* K*, transport and replay through* T*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6779.1. The rows D, W, R expose the inspected dyadic budgets, finite windows, and regular-rational readback before a completion-facing read is accepted.

Read the exactness rows next. Soundness S prevents an accepted read from escaping the displayed dyadic, stream, regular-rational, and terminal Real data, while completeness V forces every classifier-admitted displayed route to reach a read. The row K binds these two directions as the public classification equivalence.

Finally use the structural rows. Transport and replay T preserve the same finite route, provenance P records the sibling sources, and N names only that surface. Since the packet contains no row for selected limits, quotient representatives, host equality, countable choice, or unrestricted completion, the listed rows exhaust the local NameCert obligations. □

Theorem 6779.3 (Completion exactness real route)**.** *Every Real-facing completion read accepted by a* $\mathsf{CompletionExactness}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyCompletionEqualizer}^{\uparrow}.$$

The classifier equivalence row K *accepts such a read exactly when the coverage row* D*, soundness row* S*, and completeness row* V *hold over the same finite windows and readback data.*

Proof. Start with the sibling route. The dyadic tolerance row D schedules StreamName windows W, and those windows produce the regular-rational readback R before any terminal $\mathsf{Real}^{\uparrow}$ seal is available.

Use the equalizer boundary. The $\mathsf{CauchyCompletionEqualizer}^{\uparrow}$ surface compares completion reads only after the common dyadic, stream, regular-rational, and Real-facing rows have been displayed, so the completion exactness packet has no separate quotient-equality source.

Apply the classifier equivalence row. The row K reads coverage, soundness, and completeness over the same finite route, and T, P, N merely transport, replay, source, and name that route. Hence an accepted Real-facing completion read is exact precisely along the displayed L10 completion path, without selected limits or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionExactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompletionExactness}^{\uparrow}$ packet is generated from dyadic tolerance coverage, StreamName windows, RegSeqRat readback, soundness, completeness, a classifier equivalence row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionExactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6779.1, Definition 6779.2, and Definition 6779.3 seed the L10 completion exactness predicate over dyadic, StreamName, RegSeqRat, Real, CauchyCompletionEqualizer, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionExactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient Cauchy equality, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked coverage, soundness, completeness, classifier equivalence, transport, replay, provenance, and local NameCert rows for BEDC.Derived.CompletionExactnessUp.

Chapter 6780

A Concrete Naming Certificate for $\mathsf{TychonoffPlank}^{\uparrow}$

Following Kelley and Steen–Seebach point-set topology, the $\mathsf{TychonoffPlank}^{\uparrow}$ packet records the closed ordinal-rectangle surface used to test compactness and product-separation arguments without importing arbitrary Tychonoff compactness. It sits beside the finite compact-product packet of **??**, the indexed-open topology carrier of chapter 88, the compactness boundary of chapter 60, and the observable-open truth discipline of chapter 1860. The packet names only the displayed long-edge rows, corner-deletion row, product-neighbourhood rows, transport, replay, provenance, and local certificate data; it does not claim unrestricted product compactness, choice-selected subcovers, quotient open equality, or a host ordinal topology.

Definition 6780.1 (Tychonoff plank carrier)**.** *A* $\mathsf{TychonoffPlank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P_{\mathsf{tp}} = (L, R, O, K, S, H, C, G, N)$$

with the following displayed rows:

1. *L is the left long-edge row, naming the finite observations of the first ordinal interval used by the plank read.*
2. *R is the right long-edge row, naming the finite observations of the second ordinal interval used by the plank read.*
3. *O is the product-neighbourhood row, read through the* $\mathsf{Topology}^{\uparrow}$ *interface for rectangular opens and their finite meet and union ledgers.*
4. *K is the compact-side row, exposing only the compact rectangle or closed-side witness currently displayed by the packet.*
5. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row used to record whether the inspected corner, edge, or deleted-corner test is visible to the finite read.*
6. *H records componentwise* hsame *transport for the two edge rows, product-neighbourhood row, compact row, observable-open row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a plank observation through L, R, O, K, S, H, G, N.*
8. *G is the* Pkg *provenance over* $\mathsf{TychonoffPlank}^{\uparrow}$, $\mathsf{TychonoffFiniteProduct}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{TychonoffPlank}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for arbitrary indexed products, unrestricted Tychonoff compactness, host ordinal spaces, selected subcovers, quotient open equality, countable choice, Lean verification, or bridge checking.

Theorem 6780.2 (Tychonoff plank NameCert obligations)**.** *For every accepted* $\mathsf{TychonoffPlank}^{\uparrow}$ *carrier* $P_{\mathsf{tp}} = (L, R, O, K, S, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TychonoffPlank}^{\uparrow}}$ *surface consists exactly of carrier admission for the two long-edge rows, the product-neighbourhood row, the compact-side row, the observable-open row, transport, replay, provenance, and local naming; product-neighbourhood readback through* $\mathsf{Topology}^{\uparrow}$*; compact-side visibility through* $\mathsf{Compact}^{\uparrow}$*; observable corner and edge tests through* $\mathsf{SierpinskiSpace}^{\uparrow}$*; componentwise* hsame *stability; displayed* Cont *replay; provenance nonescape; and local naming exactness.*

Proof. Project the carrier of Definition 6780.1. The two edge rows and the product-neighbourhood row are the only data by which a consumer can inspect the plank.

The topology-facing obligations are read through O. Rectangular neighbourhoods, finite meets, and indexed unions must therefore use the same $\mathsf{Topology}^{\uparrow}$ row before any plank open is consumed.

The compact and observable-open obligations are rowwise. The row K exposes only the displayed compact-side witness, while S records the visible corner or edge test through the $\mathsf{SierpinskiSpace}^{\uparrow}$ classifier.

Finally H, C, G, N transport, replay, source, and name exactly the same rows. Since the carrier has no coordinate for arbitrary products, selected subcovers, quotient open equality, or host ordinal topology, those objects cannot become local NameCert data. □

Closure status for $\mathsf{NameCert}_{\mathsf{TychonoffPlank}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TychonoffPlank}^{\uparrow}}$, seed)

Scope closed: Definition 6780.1 and Definition 6780.2 seed the finite Tychonoff plank packet over displayed long-edge, topology, compactness, observable-open, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TychonoffPlank}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary Tychonoff products, choice-based product compactness, host ordinal spaces, selected subcovers, quotient open equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, long-edge readback, product-neighbourhood exactness, compact-side visibility, observable corner and edge tests, transport, replay, provenance, and local naming for BEDC.Derived.TychonoffPlankUp.

Constructive story: A $\mathsf{TychonoffPlank}^{\uparrow}$ packet is generated from two long-edge rows, a TopologyUp product-neighbourhood row, a CompactUp side row, a SierpinskiSpaceUp observable-open row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6781

A Concrete Naming Certificate for $\mathsf{DeletedTychonoffPlank}^{\uparrow}$

Following Kelley and Steen–Seebach point-set topology, the $\mathsf{DeletedTychonoffPlank}^{\uparrow}$ packet records the open deleted-corner surface of the Tychonoff plank as finite NameCert data. It sits beside the closed plank reconstruction of chapter 6780, reads rectangular neighbourhoods through chapter 88, keeps its compact-side boundary visible through chapter 60, and exposes corner tests through chapter 1860. The packet names only the displayed plank row, deleted-corner row, product-boundary row, topology row, compact row, observable-open row, transport, replay, provenance, and local naming; it does not claim unrestricted product compactness, a host ordinal topology, quotient open equality, selected subcovers, or choice-based compactness.

Definition 6781.1 (Deleted Tychonoff plank carrier)**.** *A* $\mathsf{DeletedTychonoffPlank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (P, X, B, O, K, S, H, C, G, N)$$

with the following displayed rows:

1. *P is the sibling* $\mathsf{TychonoffPlank}^{\uparrow}$ *row that supplies the closed plank surface read by the deleted packet.*
2. *X is the deleted-corner row, naming the removed top corner as displayed boundary data rather than as a host ordinal point.*
3. *B is the product-boundary row, recording which long-edge and corner-neighbourhood observations remain visible after the deletion.*
4. *O is the* $\mathsf{Topology}^{\uparrow}$ *row for rectangular neighbourhood reads, finite meet rows, finite union rows, and boundary-open observations.*
5. *K is the* $\mathsf{Compact}^{\uparrow}$ *row for the compact side or closed-rectangle witness inherited from the sibling plank packet.*
6. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row that records whether the deleted corner, remaining edge, or boundary neighbourhood is visible to a finite read.*
7. *H records componentwise* hsame *transport for $P, X, B, O, K, S, C, G, N$.*
8. *C records displayed* Cont *replay from a deleted-plank observation through $P, X, B, O, K, S, H, G, N$.*
9. *G is the* Pkg *provenance over* $\mathsf{DeletedTychonoffPlank}^{\uparrow}$*,* $\mathsf{TychonoffPlank}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{SierpinskiSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{DeletedTychonoffPlank}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $P, X, B, O, K, S, H, C, G, N$. It has no coordinate for unrestricted product compactness, a selected subcover, quotient open equality, a host ordinal topology, countable choice, Lean verification, or bridge checking.

Lean4 (statement) `BEDC.Derived.DeletedTychonoffPlankUp`

Theorem 6781.2 (Deleted Tychonoff plank NameCert obligations)**.** *For every accepted* $\mathsf{DeletedTychonoffPlank}^{\uparrow}$ *carrier $D = (P, X, B, O, K, S, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{DeletedTychonoffPlank}^{\uparrow}}$ *surface consists exactly of carrier admission for the sibling plank row, deleted-corner row, product-boundary row, topology row, compact row, observable-open row, transport, replay, provenance, and local naming; deletion visibility through X and S; rectangular neighbourhood readback through O; compact-side visibility through K; product-boundary stability through B and H; displayed* Cont *replay; provenance nonescape; and local naming exactness.*

Proof. Project the carrier of Definition 6781.1. The rows P, X, B are the only data by which a consumer can inspect the closed plank, the deleted corner, and the remaining product boundary.

The topology-facing obligations are read through O and S. Rectangular neighbourhoods and finite Boolean operations use the $\mathsf{Topology}^{\uparrow}$ row, while the visible deleted-corner and edge tests use the $\mathsf{SierpinskiSpace}^{\uparrow}$ row.

The compact-side obligation is rowwise. The row K exposes only the compact-side witness inherited by the packet, and B records which boundary observations remain available after the deleted corner is removed.

Finally H, C, G, N transport, replay, source, and name exactly the same rows. Since the carrier has no coordinate for unrestricted product compactness, selected subcovers, quotient open equality, host ordinal topology, or countable choice, those objects cannot become local NameCert data. □

Theorem 6781.3 (Deleted Tychonoff plank product-boundary handoff)**.** *Every product-boundary read exported by an accepted* $\mathsf{DeletedTychonoffPlank}^{\uparrow}$ *packet factors through*

$$P, X, B \longmapsto O, K, S \longmapsto H, C, G, N.$$

The handoff first exposes the sibling $\mathsf{TychonoffPlank}^{\uparrow}$ *row, the deleted-corner row, and the finite product-boundary row, then reads the* $\mathsf{Topology}^{\uparrow}$ *neighbourhood row, the* $\mathsf{Compact}^{\uparrow}$ *side row, and the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row before any public consumer can use the route.*

Proof. Begin with the carrier projection. A product-boundary consumer can only start from P, X, B, so the closed plank, deleted corner, and remaining edge observations are fixed as displayed rows before any topology-facing read occurs.

The rows O, K, S then expose the neighbourhood, compact-side, and observable-open interfaces. This makes the boundary handoff a finite product-neighbourhood route rather than an appeal to unrestricted product compactness or a host ordinal topology.

The structural rows H, C, G, N preserve the same route by componentwise transport, displayed replay, provenance, and local naming. Therefore the exported boundary remains the displayed finite packet and cannot be replaced by quotient open equality, a selected subcover, or countable choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{DeletedTychonoffPlank}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DeletedTychonoffPlank}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6781.1, Definition 6781.2, and Definition 6781.3 seed the finite deleted-plank packet over displayed plank, deleted-corner, product-boundary, topology, compactness, observable-open, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{DeletedTychonoffPlank}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.DeletedTychonoffPlankUp`

Bridge status: none

Not claimed: This chapter does not close unrestricted product compactness, host ordinal topology, quotient open equality, selected subcovers, countable choice, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, deleted-corner visibility, topology readback, compact-side visibility, observable-open tests, product-boundary stability, handoff factoring, transport, replay, provenance, and local naming for BEDC.Derived.DeletedTychonoffPlankUp.

Constructive story: A DeletedTychonoffPlank$^{\uparrow}$ packet is generated from a TychonoffPlankUp row, deleted-corner row, product-boundary row, TopologyUp neighbourhood row, CompactUp side row, SierpinskiSpaceUp observable-open row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6782

A Concrete Naming Certificate for $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$ packet records a paired lower-and-upper finite-net extreme-value certificate for uniformly continuous maps on compact metric sources. It is the finite-net companion to chapter 6770 and sits over the finite-net handoff of chapter 6769, the compact source row of chapter 129, the uniformly continuous map row of chapter 130, the stream schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the attained-extreme comparison surface of chapter 3984. The packet exposes located upper and lower value windows without selecting extrema, importing open-cover compactness, identifying quotient real names, invoking countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6782.1 (Located uniform extreme-value carrier)**.** *A* $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, F, N, W, R, E, L, U_b, M, H, C, P, Q)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the compact metric inspection surface consumed by finite-net reads.*
2. *F is the uniformly continuous* $\mathsf{ContinuousMap}^{\uparrow}$ *row, exposing the value request interface over K.*
3. *N is the* $\mathsf{HeineCantorFiniteNet}^{\uparrow}$ *row, recording the finite center family, radius schedule, and coverage witness through which every extreme-value request enters.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the finite family of value windows attached to the centers of N.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational lower and upper endpoints exposed by W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed value names before any comparison row is consumed.*
7. *L is the located lower-bound row, comparing each displayed center value with the finite family through rational lower windows.*

8. *U_b is the located upper-bound row, comparing each displayed center value with the finite family through rational upper windows.*
9. *M is the paired extreme-value ledger row, recording that the lower and upper rows share the same source, map, finite net, value windows, rational readback, and Real seal.*
10. *H records componentwise* hsame *transport for the compact source, map row, finite-net cover, stream schedule, rational readback, Real seal, lower row, upper row, paired ledger, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from an extreme-value request through $K, F, N, W, R, E, L, U_b, M, H, P, Q$.*
12. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$, $\mathsf{BishopLocatedMaximum}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{HeineCantorFiniteNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *Q is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformExtremeValue}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed compact source, uniformly continuous map row, finite-net cover, value-window schedule, regular rational readback, Real seal, lower and upper located comparison rows, shared ledger, transport, replay, provenance, and local naming. It has no coordinate for a selected minimum, selected maximum, open-cover compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.LocatedUniformExtremeValueUp`

Theorem 6782.2 (Located uniform extreme-value obligations)**.** *For every accepted* $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$ *carrier $U = (K, F, N, W, R, E, L, U_b, M, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformExtremeValue}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed compact source, uniformly continuous map row, finite-net cover, value windows, rational readback, Real seal, lower row, upper row, paired ledger, transport, replay, provenance, and local naming;*
2. *finite-net exposure, requiring every extreme-value request to pass through the centers and coverage witnesses named by N;*
3. *value readback through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *requiring W, R, E to be visible before either bound row is consumed;*
4. *lower-bound located comparison through L and upper-bound located comparison through U_b;*
5. *shared-ledger exactness through M, requiring both bound rows to use the same finite net and value-readback route;*
6. *refusal of selected extrema, open-cover compactness, quotient real equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6782.1. The rows K, F, N expose the compact source, map row, and finite-net coverage surface that every later value read must use.

Read the value rows next. The stream schedule W supplies finite lower and upper windows, R reads those windows as regular rational data, and E seals the displayed readbacks as $\mathsf{Real}^{\uparrow}$ names before a comparison can be used.

The lower row L and upper row U_b can consume only the Real-sealed finite family already displayed by N, W, R, E. The shared ledger M then records that both comparisons used the same

route, while H, C, P, Q transport, replay, source, and name that finite route. These rows exhaust the listed obligations. □

Theorem 6782.3 (Located uniform extreme-value finite-net exposure)**.** *Every extreme-value read exported by an accepted* $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$ *carrier factors through the displayed finite route*

$$K, F, N \longmapsto W, R, E \longmapsto L, U_b, M \longmapsto H, C, P, Q.$$

Thus a consumer can inspect only the compact source, uniformly continuous map row, finite net, value windows, located lower and upper comparisons, and Real seal before reaching the local naming row.

Proof. Start with the source and map rows. The compact metric source K and uniformly continuous map row F become visible to an extreme-value read only through the finite-net cover N.

The value route is fixed before either bound row appears. The stream schedule W records finite observation windows attached to the net, the regular rational row R reads those windows, and the terminal seal E is reached before any extreme-value comparison is available.

The located lower row L and upper row U_b compare the same Real-sealed finite family. The ledger M prevents one bound from using a different net or value-readback route. Replaying the same rows through H, C, P, Q gives the displayed factorization. □

Theorem 6782.4 (Located uniform extreme-value bounds)**.** *An accepted* $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$ *carrier exposes paired lower and upper value windows only as located finite-net comparisons. It does not expose an argmin, an argmax, a quotient equality class for real names, an open-cover compactness proof, a choice functional, or an ambient completeness principle.*

Proof. Inspect the excluded coordinates in Definition 6782.1. The carrier contains rows for L, U_b, and M, but no coordinate that names a minimizing point, maximizing point, quotient real equality token, open-cover proof, choice functional, or completeness witness.

Apply Definition 6782.2. The only comparison obligations are the lower row, the upper row, and the shared finite-net ledger. Therefore any accepted bound read is a located finite-net comparison read, not an extraction of one of the excluded objects. □

Theorem 6782.5 (Located uniform extreme-value NameCert route)**.** *The* $\mathsf{LocatedUniformExtremeValue}^{\uparrow}$ *NameCert route is the paired-bound route obtained by adding an upper located comparison row to the finite-net maximum-location route of* $\mathsf{BishopLocatedMaximum}^{\uparrow}$ *while keeping the same compact source, uniformly continuous map, finite net, value-window schedule, rational readback, and Real seal interface.*

Proof. Use the sibling route of chapter 6770 for the compact source, map row, finite net, value-window schedule, rational readback, and Real seal. The present carrier keeps those rows as K, F, N, W, R, E.

Add the lower and upper located comparison rows L and U_b and bind them with the shared ledger M. The replay and provenance rows H, C, P, Q then name the same finite route for both bounds, so the NameCert route is precisely the paired-bound route described in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformExtremeValue}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformExtremeValue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6782.1, Definition 6782.2, Definition 6782.3, Definition 6782.4, and Definition 6782.5 seed the paired finite-net lower-and-upper extreme-value route over compact-source, uniformly continuous map, value-window, rational-readback, located-comparison, and Real-seal rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedUniformExtremeValue}^{\uparrow}}$, formalTarget)
Lean target: `BEDC.Derived.LocatedUniformExtremeValueUp`
Bridge status: none
Not claimed: This chapter does not close selected extrema, full open-cover compactness, quotient real equality, countable choice, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, axiom-purity certification, or bridge checking for LocatedUniformExtremeValue$^{\uparrow}$.
Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, StreamName-RegSeqRat-Real value readback, paired lower and upper located comparisons, transport, replay, provenance, and local naming for BEDC.Derived.LocatedUniformExtremeValueUp.
Constructive story: A LocatedUniformExtremeValue$^{\uparrow}$ packet is generated from a CompactMetric source row, a uniformly continuous ContinuousMap row, a finite-net cover, StreamName value windows, RegSeqRat readbacks, a Real seal, located lower and upper comparison rows, a shared finite-net ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6783

A Concrete Naming Certificate for $\mathsf{BishopLocatedOscillation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedOscillation}^{\uparrow}$ packet records the finite NameCert route by which a continuous map on compact metric data exposes located oscillation bounds through dyadic windows and regular rational readback. It sits beside the compact finite-net carrier of chapter 129, the map carrier of chapter 130, the dyadic and stream naming rows of chapter 291 and chapter 126, the regular rational and Real readback rows of chapter 301 and chapter 38, and the explicit oscillation schedule of chapter 2224. The packet is an L10 finite-window certificate: it does not select extrema, invoke quotient equality, use Real completeness, or import choice.

Definition 6783.1 (Bishop located oscillation carrier)**.** *A* $\mathsf{BishopLocatedOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L_{\mathrm{osc}} = (K, F, D, S, Q, R, O, W, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, exposing only the bundled compact carrier, its finite coverage histories, and the named metric comparisons used by the oscillation request.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, recording the map whose local oscillation is read at the displayed compact windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the target oscillation scale and the source-window cuts.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the finite stream of windows inspected by the request.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the stream and regular rational rows have been displayed.*
7. *O is the* $\mathsf{OscillationModulus}^{\uparrow}$ *row translating the local oscillation read into an explicit tolerance-window schedule.*
8. *W is the located window row, the finite ledger that records which compact windows have been inspected and which dyadic bound each read returns.*
9. *H records componentwise* hsame *transport for the compact, map, dyadic, stream, regular-rational, Real, oscillation-modulus, located-window, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a tolerance request through K, F, D, S, Q, R, O, W and back to the exported located oscillation row.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedOscillation}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows and the displayed routes among them. It has no coordinate for selected extrema, quotient equality of streams, open-cover compactness, Real completeness, countable choice, or bridge-axis evidence.

Theorem 6783.2 (Bishop located oscillation NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedOscillation}^{\uparrow}$ *carrier $L_{\mathrm{osc}} = (K, F, D, S, Q, R, O, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the compact metric row, continuous map row, dyadic tolerance row, stream-name row, regular rational row, Real seal, oscillation-modulus row, located-window row, transport row, replay row, provenance row, and local naming row;*
2. *located-window coverage, requiring each oscillation read to name one displayed compact window from W before any Real-facing value is exposed;*
3. *dyadic precision visibility, requiring the target tolerance and source-window cut to be read from D and then replayed through S, Q, R;*
4. *oscillation-modulus handoff, requiring O to consume the same K, F, D, S, Q, R, W route before exporting the tolerance-window schedule;*
5. *ledger non-escape, requiring H, C, P, N to export no selected extrema, quotient equality of streams, open-cover compactness, Real completeness, countable choice, or bridge-axis evidence.*

No local obligation is stored outside those rows.

Proof. Project the accepted carrier. Its analytic rows are exactly K, F, D, S, Q, R, O, W, and its structural rows are exactly H, C, P, N.

Carrier admission is therefore componentwise. The compact row supplies only the finite coverage histories, the map row supplies only the named continuous-map read, and the dyadic, stream, regular rational, and Real rows supply the displayed readback route.

The located-window row is the only place where a compact window is named for the oscillation request. The oscillation-modulus row consumes that same route, so the exported schedule cannot bypass K, F, D, S, Q, R, W.

Transport, replay, provenance, and local naming preserve the same rows. Since no row stores selected extrema, quotient equality, open-cover compactness, Real completeness, countable choice, or bridge data, none of those objects can become a local obligation. □

Theorem 6783.3 (Bishop located oscillation finite-window handoff)**.** *Every Real-facing or compact-uniform consumer of an accepted* $\mathsf{BishopLocatedOscillation}^{\uparrow}$ *packet reads oscillation data through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{OscillationModulus}^{\uparrow},\ \mathsf{Bisho}$$

Consequently the consumer receives a located finite-window oscillation certificate and not a selected maximum, quotient equality of streams, open-cover compactness theorem, Real completeness principle, countable-choice schedule, or bridge certificate.

Proof. Begin with the accepted packet. By Definition 6783.1, every consumer-visible read of oscillation data must pass through the compact row K, the map row F, the dyadic tolerance row D, the stream row S, the regular rational row Q, the Real seal R, the oscillation-modulus row O, and the located-window ledger W.

The replay row C orders the route from the tolerance request to the exported schedule, while H transports the same components and P, N source and name them. Thus a Real-facing read and a compact-uniform read see the same finite-window handoff.

Because the carrier has no coordinate for selected extrema, quotient stream equality, open-cover compactness, Real completeness, choice, or bridge data, the handoff cannot import those principles. □

Falsifiable prediction: Every $\mathsf{BishopLocatedOscillation}^{\uparrow}$ consumer read factors through one CompactMetric row, one ContinuousMap row, one DyadicRatCore tolerance row, one StreamName window row, one RegSeqRat readback row, one RealUp seal, one OscillationModulus row, one located-window ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: compactmetric, continuousmap, dyadicratcore, streamname, regseqrat, real, oscillation-modulus: $\mathsf{BishopLocatedOscillation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite-window admission, continuous-map oscillation reads, dyadic precision, stream naming, regular rational readback, Real sealing, oscillation-modulus export, located-window bookkeeping, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedOscillation}^{\uparrow}$ packet is generated from CompactMetric finite-window data, a ContinuousMap row, a DyadicRatCore tolerance row, a StreamName window row, a RegSeqRat readback row, a RealUp seal, an OscillationModulus row, a located-window ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6783.1, Definition 6783.2, and Definition 6783.3 seed the finite-window located oscillation certificate used by Real-facing and compact-uniform consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected extrema, quotient equality of streams, open-cover compactness, Real completeness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window coverage, dyadic precision visibility, oscillation-modulus handoff, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.BishopLocatedOscillationUp.

Chapter 6784

A Concrete Naming Certificate for $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$

Following Bishop and Bridges on nested intervals and constructive real approximation, the DyadicNestedIntervalSelec packet records the finite selector surface used when a displayed nested dyadic interval argument is handed to Real and Completion consumers. It sits over the nested-chain surface of chapter 320, the center-radius ledger of chapter 291, the finite window source of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names only the finite displayed rows by which a selected window is inspected; it does not assert interval compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a selected completed real.

Definition 6784.1 (Dyadic nested interval selector carrier)**.** *A* $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the displayed* $\mathsf{NestedInterval}^{\uparrow}$ *chain whose retained cells are being inspected.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *center and radius ledger attached to the same retained cells.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the requested stages of the chain.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the same finite windows with regular rational observations.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for the nested-chain, dyadic-ledger, stream-window, readback, seal, provenance, route, and local naming rows.*
7. *C records displayed* Cont *replay from a dyadic selector request through I, D, S, R, E and back to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalSelector}^{\uparrow}}$ *row.*

The carrier exports only this finite displayed selector packet. It contains no coordinate for a host choice function, selected completed real, interval compactness theorem, countable-choice schedule, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicNestedIntervalSelectorUp.DyadicNestedIntervalSelectorTasteGate`
`single carrier alignment`

Theorem 6784.2 (Dyadic nested interval selector NameCert obligations)**.** *For every accepted* $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$ *carrier*

$$K = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalSelector}^{\uparrow}}$ *surface consists exactly of nested-chain exposure through* I*, dyadic center-radius exposure through* D*, finite-window exposure through* S*, regular rational readback through* R*, terminal seal admission through* E*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*. Any selector-facing consumer must read those rows before using the finite nested dyadic interval route.*

Proof. Project the carrier of Definition 6784.1. The nested chain, dyadic center-radius ledger, stream window, regular readback, Real seal, transport, replay, provenance, and local name are the complete visible packet.

The selector route first reads I and D. Thus the retained interval stage and its dyadic center-radius data are displayed before any window or Real-facing read is available.

Next read S and R. The stream row names the finite inspected stages, while the regular rational row supplies the readback for those stages. The seal row E is downstream of that finite route.

The rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no host selector, compactness theorem, countable-choice schedule, quotient equality, or ambient completeness coordinate, none of those principles can be exported by the local certificate. □

Lean4 ✓ `BEDC.Derived.DyadicNestedIntervalSelectorUp.DyadicNestedIntervalSelectorNamecertObligations`

Theorem 6784.3 (Dyadic nested interval selector Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$ *packet factors through*

$$\mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the finite rows $I, D, S, R, E, H, C, P, N$*. The handoff may transport and replay the displayed selector route, but it cannot claim* $\mathsf{Real}^{\uparrow}$ *completeness, interval compactness, countable choice, a host-selected endpoint, quotient stream equality, or a selected completed real.*

Lean4 ✓ `BEDC.Derived.DyadicNestedIntervalSelectorUp.DyadicNestedIntervalSelectorRealHandoff`

Proof. Begin with the obligation theorem. It forces the Real-facing request to expose the nested-chain row, dyadic center-radius ledger, finite stream window, and regular rational readback before the seal row can be consumed.

The sibling chapters supply the named surfaces of that route. The nested interval chapter supplies I, the dyadic rational core supplies D, the stream and regular rational chapters supply S and R, and the Real chapter supplies the terminal seal row E.

Finally use the structural rows. Componentwise hsame transport and displayed Cont replay preserve the same finite route, while P and N source and name it. No row remains from which a consumer could recover ambient completeness, compactness, choice, a host endpoint selector, quotient stream equality, or a completed selected real. □

Theorem 6784.4 (Dyadic nested interval selector prefix seal)**.** *Let $K = (I, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$ *carrier. Every prefix-window restriction of the selector packet preserves the route*

$$\mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before it exposes the terminal seal row E. Thus a Real-facing consumer cannot skip the nested interval row I, the dyadic ledger D, the finite stream window S, or the regular rational readback R by appealing to interval compactness, selected endpoints, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6784.1. A prefix-window restriction can only retain rows already displayed by the packet, so its visible selector data begins with I, D, S, R.

Use the NameCert obligations of Definition 6784.2. They force nested-chain exposure through I, dyadic center-radius exposure through D, finite-window exposure through S, and regular rational readback through R before the seal row can be consumed.

Apply the Real handoff theorem Definition 6784.3. It identifies the terminal route through $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with H, C, P, N preserving the same finite prefix under transport, replay, provenance, and naming.

No carrier coordinate supplies interval compactness, a selected endpoint, quotient stream equality, countable choice, or ambient Real completeness. The prefix seal therefore remains a finite displayed route rather than a completed-host selection principle. □

Lean4 ✓ `BEDC.Derived.DyadicNestedIntervalSelectorUp.DyadicNestedIntervalSelectorPrefixSeal`

Theorem 6784.5 (Dyadic nested interval selector nested-chain dependency)**.** *Every selector read from an accepted* $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$ *carrier must expose the* $\mathsf{NestedInterval}^{\uparrow}$ *row I before the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D,* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and* $\mathsf{Real}^{\uparrow}$ *seal E can be consumed. No selector route can bypass* $\mathsf{NestedInterval}^{\uparrow}$ *by appealing to compactness, selected endpoints, quotient equality, countable choice, or ambient completeness.*

Proof. Project the carrier in Definition 6784.1. The nested-chain row I is the first analytic coordinate of the selector packet, and the rows D, S, R, E are downstream of the retained chain.

Use the NameCert obligations of Definition 6784.2. They identify nested-chain exposure through I as part of the local certificate surface before any finite window, readback, or seal is available.

Apply the prefix seal theorem Definition 6784.4. It keeps every prefix-window restriction on the route through I, D, S, R, E, so compactness, selected endpoints, quotient equality, countable choice, and ambient completeness have no bypass coordinate. □

Lean4 ✓ `BEDC.Derived.DyadicNestedIntervalSelectorUp.DyadicNestedIntervalSelectorNestedChainDependency`

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$ packet is generated from a displayed NestedIntervalUp chain, a DyadicRatCoreUp center-radius ledger, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6784.1, Definition 6784.2, Definition 6784.3, and Definition 6784.5 seed the finite selector route for displayed nested dyadic interval arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, interval compactness, countable choice, host-selected endpoints, quotient stream equality, selected completed reals, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-chain exposure, dyadic center-radius exposure, finite-window readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicNestedIntervalSele

Chapter 6785

A Concrete Naming Certificate for $\mathsf{FinePartitionRefinement}^{\uparrow}$

Following Bishop and Bridges, and the Cousin gauge-integration route for tagged subdivisions, the $\mathsf{FinePartitionRefinement}^{\uparrow}$ packet names the finite operation that takes an already displayed fine tagged partition and a displayed refinement request to a common fine refinement. It sits between the fine tagged partition surface of chapter 6467, the local finite cover route of chapter 3426, and the Darboux–Riemann comparison handoff of chapter 5894. The packet records only interval source rows, source and target tagged-cell ledgers, refinement maps, gauge-fineness preservation, mesh comparison, handoff, transport, replay, provenance, and local naming; it does not assert an ambient partition lattice, selected refinement limit, quotient equality of tagged partitions, choice-selected tags, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6785.1 (FinePartitionRefinement carrier)**.** *A* $\mathsf{FinePartitionRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, G, S, T, \rho, L, M, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval source shared by the refined cells.*
2. *G is the positive gauge row used to test every target cell.*
3. *S is the source* $\mathsf{FinePartitionGauge}^{\uparrow}$ *tagged-cell ledger.*
4. *T is the target tagged-cell ledger after refinement.*
5. *ρ is the finite refinement map sending every target cell of T to a source cell of S with endpoint containment and tag compatibility.*
6. *L is the fineness-preservation row, recording that each target cell remains G-fine through the row ρ.*
7. *M is the mesh comparison row, displaying the finite dyadic ledger that bounds the target mesh by the source mesh and by the requested refinement tolerance.*
8. *U is the* $\mathsf{CousinCover}^{\uparrow}$ *handoff row witnessing that the refined cells still lie on the displayed local cover route.*
9. *Q is the* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ *handoff row consumed by Darboux and Riemann-sum comparison packets.*

10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the finite mesh and handoff rows have been exposed.*
11. *H records componentwise* hsame *transport for interval, gauge, source partition, target partition, refinement map, fineness, mesh, handoff, seal, replay, provenance, and local naming rows.*
12. *C records displayed* Cont *replay from a refinement request through the finite rows above.*
13. *P is the* Pkg *provenance over* $\mathsf{FinePartitionRefinement}^{\uparrow}$, $\mathsf{FinePartitionGauge}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, RiemannRefinementCr $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{FinePartitionRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, G, S, T, \rho, L, M, U, Q, E, H, C, P, N$. It has no coordinate for a host refinement relation, an infinite partition net, quotient tagged-partition equality, selected mesh limit, hidden tag choice, or ambient completeness theorem.

Theorem 6785.2 (FinePartitionRefinement NameCert obligations)**.** *For every accepted* $\mathsf{FinePartitionRefinement}^{\uparrow}$ *carrier*

$$R = (I, G, S, T, \rho, L, M, U, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FinePartitionRefinement}^{\uparrow}}$ *surface consists exactly of interval and gauge admission, source* $\mathsf{FinePartitionGauge}^{\uparrow}$ *admission, target tagged-cell admission, finite refinement-map exactness, fineness preservation, mesh comparison over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$ *locality,* RiemannRefinementCriteri *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the accepted carrier. The source data are I, G, S, where S is already a $\mathsf{FinePartitionGauge}^{\uparrow}$ packet over the displayed interval and gauge.

The target data are T, ρ, L, M. The map ρ records finite containment of target cells in source cells, L records preservation of gauge-fineness along that containment, and M records the dyadic mesh comparison. These rows are the only refinement operation stored in the carrier.

The handoff rows U and Q then expose the same refined partition to the Cousin cover and Riemann refinement criterion siblings. The remaining rows transport, replay, source, and name the packet. Since no coordinate stores a host refinement lattice, hidden selector, quotient equality, or ambient completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6785.3 (FinePartitionRefinement handoff)**.** *Every accepted* $\mathsf{FinePartitionRefinement}^{\uparrow}$ *packet turns a displayed* $\mathsf{FinePartitionGauge}^{\uparrow}$ *source row into a finite target refinement before any* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ *consumer may read the Darboux–Riemann comparison route. The consumer receives only*

$$\mathsf{FinePartitionGauge}^{\uparrow},\ \mathsf{CousinCover}^{\uparrow} \longmapsto T, \rho, L, M \longmapsto \mathsf{RiemannRefinementCriterion}^{\uparrow},\ \mathsf{Real}^{\uparrow},$$

with $\mathsf{DyadicRatCore}^{\uparrow}$ *controlling the finite mesh ledger.*

Proof. Start from the carrier of Definition 6785.1. The source row S is read as a fine tagged partition through chapter 6467, while U keeps the refined cells on the Cousin cover route of chapter 3426.

The finite target rows T, ρ, L, M expose the actual operation: a displayed target cell ledger, a displayed refinement map, a fineness-preservation row, and a dyadic mesh comparison row. No downstream consumer can read Q before these rows have been presented.

Finally Q is the $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ handoff, so the Darboux–Riemann comparison receives a finite refinement packet rather than a host-level partition principle. The terminal seal E and the structural rows H, C, P, N preserve only this route. □

Falsifiable prediction: Every accepted $\mathsf{FinePartitionRefinement}^{\uparrow}$ consumer must expose a source FinePartitionGauge row, target tagged-cell ledger, finite refinement map, fineness-preservation row, dyadic mesh comparison, CousinCover handoff, and RiemannRefinementCriterion handoff before using the refinement.

Independence witness: finepartitiongauge, cousincover, riemannrefinementcriterion, dyadicratcore: $\mathsf{FinePartitionRefinement}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite refinement map, target tagged-cell ledger, fineness preservation, mesh comparison, and two downstream handoff rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FinePartitionRefinement}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FinePartitionRefinement}^{\uparrow}$ packet is generated from interval and gauge rows, a source FinePartitionGauge row, a target tagged-cell ledger, finite refinement maps, fineness-preservation rows, DyadicRatCore mesh comparisons, CousinCover and RiemannRefinementCriterion handoffs, RealUp sealing, transport, replay, provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinePartitionRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6785.1, Definition 6785.2, and Definition 6785.3 seed the finite refinement-operation carrier between fine partitions and Riemann refinement consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinePartitionRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host partition lattices, selected mesh limits, quotient tagged-partition equality, hidden tag choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, refinement-map exactness, fineness preservation, DyadicRatCore mesh comparison, CousinCover locality, RiemannRefinementCriterion handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.FinePartitionRefinementUp.

Chapter 6786

A Concrete Naming Certificate for EnergyRefinedPrivateCoordinate$^{\uparrow}$

The EnergyRefinedPrivateCoordinate$^{\uparrow}$ packet realizes the energy-refined private-coordinate formula of Definition 9462.1675 as finite NameCert data. It refines the minimal-cover surface of chapter 5812 by adding an incidence-pattern energy ledger, a polynomial coefficient ledger, and a trigger-size projection before the enumerator may be consumed. The packet keeps the BEDC-discovered enumeration route separate from bare finite-set covers, Boolean tables, natural-number sequences, and polynomial syntax without private-coordinate witnesses.

Falsifiable prediction: Every accepted EnergyRefinedPrivateCoordinate$^{\uparrow}$ consumer must display private-coordinate witnesses, an incidence-pattern energy row, and a coefficient ledger before using the energy-refined polynomial formula.

Independence witness: private-coordinate-trigger, finset, polynomial, nat, bool: EnergyRefinedPrivateCoordinate is not bijective to these siblings because it carries the private-coordinate support ledger together with energy weights, trigger-size grading, and coefficient replay.

Definition 6786.1 (Energy-refined private-coordinate carrier)**.** *An* EnergyRefinedPrivateCoordinate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (\Omega, A, U, V, \pi, X, W, Z, Y, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row.*
3. U, V, π *are the cover, private-witness, and membership/exclusion rows inherited from* PrivateCoordinateTrigger$^{\uparrow}$.
4. X *is the incidence-pattern row, listing for each coordinate the nonempty subset of displayed supports that contain it.*
5. W *is the energy ledger, recording the finite sum of incidence-pattern sizes.*
6. Z *is the trigger-size grading row.*
7. Y *is the polynomial coefficient ledger for the displayed variables* z *and* y.
8. K *is the energy-refined formula row, readable only after* U, V, π, X, W, Z, Y *have been displayed.*

9. *H stores componentwise* hsame *transport for coordinate, support, witness, energy, grading, coefficient, and formula rows.*
10. *C stores* Cont *replay from an enumerator query through the displayed rows.*
11. *P stores* Pkg *provenance over* $\mathsf{EnergyRefinedPrivateCoordinate}^{\uparrow}$, $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EnergyRefinedPrivateCoordinate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, X, W, Z, Y, K, H, C, P, N$. It has no coordinate for an unweighted minimal-cover criterion, a bare polynomial expression, a natural-number table, a Boolean classifier, or a support family without the private-coordinate ledger.

Theorem 6786.2 (Energy-refined private-coordinate NameCert obligations)**.** *For every accepted* $\mathsf{EnergyRefinedPrivateCoordinate}^{\uparrow}$ *carrier*

$$E = (\Omega, A, U, V, \pi, X, W, Z, Y, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EnergyRefinedPrivateCoordinate}^{\uparrow}}$ *surface consists exactly of finite coordinate admission, support-family admission, private-coordinate witness replay, incidence-pattern exposure, energy-ledger exactness, trigger-size grading, polynomial coefficient replay, energy-refined formula exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier. The rows Ω, A, U, V, π display the private-coordinate minimal-cover surface inherited from chapter 5812.

The energy rows are X, W, Z, Y. The incidence-pattern row X records which displayed supports contain each coordinate, W sums the displayed pattern sizes, Z records trigger size, and Y stores the polynomial coefficient ledger.

The formula row K is downstream of both the private-coordinate witness rows and the energy rows. The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no omitted coordinate supplies a bare polynomial, natural-number table, Boolean classifier, or unweighted cover criterion, the obligation surface is exactly the displayed finite ledger. □

Theorem 6786.3 (Energy-refined polynomial handoff)**.** *Every accepted* $\mathsf{EnergyRefinedPrivateCoordinate}^{\uparrow}$ *packet exposes the energy-refined formula of Definition 9462.1675 only after the private-coordinate cover row, incidence-pattern row, energy ledger, trigger-size grading, and polynomial coefficient ledger have been read. The packet may hand the resulting coefficient surface to* $\mathsf{Poly}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, *and* $\mathsf{Bool}^{\uparrow}$ *consumers, but it does not identify the carrier with any one of those siblings.*

Proof. Start with the private-coordinate rows Ω, A, U, V, π. These rows ensure that the support family is a displayed minimal-cover carrier rather than a bare finite-set family.

Next expose the energy and coefficient rows X, W, Z, Y. They record incidence patterns, the finite energy sum, trigger size, and polynomial coefficients before the formula row K is visible.

Finally read K as the energy-refined formula row. The provenance row names the polynomial, natural-number, and Boolean siblings only as consumers of the displayed ledger; it does not replace the private-coordinate and energy rows by one of those sibling classifiers. The structural rows therefore preserve the energy-refined carrier surface for later TasteGate nontriviality and FieldFaithful projection checks. □

Closure status for $\mathsf{NameCert}_{\mathsf{EnergyRefinedPrivateCoordinate}^{\uparrow}}$.

Constructive story: An EnergyRefinedPrivateCoordinate$^{\uparrow}$ packet is generated from finite trigger-coordinate rows, support-family rows, private-coordinate witnesses, incidence-pattern rows, energy ledgers, trigger-size grading, polynomial coefficient ledgers, formula replay, transport, continuation, provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{EnergyRefinedPrivateCoordinate}\uparrow}$, seed)

Scope closed: Definition 6786.1, Definition 6786.2, and Definition 6786.3 seed the finite energy-refined enumeration carrier for private-coordinate triggers.

Formal verification: FormalStatus(NameCert$_{\mathsf{EnergyRefinedPrivateCoordinate}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, TasteGate nontriviality, FieldFaithful projection, polynomial completeness, Boolean classifier completeness, or enumeration beyond the displayed energy-refined ledger.

Upgrade path: Obligation closure requires checked carrier admission, private-coordinate witness replay, incidence-pattern exposure, energy-ledger exactness, polynomial coefficient replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.EnergyRefinedPrivateCoordinateUp.

Chapter 6787

A Concrete Naming Certificate for $\mathsf{BoundedOscillation}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{BoundedOscillation}^{\uparrow}$ packet records a finite dyadic oscillation ledger over displayed $\mathsf{Real}^{\uparrow}$ windows. It sits between the real-name boundary of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the finite Darboux-sum surface of chapter 1880, and the bounded-variation function route of chapter 3654. The packet names only the finite ledger by which Darboux-facing consumers receive an oscillation bound; it does not claim host function equality, selected suprema, measure completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6787.1 (Bounded oscillation carrier)**.** *A* $\mathsf{BoundedOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (I, W, R, D, L, B, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *window row naming the displayed interval or cell on which the oscillation ledger is read.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window for endpoint and sample reads inside I.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the observations in W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested oscillation radius, slack, and comparison budget.*
5. *L is the finite dyadic oscillation ledger, pairing the sampled upper and lower readbacks with the tolerance row D.*
6. *B is the displayed boundedness row asserting that the ledger oscillation is below the carried* $\mathsf{Real}^{\uparrow}$ *bound.*
7. *S is the* $\mathsf{DarbouxSum}^{\uparrow}$ *handoff row through which lower and upper sum consumers read the same bounded ledger.*
8. *H records componentwise* hsame *transport for I, W, R, D, L, B, S and for the continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Darboux-facing oscillation request through the window, readback, tolerance, ledger, bound, and sum-handoff rows.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundedOscillation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host function equality, selected suprema, measure completion, countable choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedOscillationUp.TasteGate.BoundedOscillationTasteGate single carrier alignment`

Theorem 6787.2 (Bounded oscillation NameCert obligations)**.** *For every accepted* $\mathsf{BoundedOscillation}^{\uparrow}$ *carrier* $O = (I, W, R, D, L, B, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedOscillation}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed real window, finite stream observations, regular rational readback, dyadic tolerance row, finite oscillation ledger, boundedness row, Darboux-sum handoff, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.BoundedOscillationUp.TasteGate.BoundedOscillationNamecertObligations`

Proof. Project the carrier of Definition 6787.1. The analytic rows are I, W, R, D, L, B, S, and the structural rows are H, C, P, N.

The window and observation obligations are finite. The row I displays the Real window, W opens only the finite inspected observations, and R supplies the corresponding regular rational readback.

The tolerance and bound obligations are also finite. The dyadic row D fixes the comparison budget, the ledger L records the upper and lower oscillation readbacks against that budget, and B records the displayed bound before any Darboux consumer can use the packet.

Finally the Darboux handoff S exposes the same bounded ledger to lower and upper sum consumers, while H, C, P, N transport, replay, source, and name the packet. Since no other coordinate exists, the listed rows exhaust the local NameCert surface and exclude host equality, selected suprema, measure completion, choice, quotient equality, and ambient completeness. □

Theorem 6787.3 (Bounded oscillation Darboux handoff)**.** *Every* $\mathsf{DarbouxSum}^{\uparrow}$ *or* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedOscillation}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ L,\ B \longrightarrow \mathsf{DarbouxSum}^{\uparrow}.$$

The consumer therefore receives a displayed Real window, finite observations, regular rational readback, dyadic tolerance budget, finite oscillation ledger, and boundedness row before the Darboux handoff is visible. It receives no host function equality, selected supremum, measure completion, countable choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedOscillationUp.TasteGate.BoundedOscillationDarbouxHandoff`

Proof. Start from an admitted consumer read. By Definition 6787.1, the Darboux row S is downstream of the Real window I, finite observations W, readback R, dyadic tolerance row D, oscillation ledger L, and bound row B.

Apply Definition 6787.2. It requires the same rows as the local NameCert surface, so a Darboux or bounded-variation consumer cannot read the handoff without exposing the finite oscillation ledger and its bound.

The structural rows H, C, P, N preserve that route componentwise. They do not add analytic coordinates, and the carrier has no row for host function equality, selected suprema, measure completion, countable choice, quotient stream equality, or ambient completeness.

Thus the packet supplies exactly the finite Darboux-facing oscillation ledger stated in the theorem, and no excluded principle can be projected from it. □

Theorem 6787.4 (BoundedVariation oscillation partition route)**.** *Every* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *consumer that reads an oscillation partition through* $\mathsf{BoundedOscillation}^{\uparrow}$ *must first expose the same* $\mathsf{Real}^{\uparrow}$ *window, finite* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget, finite oscillation ledger, boundedness row, and* $\mathsf{DarbouxSum}^{\uparrow}$ *handoff carried by Definition 6787.1. The partition route is therefore a Darboux-facing finite ledger over displayed rows; it exports no host function equality, selected suprema, variation measure, countable choice, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedOscillationUp.TasteGate.BoundedVariationOscillationPartitionRoute`

Proof. Project the carrier of Definition 6787.1. The partition-facing data are already ordered as the Real window I, finite observations W, regular readback R, dyadic tolerance row D, oscillation ledger L, boundedness row B, and Darboux handoff S.

Apply Definition 6787.2. It makes those rows the complete local NameCert surface before any bounded-variation consumer can inspect the packet.

Now apply Definition 6787.3. The Darboux row S is downstream of the same window, observation, readback, tolerance, ledger, and bound rows, so an oscillation partition read by $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ cannot bypass the finite Darboux route.

The carrier has no coordinate for host function equality, selected suprema, variation measure, countable choice, quotient stream equality, or ambient completeness. Those principles therefore cannot be projected from the bounded-variation oscillation partition route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedOscillation}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6787.1, Definition 6787.2, and Definition 6787.3 seed the finite dyadic oscillation ledger over Real windows for DarbouxSum and bounded-variation consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, selected suprema, measure completion, countable choice, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window readback, dyadic tolerance exactness, oscillation-ledger confinement, boundedness-row nonescape, Darboux handoff, and TasteGate field faithfulness for BEDC.Derived.BoundedOscillationUp.

Constructive story: A $\mathsf{BoundedOscillation}^{\uparrow}$ packet is generated from a RealUp window row, StreamName observations, RegSeqRat readback, DyadicRatCore tolerance budget, finite oscillation ledger, displayed boundedness row, DarbouxSum handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6788

A Concrete Naming Certificate for $\mathsf{MetricGraph}^{\uparrow}$

Following Diestel and Burago–Burago–Ivanov, the $\mathsf{MetricGraph}^{\uparrow}$ packet names the path metric carried by a finite weighted graph. It reads graph adjacency from chapter 118, finite path ledgers from chapter 236, center-radius requests from chapter 1450, and the generated-open handoff from chapter 1655. The packet is finite: it records visible vertex rows, edge-length rows, path ledgers, metric-ball rows, topology rows, transport, replay, provenance, and a local naming row, without importing an ambient continuum graph, a selected geodesic, quotient equality of vertices, or open-set data outside the displayed ball basis.

Definition 6788.1 (Metric graph carrier)**.** *A* $\mathsf{MetricGraph}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\text{graph}} = (G, E, W, S, L, D, B, T, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Graph}^{\uparrow}$ *carrier row, including finite vertex rows, edge-incidence rows, endpoint readback, and componentwise edge classification.*
2. *E is the finite edge inventory over G, naming the directed or undirected edge rows that may be used by a path ledger.*
3. *W is the edge-length ledger, attaching a nonnegative* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Rat}^{\uparrow}$ *length row to every displayed edge of E.*
4. *S is the* $\mathsf{ShortestPath}^{\uparrow}$ *source row, carrying finite path ledgers, endpoint rows, relaxation or comparison rows, and provenance for path-weight reads.*
5. *L is the path-length ledger. For each displayed path row it records the finite edge list, the endpoint row pair, the sum of the edge-length rows from W, and the comparison row used to read shortest-path distance.*
6. *D is the metric-distance row $d_G(x, y)$ obtained by reading the shortest displayed path length between the two endpoint rows when the packet admits such a path.*
7. *B is the* $\mathsf{MetricBall}^{\uparrow}$ *center-radius ledger whose membership row is read as $d_G(c, x) <_{\mathsf{R}} r$.*
8. *T is the* $\mathsf{MetricTopology}^{\uparrow}$ *generated-open row obtained from the finite family of metric-ball rows in B.*

9. *H records componentwise* hsame *transport for vertices, edges, edge-length rows, path ledgers, distance rows, ball rows, topology rows, replay rows, provenance, and the local certificate.*
10. *C records* Cont *replay from an endpoint request through $G, E, W, S, L, D, B, T, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{MetricGraph}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{ShortestPath}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{MetricTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricGraph}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. There is no coordinate for a hidden all-pairs distance table, a selected geodesic outside the path ledger, quotient equality of vertices, an ambient graph completion, or topology data outside the generated metric-ball surface.

Lean4 ✓ `BEDC.Derived.MetricGraphUp.MetricGraphTasteGate single carrier alignment`

Theorem 6788.2 (Metric graph NameCert obligations)**.** *For every accepted* $\mathsf{MetricGraph}^{\uparrow}$ *carrier* $M_{\text{graph}} = (G, E, W, S, L, D, B, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricGraph}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the graph row G, finite edge inventory E, edge-length ledger W, shortest-path source row S, path-length ledger L, distance row D, metric-ball row B, topology row T, transport row H, replay row C, provenance row P, and local naming row N;*
2. *edge-length stability, requiring every edge read from E to carry the displayed nonnegative* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Rat}^{\uparrow}$ *length row of W through* hsame *transport;*
3. *path-ledger exactness, requiring each finite path length in L to be computed from the edge rows admitted by G, E, W and the path source row S;*
4. *shortest-path distance readback, requiring D to be read only through the finite comparison rows of S, L;*
5. *metric-ball handoff, requiring every membership read in B to use the displayed distance row D and radius ledger before a topology consumer can see it;*
6. *metric-topology handoff, requiring every generated-open row in T to arise from the carried metric-ball rows of B;*
7. *ledger non-escape, requiring every public read to stay inside $G, E, W, S, L, D, B, T, H, C, P, N$.*

No obligation is discharged by an ambient graph metric, a selected geodesic, quotient equality of vertices, an infinite graph completion, a host powerset topology, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6788.1. The graph row G, finite edge inventory E, edge-length ledger W, shortest-path source row S, path-length ledger L, distance row D, ball row B, topology row T, and structural rows H, C, P, N are the only exported coordinates.

Read the graph and path ledgers first. The graph chapter supplies endpoint and edge-row readback, while the shortest-path chapter supplies the finite path ledger and the comparison surface for path weights. Thus every distance read in D is downstream of visible edge incidence, visible edge lengths, and a finite path ledger.

Next read the metric-ball and topology rows. The ball membership row in B consumes the distance comparison $d_G(c, x) <_{\mathsf{R}} r$, and the topology row T consumes the carried ball rows as generated-open indices. These handoffs preserve the same finite packet through H and C.

Since the packet has no coordinate for a hidden distance table, selected geodesic, quotient vertex equality, graph completion, host powerset topology, or ambient real completeness, none of those objects can discharge a local NameCert obligation. □

Theorem 6788.3 (Metric graph shortest-path metric route)**.** *Every public metric read from an accepted* $\mathsf{MetricGraph}^{\uparrow}$ *packet factors through the finite shortest-path route*

$$\mathsf{Graph}^{\uparrow}, \mathsf{ShortestPath}^{\uparrow}, \mathsf{MetricBall}^{\uparrow}, \mathsf{MetricTopology}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

In particular, a consumer that asks for the metric ball around a vertex must first read the graph endpoint rows, the edge-length rows, the finite path ledger, and the shortest-path comparison row before it can use the center-radius membership row or the generated metric topology row.

Proof. Start with a public distance request between two vertex rows of G. By Definition 6788.1, the request can reach D only through the finite edge inventory E, the edge-length ledger W, the shortest-path source row S, and the path-length ledger L.

Apply the visible path-ledger and relaxation surfaces of chapter 236. They constrain the path read to displayed endpoint rows, finite edge-incidence rows, nonnegative edge weights, finite comparison rows, and provenance over the same graph packet.

The resulting distance row is then consumed by chapter 1450. A ball membership row reads $d_G(c, x) <_{\mathsf{R}} r$ through the displayed center, radius, positive-radius ledger, and comparison row.

Finally the metric-topology consumer of chapter 1655 receives only the finite family of metric-ball rows. The route therefore exposes graph, shortest-path, ball, and topology data in order, and cannot export a selected geodesic, an all-pairs host metric, quotient equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricGraph}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricGraph}^{\uparrow}$ packet is generated from Graph rows, finite edge-length rows, ShortestPath path ledgers, MetricBall center-radius rows, MetricTopology generated-open rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricGraph}^{\uparrow}}$, seed)

Scope closed: Definition 6788.1, Definition 6788.2, and Definition 6788.3 seed the finite route from graph path ledgers to metric balls and generated metric topology.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricGraph}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, selected geodesics, all-pairs host metrics, quotient equality of vertices, graph completions, host powerset topology, ambient RealUp completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, edge-length stability, path-ledger exactness, shortest-path distance readback, ball handoff, topology handoff, transport, replay, provenance, refusal, and local naming for BEDC.Derived.MetricGraphUp.

Chapter 6789

A Concrete Naming Certificate for $\mathsf{KleeneKreiselSpace}^{\uparrow}$

Following Kleene and Kreisel and Troelstra-style constructive higher-type continuity, the $\mathsf{KleeneKreiselSpace}^{\uparrow}$ packet records the represented-space boundary for continuous functionals over finite observations of choice-sequence names. It sits between the neighbourhood-table interface of chapter 2336, the higher-type read surface of chapter 6190, the stream-window discipline of chapter 126, the represented-space carrier route, the Polish-space completion context of chapter 1490, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a finite represented-space gate for Kleene–Kreisel style spaces without adding quotient function spaces, countable choice, selected total elements, or ambient completion objects.

Definition 6789.1 (KleeneKreiselSpace carrier and classifier)**.** *A* $\mathsf{KleeneKreiselSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Nb, F, R, Pc, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, listing the finite name prefixes through which a point or functional request is inspected.*
2. *Nb is the* $\mathsf{NeighborhoodFunction}^{\uparrow}$ *table row, recording finite input-prefix requests and the output or acceptance rows released by those requests.*
3. *F is the* $\mathsf{KleeneKreiselContinuousFunctional}^{\uparrow}$ *read row, naming the higher-type finite-window functional surface that consumes S and Nb.*
4. *R is the* $\mathsf{RepresentedSpace}^{\uparrow}$ *code row, displaying the admissible representation code, its finite name requests, and the represented point row admitted by the code.*
5. *Pc is the* $\mathsf{PolishSpace}^{\uparrow}$ *completion-context row, recording the metric completion envelope used only as a context for the represented-space code.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available to numerical consumers only after the stream, neighbourhood, functional, represented-space, and Polish-context rows have been displayed.*
7. *H records componentwise* hsame *transport for $S, Nb, F, R, Pc, E, C, P, N$.*
8. *C records displayed* Cont *replay from each finite name request through the neighbourhood table, represented-space code, and functional read before any seal row is consumed.*

9. *P is the* Pkg *provenance over* $\mathsf{KleeneKreiselSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{NeighborhoodFunction}^{\uparrow}$, KleeneKreiselContinuo RepresentedSpace$^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KleeneKreiselSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these rows, their componentwise hsame *transports, their displayed* Cont *replays, their package provenance, and their local naming rows. It has no coordinate for host equality of total functionals, quotient equality of represented points, countable choice, a selected infinite name, or a completed space of all higher-type maps.*

Theorem 6789.2 (KleeneKreiselSpace NameCert obligations)**.** *For every accepted* $\mathsf{KleeneKreiselSpace}^{\uparrow}$ *carrier*

$$K = (S, Nb, F, R, Pc, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KleeneKreiselSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, StreamName observation exposure, neighbourhood-table exactness, continuous-functional handoff, represented-space code admission, Polish completion-context visibility, Real-seal boundary discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $S, Nb, F, R, Pc, E, H, C, P, N$.

Proof. Carrier admission is projection from Definition 6789.1. The displayed tuple exposes the stream observation row, neighbourhood table, continuous-functional read, represented-space code, Polish completion context, Real seal, transport row, replay row, provenance row, and local naming row.

The higher-type obligations are read from S, Nb, F. The stream row fixes the inspected finite prefixes, the neighbourhood table records which finite requests release public rows, and the continuous-functional row names the higher-type finite-window consumer that may use those requests.

The represented-space and completion-facing obligations are read from R, Pc, E. The represented-space row supplies the admissible code and represented point row, the Polish row supplies only a completion context, and the Real row is reachable only after the earlier rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for quotient function spaces, countable choice, selected total names, host equality of functionals, or ambient completion objects, the listed rows exhaust the NameCert obligations. □

Theorem 6789.3 (KleeneKreiselSpace neighbourhood stability)**.** *For accepted* $\mathsf{KleeneKreiselSpace}^{\uparrow}$ *carriers K and K' whose StreamName rows, neighbourhood tables, continuous-functional rows, represented-space codes, Polish-context rows, Real-seal rows, replay rows, provenance rows, and local naming rows are componentwise* hsame*, the classifier gives the same neighbourhood release decisions. In particular, every public output or represented-point read of K factors through the same* $\mathsf{NeighborhoodFunction}^{\uparrow}$ *table entry and finite* $\mathsf{StreamName}^{\uparrow}$ *window as the corresponding read of K'.*

Proof. Open both accepted carriers using Definition 6789.1. The classifier is defined only from the displayed rows $S, Nb, F, R, Pc, E, H, C, P, N$ and their counterparts.

Componentwise hsame in H identifies the StreamName windows, the neighbourhood-table entries, the functional handoff, the represented-space code, the Polish context, the Real seal, and the structural rows. Thus a classifier read cannot distinguish K from K' by any hidden name or external equality proof.

Displayed Cont replay in C preserves the order of release: finite StreamName request, neighbourhood-table entry, continuous-functional read, represented-space code, and then any completion-facing

seal. Hence the same neighbourhood decision and the same finite window are used on both carriers. □

Theorem 6789.4 (KleeneKreiselSpace Real-completion boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer read of an accepted* $\mathsf{KleeneKreiselSpace}^{\uparrow}$ *carrier factors through the finite route*

$$S, Nb, F, R, Pc \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer may read finite StreamName observations, neighbourhood-table entries, continuous-functional handoff rows, represented-space codes, Polish completion-context rows, the terminal Real seal, transport, replay, provenance, and local naming, but it cannot read quotient function spaces, countable choice, selected total names, host functional equality, quotient represented-space equality, or ambient Real completeness from the $\mathsf{KleeneKreiselSpace}^{\uparrow}$ *packet.*

Proof. Read the accepted carrier of Definition 6789.1. The only rows preceding a Real or completion-facing seal are S, Nb, F, R, Pc, and the seal row E is displayed after those rows.

Apply Definition 6789.2. It forces the consumer to inspect StreamName observations, neighbourhood-table entries, continuous-functional handoff, represented-space codes, and the Polish completion context before the Real seal is public.

Transport and replay do not add a new completion object. The rows H and C preserve the displayed finite route, while P and N only source and name it. Therefore every Real or completion-facing consumer factors through the stated boundary, and the refused objects have no carrier coordinate from which to escape. □

Lean4 (statement) `BEDC.Derived.KleeneKreiselSpaceUp`

Closure status for $\mathsf{NameCert}_{\mathsf{KleeneKreiselSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{KleeneKreiselSpace}^{\uparrow}$ packet is generated from finite StreamName observations, NeighborhoodFunction table rows, KleeneKreiselContinuousFunctional handoff rows, RepresentedSpace codes, PolishSpace completion-context rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KleeneKreiselSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6789.1, Definition 6789.2, Definition 6789.3, and Definition 6789.4 seed the finite represented-space boundary for Kleene–Kreisel style spaces on the L10 Real-completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KleeneKreiselSpace}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient function spaces, countable choice, selected total elements, quotient represented-space equality, host functional equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked Lean obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood-table exactness, continuous-functional handoff, represented-space code admission, Polish completion-context visibility, Real-seal nonescape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.KleeneKreiselSpaceUp.

Chapter 6790

A Concrete Naming Certificate for $\mathsf{WallisProduct}^{\uparrow}$

From Wallis' finite product bounds, the $\mathsf{WallisProduct}^{\uparrow}$ packet records the constructive route by which rational numerator and denominator ledgers, finite product rows, and terminal real-name comparisons are displayed before any Real or Completion consumer reads the classical Wallis product. It sits beside the rational source of chapter 37, the product constructor of chapter 34, the finite product boundary of chapter 464, and the terminal real-name seal of chapter 38. The packet names the Wallis product as finite BEDC data; it does not import infinite products, analytic limits, host real equality, quotient streams, or choice.

Definition 6790.1 (WallisProduct carrier)**.** *A* $\mathsf{WallisProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Q, A, B, L, R, S, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *arithmetic source row, exposing only rational numerators, rational denominators, positivity checks for the displayed denominators, and the rational comparison histories needed by the finite bounds.*
2. *A is the numerator ledger, recording the finite row of factors $2k \cdot 2k$ inspected by the current Wallis stage.*
3. *B is the denominator ledger, recording the finite row of factors $(2k-1)(2k+1)$ paired with A and licensed by Q.*
4. *L is the left rational bound row and R is the right rational bound row, each computed from the same finite numerator and denominator ledgers.*
5. *S is the* $\mathsf{Prod}^{\uparrow}$ *finite-product row that binds A, B, L, R into one displayed product-stage packet.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *comparison row reached only after the rational ledgers and the finite-product row have been displayed.*
7. *H records componentwise* hsame *transport for the rational source, numerator ledger, denominator ledger, left and right bounds, product row, terminal Real comparison, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Wallis-stage request through Q, A, B, L, R, S, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{WallisProduct}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{WallisProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows and their displayed route. It has no coordinate for an infinite product value, analytic convergence proof, host real equality, quotient real representative, selected limit, or countable-choice schedule.

Theorem 6790.2 (WallisProduct NameCert obligations)**.** *For every accepted* $\mathsf{WallisProduct}^{\uparrow}$ *carrier* $W = (Q, A, B, L, R, S, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WallisProduct}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the rational source row, numerator ledger, denominator ledger, left and right bound rows, finite-product row, terminal Real comparison row, transport row, replay row, provenance row, and local naming row;*
2. *denominator visibility, requiring every denominator factor recorded in B to be read through the displayed* $\mathsf{Rat}^{\uparrow}$ *positivity and nonzero-denominator histories in Q;*
3. *product-stage exactness, requiring S to consume precisely the numerator and denominator ledgers A, B and to export only the left and right rational bound rows L, R for that stage;*
4. *componentwise transport, requiring every comparison between accepted Wallis packets to move Q, A, B, L, R, S, E through displayed* hsame *rows and not through host rational or host real equality;*
5. *displayed replay, requiring each Real-facing request to replay the finite route through C before the terminal* $\mathsf{Real}^{\uparrow}$ *comparison row E is visible;*
6. *provenance and local naming, requiring P, N to source and name only the displayed rows and to export no infinite-product, analytic-limit, quotient-stream, selected-limit, or choice coordinate.*

No WallisProduct obligation is stored outside these finite rows.

Proof. Project the accepted carrier. Its arithmetic rows are exactly the rational source Q, the numerator ledger A, the denominator ledger B, the bound rows L, R, the product row S, and the terminal Real comparison row E.

Denominator visibility is componentwise. Each denominator factor in B is accepted only through the rational row Q, so the carrier never asks a host division operation or an ambient positivity oracle to certify the product stage.

The product-stage obligation is then read from S. The row S binds the same numerator and denominator ledgers to the left and right rational bounds, and the terminal row E is downstream of that finite product packet.

Finally H, C, P, N transport, replay, source, and name the same route. Since none of the displayed rows stores an infinite product value, analytic limit, host real equality, quotient stream, selected limit, or choice schedule, the listed obligations exhaust the local NameCert surface. □

Theorem 6790.3 (WallisProduct finite-bound route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{WallisProduct}^{\uparrow}$ *packet reads the Wallis product only through the finite route*

$$\mathsf{Rat}^{\uparrow} \longmapsto (A, B) \longmapsto \mathsf{Prod}^{\uparrow} \longmapsto (L, R) \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer receives rational numerator and denominator ledgers, denominator-validity histories, a finite product-stage row, left and right rational bounds, componentwise hsame *transport,*

displayed Cont *replay,* Pkg *provenance, and a local* NameCert *row. It receives no infinite product object, analytic convergence limit, host real equality, quotient stream, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the carrier of Definition 6790.1. The only arithmetic source is Q, and the only product-stage data are the displayed ledgers A, B together with the finite product row S and the bound rows L, R.

The terminal comparison row E is available only after those rows have been read. Thus a Real or Completion consumer must pass through the rational ledgers, product-stage packet, and rational bounds before it can inspect the terminal $\mathsf{Real}^{\uparrow}$ comparison.

The structural rows preserve the same finite route. The hsame row transports components, the Cont row replays the consumer request, and the Pkg and NameCert rows source and name the packet. Since the carrier has no coordinate for an infinite product, analytic limit, host equality, quotient stream, selected limit, choice schedule, or Real completeness, none of those principles can enter the consumer route. □

Falsifiable prediction: Every $\mathsf{WallisProduct}^{\uparrow}$ consumer read factors through one RatUp arithmetic source row, one finite numerator ledger, one finite denominator ledger, left and right rational bound rows, one ProdUp finite-product row, one terminal RealUp comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: rat, prod, cauchyproduct, real: $\mathsf{WallisProduct}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Wallis-stage numerator and denominator ledgers, rational denominator-validity histories, finite product-stage bounds, terminal Real comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{WallisProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{WallisProduct}^{\uparrow}$ packet is generated from a RatUp arithmetic source row, finite numerator and denominator ledgers, left and right rational bound rows, a ProdUp finite-product row, a terminal RealUp comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WallisProduct}^{\uparrow}}$, seed)

Scope closed: Definition 6790.1, Definition 6790.2, and Definition 6790.3 seed the finite-product Wallis route used by Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WallisProduct}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite products, analytic convergence, host real equality, quotient streams, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, denominator visibility, product-stage exactness, componentwise transport, displayed replay, provenance exhaustion, and local naming for BEDC.Derived.WallisProductUp.

Chapter 6791

A Concrete Naming Certificate for $\mathsf{BishopLocatedMinimum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedMinimum}^{\uparrow}$ packet records minimum-location data as a finite BEDC NameCert route through compact finite nets, displayed value windows, and located lower comparisons. It is the lower-comparison dual of chapter 6770, and it sits over the compact-metric source of chapter 129, the uniformly continuous map row of chapter 130, the finite-net handoff of chapter 6769, the stream schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes the finite comparison route needed by minimization consumers without selecting an argmin, importing open-cover compactness, identifying quotient real names, invoking countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6791.1 (Bishop located minimum carrier)**.** *A* $\mathsf{BishopLocatedMinimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, N, W, R, E, M, H, C, P, L)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, carrying the compact metric inspection surface and the finite center coverage consumed by minimum-location reads.*
2. *F is the uniformly continuous* $\mathsf{ContinuousMap}^{\uparrow}$ *row, exposing only displayed value requests over the compact source row K.*
3. *N is the finite-net cover row, recording the finite list of centers, radii, and coverage witnesses through which every minimum-facing request enters.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the finite value windows attached to the centers of N.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *value readback row for the rational windows exposed by W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, admitting the displayed value readbacks as Real-facing names before comparisons are consumed.*
7. *M is the located minimum comparison row, comparing each displayed candidate value with the finite net family through located lower comparison windows.*
8. *H records componentwise* hsame *transport for the compact source, uniformly continuous map row, finite-net cover, stream schedule, regular rational readback, Real seal, located lower comparison row, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from a minimum-facing request through $K, F, N, W, R, E, M, H, P, L$.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedMinimum}^{\uparrow}$, $\mathsf{BishopLocatedMaximum}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{HeineCantorFiniteNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedMinimum}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed compact source, uniformly continuous map row, finite-net cover, stream windows, regular rational readbacks, Real seals, located lower comparisons, transport, replay, provenance, and local naming. It has no coordinate for a selected argmin, open-cover compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6791.2 (Bishop located minimum NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedMinimum}^{\uparrow}$ *carrier $B = (K, F, N, W, R, E, M, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedMinimum}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed compact source, uniformly continuous map row, finite-net cover, value windows, regular rational readbacks, Real seal, located lower comparison row, transport, replay, provenance, and local naming;*
2. *finite-net exposure, requiring every minimum-facing source request to pass through the centers and coverage witnesses named by N;*
3. *value readback through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *requiring W, R, E to be visible before any lower comparison row is consumed;*
4. *located lower comparison, requiring M to compare only displayed Real-sealed value windows over the finite net;*
5. *ledger refusal for selected argmin data, open-cover compactness, quotient real equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6791.1. The rows K, F, N expose the compact source, map row, and finite-net coverage surface that every later value read must use.

Read the value rows next. The stream schedule W supplies finite windows, R reads those windows as regular rational data, and E seals the displayed readbacks as $\mathsf{Real}^{\uparrow}$ names before a lower comparison can be used.

The comparison row M has access only to the Real-sealed finite-net values already displayed by N, W, R, E. The structural rows H, C, P, L transport, replay, source, and name the same finite route, so the five listed obligations exhaust the local NameCert surface. □

Theorem 6791.3 (Bishop located minimum finite-net lower route)**.** *Every minimum-facing read exported by an accepted* $\mathsf{BishopLocatedMinimum}^{\uparrow}$ *carrier factors through the displayed finite route*

$$K, F, N \longmapsto W, R, E \longmapsto M \longmapsto H, C, P, L.$$

Thus an optimization consumer can inspect only the compact source, uniformly continuous map row, finite net, value windows, located lower comparison, and Real seal before reaching the local naming row. It cannot bypass the finite-net handoff to obtain a selected argmin, open-cover compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source and map rows. The compact metric source K and uniformly continuous map row F become visible to a minimum-facing read only through the finite-net cover N.

The value route is then fixed. The stream schedule W records the finite observation windows attached to the net, the regular rational row R reads those windows, and the terminal seal E is reached before any minimization-facing comparison is available.

Use the located lower comparison row M only after the sealed value windows are displayed. Since M compares the finite family exposed by N, W, R, E, it supplies a located minimum comparison surface rather than a selected minimizing point.

Finally replay the same route through H and C, while P and L provide provenance and local naming. The carrier has no coordinate for the excluded principles, so every consumer reaches minimum-location data only through the finite lower handoff shown above. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedMinimum}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedMinimum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6791.1, Definition 6791.2, and Definition 6791.3 seed the finite-net minimum-location route over compact-source, uniformly continuous map, value-window, located-lower-comparison, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedMinimum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected minimizers, full open-cover compactness, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{BishopLocatedMinimum}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, StreamName-RegSeqRat-Real value readback, located lower comparison, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedMinimumUp.

Constructive story: A $\mathsf{BishopLocatedMinimum}^{\uparrow}$ packet is generated from a CompactMetric source row, a uniformly continuous ContinuousMap row, a finite-net cover, StreamName value windows, RegSeqRat readbacks, a Real seal, a located lower comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6792

A Concrete Naming Certificate for $\mathsf{BishopChoiceSequence}^{\uparrow}$

Following Bishop and Bridges and Troelstra–van Dalen, the $\mathsf{BishopChoiceSequence}^{\uparrow}$ packet records a finite observation surface for choice sequences without importing a selected infinite choice function. It sits over the finite observation interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the tail-equivalence boundary of chapter 1738. The packet is designed for Real and Completion consumers that need a finite observed window and a stable handoff, not an ambient equality of streams.

Definition 6792.1 (Bishop choice-sequence carrier)**.** *A* $\mathsf{BishopChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite schedule row listing the observation indices and tolerance requests that have actually been opened.*
2. *W is the observed* $\mathsf{StreamName}^{\uparrow}$ *window read from that schedule, with no coordinate for an unobserved tail.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same finite schedule and observed window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed window and tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, D, R have been consumed.*
6. *H records componentwise* hsame *transport for the schedule, observed window, tolerance ledger, readback, seal, and local certificate rows.*
7. *C records displayed* Cont *replay for schedule opening, finite observation, dyadic tolerance checking, regular readback, and Real-name handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopChoiceSequence}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $S, W, D, R, E, H, C, P, N$. It has no coordinate for countable choice, quotient stream equality, a selected limit, trichotomy, host equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6792.2 (Bishop choice-sequence window stability)**.** *Let $X = (S, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopChoiceSequence}^{\uparrow}$ *carrier. If a later finite schedule extends the inspection while preserving the already displayed schedule row S, observed* $\mathsf{StreamName}^{\uparrow}$ *window W, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, then the original regular readback row R and terminal* $\mathsf{Real}^{\uparrow}$ *seal row E remain the same rows under the displayed H, C, P, N transport.*

Proof. Project the carrier of Definition 6792.1. The only observed analytic rows before transport are S, W, D, R, E, so the classifier has no hidden stream tail from which to obtain a second readback.

The later schedule preserves S, W, D. Therefore the finite observation and dyadic tolerance data used to form R are unchanged inside the packet.

The transport row H compares the displayed rows componentwise, and the replay row C replays the same finite route. The provenance and local naming rows P, N name that same packet, so the terminal seal E travels with R rather than being recomputed from unobserved choice data. □

Theorem 6792.3 (Bishop choice-sequence Real-name handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *name exported by an accepted* $\mathsf{BishopChoiceSequence}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

The handoff from finite choice-sequence observation to a Real-facing consumer is therefore mediated by the observed $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before the terminal seal is available.*

Proof. Start with the carrier definition. The terminal seal row E occurs after the schedule, observed window, tolerance ledger, and regular readback rows, and the classifier reads no separate Real constructor.

Use the window-stability theorem for later observations. Preserving the displayed finite window and tolerance ledger preserves R and E, so a Real-facing consumer cannot replace the finite route by a selected limit or by equality of host streams.

Thus the handoff is the displayed chain through S, W, D, R, E. The packet supplies a local name for the finite observation route and leaves ambient completeness, quotient stream equality, countable choice, trichotomy, and selected limits outside the certificate. □

Falsifiable prediction: Every accepted $\mathsf{BishopChoiceSequence}^{\uparrow}$ Real-facing read exposes one finite schedule row, one observed $\mathsf{StreamName}^{\uparrow}$ window, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchy-tail-equivalence: $\mathsf{BishopChoiceSequence}^{\uparrow}$ is not bijective to any listed sibling because it binds the finite schedule, observed window, tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local NameCert into one observation packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopChoiceSequence}^{\uparrow}$ packet is generated from a finite schedule row, an observed StreamName window, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopChoiceSequence}^{\uparrow}}$, seed)

Scope closed: Definition 6792.1, Definition 6792.2, and Definition 6792.3 seed the finite observation route from choice-sequence schedules through StreamName, DyadicRatCore, RegSeqRat, and Real-name handoff rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopChoiceSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim countable choice, selected limits, quotient stream equality, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking for BishopChoiceSequence$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, window stability, Real-name handoff, classifier transport, displayed replay, provenance, and local naming for BEDC.Derived.BishopChoiceSequenceUp.

Chapter 6793

A Concrete Naming Certificate for SquareRootContinuityModulus$^{\uparrow}$

Following Bishop and Bridges on constructive square-root continuity, the SquareRootContinuityModulus$^{\uparrow}$ packet records the finite uniform-modulus certificate that lets a bounded nonnegative interval consumer use Heron's square-root route without importing a host square-root function or a completed real continuity theorem. It sits downstream of the value-level square-root certificates in chapter 3818 and chapter 1756, and it binds that route to the continuity and compact-interval surfaces of chapter 59, chapter 369, and chapter 1591.

Definition 6793.1 (Square-root continuity-modulus carrier)**.** *A* SquareRootContinuityModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, F, U, R, H, S, T, C, P, N)$$

with the following displayed rows:

1. *I is the* ClosedBoundedInterval$^{\uparrow}$ *row naming the bounded nonnegative source interval and the rational lower-bound data used by the square-root route.*
2. *F is the* Continuous$^{\uparrow}$ *row for the square-root read on the displayed interval, with continuity evidence read only through finite regular rational windows.*
3. *U is the* UniformModulus$^{\uparrow}$ *row assigning each requested output tolerance a finite interval-window threshold.*
4. *R is the* RegularCauchySquareRoot$^{\uparrow}$ *row giving the regular rational square-root readback available at the chosen threshold.*
5. *H is the* HeronSquareRoot$^{\uparrow}$ *row giving the displayed Heron recurrence, reciprocal ledger, contraction window, and Real seal handoff used by the modulus witness.*
6. *S records componentwise* hsame *transport for the interval, continuity row, modulus row, regular square-root row, Heron route, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay from a tolerance request through I, F, U, R, H, S, P, N.*
8. *C is the compatibility row saying that the threshold chosen by U is exactly the threshold at which R and H expose the same square-root window on the source interval.*
9. *P is the* Pkg *provenance over* SquareRootContinuityModulus$^{\uparrow}$, HeronSquareRoot$^{\uparrow}$, RegularCauchySquareRoot$^{\uparrow}$, Continuous$^{\uparrow}$, UniformModulus$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SquareRootContinuityModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, F, U, R, H, S, T, C, P, N$. It has no coordinate for a host square-root operation, a selected completed limit, quotient-real equality, global real completeness, or a pointwise continuity proof that bypasses the displayed uniform-modulus row.

Theorem 6793.2 (Square-root continuity-modulus NameCert obligations)**.** *For every accepted* $\mathsf{SquareRootContinuityModulus}^{\uparrow}$ *carrier*

$$M = (I, F, U, R, H, S, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SquareRootContinuityModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded nonnegative interval, displayed continuity row, uniform-modulus row, regular Cauchy square-root readback, Heron recurrence route, componentwise transport, continuation replay, modulus-route compatibility, package provenance, and local naming.*

Proof. Project the carrier rows. The interval row I supplies the bounded nonnegative source scope, while F and U record the continuity assertion and the uniform tolerance-to-window service on that scope.

The numerical square-root read is not independent data. The row R provides the regular rational square-root readback, and the row H provides the Heron recurrence route, reciprocal ledger, contraction window, and terminal Real seal handoff used to justify the same finite window.

The structural rows S, T, C, P, N preserve and replay exactly that packet. Since no further carrier coordinate is available, the listed rows exhaust the local NameCert surface, and no host square-root operation or global completeness theorem can replace the displayed modulus certificate. □

Theorem 6793.3 (Square-root continuity-modulus Heron route)**.** *Every accepted* $\mathsf{SquareRootContinuityModulus}^{\uparrow}$ *packet factors a uniform square-root tolerance request through the route*

$$I \longmapsto F \longmapsto U \longmapsto R \longmapsto H \longmapsto C.$$

Thus a consumer first sees the bounded nonnegative interval, the displayed continuity row, the uniform-modulus threshold, the regular Cauchy square-root readback, the Heron recurrence route, and the compatibility row tying the threshold to the same finite square-root window. The route exports no host square-root function, selected completed limit, quotient-real equality, or ambient real completeness principle.

Proof. Start with an accepted carrier $M = (I, F, U, R, H, S, T, C, P, N)$. A tolerance request is replayed through T, so the first numerical datum it can read is the interval scope I together with the continuity and modulus rows F, U.

The modulus row chooses a finite threshold. At that threshold, R exposes the regular Cauchy square-root readback and H exposes the Heron recurrence window with its reciprocal and contraction ledger.

The compatibility row C identifies these finite windows as the same square-root read on the displayed interval. Transport and provenance through S, P, N preserve the route but add no extra numerical coordinate.

Consequently every uniform square-root tolerance request factors through the stated Heron route, and the packet cannot be read as a host square-root function, a selected limit, quotient-real equality, or an ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{SquareRootContinuityModulus}^{\uparrow}$ read of a square-root tolerance request factors through a ClosedBoundedInterval source row, displayed Continuous row, UniformModulus threshold row, RegularCauchySquareRoot readback, HeronSquareRoot recurrence route, componentwise hsame transport, Cont replay, compatibility, Pkg provenance, and local NameCert row.

Independence witness: heron-square-root, regular-cauchy-square-root, continuous, uniform-modulus, closed-bounded-interval: $\mathsf{SquareRootContinuityModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a bounded nonnegative interval, a displayed continuity row, a uniform tolerance-to-window threshold, regular square-root readback, Heron recurrence data, compatibility, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SquareRootContinuityModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SquareRootContinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6793.1, Definition 6793.2, and Definition 6793.3 seed the finite uniform-modulus certificate connecting Heron's square-root route to bounded nonnegative interval continuity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SquareRootContinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host square-root function, selected completed limits, quotient-real equality, global real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval nonnegativity, continuity-row exactness, uniform-modulus threshold exactness, regular Cauchy readback, Heron route compatibility, transport, replay, provenance, and local naming for BEDC.Derived.SquareRootContinuityModulusUp.

Constructive story: A $\mathsf{SquareRootContinuityModulus}^{\uparrow}$ packet is generated from a bounded nonnegative ClosedBoundedInterval row, displayed Continuous and UniformModulus rows, RegularCauchySquareRoot readback, HeronSquareRoot recurrence route, componentwise hsame transport, Cont replay, compatibility, Pkg provenance, and a local NameCert row.

Chapter 6794

A Concrete Naming Certificate for $\mathsf{BishopIntervalMap}^{\uparrow}$

Following Bishop and Bridges on constructive functions over located intervals, and Scott's interval-domain reading of approximation, the $\mathsf{BishopIntervalMap}^{\uparrow}$ packet records the finite map surface used when interval-domain approximants are handed to Real-facing continuous-map consumers. It sits after the interval-domain carrier of chapter 1543, the continuous-map graph and modulus surface of chapter 130, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed interval-domain map certificate only; it does not define quotient functions, identify host extensional equality, select completed representatives, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6794.1 (BishopIntervalMap carrier)**.** *A* $\mathsf{BishopIntervalMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, F, W, Q, E, H, C, P, N)$$

with the following visible rows:

1. *D is the* $\mathsf{IntervalDomain}^{\uparrow}$ *approximation-domain row, exposing located cells, rational refinements, directed nesting, endpoint windows, regular readbacks, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal only in that order.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-and-modulus row whose source reads from the displayed interval-domain approximants and whose target is a Real-facing naming surface.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which finite endpoint and image-approximation requests are inspected.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the same windows, carrying the regular rational observations consumed before the Real seal.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row reached only after D, F, W, Q and the structural rows are displayed.*
6. *H records componentwise* hsame *transport for the interval-domain, continuous-map, stream-window, regular-readback, Real-handoff, provenance, and local naming rows.*
7. *C records displayed* Cont *replay routes for interval-domain reads, continuous-map reads, stream requests, regular rational readbacks, and Real-facing handoffs.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalMap}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopIntervalMap}^\uparrow}$ *row.*
The carrier exports only this finite map packet. It has no coordinate for quotient functions, host function extensionality, selected Real representatives, open-cover compactness, or ambient completeness of $\mathsf{Real}^\uparrow$*.*

Theorem 6794.2 (BishopIntervalMap NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalMap}^\uparrow$ *carrier $M = (D, F, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalMap}^\uparrow}$ *surface consists exactly of carrier admission for $D, F, W, Q, E, H, C, P, N$; source-domain visibility through the* $\mathsf{IntervalDomain}^\uparrow$ *packet; graph and modulus visibility through the* $\mathsf{ContinuousMap}^\uparrow$ *row; finite endpoint and image-window replay through W and Q; Real-handoff non-escape through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Carrier admission is projection from Definition 6794.1. The displayed inventory is exactly the interval-domain row, continuous-map row, stream windows, regular rational readbacks, Real handoff, transports, replay routes, provenance, and local naming row.

Read the source through chapter 1543. The interval-domain packet already orders located cells, rational refinements, directed nesting, stream windows, regular readbacks, and the Real seal, so the map certificate cannot consume a Real-facing approximation before the source approximant rows are visible.

Read the graph through chapter 130. The continuous-map row supplies only displayed graph and modulus data tied to the same finite windows, and H, C preserve those rows under classifier transport and replay.

Finally inspect the handoff row E. Since the packet has no coordinate for quotient functions, host extensional equality, selected representatives, open-cover compactness, or ambient completeness, the local certificate can expose only the finite map route named by $D, F, W, Q, E, H, C, P, N$. □

Theorem 6794.3 (BishopIntervalMap Real handoff)**.** *Every* $\mathsf{Real}^\uparrow$*-facing consumer of an accepted* $\mathsf{BishopIntervalMap}^\uparrow$ *packet first reads the finite route*

$$\mathsf{IntervalDomain}^\uparrow \longmapsto \mathsf{ContinuousMap}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow \longmapsto (H, C, P, N).$$

The handoff therefore supplies an interval-domain map surface for Real and Completion consumers, not a quotient function, not host extensional equality, not a selected completed value, and not ambient completeness of $\mathsf{Real}^\uparrow$*.*

Proof. Begin with the source approximation. The row D is the displayed interval-domain packet, so any consumer must first read its located cells, rational refinements, directed nesting, endpoint windows, regular readbacks, and downstream Real seal discipline.

Next read the map row. The row F is a continuous-map certificate attached to those source approximants, while W and Q provide the finite request windows and regular rational readbacks used to inspect both endpoint and image data.

The Real-facing row E is downstream of D, F, W, Q. The structural rows H, C, P, N transport, replay, source, and name the same route, so the consumer receives only the displayed finite packet and not a host-level function object.

Coordinate exhaustion then gives the exclusions. Quotient functions, host extensional equality, selected completed values, and ambient Real completeness would each require a row absent from Definition 6794.1. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalMap}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalMap}^{\uparrow}$ packet is generated from an IntervalDomain source row, a ContinuousMap graph-and-modulus row, StreamName windows, RegSeqRat readbacks, a RealUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6794.1, Definition 6794.2, and Definition 6794.3 seed the finite interval-domain map route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient functions, host extensional equality, selected completed representatives, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-domain visibility, continuous-map graph visibility, finite-window replay, Real-handoff non-escape, transport stability, provenance exhaustion, and local naming for BEDC.Derived.BishopIntervalMapUp.

Chapter 6795

A Concrete Naming Certificate for $\mathsf{SymmetricAlgebra}^{\uparrow}$

Following Bourbaki and Mac Lane, the $\mathsf{SymmetricAlgebra}^{\uparrow}$ packet records the free commutative algebra generated by a displayed module or vector-space carrier through finite tensor words modulo displayed permutation-stability rows. It is grounded in the scalar ring rows of chapter 43, the module carrier of chapter 46, the vector-space specialization of chapter 47, the finite word source of **??**, the alternating companion of chapter 5144, and the coefficient-list consumer of chapter 50. The packet is a BEDC NameCert carrier for finite symmetric words and polynomial handoff rows; it is not a host quotient algebra, selected monomial basis, infinite direct sum, or ambient commutative algebra object.

Definition 6795.1 (Symmetric algebra carrier)**.** *A* $\mathsf{SymmetricAlgebra}^{\uparrow}$ *carrier over a displayed* $\mathsf{Module}^{\uparrow}$ *row* V *and scalar* $\mathsf{Ring}^{\uparrow}$ *row* R *is a finite* BHist *packet*

$$S = (R, V, T, W, \Pi, M, H, C, P, N)$$

with the following rows:

1. R *is the scalar* $\mathsf{Ring}^{\uparrow}$ *source row, and* V *is the* $\mathsf{Module}^{\uparrow}$ *source row; when the scalar row is a field, the same endpoint source may be read through* $\mathsf{VecSpace}^{\uparrow}$*.*
2. T *is the consumed* $\mathsf{TensorAlgebra}^{\uparrow}$ *finite-word row over* R *and* V*.*
3. W *is the finite symmetric-word ledger. Each entry is a displayed tensor word together with the finite multiset of carried letters it represents.*
4. Π *is the finite permutation-stability ledger. For every listed adjacent swap or finite permutation of a listed word,* Π *records the classifier comparison that keeps the word in the same symmetric class.*
5. M *is the commutative product row. It multiplies two displayed symmetric words by tensor-word concatenation through* T *and then reads the result through* W *and* Π*, so the two product orders are classified by the same permutation-stability surface.*
6. H *records componentwise* hsame *transport for scalar rows, source letters, tensor words, symmetric-word rows, permutation-stability rows, commutative product rows, and local classifiers.*
7. C *records displayed* Cont *replay from source endpoints through tensor-word formation, symmetric-word admission, permutation stability, and commutative multiplication.*

8. *P is the* Pkg *provenance over* $\mathsf{SymmetricAlgebra}^{\uparrow}$, $\mathsf{TensorAlgebra}^{\uparrow}$, $\mathsf{ExteriorAlgebra}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{SymmetricAlgebra}^{\uparrow}}$ *row.*

The carrier exports only finite symmetric tensor-word data and the displayed commutative product handoff. It does not add a quotient primitive, selected monomial basis, host polynomial syntax, infinite direct sum, or ambient algebra-library object.

Theorem 6795.2 (Symmetric algebra NameCert obligations)**.** *For every accepted* $\mathsf{SymmetricAlgebra}^{\uparrow}$ *carrier*

$$S = (R, V, T, W, \Pi, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SymmetricAlgebra}^{\uparrow}}$ *surface consists exactly of scalar admission through R, module or vector-space endpoint admission through V, finite tensor-word admission through T, symmetric-word admission through W, finite permutation-stability admission through Π, commutative product admission through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier rows of Definition 6795.1. The scalar, source-letter, tensor-word, symmetric-word, permutation-stability, and product rows are displayed before a consumer receives a commutative algebra operation.

The tensor source is read through **??**. Thus every symmetric word first appears as a finite tensor word, and only then passes through the symmetric-word ledger W and the permutation-stability ledger Π.

The commutative product row M is also visible data. Multiplying two symmetric words means concatenating their tensor representatives and applying the listed permutation-stability rows, so commutativity is recorded by the packet rather than supplied by a host quotient algebra.

Transport by H, replay by C, provenance by P, and naming by N preserve exactly the displayed packet. Because the carrier has no quotient coordinate, selected monomial basis, host polynomial syntax, infinite direct sum, or ambient commutative algebra endpoint, the listed rows exhaust the local NameCert surface. □

Theorem 6795.3 (Symmetric algebra universal polynomial route)**.** *Every polynomial-style consumer accepted by a* $\mathsf{SymmetricAlgebra}^{\uparrow}$ *packet must read a finite symmetric word through*

$$R, V, T, W, \Pi, M, H, C, P, N.$$

The route first consumes the scalar $\mathsf{Ring}^{\uparrow}$ *row and the* $\mathsf{Module}^{\uparrow}$ *or* $\mathsf{VecSpace}^{\uparrow}$ *source row, then the* $\mathsf{TensorAlgebra}^{\uparrow}$ *word row, then the finite symmetric-word and permutation-stability ledgers, and finally the commutative product row. The consumer receives a finite polynomial handoff compatible with chapter 50; it does not receive quotient algebra equality, selected monomial coordinates, host polynomial syntax, arbitrary symmetric powers, exterior alternating rows, or ambient algebra completeness.*

Proof. Use Definition 6795.2. It places T, W, Π, M after the scalar and module or vector endpoints and before any polynomial-style read is exported.

For a degree-one word, the route is the source row V with transport and replay supplied by H and C. For a longer word, read the finite tensor word through T, then read all listed adjacent swaps and finite permutations through Π before the word is admitted by W.

Finally inspect the product row M. The two possible orders of multiplying displayed symmetric words differ only by a permutation row already present in Π, so the polynomial consumer

receives a commutative finite-word route rather than a quotient object. The exterior companion of chapter 5144 uses signed transposition and repeated-letter refusal; this packet instead keeps ordinary permutation stability and exports no alternating boundary. □

Falsifiable prediction: Every consumer of a $\mathsf{SymmetricAlgebra}^{\uparrow}$ packet factors through the displayed tensor-word row, symmetric-word ledger, finite permutation-stability ledger, commutative product row, transport, replay, provenance, and local naming rows; a request that supplies only host quotient algebra equality is rejected by this certificate.

Independence witness: ring, module, vecspace, tensor-algebra, exterior-algebra, polynomial: $\mathsf{SymmetricAlgebra}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries scalar source rows, module or vector-space source rows, finite tensor words, symmetric-word ledgers, permutation-stability rows, commutative multiplication, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{SymmetricAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{SymmetricAlgebra}^{\uparrow}$ packet is generated from scalar RingUp rows, ModuleUp or VecSpaceUp endpoint rows, finite TensorAlgebraUp word rows, symmetric-word ledgers, finite permutation-stability rows, commutative product rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SymmetricAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6795.1, Definition 6795.2, and Definition 6795.3 seed the finite commutative tensor-word NameCert surface over ring, module, vector-space, tensor-algebra, exterior-algebra, and polynomial rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SymmetricAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host quotient symmetric algebras, selected monomial bases, arbitrary symmetric powers, exterior alternating rows, infinite direct sums, or completed commutative algebra structure.

Upgrade path: Obligation closure requires binding the displayed carrier, symmetric-word ledger, permutation-stability ledger, commutative product row, transport, replay, provenance, and local naming against their BEDC primitive scope.

Chapter 6796

A Concrete Naming Certificate for $\mathsf{BishopCompactRegularCover}^{\uparrow}$

Following Bishop and Bridges constructive compactness, the $\mathsf{BishopCompactRegularCover}^{\uparrow}$ packet records finite cover refinement as explicit NameCert data over a compact metric carrier. It sits beside the compact-metric route of chapter 129, the metric-space source of chapter 57, the rational radius discipline of chapter 37, the Lebesgue-number handoff of chapter 4015, and the $\mathsf{UniformModulus}^{\uparrow}$ consumer used by chapter 9237. The packet exposes a finite regular refinement route for compact-uniform-continuity and Lebesgue-number style arguments without claiming open-cover compactness, selected subcovers, quotient point equality, countable choice, or ambient completeness.

Definition 6796.1 (Bishop compact regular cover carrier)**.** *A* $\mathsf{BishopCompactRegularCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, M, Q, \mathcal{P}, C, L, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the compact finite-cover inspection surface.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to compare centers, radii, and refinement witnesses.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *positive-radius row, naming the rational radius ledgers used by cover and refinement checks.*
4. *$\mathcal{P}$ is the finite* ProbeBundle *cover row, listing centers, rational radii, and membership witnesses for the displayed finite cover.*
5. *C is the regularity row, requiring every bundled ball to carry a smaller rational core still routed through $M, Q, \mathcal{P}$.*
6. *L is the refinement ledger row, recording the finite parent map from a refined* ProbeBundle *back to the displayed cover.*
7. *H records componentwise* hsame *transport for the compact source, metric source, rational radii, cover bundle, regularity row, refinement ledger, replay row, provenance row, and local naming row.*
8. *T records displayed* Cont *replay of finite cover refinement over the same bundle.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCompactRegularCover}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCompactRegularCover}^{\uparrow}}$ *row.*
The carrier contains no open-cover compactness object, selected subcover functional, quotient point equality, countable choice, hidden Lebesgue-number selector, or ambient completion row.

Theorem 6796.2 (Bishop compact regular cover NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompactRegularCover}^{\uparrow}$ *carrier* $R = (K, M, Q, \mathcal{P}, C, L, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompactRegularCover}^{\uparrow}}$ *surface consists exactly of compact-source admission, metric-distance admission, positive rational radius admission, finite* $\mathsf{ProbeBundle}$ *cover admission, regular core exposure, refinement-ledger readback, componentwise transport, displayed replay, provenance, and local naming. The route is confined to*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{Rat}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}, \quad \mathsf{ProbeBundle}.$$

Proof. Project the carrier in Definition 6796.1. The only source rows visible to a cover-refinement consumer are $K, M, Q, \mathcal{P}$, so every cover read starts from compact metric data, metric comparisons, positive rational radii, and a finite bundle.

The regularity row C and refinement ledger L are attached to that same finite bundle. They can shrink a displayed radius and record a parent map for the refined bundle, but they cannot introduce an external subcover or an unlisted center.

The structural rows H, T, P, N transport, replay, source, and name the same finite route. Since none of the excluded compactness, choice, quotient, selector, or completion objects occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6796.3 (Bishop compact regular cover refinement induction)**.** *Every finite refinement read of an accepted* $\mathsf{BishopCompactRegularCover}^{\uparrow}$ *carrier is obtained by primitive induction over the displayed* $\mathsf{ProbeBundle}$ *spine. At the empty spine the refinement ledger is the empty ledger. At a successor probe, the read appends one regular core row from C, one positive* $\mathsf{Rat}^{\uparrow}$ *radius comparison from Q, and one parent entry in L, then replays the same route through H, T, P, N.*

Proof. Induct on the finite $\mathsf{ProbeBundle}$ row $\mathcal{P}$. The empty bundle has no cover entry and therefore supplies the empty refinement ledger.

For the successor step, read the next bundled center and rational radius through M and Q. The regularity row C supplies the smaller core for that entry, and L records the parent map back to the original cover row.

Transport and replay are componentwise. The rows H, T, P, N attach the successor entry to the same accepted carrier, so the induction never leaves the finite bundle or asks for a selected subcover. □

Theorem 6796.4 (Bishop compact regular cover nonescape)**.** *Every compact-uniform-continuity or Lebesgue-number consumer that reads a* $\mathsf{BishopCompactRegularCover}^{\uparrow}$ *packet receives only the finite route*

$$K, M, Q, \mathcal{P}, C, L, H, T, P, N.$$

In particular, a downstream $\mathsf{UniformModulus}^{\uparrow}$ *handoff may use the displayed regular refinement ledger, but it cannot import open-cover compactness, countable choice, selected representatives, quotient point equality, a hidden Lebesgue-number selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the source rows $K, M, Q, \mathcal{P}$. They expose compact metric data, metric comparisons, positive rational radii, and the finite cover bundle before any refinement is consumed.

Read the regular core and refinement ledger through C and L. These rows only relate displayed bundled balls to displayed refined cores, so they provide the finite cover-refinement boundary needed by compact-uniform-continuity and Lebesgue-number consumers.

Finally use H, T, P, N to transport, replay, source, and name the route. The carrier has no coordinate for the excluded compactness, choice, quotient, selector, representative, or completion objects, so no downstream handoff can escape the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactRegularCover}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompactRegularCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6796.1, Definition 6796.2, Definition 6796.3, and Definition 6796.4 seed the finite regular cover-refinement route over compact metric, metric-space, rational-radius, ProbeBundle, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompactRegularCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient point equality, countable choice, hidden Lebesgue-number selectors, ambient completeness, Lean verification, or bridge checking for $\mathsf{BishopCompactRegularCover}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius regularity, finite ProbeBundle refinement induction, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompactRegularCover

Constructive story: A $\mathsf{BishopCompactRegularCover}^{\uparrow}$ packet is generated from a CompactMetric source row, a MetricSpace distance row, positive RatUp radius ledgers, a finite ProbeBundle cover row, regular core rows, a refinement ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6797

A Concrete Naming Certificate for $\mathsf{ModulatedConvergence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ModulatedConvergence}^{\uparrow}$ packet records convergence data by keeping an explicit modulus beside each finite source-window read. It sits with the stream-window carrier of chapter 126, the regular rational readback of chapter 301, the Real-facing seal of chapter 38, and the modulus-controlled completion route of chapter 6766. The chapter isolates the finite rows a convergence consumer may inspect before any completed limit or ambient Real completeness is claimed.

Definition 6797.1 (Modulated convergence carrier)**.** *A* $\mathsf{ModulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, M, W, T, R, E, H, C, P, N)$$

with the following visible rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row whose displayed windows are the only observations admitted by the packet.*
2. *M is the explicit modulus row; for each displayed precision request it names the finite source-window depth after which the convergence read may be consumed.*
3. *W is the tail-window ledger pairing each precision request with the depth supplied by M and the corresponding source-window slice of S.*
4. *T is the tail-stability row recording that later displayed windows are read through the same modulus-controlled ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S, M, W, T before any Real-facing seal is visible.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the source windows, explicit modulus, tail-window ledger, tail-stability row, and regular rational readback have been consumed.*
7. *H records componentwise* hsame *transport for S, M, W, T, R, E and for the structural rows.*
8. *C records displayed* Cont *replay from precision requests to modulus depths, from depths to tail windows, from windows to regular rational readback, and from readback to the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{ModulatedConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulatedConvergence}^{\uparrow}}$ *row.*

The carrier exports only this finite explicit-modulus convergence surface. It contains no selected limit, host convergence predicate, quotient completion equality, countable-choice scheduler, host real equality, or ambient completeness row for $\mathsf{Real}^{\uparrow}$.

Theorem 6797.2 (Modulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{ModulatedConvergence}^{\uparrow}$ *carrier* $Q = (S, M, W, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ModulatedConvergence}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission exposes precisely the rows* $S, M, W, T, R, E, H, C, P, N$ *before a convergence-facing read is exported;*
2. *modulus coverage requires every displayed precision request in* W *to be served by a finite depth in* M *over the same source stream* S*;*
3. *tail-window stability requires later inspected windows to pass through the same ledger* W *and tail row* T*, not through an external convergence oracle;*
4. *regular readback and Real sealing require every Real-facing read to factor through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *before* E *is visible;*
5. *provenance and transport require* H, C, P, N *to preserve the same displayed route under* hsame *transport,* Cont *replay, package sourcing, and local naming.*

Proof. Carrier admission is projection from Definition 6797.1. The packet lists the source stream, explicit modulus, tail-window ledger, tail-stability row, regular readback, Real seal, and structural rows as its entire public surface.

For modulus coverage and tail-window stability, inspect M, W, T together. Each precision request is admitted only with a displayed depth and a finite tail-window record over the same stream row S, so the packet cannot consult a host convergence predicate or countable-choice schedule.

The regular readback then consumes S, M, W, T, R in order. The sibling chapters chapter 126 and chapter 301 supply the stream and regular rational surfaces named by the carrier.

Finally the Real seal E is downstream of that route, and H, C, P, N only transport, replay, source, and name the same packet. Since the carrier has no selected-limit, quotient-completion, host-equality, or ambient-completeness coordinate, a convergence consumer receives only the displayed $\mathsf{Real}^{\uparrow}$ seal boundary. □

Theorem 6797.3 (Modulated convergence RegSeqRat handoff)**.** *For every accepted* $\mathsf{ModulatedConvergence}^{\uparrow}$ *carrier* $Q = (S, M, W, T, R, E, H, C, P, N)$*, the L10 handoff to* $\mathsf{RegSeqRat}^{\uparrow}$ *is exactly the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto M \longmapsto W \longmapsto T \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto (H, C, P, N).$$

The handoff carries source windows, explicit modulus depths, tail-window stability, rational regular readback, Real sealing, transport, replay, provenance, and local naming. It carries no separate limit selector, host enumeration of tails, quotient completion equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or representation source outside the packet.*

Proof. Start from the carrier definition. The rows S, M, W, T display the source windows and the explicit tail depth required for each precision request.

Apply the NameCert obligation surface of Definition 6797.2. Regular readback and Real sealing require R to occur before E, and the transport-provenance rows preserve the same route after the seal is read.

The listed L10 handoff is therefore the only route available to a downstream RegSeqRat or Real consumer. Every excluded object would require a coordinate absent from Q, so it cannot be extracted from the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulatedConvergence}^{\uparrow}$ packet is generated from source StreamName windows, an explicit modulus row, a tail-window ledger, tail-stability data, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6797.1, Definition 6797.2, and Definition 6797.3 seed the finite explicit-modulus convergence route for RegSeqRat and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulatedConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, host convergence predicates, quotient completion equality, countable choice, full RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus coverage, tail-window stability, regular readback, Real-seal nonescape, and transport-provenance preservation for BEDC.Derived.ModulatedConvergenceUp.

Chapter 6798

A Concrete Naming Certificate for $\mathsf{T1Space}^{\uparrow}$

Following Engelking and Kelley on separation axioms, the $\mathsf{T1Space}^{\uparrow}$ packet records the finite singleton-closed surface needed by Real-facing topology consumers before they ask for stronger separation. It sits over the topology carrier of chapter 88, the set-like point and singleton rows of chapter 3668, the metric-neighbouring separation route of chapter 57, and the terminal real-name seal of chapter 38. The packet names only the displayed point classifier and singleton-closed witnesses; it does not assert Hausdorff separation, compactness, quotient spaces, host point equality, or choice.

Definition 6798.1 (T1 space carrier)**.** *A* $\mathsf{T1Space}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, O, Q, S, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{SetLike}^{\uparrow}$ *point-carrier row, exposing only the finite public point observations admitted by the packet.*
2. *O is the* $\mathsf{Topology}^{\uparrow}$ *open-row packet, recording the open observations and finite topology provenance currently under inspection.*
3. *Q is the point classifier row. It classifies inspected point rows only through the displayed* $\mathsf{SetLike}^{\uparrow}$ *membership and* $\mathsf{Topology}^{\uparrow}$ *open data.*
4. *S is the singleton-closed witness row. For each inspected point row accepted by Q, it records the finite boundary witness that the singleton is closed in the displayed topology packet.*
5. *B is the Real-facing boundary row, reached by metric and real consumers only after X, O, Q, S have been displayed.*
6. *H records componentwise* hsame *transport for the point carrier, topology packet, classifier row, singleton-closed witness row, boundary row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from point and open observations to singleton-closed witnesses and then to the Real-facing boundary row.*
8. *P is the* Pkg *provenance over* $\mathsf{T1Space}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{T1Space}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, O, Q, S, B, H, C, P, N$. It has no coordinate for Hausdorff separation, compactness, quotient spaces, host point equality, selected representatives, or choice.

Theorem 6798.2 (T1 space NameCert obligations)**.** *For every accepted* $\mathsf{T1Space}^\uparrow$ *carrier $T = (X, O, Q, S, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{T1Space}^\uparrow}$ *surface consists exactly of carrier admission for the displayed point carrier, topology packet, point classifier, singleton-closed witness row, Real-facing boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Any topology, metric, or Real-facing consumer must expose X, O, Q, S before the boundary row B can be read.*

Proof. Project the carrier of Definition 6798.1. The accepted packet exposes exactly the point carrier X, topology row O, classifier Q, singleton-closed witnesses S, boundary row B, and structural rows H, C, P, N.

Read the point and topology sources through chapter 3668 and chapter 88. The classifier Q is therefore tied to displayed membership and open-row data, not to host point equality.

The singleton-closed row S is then the only separation witness available to the packet. Transport, replay, provenance, and local naming preserve that witness through H, C, P, N without adding a Hausdorff, compactness, quotient, or choice coordinate. □

Theorem 6798.3 (T1 singleton-closed boundary)**.** *Every accepted* $\mathsf{T1Space}^\uparrow$ *packet that exports a Real-facing or metric-facing separation read must first expose the route*

$$\mathsf{SetLike}^\uparrow \longmapsto \mathsf{Topology}^\uparrow \longmapsto Q \longmapsto S \longmapsto B \longmapsto H, C, P, N.$$

The exported boundary is exactly singleton-closed separation for displayed point rows. It is not Hausdorff separation, not compactness, not a quotient-space theorem, not host point equality, and not a choice principle.

Proof. Start with the NameCert obligations of Definition 6798.2. They force every consumer to read the point carrier, topology packet, classifier, and singleton-closed witness row before the boundary row is available.

Use the metric and real anchors only as consumers. The chapters chapter 57 and chapter 38 may read the displayed boundary B, but the carrier gives them no coordinate for stronger separation or selected host points.

Finally inspect the structural rows. The hsame transport, Cont replay, Pkg provenance, and local NameCert row preserve the same finite singleton-closed route, so the exported boundary cannot be retyped as Hausdorff separation, compactness, quotient data, host point equality, or choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{T1Space}^\uparrow}$**.**

Constructive story: A $\mathsf{T1Space}^\uparrow$ packet is generated from a SetLikeUp point carrier, a TopologyUp open-row packet, a point classifier, singleton-closed witnesses, a Real-facing boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{T1Space}^\uparrow}$, seed)

Scope closed: Definition 6798.1, Definition 6798.2, and Definition 6798.3 seed the finite singleton-closed separation surface for Real-facing topology consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{T1Space}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Hausdorff separation, compactness, quotient spaces, host point equality, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topology packet visibility, point classifier exactness, singleton-closed witness stability, Real-facing boundary non-escape, transport, replay, provenance, and local naming for BEDC.Derived.T1SpaceUp.

Chapter 6799

A Concrete Naming Certificate for $\mathsf{PrueferSurface}^{\uparrow}$

Following Pruefer and Kelley-style topology, the $\mathsf{PrueferSurface}^{\uparrow}$ packet records a surface built from real-coordinate chart rows and a boundary fan of neighbourhood rows as finite NameCert data. It sits after the point-neighbourhood discipline of chapter 5921, the indexed-open surface of chapter 88, the binary coordinate route of chapter 2000, the real-coordinate seal of chapter 38, and the chart interface of chapter 96. The packet names only the displayed chart-boundary route; it does not import a quotient surface, a selected atlas completion, host equality of real pairs, choice-selected fans, or ambient manifold equality.

Definition 6799.1 (Pruefer surface carrier)**.** *A* $\mathsf{PrueferSurface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, Q, F, B, O, T, M, H, C, P, N)$$

with the following displayed rows:

1. *R is the real-coordinate chart row, exposing each local coordinate only through* $\mathsf{Real}^{\uparrow}$ *and the paired-coordinate readback supplied by* $\mathsf{ProductTopology}^{\uparrow}$*.*
2. *Q is the chart-index row, listing the visible ordinary coordinate charts and the boundary-indexed fan charts without importing an external atlas.*
3. *F is the boundary fan row, recording for each displayed boundary index the finite neighbourhood rows that approach that boundary coordinate from the corresponding side.*
4. *B is the boundary-neighbourhood exactness row, identifying which fan rows meet the boundary line and which ordinary rows remain in the interior chart region.*
5. *O is the chart-overlap row, recording the finite overlap incidences and transition-read requests between displayed chart rows.*
6. *T is the* $\mathsf{Topology}^{\uparrow}$ *handoff row generated from the ordinary chart rows, boundary fan rows, and displayed overlap incidences.*
7. *M is the* $\mathsf{Manifold}^{\uparrow}$ *chart-read row available only after R, Q, F, B, O, T have been displayed.*
8. *H records componentwise* hsame *transport for the chart, boundary fan, boundary-neighbourhood, overlap, topology, manifold, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from a chart request through coordinate readback, boundary fan selection, overlap incidence, topology handoff, manifold read, transport, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{PrueferSurface}^{\uparrow}$, $\mathsf{NiemytzkiPlane}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ProductTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrueferSurface}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotienting chart copies, selected atlas refinements, ambient equality of real-coordinate pairs, choice-selected neighbourhood fans, or a host manifold identity.

Theorem 6799.2 (Pruefer surface NameCert obligations)**.** *For every accepted* $\mathsf{PrueferSurface}^{\uparrow}$ *carrier*

$$S = (R, Q, F, B, O, T, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrueferSurface}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, chart compatibility through R, Q, O, boundary-neighbourhood exactness through F, B, topology handoff through T, real and product-coordinate readback through R, manifold readback through M, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, local naming through N, and nonescape from quotient surfaces, selected atlas refinements, host real-pair equality, choice-selected fans, or ambient manifold equality.*

Proof. Project the carrier of Definition 6799.1. The tuple displays chart coordinates, chart indices, boundary fan rows, boundary-neighbourhood exactness, overlap incidences, topology and manifold handoffs, transport, replay, provenance, and local naming as separate rows.

The chart and boundary rows are read before any topology handoff. The row R forces each coordinate through $\mathsf{Real}^{\uparrow}$ and $\mathsf{ProductTopology}^{\uparrow}$, while Q, F, B distinguish ordinary chart reads from boundary fan neighbourhood reads in the same finite packet.

Next inspect the overlap row O. Chart compatibility is therefore a displayed finite incidence condition between the rows already named by R, Q, F, B, not an equality of host charts or a quotient atlas.

Finally pass through T, M, H, C, P, N. These rows turn the displayed chart and boundary data into topology and manifold-facing reads while preserving the same finite route. Since no row supplies quotienting, selected atlas refinement, hidden real-pair equality, choice-selected fans, or ambient manifold identity, the listed rows exhaust the local NameCert surface. □

Theorem 6799.3 (Pruefer surface chart-boundary route)**.** *Every chart-boundary consumer of an accepted* $\mathsf{PrueferSurface}^{\uparrow}$ *carrier must factor through*

$$R, \quad Q, \quad F, \quad B, \quad O$$

before any $\mathsf{Manifold}^{\uparrow}$ *or* $\mathsf{Topology}^{\uparrow}$ *read is available. Thus the consumer sees a displayed chart row, a displayed boundary fan row, the boundary-neighbourhood exactness row, and the chart-overlap row before it may use the topology or manifold handoff.*

Proof. Start with a chart-boundary request. The only coordinate source is R, so the request first reads real-coordinate data through $\mathsf{Real}^{\uparrow}$ and $\mathsf{ProductTopology}^{\uparrow}$.

The chart-index and fan rows then determine the boundary side of the request. The rows Q and F expose the ordinary chart and the boundary-indexed fan, while B records the exact boundary-neighbourhood incidence.

Only after those rows are visible can the overlap row O compare the chart request with neighbouring chart rows. The topology row T and manifold row M are downstream of this displayed comparison, and H, C, P, N preserve the same order under transport, replay, provenance, and naming.

Consequently no chart-boundary consumer receives a host quotient surface, a selected atlas refinement, an untracked equality of real pairs, a choice-selected fan, or an ambient manifold identity before reading the displayed chart and boundary rows. □

Falsifiable prediction: Every accepted $\mathsf{PrueferSurface}^{\uparrow}$ chart-boundary read displays real-coordinate chart rows, boundary fan rows, boundary-neighbourhood exactness, chart-overlap rows, topology and manifold handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: niemytzki-plane, topology, product-topology, real, manifold: $\mathsf{PrueferSurface}^{\uparrow}$ is not bijective to any listed sibling because it binds ordinary chart rows, boundary fan neighbourhood rows, overlap incidence, and manifold-facing chart readback into one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PrueferSurface}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrueferSurface}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6799.1, Definition 6799.2, and Definition 6799.3 seed the finite real-coordinate chart, boundary fan, overlap, topology, manifold, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrueferSurface}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient surfaces, selected atlas refinements, host real-pair equality, choice-selected boundary fans, ambient manifold equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, chart compatibility, boundary-neighbourhood exactness, topology handoff, real and product-coordinate readback, manifold readback, and chart-boundary nonescape for BEDC.Derived.PrueferSurfaceUp.

Constructive story: A $\mathsf{PrueferSurface}^{\uparrow}$ packet is generated from real-coordinate chart rows, visible chart indices, boundary fan rows, boundary-neighbourhood exactness rows, chart-overlap rows, topology and manifold handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6800

A Concrete Naming Certificate for $\mathsf{OvertSpace}^{\uparrow}$

Following Bishop and Johnstone, the $\mathsf{OvertSpace}^{\uparrow}$ packet records witnessable positive contact for a displayed constructive space as finite NameCert data. It sits between the cover/refinement presentation of chapter 3967, the point-free open rows of chapter 5153, the positive real-contact surface of chapter 3354, and the compact positive-cover consumer of chapter 6548. The packet supplies positivity data to located real and formal-topology consumers without importing host open-set primitives, powersets, selected points, excluded middle over opens, or choice.

Definition 6800.1 (Overt space carrier)**.** *An* $\mathsf{OvertSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, B, P, W, R, L, H, C, G, N)$$

with the following displayed rows:

1. *S is the underlying space or formal presentation row whose positive observations are being named.*
2. *B is the basic-neighbourhood row read from* $\mathsf{FormalTopology}^{\uparrow}$ *or* $\mathsf{LocaleSpace}^{\uparrow}$*, exposing only finite cover and refinement data.*
3. *P is the positivity predicate row. It records witnessable contact with the displayed basic neighbourhood, not a host proposition over arbitrary opens.*
4. *W is the finite witness row that certifies the positive contact claimed by P.*
5. *R is the located-real specialization row through which* $\mathsf{OvertReal}^{\uparrow}$ *consumers read positive interval contact.*
6. *L is the located compact handoff row through which* $\mathsf{LocatedCompactOvert}^{\uparrow}$ *consumers combine positive contact with finite cover data.*
7. *H records componentwise* hsame *transport for the space, basis, positivity, witness, specialization, compact handoff, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay of a positive-contact request through $S, B, P, W, R, L, H, G, N$.*
9. *G is the* Pkg *provenance over* $\mathsf{OvertSpace}^{\uparrow}$, $\mathsf{FormalTopology}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{OvertReal}^{\uparrow}$, $\mathsf{LocatedCompactOvert}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OvertSpace}^{\uparrow}}$ *row.*

The carrier exposes no powerset of opens, no host open membership relation, no selected point of contact, no spatial quotient, no trichotomy over basic opens, and no choice principle for witnesses not already displayed in W.

Lean4 ✓ `BEDC.Derived.OvertSpaceUp.OvertSpaceTasteGate single carrier alignment`

Theorem 6800.2 (Overt space positivity stability)**.** *Every accepted* $\mathsf{OvertSpace}^{\uparrow}$ *carrier preserves positive contact through the displayed* hsame *and* Cont *rows. Concretely, if a consumer reads a positive neighbourhood claim from $O = (S, B, P, W, R, L, H, C, G, N)$, then the claim must be replayed from the same basis row B, the same positivity row P, and the same finite witness row W after transport. The replay may be consumed by formal-topology, locale, overt-real, or located-compact-overt siblings, but it cannot be replaced by a host open-set predicate, a selected point, a powerset operation, or a choice-selected witness.*

Theorem 6800.3 (Overt space located-real specialization)**.** *Every located-real or located-compact consumer of an accepted* $\mathsf{OvertSpace}^{\uparrow}$ *packet factors through*

$$\mathsf{FormalTopology}^{\uparrow},\ \mathsf{LocaleSpace}^{\uparrow},\ \mathsf{OvertReal}^{\uparrow},\ \mathsf{LocatedCompactOvert}^{\uparrow}.$$

The formal-topology and locale rows supply finite basic-neighbourhood and cover-refinement data, the $\mathsf{OvertReal}^{\uparrow}$ *row specializes positive contact to located real intervals, and the* $\mathsf{LocatedCompactOvert}^{\uparrow}$ *row consumes the same witness data together with finite compact-cover rows. The route exports positivity evidence, not host opens, quotient spatial equality, trichotomy, selected points, or ambient real completeness.*

Closure status for $\mathsf{NameCert}_{\mathsf{OvertSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{OvertSpace}^{\uparrow}$ packet is generated from a displayed space or formal presentation row, finite basic-neighbourhood rows, a positivity row, a finite witness row, located-real specialization, located-compact handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OvertSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6800.1, Definition 6800.2, and Definition 6800.3 seed the finite positivity surface for constructive topology consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OvertSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host open-set primitives, powersets, spatial quotient equality, selected points, trichotomy over opens, choice-selected witnesses, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, positivity stability, finite witness exactness, formal-topology and locale routing, located-real specialization, located-compact handoff, transport, replay, provenance, and local naming for BEDC.Derived.OvertSpaceUp.

Chapter 6801

A Concrete Naming Certificate for $\mathsf{KorovkinTheorem}^{\uparrow}$

Following Korovkin, the $\mathsf{KorovkinTheorem}^{\uparrow}$ packet records the classical test-function criterion for positive approximation operators on a compact interval as finite BEDC rows. It consumes the compact source surface of chapter 60, the continuous-map carrier of chapter 130, the polynomial row of chapter 50, the Bernstein approximation boundary of chapter 3730, the uniform-convergence ledger of chapter 3417, and the polynomial approximation handoff of chapter 1634. The packet names the finite test-function route; it is not an open-cover compactness theorem, a host norm-completeness argument, a selected infinite operator sequence, quotient equality of functions, or a proof of positivity outside the displayed rows.

Definition 6801.1 (Korovkin theorem carrier)**.** *A* $\mathsf{KorovkinTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, T, O, B, W, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact source row, read through* $\mathsf{Compact}^{\uparrow}$*.*
2. *F is the continuous-map target row, read through* $\mathsf{ContinuousMap}^{\uparrow}$*.*
3. *T is the three-test-function row, naming the constant, coordinate, and square-coordinate observations.*
4. *O is the positive-operator row, recording the finite operator family under inspection.*
5. *B is the Bernstein comparison row, read through* $\mathsf{BernsteinPolynomial}^{\uparrow}$*.*
6. *W is the polynomial approximation handoff row, read through* $\mathsf{WeierstrassApproximation}^{\uparrow}$ *and* $\mathsf{Poly}^{\uparrow}$*.*
7. *U is the uniform-convergence row, recording the common tolerance schedule for the target function.*
8. *H records componentwise* hsame *transport for source, target, test, operator, Bernstein, Weierstrass, uniform-convergence, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the three test functions through the polynomial handoff and into the target uniform-convergence row.*

10. *P is the* Pkg *provenance over* $\mathsf{KorovkinTheorem}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{BernsteinPolynomial}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{WeierstrassApproximation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KorovkinTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, T, O, B, W, U, H, C, P, N$. It has no coordinate for an ambient Banach-space norm proof, a hidden positivity theorem, a selected infinite subsequence, quotient equality of functions, or a compactness principle beyond the displayed compact source row.

Theorem 6801.2 (Korovkin test-function sufficiency)**.** *For every accepted* $\mathsf{KorovkinTheorem}^{\uparrow}$ *carrier $K = (X, F, T, O, B, W, U, H, C, P, N)$, a consumer may read the approximation conclusion only after the positive-operator row O has been checked on the three-test-function row T over the compact source row X. The conclusion then routes through the Bernstein row B, the polynomial handoff row W, and the continuous-map row F before it reaches the uniform-convergence row U.*

Proof. Project the carrier of Definition 6801.1. The source, target, test, operator, Bernstein, Weierstrass, and uniform-convergence rows are displayed as separate coordinates.

The test-function row is the only row that licenses the Korovkin read. It exposes the constant, coordinate, and square-coordinate observations before a consumer can use positivity of O.

The approximation route then passes through the named siblings. Bernstein supplies a finite polynomial comparison, Weierstrass supplies the polynomial approximation handoff, and the continuous-map row fixes the inspected target before the uniform-convergence ledger is read.

Thus the sufficiency claim is a finite carrier route through T, O, B, W, F, U over X, not an ambient norm argument or an unrecorded positivity theorem. □

Theorem 6801.3 (Korovkin uniform-convergence handoff)**.** *Every* $\mathsf{UniformConvergence}^{\uparrow}$ *consumer of an accepted* $\mathsf{KorovkinTheorem}^{\uparrow}$ *packet must receive the displayed route*

$$X, F, T, O, B, W, U, H, C, P, N.$$

The row U may be consumed only after T has exposed the three test functions, O has retained positivity for the inspected family, B has supplied the Bernstein comparison, and W has supplied the Weierstrass–polynomial handoff.

Proof. Start with Definition 6801.2. It forces the approximation conclusion through the compact source, continuous target, three-test-function, positive-operator, Bernstein, polynomial, and uniform-convergence rows.

Next read the structural rows H, C, P, N. They transport, replay, source, and name the same finite route, so the uniform-convergence consumer receives the full packet rather than a detached convergence assertion.

Since U is reached only after T, O, B, W are visible, the handoff cannot be retyped as a host supremum-norm theorem, a selected infinite operator sequence, quotient equality of maps, or a compactness principle outside the displayed $\mathsf{Compact}^{\uparrow}$ row. □

Theorem 6801.4 (Korovkin theorem NameCert obligations)**.** *For every accepted* $\mathsf{KorovkinTheorem}^{\uparrow}$ *carrier $K = (X, F, T, O, B, W, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KorovkinTheorem}^{\uparrow}}$ *surface consists exactly of compact-source exposure through X, continuous-target exposure through F, three-test-function exposure through T, positive-operator admission through O, Bernstein comparison through B, polynomial approximation handoff through W, uniform-convergence export through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6801.1. The analytic rows are X, F, T, O, B, W, U, and the structural rows are H, C, P, N.

The test-function sufficiency theorem keeps T and O visible before approximation is read. The uniform-convergence handoff theorem keeps B, W, U visible before the downstream convergence consumer may use the packet.

The transport, replay, provenance, and local naming rows preserve the same route. Since no further carrier coordinate exists, the listed rows exhaust the local NameCert obligations and exclude host compactness, hidden positivity, quotient equality, selected infinite data, and ambient completeness readings. □

Falsifiable prediction: An accepted $\mathsf{KorovkinTheorem}^{\uparrow}$ consumer that reaches $\mathsf{UniformConvergence}^{\uparrow}$ without first displaying the three-test-function row and the positive-operator row is outside the carrier surface.

Independence witness: compact, continuousmap, polynomial, bernstein-polynomial, uniform-convergence, weierstrass-approximation: none is bijective to $\mathsf{KorovkinTheorem}^{\uparrow}$ because only this packet binds the compact source, continuous target, Korovkin test rows, positive-operator family, Bernstein comparison, Weierstrass polynomial handoff, uniform-convergence ledger, transport, replay, provenance, and local NameCert row into one accepted route.

Closure status for $\mathsf{NameCert}_{\mathsf{KorovkinTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{KorovkinTheorem}^{\uparrow}$ packet is generated from compact source, continuous target, three-test-function, positive-operator, Bernstein comparison, polynomial approximation, uniform-convergence, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KorovkinTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6801.1, Definition 6801.2, Definition 6801.3, and Definition 6801.4 seed the finite Korovkin approximation packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KorovkinTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, arbitrary compact-space Korovkin variants, host norm-completeness arguments, or positivity outside the displayed operator row.

Upgrade path: Obligation closure requires checked carrier admission, test-function exactness, positive-operator retention, Bernstein and Weierstrass handoff exactness, uniform-convergence export, transport, replay, provenance, and local naming for BEDC.Derived.KorovkinTheoremUp.

Chapter 6802

A Concrete Naming Certificate for MetaCICConfluenceInventory$^{\uparrow}$

The MetaCICConfluenceInventory$^{\uparrow}$ packet realizes the confluence audit map of chapter 9378 as a finite inventory separating checked fragments from retained conditional premises. It sits beside the parallel-diamond frontier of chapter 4238, the critical-pair boundary of chapter 2212, the closed-normal confluence seal of chapter 741, and the residual-substitution boundary of chapter 2181. The packet is an audit inventory, not an unconditional Church–Rosser theorem or a discharged substitution-compatibility proof.

Definition 6802.1 (MetaCIC confluence inventory carrier)**.** *A* MetaCICConfluenceInventory$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, A, NF, P, D, R, O, H, C, G, M)$$

with the following displayed rows:

1. *K is the checked-fragment row, listing the closed-normal and atom-level confluence fragments already available to the audit.*
2. *A is the audit-map row, recording the finite readback from chapter 9378 that classifies each confluence-facing component.*
3. *NF is the closed-normal seal row, read through* ClosedNormalConfluenceSeal$^{\uparrow}$ *before any closed-source handoff is exposed.*
4. *P is the parallel-diamond frontier row, retaining the premise boundary named by* MetaCICParallelDiamondFrontier
5. *D is the critical-pair boundary row, recording inspected peaks and candidate common-reduct witnesses.*
6. *R is the residual-substitution premise row, keeping the substitution-compatibility boundary visible.*
7. *O is the conditional-obligation row, separating retained premises from checked fragments before any confluence handoff is consumed.*
8. *H records componentwise* hsame *transport for checked fragments, audit-map rows, closed-normal seals, frontier rows, critical-pair rows, residual-substitution rows, conditional obligations, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a confluence-audit request through K, A, NF, P, D, R, O.*
10. *G is the* Pkg *provenance over* MetaCICConfluenceInventory$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$, ClosedNormalConfluenceSeal$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *M is the local* NameCert$_{\text{MetaCICConfluenceInventory}^{\uparrow}}$ *row.*

The classifier compares accepted inventories only through $K, A, NF, P, D, R, O, H, C, G, M$. It has no coordinate for an unconditional parallel diamond, a global Church–Rosser theorem, discharged residual-substitution compatibility, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Theorem 6802.2 (MetaCIC confluence inventory NameCert obligations)**.** *For every accepted* MetaCICConfluenceInventory$^{\uparrow}$ *carrier $I = (K, A, NF, P, D, R, O, H, C, G, M)$, the local* NameCert$_{\text{MetaCICConfluenceInven}}$ *surface consists exactly of carrier admission for checked-fragment rows, confluence audit-map rows, closed-normal seal rows, parallel-diamond frontier rows, critical-pair boundary rows, residual-substitution premise rows, conditional-obligation rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The proposed Lean follow-up must provide Nontrivial* MetaCICConfluenceInventory$^{\uparrow}$ *and FieldFaithful* MetaCICConfluenceInventory$^{\uparrow}$ *instances in TasteGate.lean, so the inventory is nonempty and every displayed row is classifier-visible.*

Proof. Project the carrier of Definition 6802.1. The projection exposes the checked-fragment inventory, audit-map row, closed-normal seal, parallel frontier, critical-pair boundary, residual-substitution premise, conditional-obligation row, and structural rows.

The checked side is read through K, A, NF. These rows may expose closed-normal and atom-level fragments, but they do not discharge the residual-substitution or closed-diamond premises retained by P, D, R, O.

The conditional side is read through the frontier, critical-pair, residual-substitution, and obligation rows. Since those rows remain visible before any handoff, the packet separates checked fragments from premises instead of promoting the audit map to an unconditional confluence theorem.

Finally H, C, G, M transport, replay, source, and name the same inventory. Nontrivial and FieldFaithful TasteGate evidence must certify that the inventory carries genuine rows and that no row can be ignored by the classifier. □

Theorem 6802.3 (MetaCIC confluence inventory conditional boundary)**.** *Every confluence-facing read of an accepted* MetaCICConfluenceInventory$^{\uparrow}$ *packet must expose the substitution-compatibility premise row R and the closed-diamond premise retained by P, D, O before any Church–Rosser handoff can be consumed. Checked fragments K, A, NF remain available as finite rows, but the packet exports no unconditional parallel diamond, no global Church–Rosser theorem, no discharged residual-substitution compatibility, and no kernel-consistency endpoint.*

Proof. Begin with the NameCert obligations of Definition 6802.2. They keep the checked-fragment rows and the retained premise rows in the same accepted carrier.

Use the parallel-diamond frontier and critical-pair boundary only as displayed dependencies. The rows P and D expose the closed-diamond and critical-pair boundary data, while R keeps substitution compatibility as a premise rather than a theorem.

The conditional-obligation row O then blocks a premise-free Church–Rosser handoff. The structural rows H, C, G, M preserve that split, so a downstream confluence consumer can read the inventory but cannot read any refused unconditional endpoint. □

Falsifiable prediction: Every confluence-facing read of $\mathsf{MetaCICConfluenceInventory}^{\uparrow}$ exposes the substitution-compatibility and closed-diamond premise rows before any Church–Rosser handoff.

Independence witness: metacic-parallel-diamond-frontier, metacic-confluence-critical-pair-boundary, closednormalconfluenceseal, metacic-residual-substitution-boundary: $\mathsf{MetaCICConfluenceInventory}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries checked-fragment, audit-map, closed-normal, parallel-frontier, critical-pair, residual-substitution, conditional-obligation, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceInventory}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceInventory}^{\uparrow}$ packet is generated from checked confluence fragments, an audit-map row, a closed-normal seal row, a parallel-diamond frontier row, a critical-pair boundary row, a residual-substitution premise row, conditional-obligation data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceInventory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6802.1, Definition 6802.2, and Definition 6802.3 seed the finite inventory separating checked confluence fragments from retained premises.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceInventory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, unconditional parallel diamond, global Church–Rosser, discharged substitution compatibility, subject reduction, evaluator equality, quotient equality of terms, kernel consistency, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, checked-fragment visibility, audit-map readback, closed-normal seal exposure, parallel-frontier premise retention, critical-pair boundary retention, residual-substitution boundary retention, conditional-obligation non-escape, transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetaCICConfluenceInventoryUp.

Chapter 6803

A Concrete Naming Certificate for $\mathsf{BrownRepresentability}^{\uparrow}$

Following Brown's representability theorem and Neeman's triangulated-category formulation, the $\mathsf{BrownRepresentability}^{\uparrow}$ packet records representability as finite BEDC NameCert data for a displayed homological consumer. It sits after the category carrier of chapter 61, the functorial row of chapter 62, the natural-transformation surface of chapter 63, the homology carrier of chapter 98, the derived-category row of chapter 160, and the triangulated-category row of chapter 179. The packet names a finite representability ledger for inspected homological functors; it does not assert the host Brown theorem, arbitrary coproduct exactness, selected representing objects, quotient functor equality, or ambient set-theoretic choice.

Definition 6803.1 (Brown representability carrier)**.** *A* $\mathsf{BrownRepresentability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (C, T, F, N, H, D, R, L, S, P, M)$$

with the following displayed rows:

1. *C is the source* $\mathsf{Cat}^{\uparrow}$ *row carrying the inspected objects and morphisms.*
2. *T is the* $\mathsf{TriangulatedCat}^{\uparrow}$ *or* $\mathsf{DerivedCat}^{\uparrow}$ *structure row used by the homological consumer.*
3. *F is the* $\mathsf{Functor}^{\uparrow}$ *row for the inspected contravariant or covariant homological functor.*
4. *N is the* $\mathsf{NatTrans}^{\uparrow}$ *naturality row recording the finite naturality squares that the consumer asks to inspect.*
5. *H is the* $\mathsf{Homology}^{\uparrow}$ *row read by the finite homology consumer.*
6. *D records the displayed distinguished-triangle or derived-handoff obligations that feed the inspected homological window.*
7. *R is the representability ledger, listing the candidate representing-object name together with the finite Hom-window comparison rows.*
8. *L records local exactness and coproduct-compatibility tests only for the displayed finite window.*
9. *S records componentwise* hsame *transport for the category, triangulated, functor, naturality, homology, handoff, ledger, and local-test rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BrownRepresentability}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{DerivedCat}^{\uparrow}$, $\mathsf{TriangulatedCat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *M is the local* $\mathsf{NameCert}_{\mathsf{BrownRepresentability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a global representing object, host Hom-set equality, arbitrary coproduct preservation, quotient functor equality, selected injective resolutions, or ambient choice.

Theorem 6803.2 (Brown representability NameCert obligations)**.** *For every accepted* $\mathsf{BrownRepresentability}^{\uparrow}$ *carrier* $B = (C, T, F, N, H, D, R, L, S, P, M)$*, the local* $\mathsf{NameCert}_{\mathsf{BrownRepresentability}^{\uparrow}}$ *surface consists exactly of carrier admission for the category row, triangulated or derived row, functor row, naturality row, homology row, distinguished-triangle handoff row, representability ledger, finite exactness and coproduct tests, componentwise transport, provenance, and local naming. A consumer may read representability obligations only from those rows and receives no host Brown theorem or selected representing object.*

Proof. Project the carrier of Definition 6803.1. The category, triangulated or derived, functor, naturality, homology, handoff, representability-ledger, local-test, transport, provenance, and naming rows are the only coordinates exposed by the packet.

The representability ledger is therefore finite. It records a candidate object name and the Hom-window comparison rows inspected by the consumer, while L stores only the local exactness and coproduct tests that have been displayed.

Finally read the structural rows S, P, M. They transport, source, and name the same packet, so no additional row can provide a global representing object, arbitrary coproduct preservation, quotient functor equality, selected resolution data, host Hom equality, or ambient choice. □

Theorem 6803.3 (Brown representability finite homology consumer)**.** *Every finite homology consumer of an accepted* $\mathsf{BrownRepresentability}^{\uparrow}$ *packet must read the route*

$$C, T, F, N, H, D \longmapsto R, L$$

before it may use the structural rows S, P, M. Thus the consumer receives a displayed representability ledger for the inspected homological window, not an unrestricted Brown representability theorem, a selected representing object, quotient functor equality, arbitrary coproduct exactness, or ambient category-theoretic choice.

Proof. Start from the NameCert obligations of Definition 6803.2. They force every consumer to expose the category, triangulated or derived, functor, naturality, homology, and handoff rows before the representability ledger can be inspected.

The finite consumer then reads R, L. The ledger R supplies the displayed Hom-window comparison data, and L supplies only the local exactness and coproduct tests attached to that window.

The structural rows S, P, M preserve and name this same finite route. Since the carrier contains no row for a global representing object, quotient functor equality, selected resolutions, arbitrary coproduct preservation, host Hom equality, or ambient choice, the exported consumer surface is exactly the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrownRepresentability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BrownRepresentability}^{\uparrow}$ packet is generated from category, triangulated or derived, functor, naturality, homology, distinguished-triangle handoff, representability ledger, local exactness, transport, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrownRepresentability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6803.1, Definition 6803.2, and Definition 6803.3 seed the finite representability NameCert surface for homological consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrownRepresentability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the host Brown theorem, arbitrary coproduct exactness, selected representing objects, quotient functor equality, selected resolutions, ambient choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, functor and naturality exposure, homology handoff exactness, representability ledger readback, finite exactness tests, transport, provenance, and local naming for BEDC.Derived.BrownRepresentabilityUp.

Chapter 6804

A Concrete Naming Certificate for $\mathsf{CauchyCompleteSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyCompleteSpace}^{\uparrow}$ packet records a complete-space interface by keeping regular Cauchy names, finite stream windows, rational readback, and the completion-facing seal visible in one NameCert carrier. It sits after the finite observation surface of chapter 126, the regular rational sequence boundary of chapter 301, the terminal real-name surface of chapter 38, and the completion routes of chapter 1506 and chapter 1569. The packet names completeness through displayed regular Cauchy data; it does not import quotient streams, selected limits, countable choice, or ambient host completeness.

Definition 6804.1 (Cauchy complete space carrier)**.** *A* $\mathsf{CauchyCompleteSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, D, W, Q, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying displayed space or completion source row.*
2. *D is the distance or apartness-control row used by Cauchy consumers.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for inspected Cauchy names.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational estimates exposed by W and D.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row through which endpoint reads are consumed.*
6. *E is the completion-envelope row, read through the metric or Cauchy-filter completion siblings.*
7. *L is the limit-handoff row asserting that an accepted regular Cauchy name is read through W, Q, R, E before any complete-space consumer sees a point.*
8. *H records componentwise* hsame *transport for the space, control, window, readback, seal, envelope, limit-handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from precision requests to stream windows, regular rational readback, Real seals, completion-envelope reads, and complete-space consumers.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompleteSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompleteSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, D, W, Q, R, E, L, H, C, P, N$. It has no coordinate for quotient stream equality, a choice-selected representative, an ambient Cauchy-completion theorem, host metric completion, countable choice, or uninspected Real completeness.

Theorem 6804.2 (Cauchy complete space NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompleteSpace}^{\uparrow}$ *carrier*

$$S = (X, D, W, Q, R, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompleteSpace}^{\uparrow}}$ *surface consists exactly of space-source exposure through X, distance-control exposure through D, finite Cauchy-window exposure through* $\mathsf{StreamName}^{\uparrow}$ *row W, regular rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q, Real sealing through R, completion-envelope exposure through E, regular Cauchy limit handoff through L, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6804.1. Its visible analytic rows are X, D, W, Q, R, E, L, and its structural rows are H, C, P, N.

The Cauchy source is finite at every read. A consumer first sees stream windows through W and regular rational estimates through Q; only then can it inspect the Real seal R or the completion envelope E.

The handoff row L keeps this order attached to the same packet. Since the carrier has no coordinate for quotient streams, selected representatives, countable choice, or host completion, the listed rows exhaust the complete-space obligation surface. □

Theorem 6804.3 (Cauchy complete space regular-Cauchy handoff)**.** *Every regular Cauchy consumer of an accepted* $\mathsf{CauchyCompleteSpace}^{\uparrow}$ *packet reads the complete-space point through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Completion}^{\uparrow} \longmapsto \mathsf{CauchyCompleteSpace}^{\uparrow}.$$

Concretely, the consumer must expose the stream-window row W, the regular rational readback row Q, the Real seal row R, the completion-envelope row E, the limit-handoff row L, and the structural rows H, C, P, N before it may use the complete-space interface. The route exports no selected limit, quotient stream equality, countable-choice scheduler, host metric completion, or ambient Real completeness theorem.

Proof. Start from the NameCert obligations of Definition 6804.2. They place stream windows, regular rational readback, Real sealing, completion-envelope exposure, and the limit handoff in the same displayed carrier.

Now read the sibling route. The $\mathsf{StreamName}^{\uparrow}$ row supplies finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational estimates, $\mathsf{Real}^{\uparrow}$ supplies the endpoint seal, and $\mathsf{Completion}^{\uparrow}$ supplies the completion-facing envelope. The structural rows transport and replay that same route without adding a new limit selector.

Therefore any complete-space consumer receives exactly the displayed regular Cauchy handoff. The refused objects would require additional coordinates absent from S, so they cannot be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompleteSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompleteSpace}^{\uparrow}$ packet is generated from a displayed space row, distance-control row, StreamName windows, RegSeqRat readback, a Real seal, a completion-envelope row, a regular Cauchy limit-handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompleteSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6804.1, Definition 6804.2, and Definition 6804.3 seed the finite complete-space interface for regular Cauchy and completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyCompleteSpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host metric completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-window exposure, regular rational readback, Real-seal nonescape, completion-envelope exactness, limit-handoff stability, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompleteSpaceUp.

Chapter 6805

A Concrete Naming Certificate for $\mathsf{RiemannMapping}^{\uparrow}$

Following Riemann, Koebe, and Ahlfors, the $\mathsf{RiemannMapping}^{\uparrow}$ packet records the simply connected proper planar-domain uniformization route as finite NameCert data. It is grounded in the holomorphic-map surface of chapter 68, the disk target of chapter 377, the complex carrier of chapter 39, the normal-family compactness route of chapter 2186, the pointed disk bound of chapter 3796, and the disk-contraction comparison of chapter 3682. The certificate names the classical route without importing a host theorem about all complex domains, selected boundary prime ends, quotient function equality, or ambient compact-open function-space completeness.

Definition 6805.1 (Riemann mapping carrier)**.** *A* $\mathsf{RiemannMapping}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, U, F, I, B, NF, SL, H, C, P, L)$$

with the following displayed rows:

1. *D is the simply connected proper complex-domain row over* $\mathsf{Complex}^{\uparrow}$*, recording the finite source-domain observations and the refusal of the whole-plane case.*
2. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *target row, including the named disk origin and disk boundary observations consumed by the mapping route.*
3. *F is the holomorphic conformal-map row read through* $\mathsf{Holomorphic}^{\uparrow}$*, recording injective local coordinate preservation from D to U.*
4. *I is the inverse-map row, displaying the holomorphic inverse on the accepted image route rather than a host inverse function.*
5. *B is the boundary-refusal row, saying that the packet exports no selected boundary extension, Caratheodory boundary theorem, prime-end classifier, or boundary homeomorphism.*
6. *NF is the* $\mathsf{NormalFamily}^{\uparrow}$ *route that supplies the compactness-style search surface for the extremal disk-normalized map.*
7. *SL is the Schwarz route through* $\mathsf{SchwarzLemma}^{\uparrow}$ *and* $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$*, recording pointed normalization, disk contraction, uniqueness up to displayed disk automorphism data, and nonexpansion comparisons.*
8. *H records componentwise* hsame *transport for the domain, disk, map, inverse, boundary refusal, normal-family route, Schwarz route, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay for the same rows, so a consumer replays the finite route rather than consulting an ambient analytic-function space.*
10. *P is the* Pkg *provenance over* $\mathsf{RiemannMapping}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{NormalFamily}^{\uparrow}$, $\mathsf{SchwarzLemma}^{\uparrow}$, $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{RiemannMapping}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, U, F, I, B, NF, SL, H, C, P, L$. It has no coordinate for a selected conformal map outside the displayed normalization route, no quotient equality of holomorphic functions, no ambient compact-open completion, no boundary correspondence theorem, and no appeal to a choice principle over domains.

Theorem 6805.2 (Riemann mapping NameCert obligations)**.** *For every accepted* $\mathsf{RiemannMapping}^{\uparrow}$ *carrier $R = (D, U, F, I, B, NF, SL, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannMapping}^{\uparrow}}$ *surface consists exactly of the simply connected proper complex-domain row, the* $\mathsf{UnitDisk}^{\uparrow}$ *target row, the holomorphic conformal-map row, the inverse-map row, the boundary-refusal row, the* $\mathsf{NormalFamily}^{\uparrow}$ *route, the* $\mathsf{SchwarzLemma}^{\uparrow}$ *and* $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ *route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6805.1. The analytic rows are D, U, F, I, B, NF, SL, and the structural rows are H, C, P, L.

The domain row D is the only row that names a simply connected proper complex source, while U is the only row that names the disk target. Thus any accepted read of the mapping claim must display both endpoints before it reaches the map or inverse rows.

The map rows F, I are routed through the normal-family and Schwarz rows. The normal-family row supplies the extremal compactness-style route, and the Schwarz and Schwarz–Pick rows supply the pointed disk comparison and contraction discipline used by the uniqueness read.

Finally H, C, P, L transport, replay, source, and name the same finite route. Since the carrier has no coordinate for selected boundary values, quotient function equality, ambient compact-open completion, or a global choice over domains, those objects are outside the NameCert obligations. □

Theorem 6805.3 (Riemann mapping normal-family route)**.** *Every accepted* $\mathsf{RiemannMapping}^{\uparrow}$ *consumer that reads a disk uniformization claim must pass through the ordered route*

$$\mathsf{Complex}^{\uparrow},\ \mathsf{Holomorphic}^{\uparrow},\ \mathsf{UnitDisk}^{\uparrow},\ \mathsf{NormalFamily}^{\uparrow},\ \mathsf{SchwarzLemma}^{\uparrow},\ \mathsf{SchwarzPickDiskContraction}^{\uparrow}.$$

The route first displays the proper simply connected complex-domain source, then the disk target and holomorphic conformal-map rows, then the normal-family extremal surface, and finally the Schwarz comparison rows. It exports the displayed mapping packet and inverse-map row, not a boundary extension theorem, quotient equality of maps, host analytic continuation principle, or ambient function-space completeness.

Proof. Start with the source and target rows. The complex carrier and holomorphic-map surface provide only the displayed domain observations and the map row, while the UnitDisk row fixes the codomain used by the disk-normalized route.

Next apply the normal-family route. It is the only compactness-style row in the packet, so the extremal-map read must pass through NF before any disk uniformization conclusion is named.

The Schwarz rows then control the disk comparison. $\mathsf{SchwarzLemma}^{\uparrow}$ supplies the pointed disk bound, and $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ supplies the contraction comparison, so uniqueness

and normalization are read through the finite disk route rather than an ambient analytic-function equality.

The transport, replay, provenance, and local naming rows preserve this route unchanged. Therefore a consumer that skips the normal-family row, the Schwarz rows, or the displayed boundary-refusal row is not reading an accepted $\mathsf{RiemannMapping}^{\uparrow}$ packet. □

Falsifiable prediction: A purported $\mathsf{RiemannMapping}^{\uparrow}$ consumer that claims a disk uniformization without displaying the $\mathsf{NormalFamily}^{\uparrow}$ route and the $\mathsf{SchwarzLemma}^{\uparrow}$–$\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ comparison route is outside the carrier surface.

Independence witness: holomorphic, unitdisk, complex, normal-family, schwarz-lemma, schwarz-pick-disk-contraction: none is bijective to $\mathsf{RiemannMapping}^{\uparrow}$ because only this packet binds the simply connected proper domain, disk target, conformal map, inverse row, boundary refusal, normal-family route, Schwarz comparison route, transport, replay, provenance, and local NameCert rows into one accepted carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannMapping}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannMapping}^{\uparrow}$ packet is generated from a simply connected proper complex-domain row, UnitDisk target row, holomorphic conformal-map row, inverse-map row, boundary-refusal row, NormalFamily route, SchwarzLemma and SchwarzPickDiskContraction route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannMapping}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6805.1, Definition 6805.2, and Definition 6805.3 seed the finite Riemann mapping carrier, obligation surface, and normal-family route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannMapping}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, boundary extension theorems, quotient equality of holomorphic maps, selected conformal maps outside the displayed normalization route, or ambient compact-open function-space completeness.

Upgrade path: Obligation closure requires checked carrier admission, domain properness, simple-connectedness routing, disk target exactness, conformal-map and inverse-map exactness, boundary refusal, normal-family handoff, Schwarz comparison, transport, replay, provenance, and local naming for BEDC.Derived.RiemannMappingUp.

Chapter 6806

A Concrete Naming Certificate for $\mathsf{RealNameGauge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealNameGauge}^{\uparrow}$ packet records finite precision gauges for real names before a completed real object is exposed. It sits beside the dyadic tolerance ledger of chapter 291, the finite stream-window carrier of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located comparison service of chapter 1669. The packet names the tolerance-window discipline a consumer must inspect before treating a finite read as Real-facing data; it does not construct a quotient real, decide host equality, choose a completed representative, or assume ambient completeness.

Definition 6806.1 (RealNameGauge carrier)**.** *A* $\mathsf{RealNameGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, D, S, Q, H, C, P, N)$$

with the following visible rows:

1. *T is the tolerance-window ledger, listing the finite precision requests currently admitted by the gauge.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row attached to each displayed tolerance window, including the dyadic comparison and refinement data used by the request.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *request row through which the named real is queried at those finite tolerances.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the same stream requests with regular rational observations before any* $\mathsf{Real}^{\uparrow}$ *seal is visible.*
5. *H records componentwise* hsame *transport for tolerance windows, dyadic radii, stream requests, regular readbacks, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a tolerance request to its dyadic radius, stream read, regular rational readback, and Real-facing seal boundary.*
7. *P is the* Pkg *provenance over* $\mathsf{RealNameGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLocator}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealNameGauge}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient-real equality, host equality of real names, trichotomy, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6806.2 (RealNameGauge window obligation)**.** *For every accepted* $\mathsf{RealNameGauge}^{\uparrow}$ *carrier* $G = (T, D, S, Q, H, C, P, N)$*, a gauge read must expose the monotone tolerance windows in* T*, their dyadic radii in* D*, the stream requests in* S*, and the regular rational readbacks in* Q *before any* $\mathsf{Real}^{\uparrow}$ *seal may be consumed. The exported surface is the finite gauge route through* T, D, S, Q, H, C, P, N*; it exports no quotient real, host equality, trichotomy, selected representative, countable-choice schedule, or ambient completeness.*

Proof. Project the carrier of Definition 6806.1. The tolerance windows, dyadic radii, stream requests, regular readbacks, transports, replay routes, provenance, and local naming rows are the whole visible packet.

Read the precision discipline through T and D. A later tolerance window may refine an earlier one only by displaying the dyadic-radius row attached to the same gauge request, so monotonicity is part of the finite window ledger rather than a host property of real names.

Next read S and Q. The stream request and regular rational readback are consumed before the Real-facing seal boundary, and the replay row C preserves that order under continuation.

Finally H, P, N transport, source, and name the same packet. Since the carrier has no quotient-real, host-equality, trichotomy, selected-limit, choice-schedule, or completeness coordinate, none can be exported by the accepted gauge read. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealNameGauge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealNameGauge}^{\uparrow}$ packet is generated from finite tolerance windows, DyadicRatCore radius rows, StreamName request rows, RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealNameGauge}^{\uparrow}}$, seed)

Scope closed: Definition 6806.1 and Definition 6806.2 seed the finite precision-gauge route before Real-facing consumers read a seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealNameGauge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient reals, host equality of real names, trichotomy, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone tolerance-window exposure, dyadic radius exactness, StreamName request ordering, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealNameGaugeUp.

Chapter 6807

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusLadder}^{\uparrow}$

Following Heine–Cantor in Bishop and Bridges constructive metric analysis, the $\mathsf{CompactUniformModulusLadder}^{\uparrow}$ packet realizes the compact-uniform-continuity vision of chapter 9237 as finite NameCert data. It sits between the compact source rows of chapter 60, the metric distance rows of chapter 57, the pointwise continuity rows of chapter 59, the tolerance-only consumer row of chapter 369, and the finite ProbeBundle cover used by the compact witness. The packet records the ladder from pointwise moduli and finite cover rows to a uniform modulus row; it does not import an open-cover theorem, host compactness, choice-selected centers, semantic continuity, or ambient completeness.

Definition 6807.1 (CompactUniformModulusLadder carrier)**.** *A* $\mathsf{CompactUniformModulusLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, B, R, U, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row, exposing only the finite cover data accepted by the compact certificate.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row shared by the compact source and the continuous map.*
3. *B is the finite* ProbeBundle *cover row, listing displayed centers, membership rows, cover-radius rows, and coverage witnesses.*
4. *R is the pointwise-radius row read through* $\mathsf{Continuous}^{\uparrow}$*, assigning local modulus evidence to each displayed cover center.*
5. *U is the tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *row produced from the cover and pointwise-radius rows by a finite lower-bound fold.*
6. *H records componentwise* hsame *transport for compact rows, metric rows, bundle rows, pointwise-radius rows, uniform-modulus rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a tolerance request to finite cover inspection, pointwise-radius inspection, lower-bound folding, and the resulting uniform-modulus read.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusLadder}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, ProbeBundle, hsame, Cont, Pkg, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformModulusLadder}^{\uparrow}}$ *row.*
The carrier contains no coordinate for an ambient open-cover compactness principle, host compactness object, choice-selected center, semantic continuity theorem, quotient metric equality, or completeness of the target metric.

Theorem 6807.2 (CompactUniformModulusLadder certificate)**.** *For every accepted* CompactUniformModulusLadd *carrier $L = (K, M, B, R, U, H, C, P, N)$, a tolerance-only uniform-modulus read must factor through the compact source row K, the metric row M, the finite* ProbeBundle *cover row B, and the pointwise-radius row R before the* $\mathsf{UniformModulus}^{\uparrow}$ *row U is exposed. The certificate is the finite ladder $K, M, B, R, U, H, C, P, N$, not an open-cover compactness theorem, host-selected finite subcover, external modulus function, semantic continuity proof, quotient metric equality, or completeness argument.*

Proof. Project the carrier of Definition 6807.1. The compact source, metric row, finite bundle, pointwise-radius row, uniform-modulus row, transport, replay, provenance, and naming rows are the only coordinates available.

Read K, M, B first. The compact input is visible only through the finite ProbeBundle cover row over the shared metric, so the ladder starts from displayed cover data rather than from a host open-cover principle or an externally selected subcover.

Next read R. Each displayed center carries pointwise-radius evidence through $\mathsf{Continuous}^{\uparrow}$, and the lower-bound fold uses only the finitely many rows already listed in B and R.

Finally expose U through H, C, P, N. The replay route sends a tolerance request to the same finite cover, pointwise rows, and fold before the uniform-modulus row is consumed. Since no excluded object is a coordinate of L, none can be exported from the accepted certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusLadder}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactUniformModulusLadder}^{\uparrow}$ packet is generated from CompactUp source rows, MetricUp distance rows, finite ProbeBundle cover rows, ContinuousUp pointwise-radius rows, a UniformModulusUp tolerance-only row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformModulusLadder}^{\uparrow}}$, seed)

Scope closed: Definition 6807.1 and Definition 6807.2 seed the finite ladder from compact cover rows and pointwise moduli to a tolerance-only uniform-modulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformModulusLadder}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host compactness, choice-selected centers, semantic continuity, quotient metric equality, target completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover exposure, pointwise-radius attachment, lower-bound fold exactness, UniformModulusUp handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusLadderUp.

Chapter 6808

A Concrete Naming Certificate for $\mathsf{TaylorSeries}^{\uparrow}$

Following Taylor's finite expansion method and Bishop–Bridges constructive analysis, the $\mathsf{TaylorSeries}^{\uparrow}$ packet records a finite Taylor-jet surface before any analytic convergence claim is read. It sits after the local-linear approximation route of chapter 3632, the displayed derivative rows of chapter 122, the finite polynomial carrier of chapter 50, and the L10 real-name substrate of chapter 38, chapter 301, and chapter 291. The packet names a finite jet, its polynomial readback, and its tolerance ledger; it does not assert analytic convergence, a remainder theorem, a radius of convergence, host smoothness, quotient equality of functions, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6808.1 (TaylorSeries carrier)**.** *A* $\mathsf{TaylorSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, x, k, J, P, R, D, H, C, G, N)$$

with the following visible rows:

1. *A is the* $\mathsf{Calculus}^{\uparrow}$ *local approximation row naming the source function only through finite observation histories.*
2. *x is the* $\mathsf{Real}^{\uparrow}$ *center row at which the jet is read.*
3. *k is the finite order budget for the displayed jet.*
4. *J is the finite list of derivative-read rows, each routed through* $\mathsf{Derivative}^{\uparrow}$ *and indexed by an order at most k.*
5. *P is the* $\mathsf{Poly}^{\uparrow}$ *readback row whose coefficients are the displayed jet entries.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row used when coefficients or center data are read as regular rational names.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for finite factorial, power, and tolerance accounting.*
8. *H records componentwise* hsame *transport for the center, order, derivative rows, polynomial readback, regular-rational row, dyadic ledger, route, provenance, and local name.*
9. *C records the displayed* Cont *replay from finite calculus observations to the derivative rows, polynomial row, tolerance ledger, provenance, and local name.*
10. *G is the* Pkg *provenance over* $\mathsf{TaylorSeries}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{TaylorSeries}^{\uparrow}}$ *row.*

The carrier has no coordinate for infinite series convergence, analytic continuation, a radius-of-convergence theorem, a remainder estimate beyond the displayed finite order, host smoothness, quotient equality of functions, or ambient real completeness.

Theorem 6808.2 (TaylorSeries NameCert obligations)**.** *For an accepted* $\mathsf{TaylorSeries}^{\uparrow}$ *carrier* $T = (A, x, k, J, P, R, D, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TaylorSeries}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite center, order, derivative rows, polynomial readback, regular-rational tolerance row, dyadic arithmetic ledger, transports, replay route, provenance, and local name; derivative-to-polynomial exactness up to the displayed order k; finite coefficient stability under componentwise* hsame *transport; and ledger non-escape excluding analytic convergence, remainder bounds beyond k, host smoothness, quotient function equality, selected infinite sums, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6808.1. The tuple displays exactly the finite center row, order budget, derivative rows, polynomial readback, regular-rational tolerance row, dyadic arithmetic ledger, transport rows, replay route, provenance, and local name.

Derivative-to-polynomial exactness is also finite. The row J lists only derivative reads of order at most k, and the row P reads those entries as coefficients of the finite polynomial surface rather than as an infinite expansion.

Stability follows from H and C. Componentwise hsame transport preserves the displayed center, order, coefficient, and tolerance rows, while replay through C keeps the calculus, derivative, polynomial, regular-rational, and dyadic rows in the same order.

No remaining carrier coordinate names convergence, a remainder theorem, a radius of convergence, host smoothness, quotient equality of functions, a selected infinite sum, or real completeness. The local certificate is therefore exhausted by the finite Taylor-jet route. □

Theorem 6808.3 (TaylorSeries finite-jet non-escape)**.** *Every consumer-facing read of an accepted* $\mathsf{TaylorSeries}^{\uparrow}$ *packet factors through the finite rows*

$$A, x, k, J, P, R, D, H, C, G, N.$$

Consequently the packet exposes only a finite Taylor jet and its polynomial readback, not an infinite Taylor series convergence theorem, analytic continuation, a radius-of-convergence object, a host smoothness principle, quotient equality of functions, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier rows of Definition 6808.1. A consumer first reads the finite calculus source row A, the Real center x, and the order budget k.

The derivative data are then confined to J. Since J is indexed only by orders at most k, the polynomial row P can read exactly those entries as finite coefficients and cannot expose an infinite tail.

The tolerance and arithmetic support rows R and D account for regular-rational and dyadic coefficient reads. Transport, replay, provenance, and local naming through H, C, G, N preserve that finite route.

Because the carrier lists no convergence, analytic-continuation, radius, host-smoothness, quotient-function, selected-infinite-sum, or real-completeness coordinate, finite route exhaustion prevents any such principle from escaping the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{TaylorSeries}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaylorSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6808.1, Definition 6808.2, and Definition 6808.3 seed the finite Taylor-jet packet over calculus observations, derivative rows, polynomial readback, Real center data, regular-rational tolerances, and dyadic arithmetic ledgers.

Formal verification: FormalStatus(NameCert$_{\mathsf{TaylorSeries}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close analytic convergence, Taylor remainder theorems, a radius of convergence, host smoothness, quotient equality of functions, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-to-polynomial exactness, finite coefficient stability, and finite-jet non-escape for BEDC.Derived.TaylorSeriesUp.

Constructive story: A TaylorSeries$^{\uparrow}$ packet is generated from a finite calculus observation row, a Real center, a finite order budget, displayed derivative rows, a polynomial readback, regular-rational tolerance data, dyadic arithmetic ledgers, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 6809

A Concrete Naming Certificate for $\mathsf{RealCompletionModulusEnvelope}^{\uparrow}$

The $\mathsf{RealCompletionModulusEnvelope}^{\uparrow}$ packet realizes the finite modulus handoff isolated by the real-completeness vision of chapter 9238. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the Real-induced uniform Cauchy-filter completion route of chapter 6564. The packet gives later completion consumers a named envelope for regular-Cauchy modulus data without asserting ambient $\mathsf{Real}^{\uparrow}$ completeness, selecting limits, quotienting streams, or importing countable choice.

Definition 6809.1 (RealCompletionModulusEnvelope carrier)**.** *A* $\mathsf{RealCompletionModulusEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, Q, D, R, U, \mu, W, H, C, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the observed regular-Cauchy input by finite stream histories.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational sequence values.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare displayed windows and precision requests.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, Q, D have been replayed.*
5. *U is the* $\mathsf{RealUniformCauchyFilterCompletion}^{\uparrow}$ *handoff row recording the completion-facing uniform-Cauchy route as finite evidence.*
6. *μ is the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row, read only as a finite family of threshold requests used by the packet.*
7. *W is the finite window ledger pairing each inspected tolerance with the stream and regular-rational rows it controls.*
8. *H records componentwise* hsame *transport for the stream, regular-rational, dyadic, Real, uniform-completion, modulus, window, route, provenance, and local name rows.*
9. *C records the displayed* Cont *replay from stream observations to regular-rational readback, dyadic tolerance, Real seal, uniform-completion handoff, modulus window, provenance, and local name.*

10. *P is the* Pkg *provenance over* $\mathsf{RealCompletionModulusEnvelope}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealUniformCauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionModulusEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for ambient Real completeness, a selected limit, quotient stream equality, countable choice, a host completion object, or an unbounded modulus oracle.

Theorem 6809.2 (RealCompletionModulusEnvelope NameCert obligations)**.** *For an accepted* $\mathsf{RealCompletionModulusEnvelope}^{\uparrow}$ *carrier* $M = (S, Q, D, R, U, \mu, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionModul}}$ *surface consists exactly of carrier admission for the stream, regular-rational, dyadic, Real, uniform-completion, modulus, finite-window, transport, replay, provenance, and local name rows; modulus-window exactness for the displayed finite tolerance requests; Real-seal handoff after the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows have been replayed; uniform-completion compatibility through* U*; and ledger non-escape excluding ambient completeness, selected limits, quotient stream equality, countable choice, host completion, and unbounded modulus oracles.*

Proof. Carrier admission is projection from Definition 6809.1. The tuple displays exactly the stream window, regular-rational readback, dyadic tolerance, Real seal, uniform-completion handoff, modulus schedule, finite window ledger, transport, replay, provenance, and local name rows.

The modulus-window exactness is finite. The row μ is read only through the window ledger W, and each inspected tolerance request is paired with the visible S, Q, D rows before the Real seal R is available.

Uniform-completion compatibility is the handoff row U. It records the same displayed regular-Cauchy route consumed by the Real-induced uniform Cauchy-filter completion packet, but it does not add a selected limit or an ambient complete carrier.

Finally, H, C, P, N transport, replay, package, and name only the displayed route. Since no carrier coordinate names ambient completeness, quotient stream equality, countable choice, a host completion object, a selected limit, or an unbounded modulus oracle, none of those principles can be exported by the local certificate. □

Falsifiable prediction: Every accepted RealCompletionModulusEnvelopeUp read exposes StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, a RealUniformCauchyFilterCompletion handoff, a CauchyModulus finite schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any completion-facing consumer can inspect the packet.

Independence witness: streamname, regseqrat, dyadicratcore, real, real-uniform-cauchy-filter-completion: removing any one of these sibling routes leaves the envelope unable to display the corresponding stream window, regular-rational readback, dyadic tolerance, Real seal, or uniform-completion handoff row.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionModulusEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionModulusEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6809.1 and Definition 6809.2 seed the finite regular-Cauchy modulus envelope over stream windows, regular-rational readback, dyadic tolerances, Real seals, uniform-completion handoff, and finite modulus schedules.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionModulusEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient stream equality, countable choice, host completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite modulus-window exactness, Real-seal handoff, uniform-completion compatibility, and ledger non-escape for BEDC.Derived.RealCompletionModulusEnvelopeUp.

Constructive story: A RealCompletionModulusEnvelope$^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledgers, a RealUp seal, a RealUniformCauchyFilterCompletion handoff, a finite CauchyModulus schedule, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 6810

A Concrete Naming Certificate for $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$

Following Aronszajn–Panitchpakdi and Isbell on injective metric envelopes, the $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$ packet records the finite NameCert surface by which a displayed metric source is admitted to an injective-envelope metric boundary. It sits over the metric source of chapter 57, reads the Isbell tight-span carrier of chapter 2361, exposes the hyperconvex handoff of chapter 4013, transports the source through the metric embedding route of chapter 3339, keeps the completion boundary of chapter 128 visible, and seals all radius comparisons through chapter 38. The packet names a finite envelope admission route; it does not select a host hull point, assert arbitrary-family intersection, identify quotient completions, invoke countable choice, or close ambient real completeness.

Definition 6810.1 (Injective envelope metric carrier)**.** *An* $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, I, J, HX, K, R, T, U, V, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the inspected point classifier and distance observations.*
2. *I is the* $\mathsf{IsbellTightSpan}^{\uparrow}$ *envelope row, read through finite distance-envelope inequalities, extremal witnesses, one-point extension tests, separated comparison, and Real readback.*
3. *J is the* $\mathsf{MetricEmbedding}^{\uparrow}$ *row, recording the displayed isometric source inclusion into the envelope boundary.*
4. *HX is the* $\mathsf{HyperconvexMetric}^{\uparrow}$ *handoff row, exposing pairwise-compatible ball data and the finite intersection request only after M, I, J have been read.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion-boundary row, keeping completion-neighbour use downstream of the metric source, envelope row, embedding row, and hyperconvex handoff.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *radius seal row for all distance, envelope, ball, and separated-comparison readings.*
7. *T records componentwise* hsame *transport for M, I, J, HX, K, R, P, N and for the replay row.*
8. *U records displayed* Cont *replay from metric observations to tight-span envelopes, embedding transport, hyperconvex ball handoff, completion boundary, and Real radius seal.*
9. *V is the provenance route through the sibling certificates named above, including the local source row that prevents the envelope from being reread as an ungrounded host hull.*

10. *P is the* Pkg *provenance over* $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{IsbellTightSpan}^{\uparrow}$, $\mathsf{MetricEmbedding}^{\uparrow}$, $\mathsf{HyperconvexMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{InjectiveEnvelopeMetric}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $M, I, J, HX, K, R, T, U, V, P, N$. It has no coordinate for a selected injective hull, arbitrary ball-family intersection, quotient completion representative, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 6810.2 (Injective envelope metric NameCert obligations)**.** *For every accepted* $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$ *carrier $E = (M, I, J, HX, K, R, T, U, V, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{InjectiveEnvelopeMetric}^{\uparrow}}$ *surface consists exactly of metric-source exposure, Isbell tight-span envelope admission, metric-embedding transport, hyperconvex handoff, completion-boundary visibility, Real radius sealing, componentwise transport, displayed replay, sibling provenance, package provenance, and local naming.*

Proof. Project the carrier of Definition 6810.1. The rows $M, I, J, HX, K, R, T, U, V, P, N$ are the only displayed data admitted by the packet.

Use the metric source chapter for M, the Isbell tight-span obligations for I, and the metric embedding route for J. These rows fix the source, envelope admission, and isometric inclusion before any completion-facing read is available.

Use the hyperconvex metric obligations for HX and the complete metric boundary for K. The hyperconvex row can be consumed only as a finite handoff over the same source and envelope data, while the completion row remains downstream of that handoff.

Finally read the Real radius seal and the structural rows T, U, V, P, N. They transport, replay, source, package, and name the same finite route. Since no remaining coordinate stores a selected hull point, arbitrary-family intersection, quotient completion representative, choice selector, or ambient completeness witness, the listed rows exhaust the local NameCert surface. □

Theorem 6810.3 (Injective envelope metric hyperconvex handoff)**.** *Every completion-neighbour or Real-radius consumer of an accepted* $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$ *carrier must read*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{IsbellTightSpan}^{\uparrow} \longmapsto \mathsf{MetricEmbedding}^{\uparrow} \longmapsto \mathsf{HyperconvexMetric}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows M, I, J, HX, K, R before it treats the packet as an injective-envelope metric boundary.

Proof. Start with the carrier projection. The only route to the hyperconvex handoff row HX passes through the metric source M, the Isbell envelope row I, and the metric embedding row J.

Apply the Isbell tight-span metric handoff. It keeps finite envelope inequalities, extremal witnesses, one-point extension tests, separated comparison, completion readback, and Real readback visible before an envelope consumer can proceed.

Apply the hyperconvex metric ball-intersection handoff. It reads pairwise-compatible ball data and the finite intersection request over the same metric and Real radius rows; it does not introduce a selected global hull point or an arbitrary-family intersection coordinate.

The complete metric row K and Real radius row R are downstream of those sibling handoffs. Transport, replay, provenance, and local naming preserve that route without adding a quotient completion representative, choice function, or ambient completeness principle. Thus the injective-envelope consumer receives exactly the displayed finite handoff. □

Falsifiable prediction: Every accepted $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$ consumer that reaches a hyperconvex, completion, or Real-radius read without first exposing the displayed metric source, Isbell tight-span envelope, metric embedding, and sibling hyperconvex handoff refutes the carrier surface.

Independence witness: metric, isbell-tight-span, hyperconvex-metric, metricembedding, completemetric, real: no listed sibling supplies the whole eleven-row packet $E = (M, I, J, HX, K, R, T, U, V, P, N)$, because each sibling contributes only a source, envelope, embedding, ball-intersection handoff, completion boundary, or Real seal while this chapter binds all six faces with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{InjectiveEnvelopeMetric}^{\uparrow}}$.

Constructive story: An $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$ packet is generated from a metric source row, an Isbell tight-span envelope row, a metric embedding row, a hyperconvex handoff row, a complete-metric boundary row, a Real radius seal row, componentwise transports, displayed replay, sibling provenance, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InjectiveEnvelopeMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6810.1, Definition 6810.2, and Definition 6810.3 seed the finite injective-envelope metric admission route over the displayed metric, Isbell, embedding, hyperconvex, completion, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InjectiveEnvelopeMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected injective hulls, arbitrary ball-family intersections, quotient completion representatives, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires carrier admission, sibling envelope routing, metric-embedding transport, hyperconvex handoff, completion-boundary visibility, and Real radius sealing for the same packet.

Chapter 6811

A Concrete Naming Certificate for $\mathsf{RealitySignatureErrorBudget}^{\uparrow}$

Following Bishop-style error accounting for finite approximations and the reality-constrained signature discipline of chapter 9414, the $\mathsf{RealitySignatureErrorBudget}^{\uparrow}$ packet records the bounded mismatch budget attached to a physical-signature classifier. It sits beside the dyadic tolerance surface of chapter 1761, the model-facing budget of chapter 1184, the signature-fit route of **??**, and the tower packet of chapter 1128. The packet names finite classifier, dyadic tolerance, tower-fit, mismatch, and ledger rows; it does not assert physical truth, final model selection, unbounded validation, probabilistic calibration, selected hidden states, or ambient real completeness.

Definition 6811.1 (RealitySignatureErrorBudget carrier)**.** *A* $\mathsf{RealitySignatureErrorBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, C, D, M, T, F, E, L, H, K, P, N)$$

with the following displayed rows:

1. *S is the physical-signature bundle row naming the finite reality-facing observations currently under inspection.*
2. *C is the signature classifier row that compares observed and model-generated signatures only through the displayed bundle S.*
3. *D is the* $\mathsf{DyadicErrorBudget}^{\uparrow}$ *tolerance row assigned to the classifier comparison.*
4. *M is the* $\mathsf{RealityConstrainedModelErrorBudget}^{\uparrow}$ *row recording the model-side mismatch envelope.*
5. *T is the tower-fit row, read through* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ *and the approximation-tower source of chapter 9414.*
6. *F is the finite fit ledger that records which signature comparisons remain within D after the model budget M and tower row T have been displayed.*
7. *E is the visible error-surface row for comparisons that leave the declared budget.*
8. *L is the audit ledger tying S, C, D, M, T, F, E to the same observation window and physical-signature source.*
9. *H records componentwise* hsame *transport for the signature, classifier, tolerance, model-budget, tower-fit, fit-ledger, error-surface, audit, replay, provenance, and local naming rows.*

10. *K records displayed* Cont *replay from signature observations through the classifier and budget rows to the fit ledger and error surface.*
11. *P is the* Pkg *provenance over* $\mathsf{RealitySignatureErrorBudget}^{\uparrow}$, $\mathsf{DyadicErrorBudget}^{\uparrow}$, $\mathsf{RealityConstrainedModelErrorBu}$ $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealitySignatureErrorBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for physical truth, final model selection, unbounded validation, probabilistic calibration, hidden-state choice, host real equality, or ambient completeness.

Theorem 6811.2 (RealitySignatureErrorBudget NameCert obligations)**.** *For every accepted* RealitySignatureErrorB *carrier $R = (S, C, D, M, T, F, E, L, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealitySignatureErrorBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for the physical-signature bundle, signature classifier, dyadic tolerance, model-error budget, tower-fit row, fit ledger, error surface, audit ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. The fit ledger F may be consumed only after S, C, D, M, T are displayed, and the error surface E remains visible whenever the classifier leaves the declared budget.*

Proof. Project the carrier of Definition 6811.1. The accepted packet exposes the physical-signature bundle, classifier, dyadic tolerance, model-budget, tower-fit row, fit ledger, error surface, audit ledger, and structural rows.

The source rows come first. The classifier C is tied to the displayed signature bundle S, while D and M provide the tolerance and model-side mismatch envelope before any fit ledger is read.

The tower row T then anchors the comparison in the approximation-tower route. The fit ledger F records only comparisons that pass through S, C, D, M, T, and the error surface E records the visible boundary when the declared budget is exceeded.

Finally L, H, K, P, N preserve the same finite route under audit, transport, replay, provenance, and local naming. Since no other carrier coordinate is present, the local certificate cannot export physical truth, final model selection, unbounded validation, probabilistic calibration, hidden-state choice, host real equality, or ambient completeness. □

Theorem 6811.3 (RealitySignatureErrorBudget tower-fit handoff)**.** *Every* $\mathsf{RealitySignatureErrorBudget}^{\uparrow}$ *consumer that reads a physical-signature budget must factor through*

$$\mathsf{RealityConstrainedSignatureFit}^{\uparrow},\quad \mathsf{DyadicErrorBudget}^{\uparrow},\quad \mathsf{RealityConstrainedModelErrorBudget}^{\uparrow},\quad \mathsf{RealityConstraine}$$

The handoff exports only the displayed signature bundle, classifier, dyadic tolerance, model-budget envelope, tower-fit row, fit ledger, error surface, audit ledger, transport, replay, provenance, and local naming. It exports no final physical-truth oracle, hidden-state selector, unbounded validation theorem, probabilistic calibration, host real equality, or ambient completeness claim.

Proof. Start with the NameCert obligations of Definition 6811.2. They force the source signature bundle, classifier, dyadic tolerance, model-budget row, and tower-fit row to be displayed before the fit ledger is read.

Read the sibling routes in order. The signature-fit packet supplies the classifier boundary, the dyadic error-budget packet supplies the finite tolerance accounting, the model-error budget supplies the mismatch envelope, and the tower packet supplies the approximation-level fit row.

The audit, transport, replay, provenance, and local naming rows keep those sibling routes attached to one accepted packet. The carrier contains no coordinate for the excluded physical,

probabilistic, hidden-state, host-equality, or completeness claims, so the handoff exports only the finite budget surface stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealitySignatureErrorBudget}\uparrow}$.

Constructive story: A $\mathsf{RealitySignatureErrorBudget}^{\uparrow}$ packet is generated from a physical-signature bundle, signature classifier, DyadicErrorBudgetUp tolerance row, RealityConstrainedModelErrorBudgetUp mismatch envelope, RealityConstrainedTowerPacketUp tower-fit row, fit ledger, error surface, audit ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealitySignatureErrorBudget}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6811.1, Definition 6811.2, and Definition 6811.3 seed the finite physical-signature error-budget route through signature-fit, dyadic tolerance, model-error, tower-fit, ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealitySignatureErrorBudget}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim physical truth, final model selection, unbounded validation, probabilistic calibration, hidden-state choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signature classifier exactness, dyadic tolerance routing, model-budget compatibility, tower-fit stability, fit-ledger visibility, error-surface non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RealitySignatureErrorBudgetUp.

Chapter 6812

A Concrete Naming Certificate for $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$

Following Riemann, Caratheodory, and Bishop-style constructive complex analysis, the ConstructiveRiemannMappin packet records the finite NameCert surface needed to read a displayed simply connected planar domain through a normalized disk map route. It sits over the holomorphic source of chapter 68, the complex carrier of chapter 39, the complex-topology disk and compact-window rows of chapter 77, the normal-family surface of chapter 3693, the pointed disk control of chapter 3796, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the displayed approximation, normalization, and nonescape rows; it does not assert host open-cover compactness, select a conformal map, identify quotient function equality, invoke countable choice, or import ambient $\mathsf{Complex}^{\uparrow}$ completeness.

Definition 6812.1 (Constructive Riemann mapping carrier)**.** *A* $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, C, T, H, M, S, W, Q, E, N, Z, P, L)$$

with the following displayed rows:

1. *D is the domain row, naming a connected simply connected planar source through* $\mathsf{CplxTopo}^{\uparrow}$ *open-disk, compact-window, and boundary-separation data.*
2. *C is the* $\mathsf{Complex}^{\uparrow}$ *coordinate row for the displayed source point, disk center, boundary witnesses, and target disk coordinates.*
3. *T is the* $\mathsf{Holomorphic}^{\uparrow}$ *trial-map family row over the source and target disk surfaces.*
4. *H is the normalization row, recording the selected base point, disk origin target, positive derivative-orientation ledger, and boundary separation budget as displayed finite data.*
5. *M is the* $\mathsf{MontelTheorem}^{\uparrow}$ *normal-family row consumed only after the compact-window and local-boundedness data in D, T, H have been exposed.*
6. *S is the* $\mathsf{SchwarzLemma}^{\uparrow}$ *pointed-disk control row, used to compare any two normalized candidates through the same displayed disk route.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule for trial maps, compact windows, and boundary tests.*

8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the real and complex coordinate windows named by W.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for radii, separation budgets, and modulus comparisons.*
10. *N is the nonescape row excluding host open-cover compactness, selected conformal maps, quotient function equality, countable choice, and ambient* $\mathsf{Complex}^{\uparrow}$ *completeness from the packet.*
11. *Z records componentwise* hsame *transport for all displayed rows.*
12. *P records displayed* Cont *replay and* Pkg *provenance over* $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{CplxTopo}^{\uparrow}$, $\mathsf{MontelTheorem}^{\uparrow}$, $\mathsf{SchwarzLemma}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *L is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRiemannMapping}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, C, T, H, M, S, W, Q, E, N, Z, P, L$. It has no coordinate for a host-chosen conformal equivalence, quotient equality of holomorphic functions, arbitrary open-cover compactness, countable-choice selection, or completed ambient complex function space.

Theorem 6812.2 (Constructive Riemann mapping NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$ *carrier*

$$R = (D, C, T, H, M, S, W, Q, E, N, Z, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveRiemannMapping}^{\uparrow}}$ *surface consists exactly of domain admission through D, complex-coordinate admission through C, holomorphic trial-family exposure through T, normalization through H, normal-family compact-window routing through M, pointed-disk comparison through S, finite observation through W, regular rational readback through Q, Real seal admission through E, nonescape through N, componentwise transport through Z, displayed replay and provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 6812.1. The domain, complex-coordinate, holomorphic-family, normalization, normal-family, Schwarz-control, observation, readback, seal, nonescape, transport, provenance, and local-name rows are the complete visible packet.

The analytic route starts with D, C, T, H. These rows expose the source domain, the complex coordinates, the trial holomorphic family, and the normalization ledger before any normal-family or disk comparison read is available.

Next read M, S, W, Q, E. The normal-family row is tied to the displayed compact windows and local boundedness data, while the Schwarz row compares normalized candidates only through the same pointed disk route. The stream, regular rational, and Real rows keep the observation and modulus data finite.

Finally N, Z, P, L preserve the boundary. Since the packet has no coordinate for host open-cover compactness, selected maps, quotient function equality, countable choice, or ambient complex completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6812.3 (Constructive Riemann mapping normal-family route)**.** *Every normal-family read exported by an accepted* $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$ *packet factors through the displayed route*

$$D, C, T, H \longmapsto M \longmapsto S \longmapsto W, Q, E \longmapsto N, Z, P, L.$$

Thus a consumer may inspect compact-window normality, normalized holomorphic candidates, pointed disk comparison, finite observation windows, regular rational readbacks, Real seals, transport, replay, provenance, and local naming. It cannot read the packet as an ambient existence theorem for a selected conformal map.

Proof. Begin with the source rows. The domain row D and complex coordinate row C supply the displayed planar source, target disk coordinates, compact windows, and boundary-separation data.

The trial family and normalization rows T, H then provide the only admissible input to M. The $\mathsf{MontelTheorem}^{\uparrow}$ row can be consumed only through these displayed compact windows and local boundedness ledgers, so the route is normal-family data rather than open-cover compactness.

Use S after M. The $\mathsf{SchwarzLemma}^{\uparrow}$ row compares normalized candidates through the pointed disk route and prevents the handoff from becoming an unconstrained function-space equality.

The observation rows W, Q, E keep every approximation and modulus comparison inside finite StreamName, RegSeqRat, and Real seals. The structural rows N, Z, P, L then transport, replay, source, and name the same route without adding a selected conformal map. □

Theorem 6812.4 (Constructive Riemann mapping Real and Complex seal nonescape)**.** *Any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Complex}^{\uparrow}$ *read exported by an accepted* $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$ *packet remains inside the displayed rows* C, W, Q, E, Z, P, L *and is scoped by the domain, trial-family, normalization, normal-family, Schwarz-control, and nonescape rows* D, T, H, M, S, N*. No consumer may reinterpret those seals as host open-cover compactness, a selected conformal map, quotient equality of holomorphic functions, countable choice, or ambient* $\mathsf{Complex}^{\uparrow}$ *completeness.*

Proof. Project the carrier and isolate the seal rows. The complex coordinate row C, stream schedule W, regular rational readback Q, and Real seal E are displayed coordinates of the same packet, with transport, replay, provenance, and local naming stored in Z, P, L.

The analytic rows D, T, H, M, S scope those seals. A Real or Complex read reaches the source domain, trial family, normalization, normal-family compact-window route, and pointed disk comparison before it can use any sealed coordinate.

The nonescape row N records the excluded endpoints as absent carrier coordinates. Therefore a sealed real or complex observation remains finite BEDC data and cannot be retyped as open-cover compactness, a chosen conformal equivalence, quotient function equality, countable choice, or ambient complex completeness. □

Falsifiable prediction: If a purported $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$ packet exports a normalized disk map without displaying the MontelTheoremUp normal-family row and the SchwarzLemmaUp pointed comparison row, it is not a $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$ carrier.

Independence witness: holomorphic, complex, complex-topology, montel-theorem, schwarz-lemma, streamname, regseqrat, real: no listed sibling supplies the joint carrier containing displayed domain rows, holomorphic trial-family rows, normalization, normal-family routing, pointed disk comparison, finite observation, regular rational readback, Real and Complex seals, nonescape, transport, replay, provenance, and local NameCert data while refusing host open-cover compactness, selected conformal maps, quotient function equality, countable choice, and ambient Complex completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveRiemannMapping}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveRiemannMapping}^{\uparrow}$ packet is generated from a ComplexTopology domain row, Complex coordinate rows, Holomorphic trial-map family rows, a normalization ledger, MontelTheorem normal-family

routing, SchwarzLemma pointed-disk comparison, StreamName finite observation windows, RegSeqRat readback, Real seals, nonescape, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ConstructiveRiemannMapping}^{\uparrow}}$, seed)

Scope closed: Definition 6812.1, Definition 6812.2, Definition 6812.3, and Definition 6812.4 seed the finite normal-family and seal-nonescape route for constructive Riemann mapping data.

Formal verification: FormalStatus(NameCert$_{\text{ConstructiveRiemannMapping}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host open-cover compactness, selected conformal maps, quotient function equality, countable choice, ambient Complex completeness, Lean verification, or bridge checking for ConstructiveRiemannMapping$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, domain and complex-coordinate exposure, holomorphic trial-family routing, normalization, normal-family exactness, pointed disk comparison, finite observation, regular rational readback, Real and Complex seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveRiemannM

Chapter 6813

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionSpace}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyCompletionSpace}^{\uparrow}$ packet records the L10 completion carrier whose points are read through regular Cauchy rational data rather than through an ambient quotient-completion theorem. It uses the dyadic tolerance arithmetic of chapter 291, the finite observation schedules of chapter 126, the regular rational tail surface of chapter 301, and the terminal sealing discipline of chapter 38. The chapter names the space-level carrier sitting behind the route and functor fragments already visible in the Cauchy and completion dossiers.

Definition 6813.1 (Regular Cauchy completion space carrier)**.** *A* $\mathsf{RegularCauchyCompletionSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, Q, W, D, R, L, E, H, C, P, N)$$

with the following roadmap rows:

1. *Traditional target. X names the Bishop–Bridges regular Cauchy completion space whose completed points are represented by regular rational Cauchy data.*
2. *BEDC source. Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row and W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row through which every finite precision read is opened.*
3. *Carrier. D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational tail has been inspected.*
4. *Classifier. The local classifier compares accepted packets only through $X, Q, W, D, R, L, E, H, C, P, N$ and never through host quotient equality or selected limit representatives.*
5. *Stability obligations. L records tail stability for later windows preserving the same regular rational source, dyadic tolerance ledger, and Real seal route.*
6. *Ledger. E records the completion ledger row: every completed point read factors through the displayed Q, W, D, R, L rows before a space-level consumer sees X.*
7. *Core theorem list. The local seed surface is Definition 6813.2 and Definition 6813.3.*
8. *Exactness predicate. Exactness means that the space-level completion read is precisely the displayed route from regular Cauchy rational tails through finite windows, dyadic tolerances, and the Real seal.*

9. *Standard bridge status. No standard bridge is asserted in this chapter; the packet is a paper-side NameCert carrier awaiting a bridge theorem.*

10. *Status. H supplies componentwise* hsame *transport, C supplies displayed* Cont *replay, P supplies* Pkg *provenance over the listed sibling certificates, and N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for countable choice, a selected limit, quotient stream equality, host metric completion, trichotomy, or an ambient completeness principle.

Theorem 6813.2 (Regular Cauchy completion space NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionSpace}^{\uparrow}$ *packet*

$$S = (X, Q, W, D, R, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSpace}^{\uparrow}}$ *surface consists exactly of the space row X, regular rational source row Q, finite* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, terminal* $\mathsf{Real}^{\uparrow}$ *seal row R, tail-stability row L, completion ledger row E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N.*

Proof. Project the carrier of Definition 6813.1. Its analytic rows are X, Q, W, D, R, L, E, and its structural rows are H, C, P, N.

The source row Q and window row W expose the regular rational tail at a finite precision. The dyadic row D supplies tolerance data for that read, and the Real seal row R is reached only after those finite rows have been consumed.

Rows L and E keep the tail-stability and completion-ledger obligations attached to the same packet. Since H, C, P, N only transport, replay, source, and name these rows, the displayed list exhausts the local NameCert surface. □

Theorem 6813.3 (Regular Cauchy completion space L10 handoff)**.** *Every L10 completion consumer of an accepted* $\mathsf{RegularCauchyCompletionSpace}^{\uparrow}$ *carrier reads the completed point through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RegularCauchyCompletionSpace}^{\uparrow}.$$

The handoff exports no selected limit, quotient stream equality, countable-choice scheduler, host metric completion, or ambient Real completeness theorem.

Proof. Apply Definition 6813.2. The rows Q, W, D, R, L, E place the regular rational source, finite window, dyadic tolerance ledger, Real seal, tail-stability witness, and completion ledger in one displayed packet.

The structural rows H, C, P, N preserve that same route under componentwise transport, replay, provenance, and local naming. They do not add a second path from a host completion object to the completed point.

Thus a consumer reaches the space-level completion carrier only after the regular Cauchy tail has passed through the finite observation and Real-seal route. The refused readings would need coordinates absent from S. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyCompletionSpace}^{\uparrow}$ packet is generated from a space row, RegSeqRat source, StreamName window, DyadicRatCore tolerance ledger, Real seal, tail-stability row, completion ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionSpace}\uparrow}$, seed)

Scope closed: Definition 6813.1, Definition 6813.2, and Definition 6813.3 seed the space-level L10 regular Cauchy completion carrier and its finite read route.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionSpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host metric completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window stability, tolerance exactness, Real-seal handoff, completion-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionSpaceUp.

Chapter 6814

A Concrete Naming Certificate for $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$

Following Gagliardo and Nirenberg on interpolation inequalities, the $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which a Sobolev derivative window, a norm ledger, and a metric or complete-metric source window hand an interpolation estimate to compactness-facing consumers. It sits after the $\mathsf{Sobolev}^{\uparrow}$ carrier of chapter 440, the norm surface of chapter 89, the compact-metric route of chapter 129, and the regular rational readback of chapter 301. The packet names only finite rows: derivative windows, exponent comparisons, norm estimates, compact handoff data, transport, replay, provenance, and local $\mathsf{NameCert}$ evidence.

Definition 6814.1 (Gagliardo-Nirenberg finite-window carrier)**.** *A* $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, N, M, D, E, R, K, H, C, P, L)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, carrying the displayed function, weak-derivative budget, integrability row, and local domain window.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *target row, recording the lower-order and higher-order norm reads used by the interpolation estimate.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *base row whose finite balls and Cauchy-boundary data supply the inspection scale.*
4. *D is the finite derivative-window row, listing exactly the derivative orders, test windows, and source tolerances inspected by the estimate.*
5. *E is the interpolation exponent ledger, recording the dimension, derivative orders, norm exponents, interpolation weight, and admissibility comparisons as finite rational or regular-rational data.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for tolerance, exponent, and norm-bound observations.*
7. *K is the compact handoff row, exposing only the* $\mathsf{CompactMetric}^{\uparrow}$ *or compact-window data needed by L10/L11 compactness consumers.*
8. *H records componentwise* hsame *transport for the Sobolev, norm, metric, derivative-window, exponent-ledger, readback, compact-handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from requested precision to derivative windows, norm ledgers, regular-rational readback, and compact handoff rows.*
10. *P is the* Pkg *provenance over* $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}}$ *evidence.*

The classifier compares accepted packets only through $S, N, M, D, E, R, K, H, C, P, L$. It has no coordinate for a host Sobolev embedding theorem, nonconstructive compact embedding, quotient function equality, selected representative, countable-choice schedule, or ambient completed function space.

Theorem 6814.2 (Gagliardo-Nirenberg finite-window NameCert obligations)**.** *For every accepted* $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$ *carrier*

$$G = (S, N, M, D, E, R, K, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Sobolev}^{\uparrow}$ *source row, norm-row exposure through* $\mathsf{Norm}^{\uparrow}$*, metric or complete-metric inspection through M, finite derivative-window exposure through D, interpolation exponent-ledger exactness through E,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, compact handoff exposure through K, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 6814.1. Its analytic rows are S, N, M, D, E, R, K, and its structural rows are H, C, P, L.

The interpolation estimate is finite at every read. A consumer first sees the $\mathsf{Sobolev}^{\uparrow}$ derivative source S, the $\mathsf{Norm}^{\uparrow}$ target ledger N, the metric or complete-metric inspection row M, and the derivative-window row D before it may inspect the exponent ledger E.

The readback and handoff rows keep the estimate attached to finite data. The $\mathsf{RegSeqRat}^{\uparrow}$ row R records tolerance and bound observations, while K exposes only the compact-window information needed by downstream compactness routes.

Finally H, C, P, L transport, replay, source, and name the same packet. Since no row carries host embedding, quotient-function equality, selected representatives, countable choice, or completed function-space data, the listed rows exhaust the NameCert obligation surface. □

Theorem 6814.3 (Gagliardo-Nirenberg finite-window interpolation handoff)**.** *Every L10/L11 compactness or completion consumer of an accepted* $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$ *packet receives the interpolation estimate only through the finite route*

$$\mathsf{Sobolev}^{\uparrow} \longmapsto \mathsf{Norm}^{\uparrow} \longmapsto (\mathsf{Met}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}) \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow}.$$

The handoff may pass a displayed derivative-window estimate, exponent ledger, regular-rational tolerance readback, and compact-window row to later finite-window compactness chapters, but it exports no nonconstructive compact embedding theorem, global Sobolev embedding strength, quotient function equality, selected subsequence, countable choice, or ambient completed Sobolev carrier.

Proof. Start from the obligations of Definition 6814.2. They force the Sobolev source, norm target, metric inspection row, derivative windows, exponent ledger, readback row, and compact handoff row to appear in the same finite packet.

Read the sibling route in order. The $\mathsf{Sobolev}^{\uparrow}$ row supplies weak-derivative data, $\mathsf{Norm}^{\uparrow}$ supplies lower-order and higher-order norm observations, $\mathsf{Met}^{\uparrow}$ or $\mathsf{CompleteMetric}^{\uparrow}$ supplies inspection scale, and $\mathsf{RegSeqRat}^{\uparrow}$ supplies rational tolerance readback before the compact handoff row K is exposed.

The structural rows H, C, P, L keep that route stable under componentwise transport and replay. The compactness consumer receives a finite interpolation handoff only, not an ambient compact embedding theorem or any selected representative absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$ packet is generated from a Sobolev source row, norm target row, metric or complete-metric inspection row, finite derivative-window row, interpolation exponent ledger, RegSeqRat readback, compact handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6814.1, Definition 6814.2, and Definition 6814.3 seed the finite interpolation route for L10/L11 compactness and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close nonconstructive compact embedding strength, global Sobolev embedding theorems, quotient function equality, selected subsequences, countable choice, ambient completed Sobolev carriers, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite derivative-window exposure, exponent-ledger exactness, RegSeqRat readback, compact handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.GagliardoNirenbergFiniteWindowUp.

Chapter 6815

A Concrete Naming Certificate for $\mathsf{EhresmannConnection}^{\uparrow}$

Following Ehresmann's connection concept, the $\mathsf{EhresmannConnection}^{\uparrow}$ packet records a finite horizontal distribution over a displayed bundle projection rather than a covariant derivative on a vector bundle. It is grounded in the bundle projection surface of chapter 97, the general connection packet of chapter 134, the curvature consumer boundary of chapter 135, and the chart-local carrier discipline of chapter 96. The packet exports bundle-local horizontal lift and curvature-read rows; it does not import host smoothness, a principal-bundle action, or Riemannian metric compatibility as primitive data.

Definition 6815.1 (Ehresmann connection carrier)**.** *An* $\mathsf{EhresmannConnection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (B, \Pi, V, H, L, J, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bundle}^{\uparrow}$ *source row, displaying the total-space, base-space, fibre, projection, and local trivialization data visible to the packet.*
2. *Π is the bundle projection row whose fibre over each displayed base observation is available for local inspection.*
3. *V is the vertical-kernel row, recording the displayed kernel of the projection read at the inspected total-space observations.*
4. *H is the horizontal-row assignment, giving a chosen complement to V in each inspected tangent window.*
5. *L is the lift ledger, recording how a displayed base-direction request is lifted through H to a total-space direction over the same projection row.*
6. *J is the classifier row for projection, vertical kernel, horizontal row, lift ledger, and chart-local source data.*
7. *T records componentwise* hsame *transport for B, Π, V, H, L, J and their dependency rows.*
8. *C records displayed* Cont *replay from a base-direction request through projection, vertical-kernel readback, horizontal selection, and lift output.*
9. *P is the* Pkg *provenance over* $\mathsf{EhresmannConnection}^{\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, $\mathsf{Connection}^{\uparrow}$, $\mathsf{Curvature}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{EhresmannConnection}^{\uparrow}}$ *row.*
The carrier therefore names the horizontal distribution and lift ledger as finite bundle-local data. It has no coordinate for a host covariant derivative, a principal connection form, a Riemannian metric, or a global smooth splitting outside the displayed packet.

Theorem 6815.2 (Ehresmann connection NameCert obligation)**.** *For an accepted* $\mathsf{EhresmannConnection}^{\uparrow}$ *carrier* $E = (B, \Pi, V, H, L, J, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EhresmannConnection}^{\uparrow}}$ *surface is exhausted by carrier admission for the displayed bundle projection, vertical-kernel exposure, horizontal-row exposure, lift-ledger exposure, classifier stability under* hsame*, displayed* Cont *replay, provenance, and local naming. A replacement carrier preserving these rows componentwise preserves the accepted Ehresmann-connection packet, and no hidden host connection or metric-compatibility row is added by the name.*

Proof. Project the carrier of Definition 6815.1. The source rows B, Π, V, H, L are the only geometric rows available to the local certificate: B and Π display the bundle projection, V displays the vertical kernel, H displays the horizontal complement, and L displays the lift ledger.

The classifier row J records the admitted comparison of those rows. Componentwise transport through T can therefore preserve the accepted packet only by preserving projection, vertical-kernel, horizontal-row, lift-ledger, and chart-local source data together.

Replay is supplied by C. A base-direction request is accepted only after the projection, vertical-kernel readback, horizontal selection, and lift output have been replayed in that order.

Finally P and N package and name the same finite route. Since no carrier coordinate names a host covariant derivative, principal connection form, Riemannian metric, or global smooth splitting, none of those objects can be exported by the local NameCert row. □

Theorem 6815.3 (Ehresmann connection curvature consumer)**.** *Every* $\mathsf{Curvature}^{\uparrow}$ *consumer of an accepted* $\mathsf{EhresmannConnection}^{\uparrow}$ *carrier reads the horizontal distribution through finite bracket and transport rows derived from the route*

$$\mathsf{Bundle}^{\uparrow} \longmapsto \Pi \longmapsto V \longmapsto H \longmapsto L \longmapsto T, C, P, N.$$

The consumer may inspect the obstruction to horizontal lifts closing under bracket only after the bundle projection, vertical kernel, horizontal row, lift ledger, transport, replay, provenance, and local naming rows have been displayed. It receives no detached curvature tensor, host connection form, or metric-derived curvature object.

Proof. Start with a curvature request. The accepted carrier supplies the horizontal row H only as a complement to the displayed vertical-kernel row V over the projection row Π.

The bracket or transport read needed by a curvature consumer is therefore not a free-standing tensor. It is read through the lift ledger L and then transported and replayed by T and C over the same bundle source B.

The curvature chapter can consume such a route because chapter 135 reads curvature through finite boundary and transport data, while chapter 134 supplies the general connection-facing boundary discipline. Here the Ehresmann packet supplies the horizontal distribution route that those consumers inspect.

Since the carrier exports only $B, \Pi, V, H, L, J, T, C, P, N$, any curvature read that omits the displayed horizontal distribution, lift ledger, transport, replay, provenance, or local name leaves the accepted packet. No detached curvature tensor, host connection form, or metric-derived curvature object is present to be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{EhresmannConnection}^{\uparrow}}$.

Constructive story: An $\mathsf{EhresmannConnection}^{\uparrow}$ packet is generated from a displayed bundle projection, its vertical-kernel row, a horizontal complement row, a lift ledger, classifier stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EhresmannConnection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6815.1, Definition 6815.2, and Definition 6815.3 seed the finite bundle-projection, vertical-kernel, horizontal-row, lift-ledger, classifier, transport, replay, provenance, and local naming surface for Ehresmann connection packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EhresmannConnection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host smoothness, principal-bundle actions, metric compatibility, detached curvature tensors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projection exposure, vertical-kernel exposure, horizontal-row exposure, lift-ledger exactness, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.EhresmannConnectionUp.

Chapter 6816

A Concrete Naming Certificate for $\mathsf{WijsmanConvergence}^{\uparrow}$

Following Wijsman and Kelley, the $\mathsf{WijsmanConvergence}^{\uparrow}$ packet records the convergence read induced by distance-to-set probes on a metric hyperspace. It consumes the Wijsman topology surface of chapter 6182, the metric source of chapter 57, the closed-subset source of chapter 1660, and the finite name/readback chain of chapter 126, chapter 301, and chapter 38. The packet names convergence of hyperspace objects by finite distance-evaluation rows; it is not a host sequential topology, a quotient of closed-set equality, a selected nearest-point principle, or an ambient completeness theorem.

Definition 6816.1 (Wijsman convergence carrier)**.** *A* $\mathsf{WijsmanConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (T, M, H, S, R, E, Q, A, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{WijsmanTopology}^{\uparrow}$ *source row whose distance-evaluation opens supply the convergence classifier.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source row from which all point-to-set distance requests are read.*
3. *H is the* $\mathsf{Hyperspace}^{\uparrow}$ *closed-subset source row carrying the finite hyperspace names being compared.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family for the approximating hyperspace name, the candidate limit name, and the finite probe points.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the stream windows and distance requests.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the displayed distance values.*
7. *Q is the finite convergence-question row, recording which probe windows require the distance-to-set values of the approximating names to agree with the limit name at the displayed rational tolerance.*
8. *A records componentwise* hsame *transport for T, M, H, S, R, E, Q.*
9. *C records displayed* Cont *replay for topology-source admission, metric-source admission, hyperspace-source admission, stream-window inspection, regular rational readback, real comparison, and convergence-question reads.*

10. *P is the* Pkg *provenance over* $\mathsf{WijsmanConvergence}^{\uparrow}$, $\mathsf{WijsmanTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{WijsmanConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, H, S, R, E, Q, A, C, P, N$. It exports no host sequential topology, quotient closed-set equality, selected nearest point, pointwise choice over all probes, or ambient completeness coordinate.

Theorem 6816.2 (Wijsman convergence NameCert obligations)**.** *For every accepted* $\mathsf{WijsmanConvergence}^{\uparrow}$ *carrier*

$$V = (T, M, H, S, R, E, Q, A, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WijsmanConvergence}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Wijsman topology source, metric source, hyperspace source, stream windows, regular rational readbacks, real comparison seal, convergence-question row, transport, replay, provenance, and local naming rows;*
2. *topology-source compatibility, requiring every convergence read to cite the* $\mathsf{WijsmanTopology}^{\uparrow}$ *distance-evaluation surface before it can inspect a probe;*
3. *metric readback exposure, requiring each probe comparison to pass through* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows for the same finite window;*
4. *hyperspace-name attachment, requiring the approximating name and candidate limit name to remain attached to the displayed* $\mathsf{Hyperspace}^{\uparrow}$ *row;*
5. *componentwise* hsame *transport through A, displayed* Cont *replay through C, and* Pkg *provenance through P for the same finite route;*
6. *local naming through N, excluding host sequential topologies, quotient closed-set equality, selected nearest points, pointwise choice over all probes, and ambient completeness.*

No Wijsman convergence obligation is stored outside these rows.

Proof. Project the carrier of Definition 6816.1. The displayed rows contain the Wijsman topology source, metric source, hyperspace names, stream windows, regular rational readbacks, real comparison seal, convergence-question row, transport, replay, provenance, and local naming row.

Use the topology source row T to bind the convergence classifier to the distance-evaluation topology of chapter 6182. A convergence read therefore cannot be a free host sequential-topology read; it must cite the finite Wijsman distance probes.

Read each probe through the metric and name rows. The rows M, H, S, R, E, Q expose the metric distance request, the hyperspace names under inspection, the finite stream windows, the regular rational readbacks, the real comparison seal, and the rational tolerance question as one displayed route.

Finally, A, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinates for quotient closed-set equality, selected nearest points, pointwise choice over all probes, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6816.3 (Wijsman convergence metric readback route)**.** *Every convergence-facing read from an accepted* $\mathsf{WijsmanConvergence}^{\uparrow}$ *carrier factors through*

$\mathsf{WijsmanTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

The exported read is the displayed distance-to-set convergence route over finite metric probes and hyperspace names. It exports no host sequential topology, quotient closed-set equality, selected endpoint or nearest point, pointwise choice over all probes, or ambient completeness of the metric hyperspace.

Proof. Start with the NameCert obligations of Definition 6816.2. Topology-source compatibility places the $\mathsf{WijsmanTopology}^{\uparrow}$ row before any convergence question can be consumed.

Next read the metric route. The metric source M and hyperspace source H provide the only distance-to-set inputs, while S, R, E replay the stream windows, regular rational readbacks, and real comparison seals for the same finite probes.

Then consume the convergence-question row Q. It records finite tolerance checks for the approximating hyperspace name and the candidate limit name, so the consumer sees convergence only through the displayed metric readback route.

Finally use the structural rows A, C, P, N. They keep the read inside BHist, hsame, Cont, Pkg, and NameCert data and supply no coordinate for a host sequential topology, quotient closed-set equality, selected endpoint or nearest point, pointwise choice over all probes, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{WijsmanConvergence}^{\uparrow}$ convergence read factors through $\mathsf{WijsmanTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any completion-facing hyperspace consumer can inspect it.

Independence witness: wijsman-topology, metric, hyperspace, streamname, regseqrat, real: $\mathsf{WijsmanConvergence}^{\uparrow}$ is not bijective to any listed sibling because it binds Wijsman distance-evaluation opens to a finite convergence-question row over approximating and limit hyperspace names.

Closure status for $\mathsf{NameCert}_{\mathsf{WijsmanConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{WijsmanConvergence}^{\uparrow}$ packet is generated from a WijsmanTopology row, Metric row, Hyperspace row, StreamName windows, RegSeqRat readbacks, Real comparison seals, a finite convergence-question row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WijsmanConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6816.1, Definition 6816.2, and Definition 6816.3 seed the finite Wijsman convergence surface over WijsmanTopology, Metric, Hyperspace, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WijsmanConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequential topologies, quotient closed-set equality, selected nearest points, pointwise choice over all probes, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topology-source compatibility, metric readback exposure, hyperspace-name attachment, transport, replay, provenance, and local naming for BEDC.Derived.WijsmanConvergenceUp.

Chapter 6817

A Concrete Naming Certificate for $\mathsf{JacksonTheorem}^{\uparrow}$

Following Jackson's approximation theorem and its constructive approximation-theory readings, the $\mathsf{JacksonTheorem}^{\uparrow}$ packet records a quantitative approximation route from displayed smoothness or modulus data to polynomial or trigonometric approximation bounds. It sits beside the polynomial approximation surface of chapter 1634, the positive trigonometric-kernel route of chapter 1939, the compact-uniform continuity route of chapter 388, the uniform-modulus consumer of chapter 369, the finite polynomial carrier of chapter 50, and the terminal real-name seal of chapter 38. The packet names only the finite quantitative ledger by which an approximation consumer receives a rate, a degree or frequency budget, and an error comparison; it is not a host smoothness theorem, a selected best approximant, a quotient function-space construction, an open-cover compactness argument, or a completeness principle for ambient $\mathsf{Real}^{\uparrow}$.

Definition 6817.1 (JacksonTheorem carrier)**.** *A* $\mathsf{JacksonTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (X, F, M, R, D, P, T, E, H, C, Q, N)$$

with the following displayed rows:

1. *X is the compact real source row, read through the displayed* $\mathsf{Real}^{\uparrow}$ *and compact-interval surfaces.*
2. *F is the inspected continuous-map row.*
3. *M is the uniform-modulus row, read through* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *and* $\mathsf{UniformModulus}^{\uparrow}$*.*
4. *R is the requested quantitative rate row, recording the modulus-to-degree or modulus-to-frequency budget.*
5. *D is the finite degree or frequency row used by the approximating family.*
6. *P is the* $\mathsf{Poly}^{\uparrow}$ *or trigonometric-polynomial row whose coefficients and evaluation ledger are finite.*
7. *T is the Fejer-kernel handoff row, present when the approximation route is trigonometric rather than algebraic.*
8. *E is the displayed error-comparison row binding F, M, R, D, and P to the requested tolerance.*
9. *H records componentwise* hsame *transport for source, function, modulus, rate, degree, polynomial, Fejer handoff, error, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from finite source windows through the modulus and approximation rows into the error comparison.*
11. *Q is the* Pkg *provenance over* JacksonTheorem$^{\uparrow}$, WeierstrassApproximation$^{\uparrow}$, FejerKernel$^{\uparrow}$, CompactUniformContin UniformModulus$^{\uparrow}$, Poly$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* NameCert$_{\text{JacksonTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, M, R, D, P, T, E, H, C, Q, N$. It has no coordinate for a selected optimal polynomial, a host modulus theorem, quotient equality of functions, unbounded Fourier convergence, countable choice, open-cover compactness, or ambient real completeness.

Theorem 6817.2 (JacksonTheorem NameCert obligations)**.** *For every accepted* JacksonTheorem$^{\uparrow}$ *carrier $J = (X, F, M, R, D, P, T, E, H, C, Q, N)$, the local* NameCert$_{\text{JacksonTheorem}^{\uparrow}}$ *surface consists exactly of compact source exposure through X, continuous-map exposure through F, uniform-modulus exposure through M, quantitative rate admission through R, degree or frequency admission through D, polynomial or trigonometric-polynomial admission through P, optional Fejer-kernel handoff through T, displayed error comparison through E, componentwise transport through H, replay through C, provenance through Q, and local naming through N.*

Proof. Project the carrier of Definition 6817.1. The analytic rows are X, F, M, R, D, P, T, E, and the structural rows are H, C, Q, N.

The modulus row M is the only source of quantitative continuity data. The rate row R and the degree or frequency row D therefore read a finite budget from the displayed modulus rather than from an external smoothness theorem.

The polynomial row P and the Fejer row T supply the approximation family. The error row E then binds that family to the inspected function and tolerance, while H, C, Q, N transport, replay, source, and name the same route.

Since no further coordinate is present, the listed rows exhaust the local NameCert obligations and exclude selected best approximants, quotient function equality, host compactness, unbounded Fourier convergence, choice, and ambient real completeness. □

Theorem 6817.3 (JacksonTheorem Weierstrass handoff)**.** *Every* WeierstrassApproximation$^{\uparrow}$ *or* FejerKernel$^{\uparrow}$ *consumer of an accepted* JacksonTheorem$^{\uparrow}$ *packet receives a quantitative route*

$$X, F, M, R, D, P, T, E, H, C, Q, N.$$

The Weierstrass-facing read consumes P as a finite Poly$^{\uparrow}$ *approximation row after M, R, D are displayed; the Fejer-facing read consumes T only as a finite positive-kernel handoff before the same error row E is exported.*

Proof. Start with the obligation surface of Definition 6817.2. It forces compact source data, the inspected continuous map, the uniform modulus, the quantitative rate row, and the degree or frequency row to be visible before any approximation family is read.

For the Weierstrass-facing route, read P through the polynomial surface of chapter 1634. The consumer receives the finite coefficient and evaluation ledger only after the modulus-to-degree budget has been displayed.

For the trigonometric route, read T through chapter 1939. The Fejer handoff supplies positivity and finite kernel averaging, but it does not add a host Fourier convergence theorem.

The error row E and structural rows H, C, Q, N then repack the same finite data for downstream approximation consumers. Thus the handoff is quantitative BEDC carrier data, not a selected best approximant or a quotient function-space assertion. □

Falsifiable prediction: An accepted $\mathsf{JacksonTheorem}^{\uparrow}$ consumer that reaches an approximation error row without first displaying a uniform-modulus row and a finite degree or frequency budget is outside the carrier surface.

Independence witness: weierstrass-approximation, fejer-kernel, compactuniformcontinuity, uniformmodulus, polynomial, real: none is bijective to $\mathsf{JacksonTheorem}^{\uparrow}$ because only this packet binds compact source data, a continuous-map row, a modulus-to-rate ledger, a finite degree or frequency budget, polynomial or trigonometric approximation rows, an error comparison, transport, replay, provenance, and local NameCert naming into one quantitative approximation route.

Closure status for $\mathsf{NameCert}_{\mathsf{JacksonTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{JacksonTheorem}^{\uparrow}$ packet is generated from compact Real source rows, a continuous-map row, compact-uniform and uniform-modulus rows, a quantitative rate ledger, a finite degree or frequency budget, polynomial or Fejer approximation rows, an error-comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JacksonTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6817.1, Definition 6817.2, and Definition 6817.3 seed the quantitative Jackson approximation packet over compact-uniform modulus data, finite polynomial or trigonometric approximation rows, and displayed error comparison.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JacksonTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, selected best approximants, host smoothness theorems, quotient equality of functions, unbounded Fourier convergence, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, modulus-to-rate exactness, degree or frequency budget admission, polynomial and Fejer handoff exactness, error comparison, transport, replay, provenance, and local naming for BEDC.Derived.JacksonTheoremUp.

Chapter 6818

A Concrete Naming Certificate for $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$

Following Bishop–Bridges Riemann–Darboux constructive analysis, the $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$ packet records the finite compact-oscillation handoff that lets a regulated-function window be read through a compact finite partition before Darboux data is consumed. It sits over the regulated-function schedule of chapter 1906, the finite oscillation partition of chapter 3800, the Darboux sum boundary of chapter 1880, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite windows, cell ledgers, oscillation bounds, sum handoff rows, transport, replay, provenance, and local naming data.

Definition 6818.1 (Regulated function compact oscillation carrier)**.** *A* $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, W, M, O, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, exposing the regulated-function approximation schedule through the window requested by the consumer.*
2. *W is the finite window row over the inspected regulated-function schedule.*
3. *M is the compact finite partition-cell row supplied by* $\mathsf{FiniteOscillationPartition}^{\uparrow}$*, including the displayed cells and their common finite index ledger.*
4. *O is the oscillation ledger assigning each cell of M a tolerance-indexed upper and lower read of the regulated source.*
5. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *handoff row, available only after F, W, M, O have been displayed.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational endpoints and cellwise bounds used by O and D.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the displayed regular rational reads.*
8. *H records componentwise* hsame *transport for $F, W, M, O, D, Q, R, C, P, N$.*
9. *C records displayed* Cont *replay from a regulated-function request through the finite window, compact finite partition cells, oscillation ledger, Darboux handoff, regular rational readback, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, FiniteOscillationPartitio DarbouxSum$^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}}$ *row.*

The carrier contains no open-cover compactness witness, no selected supremum, no quotient equality of functions, no measure completion, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegulatedFunctionCompactOscillationUp.RegulatedFunctionCompactOscillationTasteGate single carrier alignment`

Theorem 6818.2 (Regulated compact oscillation obligation surface)**.** *For every accepted* RegulatedFunctionCompac *carrier* $K = (F, W, M, O, D, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}}$ *surface consists exactly of regulated-function source admission, finite window exposure, compact finite partition-cell admission, oscillation-ledger accounting, Darboux handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6818.1. The analytic rows are F, W, M, O, D, Q, R, and the structural rows are H, C, P, N.

The source and partition rows are finite. The row F opens the regulated-function schedule, W confines the read to the inspected window, and M lists the compact finite partition cells supplied by the finite oscillation partition packet.

The oscillation and seal rows are also finite. The ledger O records the cellwise upper and lower reads, D records the Darboux handoff, Q records the regular rational readback, and R records the terminal real-name seal reached from those displayed reads.

Rows H, C, P, N only transport, replay, source, and name the same data. Since the carrier has no coordinate for open-cover compactness, selected suprema, quotient function equality, measure completion, or ambient completeness, the displayed list exhausts the local NameCert surface. □

Theorem 6818.3 (Regulated compact oscillation Darboux handoff)**.** *Every Darboux-facing consumer of an accepted* $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow},\ \mathsf{FiniteOscillationPartition}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{DarbouxSum}^{\uparrow}.$$

The Darboux row is available only after the regulated-function window, compact finite partition cells, oscillation ledger, regular rational readback, Real seal, transport, replay, provenance, and local naming rows have been displayed.

Proof. Apply the obligation surface of Definition 6818.2. It forces every consumer to read $F, W, M, O, Q, R, H, C, P,$ before the Darboux handoff row D can be consumed.

The row F supplies the regulated-function source, while M supplies the compact finite partition cells. The oscillation ledger O binds the two by attaching cellwise upper and lower reads to the same inspected window.

The readback rows Q and R then route the cell bounds through $\mathsf{RegSeqRat}^{\uparrow}$ and the terminal $\mathsf{Real}^{\uparrow}$ seal. Thus D is a finite Darboux handoff over displayed rows, not a selected-extrema or open-cover compactness argument. □

Theorem 6818.4 (Regulated compact oscillation Real seal route)**.** *Every real-valued read exported by an accepted* $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$ *carrier reaches* $\mathsf{Real}^{\uparrow}$ *only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q attached to the same regulated window, finite partition cells, oscillation ledger, and Darboux handoff. No exported read factors through quotient function equality, measure completion, selected suprema, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project $K = (F, W, M, O, D, Q, R, H, C, P, N)$ from Definition 6818.1. The only real-facing rows are the regular rational readback Q and the terminal seal R.

Apply Definition 6818.3. Any integration-facing consumer has already read the regulated source, window, partition cells, oscillation ledger, and Darboux handoff before the real-valued cell data is used.

Since Q is the displayed readback for those same cells and R is downstream of Q, every exported real-valued read stays on the listed route. The refused readings would require carrier coordinates absent from K. □

Falsifiable prediction: Any accepted RegulatedFunctionCompactOscillationUp packet that exposes a Darboux row while omitting the regulated-function window, compact finite partition cells, oscillation ledger, RegSeqRat readback, Real seal, transport, replay, provenance, or local naming rows refutes the packet.

Independence witness: regulated-function, finite-oscillation-partition, darboux-sum, regseqrat, real: none is bijective with $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$ because this packet jointly carries the regulated window, compact finite cells, oscillation ledger, Darboux handoff, rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$ packet is generated from a regulated-function source, finite window row, compact finite partition cells, oscillation ledger, Darboux handoff, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6818.1, Definition 6818.2, Definition 6818.3, and Definition 6818.4 seed the compact finite oscillation handoff from regulated-function windows to Darboux and Real readbacks.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected suprema, quotient function equality, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite partition-cell admission, oscillation-ledger exactness, Darboux handoff, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedFunctionCompactOscillationUp.

Chapter 6819

A Concrete Naming Certificate for $\mathsf{ArithmeticalContinuum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ArithmeticalContinuum}^{\uparrow}$ packet records the arithmetical continuum as the finite BEDC route from rational and dyadic arithmetic through regular Cauchy names to the Real seal. It sits over the rational carrier of chapter 37, the dyadic ledger of chapter 291, the finite stream-window carrier of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names the displayed construction-order surface; it does not import Dedekind cuts, quotient reals, trichotomy, countable choice, selected representatives, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6819.1 (ArithmeticalContinuum carrier)**.** *An* $\mathsf{ArithmeticalContinuum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, D, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *arithmetic row naming the rational operations and rational comparison requests admitted by the packet.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger used to refine the rational requests into dyadic cells, dyadic tolerances, and dyadic comparison windows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which construction-order consumers inspect the displayed arithmetic stream.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row serving the same finite stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the rational, dyadic, stream, and regular-readback rows have been replayed.*
6. *H records componentwise* hsame *transport for rational arithmetic, dyadic refinement, stream windows, regular readback, Real seals, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from rational requests to dyadic refinement, stream inspection, regular readback, and the terminal Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{ArithmeticalContinuum}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArithmeticalContinuum}^{\uparrow}}$ *row.*

The carrier contains no coordinate for Dedekind cuts, quotient-real equality, trichotomy, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6819.2 (ArithmeticalContinuum NameCert obligations)**.** *For every accepted* $\mathsf{ArithmeticalContinuum}^{\uparrow}$ *carrier* $A = (Q, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArithmeticalContinuum}^{\uparrow}}$ *surface consists exactly of carrier admission for the rational, dyadic, stream, regular-readback, Real-seal, transport, replay, provenance, and local name rows; dyadic refinement exactness for rational arithmetic requests; finite stream-window coverage before regular readback; Real-seal handoff after* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *have been displayed; and nonescape excluding Dedekind cuts, quotient reals, trichotomy, selected representatives, countable choice, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6819.1. The tuple displays exactly the rational arithmetic row, dyadic refinement ledger, finite stream windows, regular rational readback, Real seal, transport, replay, provenance, and local name.

Dyadic refinement exactness is read through Q and D. Each rational arithmetic request must expose its dyadic tolerance or comparison window before the request can be consumed downstream.

The construction-order read then passes through S and R. The stream window names the finite observations, and the regular rational row supplies the readback tied to those observations before the Real seal E is visible.

Finally H, C, P, N transport, replay, source, and name only the displayed route. Since the carrier has no Dedekind-cut, quotient-real, trichotomy, selected-representative, choice, host-equality, or completeness coordinate, none of those objects can be exported by the certificate. □

Theorem 6819.3 (ArithmeticalContinuum regular Cauchy handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{ArithmeticalContinuum}^{\uparrow}$ *carrier factors through the construction-order route*

$$\mathsf{Rat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the displayed rows $Q, D, S, R, E, H, C, P, N$*. The handoff may transport and replay this finite route, but it cannot claim Dedekind-cut completeness, quotient-real equality, trichotomy, a selected representative, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the accepted carrier of Definition 6819.1. A Real-facing consumer has access to the terminal seal only at the row E.

Apply Definition 6819.2. The obligation surface forces the consumer to expose Q, D, S, R in order: rational arithmetic request, dyadic refinement, finite stream inspection, and regular rational readback.

The rows H and C preserve that route under componentwise transport and displayed replay, while P and N only record provenance and local naming. Thus the handoff reaches $\mathsf{Real}^{\uparrow}$ through the displayed regular Cauchy route, with no carrier coordinate from which to read the excluded classical objects. □

Falsifiable prediction: Every accepted ArithmeticalContinuumUp read exposes Rat arithmetic, DyadicRatCore refinement, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any Real-facing consumer can inspect the packet.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real: removing any one of these sibling routes leaves the packet unable to display the corresponding rational request, dyadic refinement, stream window, regular-rational readback, or terminal Real seal row.

Closure status for $\mathsf{NameCert}_{\mathsf{ArithmeticalContinuum}^{\uparrow}}$.

Constructive story: An $\mathsf{ArithmeticalContinuum}^{\uparrow}$ packet is generated from Rat arithmetic rows, DyadicRatCore refinement ledgers, StreamName finite windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArithmeticalContinuum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6819.1, Definition 6819.2, and Definition 6819.3 seed the arithmetical-continuum route from rational and dyadic arithmetic through regular Cauchy names to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArithmeticalContinuum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, quotient reals, trichotomy, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic refinement exactness, stream-window coverage, regular rational readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.ArithmeticalContinuu

Chapter 6820

A Concrete Naming Certificate for $\mathsf{RootChoiceSeparation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RootChoiceSeparation}^{\uparrow}$ packet records the finite data needed to choose the separated root window of a displayed sign-changing real interval without invoking a general root-choice principle. It consumes the real-name seal of chapter 38, the regular rational readback surface of chapter 301, the finite stream-window route of chapter 126, the located real interval bisection route of chapter 5546, and the sign-change isolation packet of chapter 1407. The chapter names one separated root-choice surface over displayed interval data; it does not assert the general intermediate value theorem, compactness of intervals, quotient equality of real names, root selection without separation, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6820.1 (Separated root-choice carrier)**.** *A* $\mathsf{RootChoiceSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, I, A, B, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the function-read row, storing the finite endpoint and midpoint sign inspections used by the root-choice request.*
2. *I is the located real interval row, exposing the source interval and its* $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ *refinement route.*
3. *A is the apartness row, recording the displayed separation between the retained sign-changing window and every excluded candidate window.*
4. *B is the bisection schedule row, read through the* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *sign-change packet and its retained-window ledger.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the retained endpoints and midpoint inspections.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained stream windows and the displayed bisection schedule.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the selected separated window, available only after F, I, A, B, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for the function reads, interval row, apartness row, bisection schedule, stream windows, regular readback, real seal, replay, provenance, and local name.*

9. *C records displayed* Cont *replay from a root-choice request through the same finite rows.*
10. *P is the* Pkg *provenance over* $\mathsf{RootChoiceSeparation}^{\uparrow}$, $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$, $\mathsf{BisectionRootIsolation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RootChoiceSeparation}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for a general intermediate-value theorem, Heine–Borel compactness, quotient equality of real names, a root chosen without displayed separation, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RootChoiceSeparationUp.RootChoiceSeparationTasteGate single carrier alignment`

Theorem 6820.2 (Separated root-choice NameCert surface)**.** *For every accepted* $\mathsf{RootChoiceSeparation}^{\uparrow}$ *carrier*

$$R = (F, I, A, B, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RootChoiceSeparation}^{\uparrow}}$ *surface consists exactly of function-read exposure through F, located interval exposure through I, sign-change and apartness exposure through A, retained bisection scheduling through B, finite stream-window readout through S, regular rational readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every admitted root-choice read must display the separated sign-changing window before it reaches Q or E. The packet exports no general intermediate value theorem, no Heine–Borel theorem, no quotient real equality, no root selected without separation, and no ambient real-completeness principle.*

Proof. Project the carrier of Definition 6820.1. The rows F, I, A, B are the only pre-read rows available to the choice request, and they jointly display the function inspections, the located interval source, the separation witness, and the retained sign-change bisection schedule.

Read the neighboring bisection surfaces next. The located interval route of chapter 5546 supplies finite interval refinement, while chapter 1407 supplies the retained sign-changing window. The apartness row A keeps the retained window separated from excluded windows before any regular readback is consumed.

The downstream read is then forced through S, Q, E. The $\mathsf{StreamName}^{\uparrow}$ row records the finite endpoint windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row repacks those windows as regular rational readback, and the $\mathsf{Real}^{\uparrow}$ row seals only that displayed route.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate contains a general intermediate-value theorem, Heine–Borel compactness, quotient real equality, unseparated root choice, countable choice, or ambient real completeness, none of those objects can be exported by the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{RootChoiceSeparation}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without the displayed function-read row, located interval row, apartness row, retained bisection schedule, finite $\mathsf{StreamName}^{\uparrow}$ window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: real, regseqrat, streamname, located-real-interval-bisection, bisection-rootisolation: no listed sibling supplies the joint packet containing function reads, a located interval source, a separated sign-changing window, retained bisection scheduling, finite stream windows, regular readback, Real sealing, transport, replay, provenance, and local naming while refusing unseparated root choice and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RootChoiceSeparation}^{\uparrow}}$.

Constructive story: A RootChoiceSeparation$^{\uparrow}$ packet is generated from function-read rows, a located real interval row, a separated sign-change apartness row, a retained bisection schedule, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RootChoiceSeparation}\uparrow}$, seed)

Scope closed: Definition 6820.1 and Definition 6820.2 seed the separated root-choice surface over located interval bisection, bisection root isolation, finite stream windows, regular readback, and Real sealing.

Formal verification: FormalStatus(NameCert$_{\text{RootChoiceSeparation}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close the general intermediate value theorem, Heine–Borel compactness, quotient real equality, root choice without displayed separation, countable choice, ambient Real$^{\uparrow}$ completeness, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separation visibility, retained bisection scheduling, readback handoff, Real seal nonescape, and classifier stability for BEDC.Derived.RootChoiceSeparationUp.

Chapter 6821

A Concrete Naming Certificate for $\mathsf{DedekindCompletionBoundary}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DedekindCompletionBoundary}^{\uparrow}$ packet names the finite L10 boundary around the Dedekind-cut route to the real line. It sits beside the located-cut presentation of chapter 3773, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, and the terminal real-name seal of chapter 38. The packet records where a cut-based presentation may be read as finite BEDC data; it refuses quotient completion and does not construct $\mathsf{Real}^{\uparrow}$ from Dedekind cuts.

Definition 6821.1 (DedekindCompletionBoundary carrier)**.** *A* $\mathsf{DedekindCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, R, D, S, E, H, C, P, N)$$

with the following visible rows:

1. *L is the* $\mathsf{LocatedCutReal}^{\uparrow}$ *located-cut exposure row, recording lower–upper cut evidence only through displayed finite observations.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row used when a cut-side observation is compared with a regular-Cauchy presentation.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds every comparison window used by L and R.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row carrying the bounded stream observations through which the comparison is replayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the located-cut, regular-readback, dyadic, and stream rows have been displayed.*
6. *H records componentwise* hsame *transport for the located-cut, regular-readback, dyadic, stream, Real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion-facing request through L, R, D, S, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindCompletionBoundary}^{\uparrow}$, $\mathsf{LocatedCutReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCompletionBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, quotient-real equality, a selected representative, host real equality, countable choice, trichotomy, or an ambient construction of $\mathsf{Real}^{\uparrow}$ *from Dedekind cuts.*

Lean4 (statement) BEDC.Derived.DedekindCompletionBoundaryUp

Theorem 6821.2 (Dedekind boundary located-cut route)**.** *Every completion-facing consumer of an accepted* $\mathsf{DedekindCompletionBoundary}^{\uparrow}$ *carrier* $B = (L, R, D, S, E, H, C, P, N)$ *reads the cut-side data only through the displayed route*

$$\mathsf{LocatedCutReal}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may expose located cut evidence, regular rational readback, dyadic tolerances, finite stream windows, and the terminal Real seal, but it does not export quotient completion or construct $\mathsf{Real}^{\uparrow}$ *from Dedekind cuts.*

Proof. Project the accepted carrier of Definition 6821.1. The only cut-side row is L, and it is paired in the same packet with the regular rational readback R, the dyadic ledger D, and the finite stream-window row S.

The continuation row C fixes the order in which a completion-facing request can inspect those rows. A request first sees located-cut evidence, then compares it against regular rational readback, then checks the dyadic tolerance ledger and the finite stream observations before the Real seal E is visible.

The structural rows H, P, N transport, source, and name only that displayed route. Since the carrier has no quotient-completion or Dedekind-construction coordinate, the consumer receives a boundary certificate rather than a construction of $\mathsf{Real}^{\uparrow}$ from cuts. □

Theorem 6821.3 (Dedekind boundary no quotient scope)**.** *For every accepted* $\mathsf{DedekindCompletionBoundary}^{\uparrow}$ *carrier, the public scope is confined to the rows* $L, R, D, S, E, H, C, P, N$ *of Definition 6821.1. In particular, the packet refuses quotient completion, quotient-real equality, selected representatives, host real equality, countable choice, trichotomy, and any claim that* $\mathsf{Real}^{\uparrow}$ *is constructed from Dedekind cuts.*

Proof. The carrier definition lists every visible row. None of those rows stores a quotient relation, an equivalence class, a selected representative, a host equality proof, a choice schedule, or a trichotomy decision.

Apply the located-cut route of Definition 6821.2. It shows that the only Real-facing handoff passes through $\mathsf{LocatedCutReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

It remains only to inspect the structural rows. The hsame, Cont, Pkg, and local NameCert entries preserve, replay, source, and name the displayed finite route; they do not add a quotient completion object or a construction principle for $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{DedekindCompletionBoundary}^{\uparrow}$ read exposes located-cut evidence, RegSeqRat readback, DyadicRatCore tolerances, StreamName finite windows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any completion-facing consumer can inspect the packet.

Independence witness: located-cut-real, regseqrat, dyadicratcore, streamname, real: DedekindCompletionBounda is not reducible to any listed sibling because it binds the located-cut exposure, regular rational

readback, dyadic tolerance ledger, finite stream windows, terminal Real seal, transport, replay, provenance, and local NameCert rows as one boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCompletionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCompletionBoundary}^{\uparrow}$ packet is generated from a LocatedCutReal exposure row, RegSeqRat readback, DyadicRatCore tolerance ledger, StreamName finite windows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCompletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6821.1, Definition 6821.2, and Definition 6821.3 seed the L10 boundary around the Dedekind-cut completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCompletionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, quotient-real equality, selected representatives, host real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a construction of $\mathsf{Real}^{\uparrow}$ from Dedekind cuts.

Upgrade path: Obligation closure requires checked carrier admission, located-cut exposure, regular rational readback, dyadic tolerance coverage, stream-window replay, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DedekindCompletionBoundaryUp.

Chapter 6822

A Concrete Naming Certificate for $\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}$ packet records the finite prefix-modulus data by which a regular Cauchy rational name exposes a requested real tolerance without appealing to tail choice or quotient stream equality. It sits between the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback surface of chapter 301, and the terminal seal handoff of chapter 38. The packet names only the finite prefix length, the displayed dyadic tolerance, the observed stream prefix, the regularity readback, the Real seal, componentwise transport, replay, provenance, and local $\mathsf{NameCert}$ evidence.

Definition 6822.1 (Regular Cauchy finite prefix modulus carrier)**.** *A* $\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, D, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite prefix length at which the requested regular Cauchy read is opened.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic radius certified for that prefix.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row listing exactly the stream entries inspected below K.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity readback row witnessing that the observed prefix belongs to the regular rational Cauchy source.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row reached after the prefix, tolerance, observation, and regularity rows have been displayed.*
6. *H records componentwise* hsame *transport for K, D, W, Q, R, C, P, N.*
7. *C records displayed* Cont *replay from a requested dyadic tolerance to the same prefix length, observation window, regularity readback, and seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}}$ *evidence.*

The classifier compares accepted packets only through $K, D, W, Q, R, H, C, P, N$. It has no coordinate for an infinite tail selector, quotient stream equality, a chosen limit representative, countable choice, trichotomy of rationals beyond the displayed tolerance row, or an ambient Real completeness theorem.

Theorem 6822.2 (Regular Cauchy finite prefix modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}$ *carrier*

$$M = (K, D, W, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}}$ *surface consists exactly of finite prefix length K, dyadic tolerance row D, stream observation row W, regular rational readback row Q, Real seal handoff row R, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N.*

Proof. Project the carrier of Definition 6822.1. The finite analytic rows are K, D, W, Q, R, and the structural rows are H, C, P, N.

The prefix length K bounds every observation made through W. The dyadic tolerance row D fixes the requested radius, while the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q states regularity for the displayed prefix before the $\mathsf{Real}^{\uparrow}$ seal row R is consumed.

Rows H, C, P, N transport, replay, source, and name the same displayed packet. Since the carrier includes no tail selector, quotient-stream equality, chosen representative, countable-choice schedule, or ambient completeness coordinate, the listed rows exhaust the NameCert obligation surface. □

Theorem 6822.3 (Regular Cauchy finite prefix modulus L10 handoff)**.** *Every L10 Real or completion consumer of an accepted* $\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}$ *packet receives the modulus data only through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff may expose the prefix length, tolerance row, stream observations, regularity readback, and Real seal, but it exports no hidden infinite tail, quotient stream equality, selected limit, countable-choice scheduler, or host completeness principle.

Proof. Apply Definition 6822.2. The rows K, D, W, Q, R place the finite prefix length, dyadic tolerance, observed stream prefix, regular rational readback, and Real seal in one packet.

The structural rows H, C, P, N preserve that same route under componentwise transport, replay, provenance, and local naming. A consumer therefore reaches the Real or completion handoff only after reading the displayed finite prefix-modulus data, and every refused reading would require a coordinate absent from M. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}$ packet is generated from finite prefix length, DyadicRatCore tolerance, StreamName observations, RegSeqRat regularity readback, Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6822.1, Definition 6822.2, and Definition 6822.3 seed the finite prefix-modulus carrier and its L10 Real/completion handoff route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyFinitePrefixModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close tail choice, quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix exactness, dyadic tolerance exactness, stream observation exactness, RegSeqRat readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFinitePrefixModulusUp.

Chapter 6823

A Concrete Naming Certificate for $\mathsf{MinkowskiQuestionMark}^{\uparrow}$

Following Minkowski's question-mark function and the continued-fraction/Stern-Brocot coding of real numbers, the $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ packet records the finite route by which a continued-fraction or Stern–Brocot prefix is read as a dyadic real-name prefix before any $\mathsf{Real}^{\uparrow}$ consumer inspects it. It sits over the Stern–Brocot tree of chapter 1704, the continued-fraction prefix carrier of chapter 342, the bridge packet of chapter 3781, the dyadic arithmetic surface of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite prefix conversion data; it does not assert quotient equality of real names, completed functional equality, selected infinite expansions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6823.1 (Minkowski question-mark carrier)**.** *A* $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, F, B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *branch-prefix row, recording the finite left/right address and boundary interval inspected by the consumer.*
2. *F is the* $\mathsf{ContinuedFraction}^{\uparrow}$ *prefix row, recording the finite partial-quotient block corresponding to the same branch-prefix request.*
3. *B is the Stern–Brocot/continued-fraction bridge row, read through chapter 3781 before any dyadic row is exposed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *output-prefix ledger, recording the dyadic denominator scale and numerator prefix generated from the displayed branch or partial-quotient block.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row scheduling which branch, partial-quotient, and dyadic prefix cells are visible.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same dyadic prefix and window data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, F, B, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the Stern–Brocot, continued-fraction, bridge, dyadic-prefix, window, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a question-mark request through finite prefix inspection, dyadic prefix conversion, regular rational readback, and the terminal Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{MinkowskiQuestionMark}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{SternBrocotContinued}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MinkowskiQuestionMark}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, F, B, D, W, R, E, H, C, P, N$. The carrier has no coordinate for quotient real equality, completed function equality, trichotomy, countable choice, a selected infinite expansion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6823.2 (Minkowski question-mark NameCert obligations)**.** *For every accepted* $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ *carrier $Q = (S, F, B, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MinkowskiQuestionMark}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the displayed Stern–Brocot branch prefix, continued-fraction prefix, bridge row, dyadic-prefix ledger, finite window, regular readback, Real seal, transport, replay, provenance, and local naming rows;*

2. *prefix compatibility, requiring S and F to be read through the same bridge row B before D is available;*

3. *dyadic conversion, requiring D to expose only the dyadic prefix generated from the displayed branch or partial-quotient prefix and the window row W;*

4. *real-name routing, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *read to pass through D, W, R, E in that order;*

5. *transport, replay, provenance, and local-name stability through H, C, P, N.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6823.1. The accepted tuple exposes exactly the branch-prefix, partial-quotient, bridge, dyadic-prefix, window, readback, seal, and structural rows listed in the statement.

Prefix compatibility reads S, F, B together. The Stern–Brocot side supplies the finite branch address, the continued-fraction side supplies the finite partial-quotient block, and the bridge row records that both are the same finite prefix route before a dyadic prefix is presented.

The dyadic conversion row D is downstream of that bridge and of the window row W. Thus a consumer can inspect only the dyadic prefix generated from the displayed finite prefix, not a completed real function value.

The regular readback and Real seal are ordered by the carrier. The row R is obtained from D, W, and E is terminal after R.

Finally H, C, P, N transport, replay, source, and name only this route. Since no excluded completed-real or choice-theoretic coordinate is present, the five rows exhaust the local NameCert surface. □

Theorem 6823.3 (Minkowski question-mark prefix compatibility)**.** *Every accepted* $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ *carrier reads a Stern–Brocot branch prefix and a continued-fraction prefix through the same bridge row before exposing a dyadic prefix. In the notation of Definition 6823.1, the visible prefix route is*

$$S \longmapsto B \longleftarrow F \quad \textit{and then} \quad B, W \longmapsto D.$$

The compatibility claim is only about displayed finite prefixes; it is not equality of completed real functions or quotient equality of real names.

Proof. Project the accepted carrier $Q = (S, F, B, D, W, R, E, H, C, P, N)$. The branch-prefix coordinate is S, the partial-quotient coordinate is F, and the only row relating them is the bridge coordinate B.

Read B through the Stern–Brocot/continued-fraction bridge chapter. It mediates between finite tree intervals and finite continued-fraction prefixes by displayed rational-approximation data.

The dyadic row D is exposed only after B and the window row W have been read. Therefore both prefix descriptions feed the same dyadic prefix route, while completed function equality and quotient real equality remain outside the carrier. □

Theorem 6823.4 (Minkowski question-mark dyadic route)**.** *Every real-facing read exported by an accepted* $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ *carrier factors through*

$$\mathsf{SternBrocot}^{\uparrow},\ \mathsf{ContinuedFraction}^{\uparrow},\ \mathsf{SternBrocotContinuedFractionBridge}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto$$

The exported route is a finite dyadic real-name prefix route. It does not claim completeness of $\mathsf{Real}^{\uparrow}$*, quotient equality between real names, or total equality of Minkowski's question-mark function as a completed map.*

Proof. Apply Definition 6823.3. Any branch or partial-quotient source must pass through the bridge row before the dyadic prefix row is available.

The dyadic row is then read with the finite window row. The same window schedules the prefix cells passed to $\mathsf{StreamName}^{\uparrow}$, and the regular rational row R reads that dyadic prefix as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

The terminal Real seal E is downstream of R. Since the structural rows only transport, replay, source, and name the same finite route, no ambient real completeness or completed functional equality can be read from the packet. □

Falsifiable prediction: Every $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ Real-facing read factors through a Stern–Brocot prefix, a continued-fraction prefix, their bridge row, a dyadic-prefix ledger, finite StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Independence witness: stern-brocot, continuedfraction, stern-brocot-continued-fraction-bridge, dyadicratcore, streamname, regseqrat, real: $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite prefix bridge, dyadic conversion ledger, real-name readback route, and structural support while refusing completed function equality, quotient real equality, selected infinite expansions, choice, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{MinkowskiQuestionMark}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MinkowskiQuestionMark}^{\uparrow}$ packet is generated from Stern–Brocot branch prefixes, continued-fraction prefixes, their bridge row, a DyadicRatCore prefix ledger, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinkowskiQuestionMark}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6823.1, Definition 6823.2, Definition 6823.3, and Definition 6823.4 seed the finite route from continued-fraction and Stern–Brocot prefixes to dyadic Real-name readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinkowskiQuestionMark}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, completed functional equality, selected infinite expansions, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix compatibility, dyadic conversion, real-name routing, transport, replay, provenance, and local naming for BEDC.Derived.MinkowskiQuestionMarkUp.

Chapter 6824

A Concrete Naming Certificate for $\mathsf{CompactFanModulusSelector}^{\uparrow}$

Following Bishop–Bridges compact uniform continuity and the fan-bar proof of uniform moduli, the $\mathsf{CompactFanModulusSelector}^{\uparrow}$ packet records the finite selector that turns a fan-bar depth ledger and compact finite-net pointwise moduli into a single $\mathsf{UniformModulus}^{\uparrow}$ handoff. It realizes the compact-uniform-continuity direction of chapter 9237 as a concrete packet between the finite fan theorem of chapter 400, the Bishop fan-modulus route of chapter 1707, the compact-uniform-continuity carrier of chapter 388, and the downstream uniform-modulus consumer of chapter 369. The packet names only finite fan bars, compact ProbeBundle windows, pointwise modulus rows, rational lower-bound folds, transport, replay, provenance, and local naming data.

Definition 6824.1 (Compact fan modulus selector carrier)**.** *A* $\mathsf{CompactFanModulusSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, B, K, G, R, U, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite bar row, including the binary-prefix spread, decidable bar classifier, and unary depth bound.*
2. *B is the* $\mathsf{BishopFanModulus}^{\uparrow}$ *fan-to-window row, turning the depth bound into a finite observation schedule.*
3. *K is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *source row, exposing compact finite-net and continuous-map pointwise modulus data for the inspected tolerance.*
4. *G is the finite* $\mathsf{ProbeBundle}$ *selector row, listing the compact-net probes whose pointwise moduli are inspected.*
5. *R is the positive rational lower-bound fold row over the selected probe radii and pointwise modulus margins.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row obtained from F, B, K, G, R.*
7. *H records componentwise* hsame *transport for the fan, fan-modulus, compact-uniform, probe-selector, rational-fold, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-uniform-continuity request through the fan-bar selector, ProbeBundle fold, and UniformModulus handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactFanModulusSelector}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BishopFanModulus}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactFanModulusSelector}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, B, K, G, R, U, H, C, P, N$. The carrier has no coordinate for open-cover compactness, countable choice, selected branches, selected real limits, quotient cover equality, host analytic moduli, Lean verification, or bridge checking.

Theorem 6824.2 (Compact fan modulus selector NameCert obligations)**.** *For every accepted* $\mathsf{CompactFanModulusSelector}^{\uparrow}$ *carrier $S = (F, B, K, G, R, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactFanModulusSelector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed fan bar, Bishop fan-modulus, compact-uniform source, ProbeBundle selector, rational fold, UniformModulus handoff, transport, replay, provenance, and local naming rows;*
2. *fan-bar coverage, requiring the row F to supply the finite branch-prefix depth consumed by B;*
3. *compact selector coverage, requiring G to list the finite probes and pointwise modulus rows exposed by K;*
4. *rational fold exactness, requiring R to be the finite lower-bound fold over the selected probe margins;*
5. *UniformModulus handoff, requiring U to read only the displayed rows F, B, K, G, R before exposing a uniform precision schedule;*
6. *transport, replay, provenance, and local-name stability through H, C, P, N.*

No local selector obligation is stored outside these six rows.

Proof. Carrier admission is projection from Definition 6824.1. The accepted tuple displays exactly the fan, Bishop fan-modulus, compact-uniform source, ProbeBundle selector, rational fold, uniform handoff, and structural rows.

The fan-bar coverage row is finite. The fan theorem row F supplies the bounded branch-prefix inspection, and B converts that depth into the observation schedule used by the selector.

The compact selector rows are also finite. The compact-uniform source K exposes pointwise modulus data, while G lists the probes whose margins are used by the fold.

The fold row R performs only a finite positive-rational lower-bound comparison. The uniform row U consumes that fold together with the fan-bar and compact rows, so it is a handoff from displayed data rather than a choice-selected modulus.

Finally H, C, P, N transport, replay, source, and name the same finite selector. Since the carrier has no coordinate for open-cover compactness, choice, selected branches, selected limits, quotient cover equality, host analytic moduli, Lean verification, or bridge checking, the listed obligations exhaust the local NameCert surface. □

Theorem 6824.3 (Compact fan selector uniform handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactFanModulusSelector}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{FanTheorem}^{\uparrow} \longmapsto \mathsf{BishopFanModulus}^{\uparrow} \longmapsto \mathsf{CompactUniformContinuity}^{\uparrow} \longmapsto \mathsf{ProbeBundle} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformMod}$$

The handoff exports a displayed precision schedule from the fan-bar depth, compact finite-net probes, pointwise modulus rows, and rational lower-bound fold; it exports no open-cover compactness theorem, selected branch, countable-choice schedule, quotient cover equality, or host analytic modulus.

Proof. Begin with the fan-bar side. The row F exposes the finite fan data, and B converts its depth into a finite observation schedule.

Read the compact-uniform side next. The row K supplies the compact finite-net and pointwise modulus data, while G selects the finite probe rows that participate in the fold.

The rational fold R produces the displayed lower bound over those rows. The $\mathsf{UniformModulus}^{\uparrow}$ handoff U can therefore read one precision schedule from finite data already present in the packet.

The structural rows preserve the same route under transport, replay, provenance, and local naming. Since no excluded compactness or choice coordinate is present, the handoff remains a finite selector packet. □

Theorem 6824.4 (Compact fan selector nonescape)**.** *An accepted* $\mathsf{CompactFanModulusSelector}^{\uparrow}$ *carrier exports no open-cover compactness, countable choice, selected branch, selected real limit, quotient cover equality, host analytic modulus, Lean verification, or bridge checking. Every exported read factors through* $F, B, K, G, R, U, H, C, P, N$*.*

Proof. Project the accepted carrier rows. The analytic coordinates are the fan row F, Bishop fan-modulus row B, compact-uniform source row K, ProbeBundle selector row G, rational fold row R, and UniformModulus handoff row U.

The remaining coordinates H, C, P, N provide componentwise transport, continuation replay, provenance, and local naming for those same rows. They do not add compactness, choice, branch-selection, limit-selection, quotient-cover, host-modulus, verification, or bridge data.

Thus every consumer is confined to the displayed finite selector route, and each excluded reading lacks a carrier coordinate from which it could be consumed. □

Falsifiable prediction: Every accepted CompactFanModulusSelectorUp handoff factors through a finite fan bar, Bishop fan-modulus schedule, compact-uniform source, ProbeBundle selector, rational lower-bound fold, UniformModulus row, transport, replay, provenance, and local naming.

Independence witness: fantheorem, bishop-fan-modulus, compactuniformcontinuity, uniform-modulus: $\mathsf{CompactFanModulusSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the fan-bar depth, compact finite-net selector, pointwise modulus rows, rational lower-bound fold, uniform handoff, and structural support while refusing compactness, choice, branch selection, quotient cover equality, host moduli, verification, and bridge checking.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFanModulusSelector}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactFanModulusSelector}^{\uparrow}$ packet is generated from a FanTheorem finite bar, a BishopFanModulus schedule, CompactUniformContinuity finite-net and pointwise-modulus rows, a ProbeBundle selector, a rational lower-bound fold, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactFanModulusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6824.1, Definition 6824.2, Definition 6824.3, and Definition 6824.4 seed the finite selector from fan-bar depth and compact pointwise moduli to a UniformModulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactFanModulusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected branches, selected real limits, quotient cover equality, host analytic moduli, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan-bar coverage, compact selector coverage, rational fold exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactFanModulusSelecto

Chapter 6825

A Concrete Naming Certificate for $\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}$

Following Kuratowski and Zorn on maximal principles, the $\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}$ packet records the finite BEDC boundary at which a maximality request is visible without importing choice or a host-level maximal selector. It sits beside the ordered-carrier rows of chapter 1378 and chapter 53, the set-like membership rows of chapter 3668, the finite chain discipline of Definition 53.56, and the NameCert, BHist, Cont, and Pkg support surfaces already used by finite certificate packets. The chapter names the displayed pressure surface around Zorn-style maximality; it does not prove Zorn's lemma, does not add choice, and exports only finite displayed boundary data.

Definition 6825.1 (Kuratowski-Zorn lemma boundary carrier)**.** *A* $\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (O, S, C, U, M, F, H, R, P, N)$$

with the following displayed rows:

1. *O is the underlying* $\mathsf{Order}^{\uparrow}$ *or* $\mathsf{POSet}^{\uparrow}$ *source row whose comparison relation is being inspected through finite BEDC data.*
2. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership row for the displayed carrier fragment under inspection.*
3. *C is the chain-window row, recording a finite chain-like order window and its local comparison entries.*
4. *U is the upper-bound row, recording a proposed upper-bound witness for the same displayed chain window.*
5. *M is the maximality-request row, recording the consumer request that asks whether a displayed element can be extended inside the same order surface.*
6. *F is the refusal row for global choice, an unrestricted maximal selector, host powerset search, quotient collapse of chains, and an ambient proof of Zorn's lemma.*
7. *H records componentwise* hsame *transport for the order, membership, chain-window, upper-bound, maximality-request, refusal, provenance, and local naming rows.*
8. *R records displayed* Cont *replay for finite inspection of the same rows.*
9. *P is the* Pkg *provenance over the order, set-like, chain-window, upper-bound, maximality-request, refusal, transport, replay, and local naming surfaces.*

10. N is the local $\mathsf{NameCert}_{\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}}$ *row.*
The carrier contains no coordinate for a choice function, a maximal-element selector, a completed chain union outside the displayed upper-bound row, a host powerset traversal, or a proof of Zorn's lemma.

Theorem 6825.2 (Kuratowski-Zorn lemma boundary NameCert obligations)**.** *For the carrier of Definition 6825.1, the local* $\mathsf{NameCert}_{\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}}$ *surface consists exactly of finite carrier admission for $Z = (O, S, C, U, M, F, H, R, P, N)$, order and set-like source exposure through O, S, chain-window exposure through C, upper-bound exposure through U, maximality-request exposure through M, refusal exactness through F, componentwise transport through H, replay through R, provenance through P, and local naming through N.*

Proof. Project the carrier rows. The order source and set-like membership rows are read through chapter 1378, chapter 53, and chapter 3668, while the finite chain-window row is read through the finite chain-like order surface of Definition 53.56.

Read the maximality-facing rows next. The upper-bound row U is attached to the same displayed chain window C, and the maximality-request row M records only the finite request seen by the consumer. The row F refuses a global choice function, a maximal selector, host powerset traversal, quotient collapse of chain data, and a proof of Zorn's lemma.

Finally transport, replay, source, and name the packet through H, R, P, N. These rows are the standard NameCert, BHist, Cont, and Pkg support surface for finite BEDC certificates, so the obligation list is exhausted by the displayed packet and no hidden maximal-principle resource is exported. □

Theorem 6825.3 (Kuratowski-Zorn lemma boundary choice refusal)**.** *Every accepted* KuratowskiZornLemmaBound *read that exposes a Zorn-style maximality request must factor through the finite chain-window row C, the displayed upper-bound row U, the maximality-request row M, and the refusal row F before any order consumer reads the packet. Consequently the boundary does not prove Zorn's lemma, does not add choice, does not select a maximal element, and exports only finite displayed boundary data.*

Proof. Begin with the NameCert obligations of Definition 6825.2. They force the order source, set-like source, chain-window, upper-bound, maximality request, refusal, transport, replay, provenance, and local naming rows to be read as one finite packet.

If the refusal row is absent, the consumer has no BEDC record separating a finite maximality request from a host choice principle or maximal selector. If the chain-window or upper-bound row is absent, the request is no longer grounded in displayed finite order data. If transport, replay, provenance, or local naming is absent, the request is detached from the certificate surface.

Thus an accepted read can expose only the finite boundary around a maximal-principle request. The carrier records where Zorn-style pressure appears, while refusing a proof of Zorn's lemma, choice, global maximal selection, and ambient powerset search. □

Falsifiable prediction: Any accepted KuratowskiZornLemmaBoundaryUp packet that exposes a maximality request while omitting the finite chain-window, displayed upper-bound, refusal, transport, replay, provenance, or local naming rows refutes the packet.

Independence witness: order, poset, setlike, finite-chain: none is bijective with $\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}$ because this packet jointly carries chain-window rows, upper-bound rows, a maximality request, and explicit refusal of global choice and maximal selectors.

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}$ packet is generated from order or POSet source rows, SetLike membership rows, finite chain-window rows, displayed upper-bound rows, a maximality-request row, a refusal row for choice and maximal selectors, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6825.1, Definition 6825.2, and Definition 6825.3 seed the finite boundary around Zorn-style maximality requests without proving Zorn's lemma or adding choice.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiZornLemmaBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Zorn's lemma, global choice, maximal-element selection, host powerset traversal, quotient chain collapse, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite chain-window exposure, upper-bound exposure, maximality-request exactness, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.KuratowskiZornLem

Chapter 6826

A Concrete Naming Certificate for $\mathsf{ClassifyingSpace}^{\uparrow}$

Following Steenrod and May on universal bundles, classifying spaces, and simplicial models for topological classification, the $\mathsf{ClassifyingSpace}^{\uparrow}$ packet records a finite NameCert seed for the route from a displayed topological group action to a bundle classifier. It sits after the $\mathsf{TopGroup}^{\uparrow}$ operation and continuity surface of chapter 204, the $\mathsf{Bundle}^{\uparrow}$ local-trivialization surface of chapter 97, the $\mathsf{Homotopy}^{\uparrow}$ deformation route of chapter 156, the $\mathsf{SimplicialSet}^{\uparrow}$ face-and-degeneracy ledger of chapter 157, and the $\mathsf{Cat}^{\uparrow}$ object-and-arrow carrier of chapter 61. The chapter names only finite classifier rows, universal-bundle dependency rows, simplicial approximation rows, homotopy transport, categorical provenance, replay, and local naming; it does not construct quotient spaces, choose representatives of orbits, assert ambient homotopy equivalence, or import a host principal-bundle classification theorem.

Definition 6826.1 (ClassifyingSpace carrier)**.** *A* $\mathsf{ClassifyingSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (G, U, S, H, C, T, R, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{TopGroup}^{\uparrow}$ *row whose multiplication, unit, inverse, and continuity data are used by the classifier.*
2. *U is the* $\mathsf{Bundle}^{\uparrow}$ *row naming the displayed universal-bundle dependency and its local trivialization data.*
3. *S is the* $\mathsf{SimplicialSet}^{\uparrow}$ *row carrying finite face and degeneracy ledgers used to present the classifying object.*
4. *H is the* $\mathsf{Homotopy}^{\uparrow}$ *row recording the deformation route through which bundle classifiers are compared.*
5. *C is the* $\mathsf{Cat}^{\uparrow}$ *row naming the finite object and arrow context for classifier morphisms and pullback-shaped reads.*
6. *T records componentwise* hsame *transport for the topological-group, bundle, simplicial, homotopy, and category rows.*
7. *R records displayed* Cont *replay of classifier reads through G, U, S, H, C, T.*

8. *P is the* Pkg *provenance over* $\mathsf{ClassifyingSpace}^{\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassifyingSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-space formation, orbit-representative choice, host homotopy equivalence, ambient universal object selection, or an unrestricted principal-bundle classification theorem.

Lean4 ✓ `BEDC.Derived.ClassifyingSpaceUp.ClassifyingSpaceTasteGate single carrier alignment`

Theorem 6826.2 (ClassifyingSpace NameCert obligations)**.** *For the carrier of Definition 6826.1, the local* $\mathsf{NameCert}_{\mathsf{ClassifyingSpace}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed packet $B = (G, U, S, H, C, T, R, P, N)$;*
2. *topological-group exposure through the* $\mathsf{TopGroup}^{\uparrow}$ *row G;*
3. *universal-bundle and classifier exposure through the* $\mathsf{Bundle}^{\uparrow}$ *row U together with the* $\mathsf{SimplicialSet}^{\uparrow}$ *row S;*
4. *homotopy and categorical transport through the* $\mathsf{Homotopy}^{\uparrow}$ *row H, the* $\mathsf{Cat}^{\uparrow}$ *row C, and componentwise transport T;*
5. *replay, provenance, and local naming through R, P, N.*

Ledger exactness says that every accepted classifying-space read exposes precisely those rows before a bundle-classifier route is consumed. The obligations do not add quotient spaces, selected orbit representatives, host universal bundles, ambient homotopy equivalences, or a principal-bundle classification theorem.

Theorem 6826.3 (ClassifyingSpace principal-bundle route)**.** *Every accepted* $\mathsf{ClassifyingSpace}^{\uparrow}$ *packet routes a principal-bundle classifier read through*

$$\mathsf{TopGroup}^{\uparrow},\ \mathsf{Bundle}^{\uparrow},\ \mathsf{SimplicialSet}^{\uparrow},\ \mathsf{Homotopy}^{\uparrow},\ \mathsf{Cat}^{\uparrow}.$$

The topological-group row fixes the structure group surface, the bundle row fixes the local-trivialization dependency, the simplicial row presents the finite classifying object ledger, the homotopy row records classifier comparison, and the category row records the object-and-arrow context for pullback-shaped reads. A consumer that omits one of these rows is outside the accepted $\mathsf{ClassifyingSpace}^{\uparrow}$ *carrier.*

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifyingSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassifyingSpace}^{\uparrow}$ packet is generated from TopGroupUp operation data, BundleUp local-trivialization data, SimplicialSetUp face and degeneracy ledgers, HomotopyUp comparison routes, CategoryUp object and arrow context, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClassifyingSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6826.1, Definition 6826.2, and Definition 6826.3 seed the finite classifying-space NameCert surface over topological groups, bundles, homotopy, simplicial carriers, and categories.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClassifyingSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient-space formation, orbit-representative choice, ambient universal-object selection, host homotopy equivalence, principal-bundle classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topological-group exposure, universal-bundle dependency, simplicial ledger exactness, homotopy comparison, categorical context, transport, replay, provenance, and local naming for BEDC.Derived.ClassifyingSpaceUp.

Chapter 6827

A Concrete Naming Certificate for $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$ packet records the finite boundary around Dedekind completeness for the real-name route. It sits beside the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the Cauchy route of chapter 3380, and the located substitute of chapter 1427. The packet names the separation between accepted Cauchy and located real-name handoffs and the unavailable assertion that $\mathsf{Real}^{\uparrow}$ is Dedekind complete.

Definition 6827.1 (Real Dedekind-completeness boundary carrier)**.** *A* $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, R, S, L, C, H, P, N)$$

with the following displayed rows:

1. *D is the cut-style request row, recording the attempted least-upper-bound or cut-completion read without admitting a Dedekind-cut carrier.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposing only the existing real-name endpoint accepted by the surrounding real-name route.*
3. *S is the joint* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, requiring every accepted real-facing observation to pass through finite stream windows and regular rational data.*
4. *L is the located substitute row, pointing the request toward located supremum or located Cauchy-completeness surfaces when those rows are present.*
5. *C records displayed* Cont *replay from the cut-style request to the real-name seal, the readback row, the located substitute, and the local boundary name.*
6. *H records componentwise* hsame *transport for D, R, S, L, C, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{RealCauchyCompleteness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, R, S, L, C, H, P, N. It has no coordinate for a Dedekind-cut construction, quotient real equality, trichotomy, countable choice, selected suprema, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6827.2 (Real Dedekind-completeness boundary NameCert obligations)**.** *For every accepted* $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$ *carrier* $K = (D, R, S, L, C, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealDedekindCompl}}$ *surface consists exactly of carrier admission for the eight displayed rows, route exposure through the* $\mathsf{Real}^{\uparrow}$ *seal and the* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *readback row, located substitute exactness through* L*, non-claim boundary for the omitted Dedekind-completeness coordinates, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 6827.1. The packet exposes only D, R, S, L, C, H, P, N, so any boundary read must begin with those rows.

Route exposure is forced by R and S. The real-facing endpoint is the existing $\mathsf{Real}^{\uparrow}$ seal R, and the readback surface S requires finite $\mathsf{StreamName}^{\uparrow}$ windows together with $\mathsf{RegSeqRat}^{\uparrow}$ data before the endpoint can be consumed.

The located substitute is exactly the row L. When a supremum-shaped request has located evidence, L points to the located route rather than to an arbitrary cut-completion assertion; otherwise the request remains only the displayed boundary row D.

The non-claim boundary follows from the missing coordinates. Since no row stores Dedekind-cut construction data, quotient real equality, trichotomy, countable choice, selected suprema, or ambient completeness, the local certificate cannot export any of those principles.

Finally H, C, P, N transport, replay, source, and name precisely the same rows. Componentwise transport preserves the boundary inventory, continuation replay preserves the read order, and the provenance ledger adds no independent completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$ consumer that presents a Dedekind-completeness read for RealUp must display the cut-style request row, the RealUp seal row, the StreamName and RegSeqRat readback row, the located substitute row, transport, continuation replay, provenance, and local naming.

Independence witness: real, streamname, regseqrat, locatedsupremum, real-cauchy-completeness: $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$ is not bijective to any listed sibling because it stores the rejected cut-style request together with the accepted real-name seal, finite readback route, located substitute, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}$ packet is generated from a cut-style request row, a RealUp seal row, StreamName and RegSeqRat readback, a located substitute row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6827.1 and Definition 6827.2 seed the finite boundary separating accepted Cauchy and located RealUp routes from a Dedekind-completeness claim.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealDedekindCompletenessBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter excludes Dedekind-cut construction, quotient real equality, trichotomy, countable choice, selected suprema, ambient Real completeness, Lean verification, and bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed Real Dedekind-completeness boundary route.

Chapter 6828

A Concrete Naming Certificate for $\mathsf{DyadicIntervalCompletion}^{\uparrow}$

Following Bishop and Bridges on interval methods and regular real approximation, the $\mathsf{DyadicIntervalCompletion}^{\uparrow}$ packet realizes the L10 interval-completion route of chapter 9238 as finite NameCert data. It consumes the dyadic endpoint surface of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite route from shrinking dyadic intervals to a Real-facing seal; it does not add a quotient stream, selected limit, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6828.1 (Dyadic interval completion carrier)**.** *A* $\mathsf{DyadicIntervalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, T, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the shrinking dyadic interval row, recording left and right endpoint data over* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *T is the endpoint tolerance ledger, recording the finite radius and endpoint comparison obligations attached to the same interval row.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the inspected interval stages.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows and tolerance ledgers.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, T, S, R have been displayed.*
6. *H records componentwise* hsame *transport for the interval, tolerance, stream-window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an interval-completion request through I, T, S, R, E and back to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalCompletion}^{\uparrow}}$ *row.*

The carrier exports only this finite interval-completion packet. It has no coordinate for quotient streams, selected limits, countable-choice schedules, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.DyadicIntervalCompletionUp`

Theorem 6828.2 (Dyadic interval completion NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalCompletion}$ *carrier* $K = (I, T, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission through the displayed packet, interval shrinking through* I*, endpoint tolerance ledger exposure through* T*, finite-window readback through* S *and* R*, Real-seal nonescape through* E*, componentwise transport through* H*, displayed replay through* C*, provenance exhaustion through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6828.1. The rows $I, T, S, R, E, H, C, P, N$ are the complete visible packet, so carrier admission can only admit data already displayed in those rows.

The interval route first reads I and T. Thus the shrinking dyadic endpoints and their endpoint tolerance ledger are exposed before any stream window, regular readback, or real seal can be consumed.

Next read S and R. The stream row names the finite inspected stages, while the regular rational row supplies readback from the same finite data. The seal row E is downstream of that finite route and cannot introduce an independent completeness principle.

Finally use H, C, P, N. These rows transport, replay, source, and name the same packet, so the provenance ledger is exhausted by the displayed carrier surface. □

Theorem 6828.3 (Dyadic interval completion Real-seal route)**.** *Every completion-facing read of an accepted* $\mathsf{DyadicIntervalCompletion}^{\uparrow}$ *packet factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the finite rows $I, T, S, R, E, H, C, P, N$*. The route may transport and replay the displayed interval-completion packet, but it cannot export a quotient stream, selected limit, countable choice, host equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the obligation theorem. It forces every completion-facing consumer to expose the dyadic interval row, endpoint tolerance ledger, finite stream window, and regular rational readback before the terminal Real seal can be inspected.

The cited sibling chapters supply exactly those surfaces. DyadicRatCore supplies the endpoint and tolerance rows, StreamName supplies finite windows, RegSeqRat supplies regular rational readback, and the Real chapter supplies the terminal seal row.

The structural rows then preserve the same route. Componentwise hsame transport and displayed Cont replay cannot add a new completion coordinate, while P and N source and name the finite packet. No row remains from which a consumer could recover quotient streams, selected limits, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalCompletion}^{\uparrow}$ packet is generated from shrinking DyadicRatCoreUp interval rows, endpoint tolerance ledgers, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicIntervalCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 6828.1, Definition 6828.2, and Definition 6828.3 seed the finite interval-completion route from dyadic endpoints to a Real-facing seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicIntervalCompletion}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.DyadicIntervalCompletionUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval shrinking, endpoint tolerance ledger exposure, finite-window readback, Real-seal nonescape, transport, replay, provenance exhaustion, and local naming for BEDC.Derived.DyadicIntervalCompletionUp.

Chapter 6829

A Concrete Naming Certificate for $\mathsf{HopfFibration}^{\uparrow}$

Following Hopf's fibration theorem, the $\mathsf{HopfFibration}^{\uparrow}$ packet records the circle-fibre projection from the displayed three-sphere source to the displayed two-sphere target as finite BEDC NameCert data. It sits over the circle carrier of chapter 58, the bundle surface of chapter 97, the Lie-group endpoint rows of chapter 140, the vector-bundle bookkeeping of chapter 210, and the Riemann-sphere chart target of chapter 6698. The packet names the fibration route only through displayed rows; it does not import a host quotient sphere, ambient smooth map equality, selected local sections, or a completed principal-bundle theorem.

Definition 6829.1 (Hopf fibration carrier)**.** *A* $\mathsf{HopfFibration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (S^3, S^2, F, \Pi, C, L, V, T, R, P, N)$$

with the following displayed rows:

1. S^3 *is the source sphere row whose circle-phase boundary is read through* $\mathsf{NameCert}_{\mathsf{S}^{1\uparrow}}$.
2. S^2 *is the target sphere row, read through the* $\mathsf{RiemannSphere}^{\uparrow}$ *chart surface.*
3. F *is the circle-fibre row, displaying the* $\mathsf{S}^{1\uparrow}$ *fibre over each inspected target observation.*
4. Π *is the projection row from the source packet to the target packet.*
5. C *is the componentwise classifier for source, target, fibre, projection, chart, and fibre-action rows.*
6. L *is the local trivialization ledger supplied through the* $\mathsf{Bundle}^{\uparrow}$ *dependency surface.*
7. V *records the vector-bundle and tangent-window rows used only to compare displayed local coordinates.*
8. T *records componentwise* hsame *transport for* $S^3, S^2, F, \Pi, C, L, V$ *and their dependency rows.*
9. R *records displayed* Cont *replay from a fibre request through projection, chart readback, circle-fibre readback, and local trivialization.*
10. P *is the* Pkg *provenance over* $\mathsf{HopfFibration}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, $\mathsf{LieGroup}^{\uparrow}$, $\mathsf{VectorBundle}^{\uparrow}$, $\mathsf{RiemannSphere}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. N *is the local* $\mathsf{NameCert}_{\mathsf{HopfFibration}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of spheres, selected global section, ambient smooth-map extensionality, or a host principal-bundle object outside the displayed packet.

Theorem 6829.2 (Hopf fibration NameCert obligations)**.** *For every accepted* $\mathsf{HopfFibration}^{\uparrow}$ *carrier* $H = (S^3, S^2, F, \Pi, C, L, V, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HopfFibration}^{\uparrow}}$ *surface consists exactly of source-sphere admission, target-chart admission, circle-fibre exposure, projection exposure, classifier stability, local trivialization ledger exposure, vector-window comparison, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6829.1. The geometric rows are S^3, S^2, F, Π, L, V, while C, T, R, P, N are the classifier, transport, replay, provenance, and naming rows attached to the same packet.

The source and target rows are read only through their displayed dependencies. The source circle phase reaches chapter 58; the target chart reaches chapter 6698; and the local trivialization reaches chapter 97.

The fibre row F is then compared through the $\mathsf{S}^{1\uparrow}$ and $\mathsf{LieGroup}^{\uparrow}$ rows, while V supplies only the finite vector-window comparison used by local coordinates. Componentwise transport through T and replay through R preserve exactly those rows.

Since no carrier coordinate names a host quotient sphere, selected global section, smooth-map extensionality principle, or external principal bundle, the listed rows exhaust the local NameCert surface. □

Theorem 6829.3 (Hopf fibration circle-fibre handoff)**.** *Every* $\mathsf{Bundle}^{\uparrow}$*,* $\mathsf{LieGroup}^{\uparrow}$*, or* $\mathsf{RiemannSphere}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{HopfFibration}^{\uparrow}$ *packet must expose the source row* S^3*, target row* S^2*, circle-fibre row* F*, projection row* Π*, local trivialization ledger* L*, vector-window row* V*, transport row* T*, replay row* R*, provenance row* P*, and local name row* N *before the circle-fibre handoff can be consumed. The handoff exports only the displayed* $\mathsf{S}^{1\uparrow}$ *fibre over the displayed target row.*

Proof. Start with Definition 6829.2. It makes the source sphere, target chart, circle fibre, projection, local trivialization, and vector-window comparison rows first-class parts of the accepted packet.

A bundle consumer can therefore read a fibre only after the projection and local trivialization rows have been displayed. A Lie-group consumer reaches only the circle action already present in the $\mathsf{S}^{1\uparrow}$ fibre row, and a Riemann-sphere consumer reaches only the target chart row S^2.

Finally the structural rows T, R, P, N keep the same packet boundary under transport, replay, provenance, and naming. Thus the handoff is the displayed circle-fibre route itself, with no selected global section, quotient sphere equality, ambient smooth-map equality, or completed principal-bundle theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{HopfFibration}^{\uparrow}}$.

Constructive story: A $\mathsf{HopfFibration}^{\uparrow}$ packet is generated from displayed source-sphere rows, target Riemann-sphere chart rows, circle-fibre rows, projection rows, classifier stability, local trivialization ledgers, vector-window comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HopfFibration}^{\uparrow}}$, seed)

Scope closed: Definition 6829.1, Definition 6829.2, and Definition 6829.3 seed the finite circle-fibre projection route from the displayed three-sphere source to the displayed Riemann-sphere target.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HopfFibration}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.HopfFibrationUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality of spheres, selected global sections, ambient smooth-map equality, host principal bundles, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, target-chart exposure, circle-fibre exposure, projection exposure, local trivialization exactness, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.HopfFibrationUp.

Lean4 (statement) `BEDC.Derived.HopfFibrationUp`

Chapter 6830

A Concrete Naming Certificate for $\mathsf{Kelleyfication}^{\uparrow}$

Following Kelley and Steenrod compactly generated topology, the $\mathsf{Kelleyfication}^{\uparrow}$ packet records the compactly generated reflection of a topology as finite BEDC data. It sits after the topology carrier of chapter 88, the core-compact neighbourhood route of chapter 6350, and the compact-open topology ledger of chapter 4138. The packet names only the compact-window tests through which a topology is reflected; it does not import a host category of spaces, arbitrary open-cover compactness, quotient-open equality, or choice-selected compact witnesses.

Definition 6830.1 (Kelleyfication carrier)**.** *A* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, C, O, W, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row whose carrier, open-incidence rows, and classifier are already admitted as finite topology data.*
2. *C is the* $\mathsf{CoreCompact}^{\uparrow}$ *row, or an equivalent compactly generated test row, recording which compact-window probes may be used to inspect the source topology.*
3. *O is the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *finite compact-window ledger. It lists the compact-domain windows and open-target tests used to decide reflected openness.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *inspection window, recording the finite observations through which a consumer reads the compact-window ledger.*
5. *H records componentwise* hsame *transport for the source topology, compact-generation tests, compact-open ledger, inspection window, replay, provenance, and local naming rows.*
6. *R records displayed* Cont *replay from a reflected-open request through T, C, O, W, H before any downstream topology or function-space consumer reads the result.*
7. *P is the* Pkg *provenance over* $\mathsf{Kelleyfication}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CoreCompact}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Kelleyfication}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through T, C, O, W, H, R, P, N. It has no coordinate for arbitrary host opens, quotient-open equality, an unrestricted category of compactly generated

spaces, open-cover compactness, countable choice, or selected compact tests outside the displayed ledger.

Lean4 ✓ `BEDC.Derived.KelleyficationUp.KelleyficationTasteGate single carrier alignment`

Theorem 6830.2 (Kelleyfication NameCert obligations)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier* $K = (T, C, O, W, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Kelleyfication}^{\uparrow}}$ *surface consists exactly of source-topology exposure through* T*; compactly generated test exposure through* C*; compact-open finite-window exposure through* O*; finite inspection through* W*; componentwise transport through* H*; displayed replay through* R*; provenance through* P*; and local naming through* N*. Every reflected-open read must first pass through the topology source of chapter 88, the core-compact route of chapter 6350, and the compact-open topology ledger of chapter 4138.*

Lean4 ✓ `BEDC.Derived.KelleyficationUp.KelleyficationCarrier namecert obligations`

Proof. Project the carrier in Definition 6830.1. The displayed rows are exactly T, C, O, W, H, R, P, N, so any accepted read begins with the source topology, the compact-generation test row, the compact-window ledger, and the finite inspection window.

The compactly generated reflection is read through sibling rows rather than through a host topology predicate. The topology source supplies the original open-incidence data, the core-compact row supplies compact-neighbourhood tests, and the compact-open topology row supplies the finite compact-window ledger.

Transport and replay preserve those rows componentwise. Provenance and local naming then bind the same packet as a $\mathsf{Kelleyfication}^{\uparrow}$ certificate. Since no quotient-open equality, arbitrary open-cover compactness, selected compact-test family, or ambient category row occurs in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 6830.3 (Kelleyfication compact-generated obligation)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier* $K = (T, C, O, W, H, R, P, N)$*, the compact-generated obligation is a row projection from the displayed carrier:* T *supplies the* $\mathsf{Topology}^{\uparrow}$ *source,* C *supplies the* $\mathsf{CoreCompact}^{\uparrow}$ *compact-generation tests,* O *supplies the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *compact-window ledger,* W *supplies the* $\mathsf{StreamName}^{\uparrow}$ *inspection window,* H *supplies componentwise* hsame *transport,* R *supplies displayed* Cont *replay,* P *supplies* Pkg *provenance, and* N *supplies the local* $\mathsf{NameCert}$ *row. No compact-generated read may be certified by a host topology predicate or by a compactness witness outside* T, C, O, W, H, R, P, N*.*

Lean4 ✓ `BEDC.Derived.KelleyficationUp.KelleyficationCarrier compact generated obligation`

Proof. Project the carrier of Definition 6830.1. The rows T, C, O, W, H, R, P, N are the only rows available to an accepted $\mathsf{Kelleyfication}^{\uparrow}$ packet.

The compact-generated obligation is therefore read from the carrier, not transported in as an external parameter. The topology source T fixes the open-incidence data, the CoreCompact row C fixes the compact-generation tests, and the CompactOpenTopology row O fixes the finite compact-window ledger inspected through the StreamName row W.

The support rows preserve that same inventory. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming cannot create an additional compactness coordinate, so the compact-generated obligation is exhausted by the displayed rows. □

Theorem 6830.4 (Kelleyfication compact-open scope)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier* $K = (T, C, O, W, H, R, P, N)$*, the compact-open scope of a reflected-open read is exactly the finite*

route through the $\mathsf{Topology}^{\uparrow}$ *row* T*, the* $\mathsf{CoreCompact}^{\uparrow}$ *row* C*, the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *row* O*, the* $\mathsf{StreamName}^{\uparrow}$ *row* W*, the* BHist *packet rows, componentwise* hsame *transport* H*, displayed* Cont *replay* R*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. A downstream read cannot leave this route to consult quotient-open equality, ambient compact-open structure, or a selected family of compact witnesses.*

Proof. Read the carrier rows in order. The reflected-open request begins at the source topology row T, is restricted by the compact-generation row C, and reaches the compact-open ledger only through the finite window row O.

The inspection row W turns that compact-open ledger into a StreamName-visible finite observation. Since the underlying packet is a finite BHist carrier, the observation has no independent ambient compact-open coordinate.

Finally apply the support rows. The hsame row H and Cont row R replay the same T, C, O, W scope, while P and N record provenance and local naming for the same packet. Thus the compact-open scope is a carrier projection and not parameter transport. □

Theorem 6830.5 (Kelleyfication compact-open exactness)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier* $K = (T, C, O, W, H, R, P, N)$*, a reflected-open read is admitted exactly through the finite route*

$$T \to C \to O \to W \to H \to R \to P \to N.$$

The source topology row T *supplies the underlying open-incidence data, the* $\mathsf{CoreCompact}^{\uparrow}$ *row* C *supplies the compact-generation tests, the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *row* O *supplies the finite compact-window ledger, and the* $\mathsf{StreamName}^{\uparrow}$ *row* W *supplies the inspection windows. No reflected-open read is accepted from a host topology predicate, quotient-open equality, arbitrary compact-cover test, or selected compact family outside those rows.*

Proof. Project the carrier rows of Definition 6830.1. A reflected-open request has no coordinate before T, C, O, W are visible, so it first reads the topology source, core-compact test row, compact-open ledger, and inspection window.

The exactness assertion is row-local. The compact-generation row decides which compact-window probes are available, and the compact-open ledger records the corresponding source-open tests before the StreamName window exposes any finite observation.

The structural rows then preserve the same route. Componentwise hsame transport, displayed Cont replay, provenance, and local naming can only replay T, C, O, W; since the carrier contains no host-open coordinate or selected compact-family coordinate, every accepted reflected-open read factors through the displayed compact-open route. □

Theorem 6830.6 (Kelleyfication core-compact scope)**.** *In an accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier, compact-generation tests are scoped by the displayed rows* C *and* O*. A downstream topology or function-space consumer may inspect only the core-compact probes named by* C *and the compact-open windows named by* O*, after reading the source topology row* T *and before replay through* H, R, P, N*.*

Proof. Read the rows T, C, O from Definition 6830.1. The source topology row fixes the open-incidence data being reflected, while the core-compact row names the allowed compact-generation probes.

The compact-open ledger refines that scope to finite windows. Any consumer-facing test therefore has to pass through O after C, so it cannot introduce an unlisted compact test or a host compactness predicate.

Finally, the replay and naming rows preserve only the displayed ledger. The rows H, R, P, N transport, replay, source, and name the same compact-generation scope, so the accepted packet exports no additional compact-generation surface. □

Theorem 6830.7 (Kelleyfication inspection-window stability)**.** *Let $K = (T, C, O, W, H, R, P, N)$ be an accepted* Kelleyfication$^{\uparrow}$ *carrier. Componentwise* hsame *transport and displayed* Cont *replay preserve the finite inspection window W: after transport and replay, every reflected-open observation still reads the same source topology row, core-compact test row, compact-open ledger, and StreamName window. Transport and replay cannot add host opens, quotient-open equality, arbitrary open-cover compactness, or selected compact tests.*

Proof. Use the transport row H componentwise. It relates the source topology, compact-generation tests, compact-open ledger, inspection window, replay, provenance, and local naming rows without adding a new coordinate.

Now apply the replay row R. A replayed reflected-open observation must still traverse T, C, O, W before it reaches provenance or local naming, so the finite inspection window is unchanged.

The nonescape claim follows from the carrier shape. Host opens, quotient-open equality, arbitrary open-cover compactness, and selected compact tests are absent from K, and neither hsame nor Cont creates carrier fields. Thus stability preserves exactly the displayed Kelleyfication inspection route. □

Theorem 6830.8 (Kelleyfication compact-window exhaustion)**.** *For every accepted* Kelleyfication$^{\uparrow}$ *carrier $K = (T, C, O, W, H, R, P, N)$, every accepted reflected-open read is exhausted by the displayed rows T, C, O, W, H, R, P, N. The compact-window ledger O and the core-compact test row C must be read before any downstream topology or function-space consumer receives the reflected-open result. No such read may be supplied by host opens, quotient-open equality, arbitrary open-cover compactness, or a selected compact-test family outside the carrier.*

Proof. Project the carrier of Definition 6830.1. Its only reflected-open route starts at the source topology row T, then exposes the compact-generation tests C, the compact-window ledger O, and the finite inspection window W before any structural replay.

Apply compact-open exactness from Definition 6830.5. It identifies the accepted reflected-open read with the finite route

$$T \to C \to O \to W \to H \to R \to P \to N.$$

Next use core-compact scope from Definition 6830.6. A downstream topology or function-space consumer may inspect only the compact-generation probes named by C and the compact-open windows named by O, so both rows precede every consumer-facing read.

Finally replay inspection-window stability. Transport and continuation preserve the same T, C, O, W rows, while the carrier contains no coordinate for host opens, quotient-open equality, arbitrary open-cover compactness, or a selected compact-test family. Thus the displayed rows exhaust the reflected-open read. □

Lean4 ✓ `BEDC.Derived.KelleyficationUp.KelleyficationCarrier compact window exhaustion`

Theorem 6830.9 (Kelleyfication obligation-closure route)**.** *For every accepted* Kelleyfication$^{\uparrow}$ *carrier $K = (T, C, O, W, H, R, P, N)$, the obligation-closure route is the row projection that combines the compact-generated obligation, compact-open scope and exactness, core-compact scope,*

inspection-window stability, and compact-window exhaustion. The route exports exactly the topology source row T, compact-generation row C, compact-open ledger O, inspection window W, componentwise transport H, displayed replay R, provenance P, and local naming N, and it exports no host topology predicate, quotient-open equality, arbitrary open-cover compactness, or selected compact-test family.

Proof. Begin with the compact-generated obligation of Definition 6830.3. It makes the compact-generated read a projection from T, C, O, W, H, R, P, N.

Use compact-open scope and exactness, Definition 6830.4 and Definition 6830.5, together with core-compact scope Definition 6830.6. These force every reflected-open read through the finite route

$$T \to C \to O \to W \to H \to R \to P \to N.$$

Finally apply inspection-window stability and compact-window exhaustion, Definition 6830.7 and Definition 6830.8. They keep the same rows visible after transport and replay, so the obligation route contains no external compactness or quotient-open coordinate. □

Theorem 6830.10 (Kelleyfication transport replay obligation)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier $K = (T, C, O, W, H, R, P, N)$, the transport and replay obligation is local to the displayed rows: H transports the source topology, compact-generation tests, compact-open ledger, inspection window, replay, provenance, and local naming componentwise, while R replays only the reflected-open route already fixed by T, C, O, W. No transported or replayed read may introduce host opens, quotient-open equality, arbitrary open-cover compactness, or selected compact tests.*

Proof. Project the transport row H from Definition 6830.1. It has components only for the rows already displayed in the carrier, so it cannot add a new topology or compactness coordinate.

Now read the replay row R through compact-open exactness, Definition 6830.5. The replayed request must pass through T, C, O, W before provenance or local naming is exposed.

Inspection-window stability and compact-window exhaustion, Definition 6830.7 and Definition 6830.8, then identify the transported and replayed route with the same finite compact-window ledger. The excluded host and choice-selected objects are absent from every row used in the projection. □

Theorem 6830.11 (Kelleyfication carrier reflection)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier $K = (T, C, O, W, H, R, P, N)$, reflected topology data is visible only through the displayed rows T, C, O, W, H, R, P, N. In particular, a compact-open or topology consumer may read the* $\mathsf{Topology}^{\uparrow}$ *source,* $\mathsf{CoreCompact}^{\uparrow}$ *compact-generation tests,* $\mathsf{CompactOpenTopology}^{\uparrow}$ *ledger, StreamName inspection window, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming, but it may not read a host compactly generated topology or quotient-open equality outside those rows.*

Proof. Project the carrier of Definition 6830.1. The only reflected topology data carried by K are the source topology row T, compact-generation row C, compact-open ledger O, and inspection row W.

Apply the compact-generated obligation of Definition 6830.3. It makes every compact-generation read a row projection from the same carrier rather than an external topology predicate.

Now use compact-open exactness, Definition 6830.5. The reflected-open read follows T, C, O, W before the structural rows H, R, P, N can transport, replay, source, or name it. Since no host topology or quotient-open coordinate is present, reflection is exhausted by the displayed rows. □

Theorem 6830.12 (Kelleyfication compact-open test stability)**.** *Let $K = (T, C, O, W, H, R, P, N)$ be an accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier. Compact-open tests named by O remain stable under componentwise* hsame *transport and displayed* Cont *replay: after transport and replay, a reflected-open observation still reads the same source topology row, core-compact test row, compact-open ledger, and StreamName inspection window before any consumer sees the result.*

Proof. Begin with compact-open exactness, Definition 6830.5. It identifies an accepted reflected-open observation with the finite route through T, C, O, W, H, R, P, N.

Apply inspection-window stability from Definition 6830.7. The transport row H preserves the source topology, compact-generation tests, compact-open ledger, inspection window, replay, provenance, and local naming componentwise.

Finally use the transport replay obligation of Definition 6830.10. The replay row R replays only the compact-open route already fixed by T, C, O, W, so the transported test cannot acquire host opens, quotient-open equality, arbitrary open-cover compactness, or selected compact tests. □

Theorem 6830.13 (Kelleyfication StreamName scope)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier $K = (T, C, O, W, H, R, P, N)$, the StreamName row W bounds all reflected-open observations before a topology or function-space consumer reads the result. A consumer receives only compact-open observations visible through the finite route*

$$T \to C \to O \to W \to H \to R \to P \to N,$$

and receives no unwindowed compact-open test, host open predicate, quotient-open equality, or selected compact-test family.

Proof. Use core-compact scope, Definition 6830.6. It places the compact-generation tests in C and the compact-open windows in O after the source topology row T and before any downstream consumer.

Next apply inspection-window stability, Definition 6830.7. The StreamName row W remains attached to the same T, C, O route under componentwise transport and replay.

Finally apply compact-window exhaustion, Definition 6830.8. It forces every reflected-open read through T, C, O, W, H, R, P, N, so topology and function-space consumers cannot bypass the window by consulting unlisted compact-open tests or host open predicates. □

Theorem 6830.14 (Kelleyfication local naming obligation)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier $K = (T, C, O, W, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{Kelleyfication}^{\uparrow}}$ *row N names only the obligation surface already exposed by T, C, O, W, H, R, P. The naming row records the compact-generated source, compact-open window, core-compact scope, inspection-window stability, transport, replay, and provenance obligations; it does not name a host compactly generated topology object, quotient-open equality, arbitrary open-cover compactness, or selected compact-test family.*

Proof. Use the NameCert obligations theorem Definition 6830.2. It states that local naming is one row of the same accepted carrier and follows after source topology, compact-generation tests, compact-open ledger, inspection window, transport, replay, and provenance.

The obligation-closure route of Definition 6830.9 supplies the required row inventory. It combines compact-generated obligation, compact-open exactness, core-compact scope, inspection-window stability, and compact-window exhaustion without adding an external object.

Thus N names exactly the displayed Kelleyfication packet. Since the carrier lacks host compactly generated topology, quotient-open equality, arbitrary open-cover compactness, and selected compact-test coordinates, local naming cannot export them. □

Theorem 6830.15 (Kelleyfication compact-open subbase)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier* $K = (T, C, O, W, H, R, P, N)$*, the compact-open subbase visible to a downstream consumer is exactly the* BHist*-visible route through the* $\mathsf{Topology}^{\uparrow}$ *source row* T*, the* $\mathsf{CoreCompact}^{\uparrow}$ *window row* C*, the compact-open test ledger* O*, the StreamName inspection row* W*, componentwise* hsame *transport* H*, displayed* Cont *replay* R*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *naming* N*. No subbase element is certified by host compact-open topology data, selected compact witnesses, or quotient-open equality outside those rows.*

Proof. Project the carrier of Definition 6830.1. The compact-open ledger O is a row in the same finite BHist packet as the topology source T and the core-compact window row C.

The subbase read is therefore row-visible. It may inspect the $\mathsf{Topology}^{\uparrow}$ source, the $\mathsf{CoreCompact}^{\uparrow}$ windows, and the finite compact-open tests only through O and the StreamName window W.

The structural rows preserve that same inventory. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row authenticate the compact-open tests without adding host compact-open data or selected compact witnesses. □

Theorem 6830.16 (Kelleyfication corecompact window)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier* $K = (T, C, O, W, H, R, P, N)$*, each* $\mathsf{CoreCompact}^{\uparrow}$ *window exposed by* C *is read after the* $\mathsf{Topology}^{\uparrow}$ *source row* T *and before the compact-open test ledger* O*. The row sequence*

$$T \to C \to O \to W \to H \to R \to P \to N$$

is the complete consumer-facing path through BHist*-visible compact-open tests, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming.*

Proof. Begin with the source row T. It fixes the open-incidence data on which any core-compact window can be tested.

The row C then names the allowed compact-generation windows, and O records how those windows are used by compact-open tests. The StreamName row W is the only finite observation channel for those tests.

Finally apply the support rows. Transport H and replay R keep the displayed order, while P and N record provenance and local naming for the same packet. Since no other carrier coordinate exists, the displayed route is complete. □

Theorem 6830.17 (Kelleyfication NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{Kelleyfication}^{\uparrow}}$ *obligation surface for an accepted carrier* $K = (T, C, O, W, H, R, P, N)$ *consists exactly of* BHist*-visible compact-open tests over the* $\mathsf{Topology}^{\uparrow}$ *source row,* $\mathsf{CoreCompact}^{\uparrow}$ *windows, finite inspection through* W*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the naming row* N*. Every compact-open or corecompact consumer route must factor through these rows before it can cite the Kelleyfication packet.*

Proof. Use Definition 6830.15. It identifies compact-open subbase reads with the finite row route through T, C, O, W, H, R, P, N.

Use Definition 6830.16. It places each corecompact window between the topology source and the compact-open ledger, with StreamName inspection before transport, replay, provenance, and naming.

The local NameCert row cannot name anything outside that route. Thus the obligation surface is exactly the displayed compact-open and corecompact packet, not an ambient topology predicate or an external compactness witness. □

Theorem 6830.18 (Kelleyfication compact-window scope route)**.** *Every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *reflected-open consumer factors through the ordered finite route*

$$T \to C \to O \to W \to H \to R \to P \to N$$

of Definition 6830.1. The route is fixed by the compact-open subbase of Definition 6830.15, the corecompact window ordering of Definition 6830.16, and the local NameCert obligation surface of Definition 6830.17. It exports no host compactly generated topology, quotient-open equality, arbitrary open-cover compactness, selected compact-test family, or ambient category datum.

Proof. Start with the carrier of Definition 6830.1. A reflected-open consumer has access only to the displayed rows T, C, O, W, H, R, P, N, so its first possible route is the source topology, compact-generation test row, compact-open ledger, and finite inspection window.

Apply the compact-open subbase theorem, Definition 6830.15. It identifies consumer-visible compact-open tests with the same finite row route and prevents a consumer from reading host compact-open data or selected compact witnesses.

Next apply the corecompact window theorem, Definition 6830.16. It places each corecompact window after the topology source and before the compact-open ledger, so the compact-window request has the ordered prefix $T \to C \to O \to W$ before transport and replay.

Finally use the NameCert obligation surface of Definition 6830.17. The local naming row authenticates only the compact-open and corecompact route already displayed through H, R, P, N. Since the carrier has no coordinate for host compactly generated topology, quotient-open equality, arbitrary open-cover compactness, selected compact tests, or ambient category data, no accepted reflected-open consumer can leave the ordered finite route. □

Theorem 6830.19 (Kelleyfication reflection public interface)**.** *Every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier* $K = (T, C, O, W, H, R, P, N)$ *exposes a reflected-open public interface only through compact-generated rows. A consumer that asks for a reflected-open read must first pass through the* $\mathsf{Topology}^{\uparrow}$ *source row, the* $\mathsf{CoreCompact}^{\uparrow}$ *compact-window row, the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *compact-open ledger, the inspection window* W*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. No accepted read exports host compactly generated topology, quotient-open equality, selected compact witnesses, arbitrary open-cover compactness, or ambient category data.*

Proof. Start with the carrier of Definition 6830.1. Its visible route is exactly T, C, O, W, H, R, P, N, so a reflected-open consumer has no coordinate outside the topology source, compact-window row, compact-open ledger, inspection window, and structural rows.

Use the compact-generated obligation and compact-open exactness surfaces, Definition 6830.15 and Definition 6830.17. They force each reflected-open read to remain attached to the displayed compact-window and compact-open ledger before replay and naming.

Finally apply the corecompact scope and inspection-window stability blocks, Definition 6830.16 and Definition 6830.18. These place the $\mathsf{CoreCompact}^{\uparrow}$ window before the compact-open read and keep W, H, R, P, N downstream. Since no other row is present, the public interface exports only the compact-generated reflected-open rows. □

Theorem 6830.20 (Kelleyfication compact-window public export)**.** *For every accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *carrier, compact-window tests remain visible before any reflected-open read is exported. The public export route is*

$$T \to C \to O \to W \to H \to R \to P \to N,$$

so the compact-window row C and compact-open ledger O are part of the exported certificate rather than hidden witnesses.

Proof. Project the carrier of Definition 6830.1. The only route to a reflected-open read starts with the $\mathsf{Topology}^{\uparrow}$ source row T and then exposes the compact-window row C.

Apply the compact-open exactness theorem Definition 6830.15. It identifies the reflected-open read with the displayed compact-open ledger O over the same compact-window data.

Use the inspection-window stability route of Definition 6830.18. It keeps W visible before transport, replay, provenance, and naming are consumed. Therefore the public export cannot hide compact-window tests behind quotient-open equality or an ambient compactly generated topology. □

Theorem 6830.21 (Kelleyfication corecompact consumer boundary)**.** *Every* $\mathsf{CoreCompact}^{\uparrow}$ *consumer of an accepted* $\mathsf{Kelleyfication}^{\uparrow}$ *packet receives the finite neighbourhood route through* T, C, O, W, H, R, P, N *and does not receive quotient-open equality. The consumer may cite the compact-generated source, compact-window tests, compact-open ledger, inspection window, transport, replay, provenance, and local naming, but no selected compact-test family or host topology predicate is exported.*

Proof. Begin with the corecompact window theorem Definition 6830.16. It places the $\mathsf{CoreCompact}^{\uparrow}$ request after the source topology row and before the compact-open ledger.

Apply the NameCert obligation surface Definition 6830.17. The local certificate records only compact-open tests over the displayed source row, compact windows, inspection window, transport, replay, provenance, and naming.

The compact-window scope route Definition 6830.18 then gives the finite neighbourhood path $T \to C \to O \to W \to H \to R \to P \to N$. Since quotient-open equality, selected compact-test families, host topology predicates, and ambient category data are absent from the carrier, no corecompact consumer can read them. □

Closure status for $\mathsf{NameCert}_{\mathsf{Kelleyfication}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Kelleyfication}^{\uparrow}$ packet is generated from a topology source row, a compactly generated or CoreCompact test row, a compact-open finite-window ledger, a StreamName inspection window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Kelleyfication}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 6830.1 and the checked obligation theorem Definition 6830.2 enumerate the compact-generation, compact-open, inspection-window, transport, replay, provenance, and local naming obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Kelleyfication}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.KelleyficationUp.KelleyficationCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close host compactly generated topology, quotient-open equality, arbitrary open-cover compactness, choice-selected compact tests, Lean verification, or bridge checking.

Upgrade path: Public export requires the same compact-generation, compact-open, StreamName inspection, transport, replay, provenance, and local naming route to be exposed as a public reflected-open interface.

Chapter 6831

A Concrete Naming Certificate for $\mathsf{FiniteObservationTopology}^{\uparrow}$

The $\mathsf{FiniteObservationTopology}^{\uparrow}$ packet realizes the observer-expansion window of chapter 9463 as a concrete NameCert carrier. It sits beside the finite observation substrate of chapter 126, the topology carrier of chapter 88, and the hyperbolic observer-expansion packets referenced by the vision. The packet names a finite observation topology only through displayed windows, residue-boundary rows, transport, replay, provenance, and local naming; it does not install an ambient observer space, a completed boundary, or a host topological quotient.

Definition 6831.1 (Finite observation topology carrier)**.** *A* $\mathsf{FiniteObservationTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, E, B, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation source row, recording the finite windows through which an observer-expansion ledger may be inspected.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *row whose open-incidence data are restricted to the finite observation surface exposed by S.*
3. *E is the observer-expansion ledger row read from chapter 9463; it records the finite expansion coordinates without turning them into a global observer object.*
4. *B is the residue-boundary row, naming the visible boundary of the finite observation window and the hidden remainder left outside that window.*
5. *W is the finite topology-window ledger, listing which observations from S are used to test the topology row T and the expansion row E.*
6. *H records componentwise* hsame *transport for observation source, topology row, expansion ledger, residue boundary, topology-window ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite observation-topology request through S, T, E, B, W, H.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationTopology}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationTopology}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, E, B, W, H, C, P, N$. It has no coordinate for a completed observer manifold, a selected far-end point, a quotient topology on unseen observations, a global boundary compactification, or an unledgered hidden residue.

Theorem 6831.2 (Finite observation topology NameCert obligations)**.** *For every accepted* FiniteObservationTopolo *carrier $F = (S, T, E, B, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationTopology}^{\uparrow}}$ *surface consists exactly of finite observation source exposure through S; topology-row exposure through T; observer-expansion ledger exposure through E; residue-boundary exposure through B; finite topology-window exposure through W; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N. Lean follow-up requires* `Nontrivial` *and* `FieldFaithful` *instances before the corresponding TasteGate surface can be checked.*

Proof. Project the carrier in Definition 6831.1. The public observation-topology rows are exactly $S, T, E, B, W, H, C, P, N$.

The topology row is finite-facing. It can be inspected only through the windows listed by S and W, while E records the observer-expansion ledger and B records the residue boundary left outside the visible window.

Transport and replay preserve those rows componentwise. Provenance and local naming then bind the same finite observation surface as a $\mathsf{FiniteObservationTopology}^{\uparrow}$ certificate. Since no completed observer space, selected far-end point, quotient topology, global compactification, or unledgered residue row occurs in the carrier, the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: No accepted $\mathsf{FiniteObservationTopology}^{\uparrow}$ consumer can cite observer-expansion topology unless it first exposes the StreamName observation source, topology row, observer-expansion ledger, residue-boundary row, finite topology-window ledger, transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: finiteobservationresidueboundary, sierpinski-space, topology, streamname: no listed sibling is bijective with $\mathsf{FiniteObservationTopology}^{\uparrow}$ because this carrier alone binds finite observation windows, observer-expansion ledger rows, residue-boundary data, topology-window tests, transport, replay, provenance, and local NameCert rows into one accepted packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteObservationTopology}^{\uparrow}$ packet is generated from StreamName finite observation windows, a Topology row, an observer-expansion ledger, a residue-boundary row, finite topology-window tests, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteObservationTopology}^{\uparrow}}$, seed)

Scope closed: Definition 6831.1 and Definition 6831.2 seed the finite observer-expansion topology surface over observation, topology, residue-boundary, and provenance rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteObservationTopology}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a completed observer space, a selected far-end point, quotient topology on unseen observations, global boundary compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite observation source exposure, topology-window exactness, observer-expansion ledger stability, residue-boundary nonescape, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for BEDC.Derived.FiniteObservationTopologyUp.

Chapter 6832

CantorModulusContinuity name certificate construction

Following Brouwer and Bishop–Bridges, the $\mathsf{CantorModulusContinuity}^{\uparrow}$ packet records the constructive compact-prefix fact that a continuous map out of Cantor space is read through a finite inspected prefix before any modulus consumer acts. It sits beside the Cantor-space carrier of chapter 1475, the stream naming surface of chapter 126, the continuous-map row of chapter 130, the uniform-modulus route of chapter 369, and the compact-metric source of chapter 129. The packet is a finite certificate for compact-prefix continuity; it does not assert open-cover compactness, choose a bar-recursion branch, import countable choice, or identify host quotient function spaces.

Definition 6832.1 (Cantor modulus-continuity carrier)**.** *A* $\mathsf{CantorModulusContinuity}^{\uparrow}$ *carrier is a finite row*

$$K = (B, F, P, M, S, U, H, C, G, N),$$

where B *is the accepted* $\mathsf{CantorSpace}^{\uparrow}$ *source row,* F *is a* $\mathsf{ContinuousMap}^{\uparrow}$ *row out of* B*,* P *is the inspected prefix ledger,* M *is the finite modulus bound,* S *is the* $\mathsf{StreamName}^{\uparrow}$ *readback row,* U *is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay,* G *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{CantorModulusContinuity}^{\uparrow}}$ *row.*

Theorem 6832.2 (Cantor modulus-continuity classifier)**.** *An accepted* $\mathsf{CantorModulusContinuity}^{\uparrow}$ *packet classifies exactly those finite routes in which the continuous-map read* F *from the Cantor-space row* B *is exhausted by the displayed prefix ledger* P*, and the resulting modulus bound* M *is handed to the* $\mathsf{UniformModulus}^{\uparrow}$ *row* U *through the same stream row* S*. It rejects any route that obtains uniformity from open-cover compactness, a selected infinite cover, a host fan theorem oracle, quotient equality of functions, or ambient real-completion data.*

Proof. Read the source through chapter 1475. The Cantor-space row supplies finite binary prefix windows, so a continuity read can be inspected as a finite prefix request rather than as a host compact space.

The continuous-map and stream rows then determine the route F, P, S. The prefix ledger records which finite windows were read, and the modulus row M is the first carrier coordinate allowed to summarize those reads for downstream use.

Finally pass through U, H, C, G, N. The uniform-modulus handoff, transport, replay, provenance, and local name rows preserve the same finite packet, so no excluded compactness or choice source can be inserted without changing the carrier. □

Theorem 6832.3 (Cantor modulus-continuity NameCert obligations)**.** *For every accepted carrier $K = (B, F, P, M, S, U, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorModulusContinuity}^{\uparrow}}$ *row verifies the following five obligations:*

1. *the carrier binds one* $\mathsf{CantorSpace}^{\uparrow}$ *source row B, one* $\mathsf{ContinuousMap}^{\uparrow}$ *row F, one prefix ledger P, one modulus row M, and one* $\mathsf{StreamName}^{\uparrow}$ *row S;*
2. *the classifier accepts only routes where P records finite prefix windows read from B before M is exported;*
3. *the exactness row sends the same modulus bound M to the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff U and to no other modulus source;*
4. *the transport and replay rows H, C preserve the prefix ledger, continuous-map read, and modulus handoff componentwise;*
5. *the provenance and local naming rows G, N expose the route as finite BEDC NameCert data and not as open-cover compactness, countable choice, quotient function equality, or ambient completion.*

Proof. The carrier obligation is a projection from Definition 6832.1. It lists the rows that may be read by a consumer and leaves no coordinate for a host compactness theorem.

For classifier and exactness, use Definition 6832.2. It fixes the order B, F, P, M, S, U and makes M the finite summary of prefix inspection before the uniform-modulus handoff.

The remaining obligations are structural. The rows H, C, G, N transport, replay, source, and name the same finite route, so any attempted replacement by a selected cover, quotient equality, or external completion datum changes the packet rather than satisfying the local certificate. □

Theorem 6832.4 (Cantor modulus-continuity compact-prefix nonescape)**.** *Every accepted* $\mathsf{CantorModulusContinuit}$ *carrier $K = (B, F, P, M, S, U, H, C, G, N)$ exposes compact-prefix continuity only through the finite route $B, F, P, M, S, U, H, C, G, N$. A downstream* $\mathsf{UniformModulus}^{\uparrow}$ *consumer may read the modulus bound M through U, but it cannot split the read into open-cover compactness, selected subcovers, countable choice, quotient equality of continuous functions, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 6832.3. They bind B, F, P, M, S, U as one finite prefix-to-modulus route.

The structural rows H, C, G, N only preserve that route. Since the carrier has no coordinate for open-cover compactness, selected subcovers, quotient function equality, or ambient completion, a consumer that reads any such object has left the accepted packet. □

Falsifiable prediction: Any accepted $\mathsf{CantorModulusContinuity}^{\uparrow}$ packet that exports a $\mathsf{UniformModulus}^{\uparrow}$ row without first exhibiting the shared Cantor-space prefix ledger P and StreamName row S refutes this carrier.

Independence witness: cantorspace, streamname, continuousmap, uniformmodulus, compactmetric: no listed sibling is bijective with $\mathsf{CantorModulusContinuity}^{\uparrow}$, because this packet alone binds the Cantor source, continuous-map read, finite prefix ledger, modulus bound, StreamName readback, UniformModulus handoff, transport, replay, provenance, and local naming into one compact-prefix certificate.

Lean4 (statement) `BEDC.Derived.CantorModulusContinuityUp.CantorModulusContinuityUp`

Closure status for $\mathsf{NameCert}_{\mathsf{CantorModulusContinuity}^{\uparrow}}$ **·**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorModulusContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6832.1, Definition 6832.2, Definition 6832.3, and Definition 6832.4 seed the finite compact-prefix modulus carrier and its consumer boundary.

Constructive story: A CantorModulusContinuity$^{\uparrow}$ packet is generated from a CantorSpace source row, a ContinuousMap row, finite prefix ledger, modulus bound, StreamName readback, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Formal verification: FormalStatus(NameCert$_{\text{CantorModulusContinuity}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.CantorModulusContinuityUp.CantorModulusContinuityUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, fan theorem variants, quotient equality of maps, selected subcovers, or ambient real-completion principles.

Upgrade path: Obligation closure requires checked carrier admission, prefix-ledger exactness, StreamName readback stability, UniformModulus handoff, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorModulusContinuityUp

Chapter 6833

MetaCICClosedNormalJoinCertificate name certificate construction

The $\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}$ packet realizes the unconditional fragment of chapter 9378 as finite NameCert data. It consumes the normalization frontier of chapter 892 before exposing its local join ledger, so the closed-normal joins are routed through the sibling normalization lattice rather than floated as an isolated confluence row. It records closed-normal joins, closed sort joins, impossible closed-variable cases, atom-shape inversions, and the retained substitution-compatibility boundary without promoting those fragments to arbitrary closed Church–Rosser.

Definition 6833.1 (MetaCIC closed-normal join carrier)**.** *A* $\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}$ *carrier is a finite row*

$$J = (T, N, A, S, V, B, L, O, H, C, G, R),$$

where T is the closed MetaCIC term-window row, N is the closed-normal source row, A is the atom-shape row, S is the closed sort-join row, V is the impossible closed-variable row, B is the named substitution-boundary row, L is the local join ledger, O is the obstruction-retention row, H is componentwise hsame *transport, C is displayed* Cont *replay, G is* Pkg *provenance, and R is the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}}$ *row.*

Theorem 6833.2 (MetaCIC closed-normal join classifier)**.** *An accepted* $\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}$ *packet classifies exactly the checked closed-normal, closed-sort, closed-variable-impossible, and atom-shape confluence fragments named in chapter 9378. It refuses any packet that drops the displayed substitution boundary B, replaces the local join ledger L by a full* BetaParallelSubstitutionCompatibility *proof, or claims arbitrary closed Church–Rosser for* BetaStarStep *without that boundary.*

Proof. Read the confluence audit map. Its established section names closed normal confluence, closed sort confluence, closed variable impossibility, atom joins, and atom-shape inversions as available fragments.

The conditional section names the substitution-sensitive boundary. The carrier therefore keeps B as a row rather than erasing it when the local fragments N, A, S, V, L are packaged.

Transport, replay, provenance, and local naming preserve this separation. Thus the accepted classifier is finite and fragmentary: it is a join certificate for displayed closed-normal and atom sources, not a full closed Church–Rosser theorem. □

Theorem 6833.3 (MetaCIC closed-normal join NameCert obligations)**.** *For every accepted carrier $J = (T, N, A, S, V, B, L, O, H, C, G, R)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}}$ *row verifies the following five obligations:*

1. *the carrier binds closed term windows, closed-normal sources, atom-shape rows, sort joins, impossible closed-variable rows, substitution-boundary data, and local join ledgers as distinct fields;*
2. *the classifier accepts the unconditional closed-normal and atom fragments while preserving the conditional full-confluence boundary named by chapter 9378;*
3. *exactness requires L to cite only joins licensed by N, A, S, V and to retain B whenever a consumer asks for a stronger closed-source confluence claim;*
4. *the obstruction row O records that arbitrary closed Church–Rosser is outside the packet until the substitution boundary is discharged;*
5. *the transport, replay, provenance, and local-name rows H, C, G, R preserve the same fragmentary carrier for downstream proof-obligation consumers.*

Proof. Project the carrier of Definition 6833.1. The rows are separate fields, so the substitution boundary cannot be hidden inside the local join ledger.

Apply the classifier theorem. It reads the established closed-normal and atom fragments from the audit map and keeps the conditional full-confluence interface visible as B.

The exactness, obstruction, and structural obligations follow by preserving that same row order through O, H, C, G, R. A consumer that claims arbitrary closed Church–Rosser without the boundary has changed the packet rather than read this certificate. □

Theorem 6833.4 (MetaCIC closed-normal join boundary retention)**.** *Every accepted* MetaCICClosedNormalJoinCer *packet exports closed-normal and atom confluence data only along the route $T, N, A, S, V, B, L, O, H, C, G, R$. The packet may feed proof-obligation consumers that need the unconditional fragments, but any consumer that asks for arbitrary closed Church–Rosser must still supply the displayed substitution-compatibility boundary.*

Proof. Use Definition 6833.3. The local join ledger L is licensed by the closed-normal, atom, sort, and impossible-variable rows, and it is paired with the boundary row B.

The obstruction row O records the non-escape condition. The structural rows then replay the same route without creating a full confluence theorem, so the stronger arbitrary closed-source claim remains conditional. □

Falsifiable prediction: Any MetaCICClosedNormalJoinCertificate$^{\uparrow}$ packet that claims arbitrary closed Church–Rosser for BetaStarStep without the displayed substitution boundary B refutes this carrier.

Independence witness: normalformconsistencyseal, metaciccriticalpath, subject-reduction-discharge-socket, metacicconfluenceauditwitness, metacicconfluencenormalfragment: no listed sibling is bijective with MetaCICClosedNormalJoinCertificate$^{\uparrow}$, because this packet jointly carries closed term windows, closed-normal joins, atom-shape rows, sort and impossible-variable fragments, the substitution boundary, the local join ledger, obstruction retention, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit Nontrivial MetaCICClosedNormalJoinCertificate$^{\uparrow}$ and FieldFaithful MetaCICClosedNormalJoinCertificate$^{\uparrow}$ TasteGate instances. Those instances must preserve $T, N, A, S, V, B, L, O, H, C, G, R$ as distinct rows before any checked carrier-alignment theorem can serve as the public TasteGate witness.

Lean4 (statement) `BEDC.Derived.MetaCICClosedNormalJoinCertificateUp.MetaCICClosedNormalJoinCertificateUp`

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6833.1, Definition 6833.2, Definition 6833.3, and Definition 6833.4 seed the closed-normal and atom confluence fragment carrier with substitution-boundary retention.

Constructive story: A $\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}$ packet is generated from closed term windows, closed-normal source rows, atom-shape rows, sort-join rows, impossible closed-variable rows, a substitution-boundary row, local join ledger, obstruction-retention row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICClosedNormalJoinCertificate}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MetaCICClosedNormalJoinCertificateUp.MetaCICClosedNormalJoinCertificateUp`

Bridge status: none

Not claimed: This chapter does not close arbitrary closed Church–Rosser, BetaParallelSubstitutionCompatibility, BetaParallelDiamondClosed, subject reduction, or full MetaCIC confluence.

Upgrade path: Obligation closure requires checked carrier admission, fragment classifier exactness, local join ledger stability, substitution-boundary retention, TasteGate nontriviality, field faithfulness, replay, provenance, and local naming for BEDC.Derived.MetaCICClosedNormalJoinCertificateUp.

Chapter 6834

A Concrete Naming Certificate for MetaCICSubjectReductionSocketCut$^{\uparrow}$

Following the standard subject-reduction proof-obligation discipline for dependent type theory, the MetaCICSubjectReductionSocketCut$^{\uparrow}$ packet records the exact finite cut separating the parameterised MetaCIC subject-reduction theorem from the blocked closed theorem. It sits beside the four-row discharge socket of chapter 719, the obligation packet of chapter 712, the trace packet of chapter 723, and the audit map of chapter 9377. The packet names the four discharge sockets, the parameterised theorem row, the checked obstruction row, transport, replay, provenance, and local naming; it does not close subject reduction.

Definition 6834.1 (MetaCIC subject-reduction socket-cut carrier)**.** *A* MetaCICSubjectReductionSocketCut$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, A, L, P, T, O, H, C, G, N)$$

with the following displayed rows:

1. *B is the beta-substitution socket, carrying* BetaSubstitutionPreservation *for the beta-redex case.*
2. *A is the application-argument socket, carrying* AppArgTypeStable *for argument congruence.*
3. *L is the lambda-domain socket, carrying* LamDomainSubjectReduction *for lambda-domain reduction.*
4. *P is the Pi-domain socket, carrying* PiDomainSubjectReduction *for Pi-domain reduction.*
5. *T is the parameterised* BEDC.MetaCIC.subject_reduction *row, readable only as consuming the four sockets B, A, L, P.*
6. *O is the checked obstruction row* BEDC.MetaCIC.closed_consistency_reduction_obstruction_not_available.
7. *H records componentwise* hsame *transport for the four sockets, the parameterised row, the obstruction row, provenance, replay, and local naming.*
8. *C records displayed* Cont *replay from socket reads to the parameterised row and from closed-theorem requests to the obstruction row.*
9. *G is the* Pkg *provenance row over MetaCIC typed reduction,* SubjectReduction$^{\uparrow}$*, the discharge socket, the obstruction audit,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{MetaCICSubjectReductionSocketCut}^{\uparrow}}$ *row.*

The carrier contains no unparameterised closed subject-reduction theorem, no host conversion rule, no erased derivation semantics, no quotient equality of MetaCIC terms, and no hidden normalization principle.

Theorem 6834.2 (MetaCIC subject-reduction socket-cut obligations)**.** *For an accepted* MetaCICSubjectReductionS *carrier $S = (B, A, L, P, T, O, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionSocketCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the four discharge sockets, parameterised-row exactness for T, obstruction-row exactness for O, componentwise transport through H, displayed replay through C, provenance through G, and local naming through N. A consumer may read T only after the four sockets B, A, L, P have all been displayed; a consumer asking for the closed theorem is routed to O.*

Proof. Project the accepted carrier. The four visible discharge sockets are B, A, L, P, and the only parameterised subject-reduction row is T.

Read the socket discipline through chapter 719. That packet already separates the four inputs consumed by parameterised subject reduction from the closed obstruction boundary.

Now inspect T and O. The row T records the checked parameterised theorem as a consumer of all four sockets, while O records the checked obstruction described in Definition 9377.5. These rows are different coordinates, so the obstruction row cannot be used as a substitute proof of closed subject reduction.

Finally H, C, G, N transport, replay, source, and name the same cut. Since no coordinate stores host conversion, erased derivation semantics, quotient equality, global normalization, or an unparameterised closed theorem, the listed rows exhaust the NameCert surface. □

Theorem 6834.3 (MetaCIC subject-reduction socket-cut non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{MetaCICSubjectReductionSocketCut}^{\uparrow}$ *packet factors through*

$$B, A, L, P, T, O, H, C, G, N.$$

The consumer receives the four discharge sockets, the parameterised theorem row, the checked obstruction row, componentwise hsame *transport, displayed* Cont *replay, provenance, and local naming. It cannot export a closed subject-reduction theorem, host conversion, erased derivation semantics, quotient equality of MetaCIC terms, or an unrecorded MetaCIC premise.*

Proof. Start from the row inventory of Definition 6834.1. The packet has exactly ten displayed coordinates, so every public read is routed through $B, A, L, P, T, O, H, C, G, N$.

For a parameterised subject-reduction read, apply Definition 6834.2. The route reaches T only after the beta, application-argument, lambda-domain, and Pi-domain sockets have all been exposed and transported.

For a closed subject-reduction request, the same theorem routes the consumer to O. This row is the checked obstruction boundary, not a closed preservation proof, and its replay through C records refusal rather than theorem export.

The provenance row G cites only the displayed MetaCIC audit and socket surfaces. With no carrier coordinate for host conversion, erased derivation semantics, quotient equality, global normalization, or hidden premises, none of those objects can be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionSocketCut}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICSubjectReductionSocketCut}^{\uparrow}$ packet is generated from the four MetaCIC subject-reduction discharge sockets, the parameterised subject-reduction theorem row, the checked obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetaCICSubjectReductionSocketCut}\uparrow}$, seed)

Scope closed: Definition 6834.1, Definition 6834.2, and Definition 6834.3 seed the finite socket-cut packet separating parameterised subject reduction from the blocked closed theorem.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICSubjectReductionSocketCut}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, host conversion, global normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four-socket exposure, parameterised-row exactness, obstruction-row exactness, transport replay, provenance accounting, and non-escape for BEDC.Derived.MetaCICSubjectReductionSocket

Chapter 6835

A Concrete Naming Certificate for $\mathsf{RegularOpenAlgebra}^{\uparrow}$

Following Stone and Birkhoff on Boolean algebras of regular open sets, the $\mathsf{RegularOpenAlgebra}^{\uparrow}$ packet records the topology-facing Boolean algebra obtained by regularizing displayed opens through closure and interior. It sits beside the indexed-open topology of chapter 88, the finite closure rows of chapter 2145, the Boolean operation packet of chapter 3733, the generated-set consumer of chapter 3384, and the clopen handoff of chapter 261. The chapter names the regular-open algebra as finite NameCert data; it does not import a host powerset algebra, ultrafilter space, choice principle, or completed locale.

Definition 6835.1 (RegularOpenAlgebra carrier)**.** *A* $\mathsf{RegularOpenAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (O, C, I, K, J, M, H, R, P, N)$$

with the following displayed rows:

1. *O is the indexed open-set row read through* $\mathsf{Topology}^{\uparrow}$*.*
2. *C is the closure row read through the Kuratowski closure surface.*
3. *I is the interior row, displayed as the topology-facing open extractor paired with C.*
4. *K is the regularization row $I(C(O))$, naming the regular open representative obtained from the displayed open row.*
5. *J is the Boolean join row, read as regularized union on displayed regular-open rows.*
6. *M is the Boolean meet row, read as displayed intersection on regular-open rows.*
7. *H records Boolean complement as interior of the displayed closed complement boundary, transported only through the topology and closure rows already present.*
8. *R records componentwise* hsame *transport for open, closure, interior, regularization, Boolean operation, complement, provenance, replay, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularOpenAlgebra}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{BooleanAlgebra}^{\uparrow}$*, Kuratowski closure, Borel generated-set,* $\mathsf{StoneDuality}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularOpenAlgebra}^{\uparrow}}$ *row.*

The carrier contains no host powerset of opens, arbitrary complement oracle, selected ultrafilter, quotient locale, ambient Borel universe, or external Stone representation theorem.

Theorem 6835.2 (RegularOpenAlgebra NameCert obligations)**.** *For an accepted* $\mathsf{RegularOpenAlgebra}^{\uparrow}$ *carrier* $A = (O, C, I, K, J, M, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularOpenAlgebra}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, topology-row exposure through* O*, closure exposure through* C*, interior and regularization exactness through* I, K*, Boolean operation exposure through* J, M, H*, componentwise transport through* R*, provenance and replay through* P*, and local naming through* N*. Every topology, Boolean-algebra, Borel-facing, or Stone-duality consumer must read those rows before treating a displayed open as a regular-open algebra element.*

Proof. Project the accepted carrier. The visible inventory is exactly $O, C, I, K, J, M, H, R, P, N$, with no additional host set or algebra coordinate.

Read the topology and closure rows first. The row O supplies the indexed open surface, while C supplies the closure route already recorded by the Kuratowski closure packet. The interior row I is paired with the same topology surface, so the regularization row $K = I(C(O))$ is a displayed finite route rather than a powerset operation.

Read the Boolean rows next. Join J, meet M, and complement H are accepted only after regularization has exposed the relevant open, closure, and interior rows. Thus the Boolean-algebra consumer receives the finite complemented distributive-lattice interface of chapter 3733 through topology-facing data.

Finally R, P, N transport, source, replay, and name the same row inventory. Since no row stores host powersets, arbitrary complements, ultrafilters, quotient locales, completed Borel universes, or ambient Stone representation data, the listed obligations exhaust the local NameCert surface. □

Theorem 6835.3 (RegularOpenAlgebra closure-interior handoff)**.** *Every consumer of an accepted* $\mathsf{RegularOpenAlgebra}^{\uparrow}$ *packet that reads a regular-open element must factor through the finite handoff*

$$\mathsf{Topology}^{\uparrow},\ C,\ I,\ K,\ \mathsf{BooleanAlgebra}^{\uparrow},\ \mathsf{StoneDuality}^{\uparrow},\ R, P, N.$$

The handoff first reads the indexed open row, then the closure row, then the interior row, then the regularization row $I(C(O))$*, and only then exposes Boolean meet, join, and complement rows for Stone-duality or Borel-facing consumers. It exports no powerset algebra, selected ultrafilter, quotient locale, arbitrary complement choice, or ambient Borel completion.*

Proof. Start from the regularization row K. By carrier admission, K is readable only after the open row O, closure row C, and interior row I have been displayed.

Use Definition 6835.2. It forces Boolean join, meet, and complement reads to pass through the regularization route before a Boolean-algebra or Stone-duality consumer receives the packet.

The Borel-facing route is only a generated-set consumer route: it can observe the displayed regular open through the same topology and regularization rows, but it receives no completed Borel universe. The Stone-duality route likewise receives the Boolean rows after regularization, not an ultrafilter or point-space construction.

The structural rows R, P, N preserve and name this handoff. Since the carrier has no coordinate for host powersets, selected ultrafilters, quotient locales, arbitrary complement choice, or ambient Borel completion, those objects cannot be exported by the closure-interior route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularOpenAlgebra}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularOpenAlgebra}^{\uparrow}$ packet is generated from an indexed open row, closure row, interior row, regularization row, Boolean join, meet, and complement rows, componentwise hsame transport, provenance and replay rows, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularOpenAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6835.1, Definition 6835.2, and Definition 6835.3 seed the finite regular-open algebra packet over topology, closure, interior, regularization, Boolean operation, transport, provenance, replay, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularOpenAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host powerset algebras, ultrafilter construction, quotient locales, arbitrary complement choice, completed Borel universes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closure-interior regularization exactness, Boolean operation exposure, topology and Stone-duality handoff, transport stability, provenance replay, and non-escape for BEDC.Derived.RegularOpen

Chapter 6836

A Concrete Naming Certificate for $\mathsf{HeineCantorFiniteModulus}^{\uparrow}$

Following Heine–Cantor and Bishop–Bridges constructive analysis, the $\mathsf{HeineCantorFiniteModulus}^{\uparrow}$ packet records the finite-modulus route by which compact metric continuity becomes a uniform-modulus read without importing an open-cover compactness theorem. It sits beside the compact metric source of chapter 129, the continuous-map pointwise rows of chapter 130, the finite-net route of chapter 6769, the finite lower-bound fold of chapter 4096, the $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369, and the L10 readback boundary of chapter 126, chapter 301, and chapter 38. The certificate names the finite rows that a compact-uniform-continuity consumer may inspect; it does not select a host modulus or identify quotient functions.

Definition 6836.1 (Heine-Cantor finite-modulus carrier)**.** *A* $\mathsf{HeineCantorFiniteModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, N, J, L, U, W, R, E, H, C, P, Z)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row displaying the compact metric carrier and its finite-net coverage surface.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose pointwise modulus data are read only at the centers exposed by K and N.*
3. *N is the compact finite-net selector row, using the same finite center bundle and coverage ledger as* $\mathsf{HeineCantorFiniteNet}^{\uparrow}$*.*
4. *J is the pointwise modulus ledger pairing each center in N with the corresponding local continuity radius and target tolerance row from F.*
5. *L is the* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *row that folds the finitely many displayed lower-bound candidates in J into one positive precision row.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row reached only after K, F, N, J, L have been displayed.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *readback window opened for the source and target values used by the uniform-modulus consumer.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the observations in W.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite-net, fold, uniform-modulus, stream-window, and regular-rational rows have been consumed.*

10. *H records componentwise* hsame *transport for the compact source, continuous-map row, finite-net selector, pointwise ledger, fold, uniform-modulus consumer, L10 readback rows, replay row, provenance row, and local naming row.*
11. *C records displayed* Cont *replay from a target-tolerance request through the finite-net selector, pointwise modulus ledger, finite fold, uniform-modulus consumer, and L10 readback route.*
12. *P is the* Pkg *provenance over* $\mathsf{HeineCantorFiniteModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{HeineCantorFiniteNet}^{\uparrow}$, $\mathsf{FiniteLowerBoundFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *Z is the local* $\mathsf{NameCert}_{\mathsf{HeineCantorFiniteModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, a host-selected modulus, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6836.2 (Heine-Cantor finite-modulus NameCert obligations)**.** *For every accepted* HeineCantorFiniteModu *carrier $M = (K, F, N, J, L, U, W, R, E, H, C, P, Z)$, the local* $\mathsf{NameCert}_{\mathsf{HeineCantorFiniteModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, compact-net exposure through K, N, pointwise-to-uniform modulus handoff through F, J, L, U, L10 readback nonescape through W, R, E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through Z.*

Proof. Project the carrier of Definition 6836.1. The analytic rows are the compact source K, continuous-map row F, finite-net selector N, pointwise ledger J, fold row L, uniform-modulus consumer U, and readback rows W, R, E.

Read the compact-net exposure first. The selector row N uses only the finite centers and coverage ledger supplied by $\mathsf{CompactMetric}^{\uparrow}$ and the sibling $\mathsf{HeineCantorFiniteNet}^{\uparrow}$ route, so no open-cover compactness or host-selected cover is present.

Next pass from pointwise continuity to a uniform modulus. The ledger J pairs each displayed center with its pointwise modulus row from F, and the fold row L is the finite lower-bound fold consumed by U.

Finally attach the L10 readback route. The rows W, R, E expose StreamName windows, RegSeqRat readback, and the terminal Real seal only after the finite-modulus route has been displayed, while H, C, P, Z transport, replay, source, and name the same packet. Thus the listed obligations exhaust the local certificate surface and export no host modulus selection, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{HeineCantorFiniteModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HeineCantorFiniteModulus}^{\uparrow}$ packet is generated from a CompactMetric source row, ContinuousMap pointwise modulus rows, a compact finite-net selector, a pointwise modulus ledger, a FiniteLowerBoundFold row, a UniformModulus consumer row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HeineCantorFiniteModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6836.1 and Definition 6836.2 seed the finite-modulus route from compact metric pointwise continuity to a UniformModulus consumer with L10 readback rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HeineCantorFiniteModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host modulus selection, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, pointwise-to-uniform modulus handoff, L10 readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HeineCantorFiniteModulusUp.

Chapter 6837

A Concrete Naming Certificate for $\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}$

Following Sobolev, Poincare, Brezis, and Evans, the $\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}$ packet records the finite-energy handoff by which a displayed Sobolev packet and a displayed Poincare-control packet jointly expose bounded-domain energy data. It sits over the weak-derivative carrier of chapter 440, the norm-control estimate of chapter 2329, the energy ledger of chapter 5956, the rational readback route of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real seal of chapter 38. The packet names a finite energy-control certificate; it does not import Hahn–Banach separation, measure completion, selected representatives, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6837.1 (Sobolev–Poincare finite-energy carrier)**.** *A* $\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, Q, D, W, Y, A, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *weak-derivative source row whose function, domain, codomain, magnitude, and derivative-window data are exposed before any energy read.*
2. *Q is the* $\mathsf{PoincareInequality}^{\uparrow}$ *control row, recording the bounded-domain, boundary, or zero-mean route used to compare the displayed function magnitude with its derivative magnitude.*
3. *D is the bounded domain or bounded inspection window row through which the Poincare control is read.*
4. *W is the dyadic tolerance schedule supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$ *for the finite energy comparison.*
5. *Y is the* $\mathsf{ConstructiveSobolevEnergy}^{\uparrow}$ *row that stores the displayed derivative-energy and magnitude ledgers.*
6. *A is the dyadic accounting row, recording the finite rational inequalities consumed by the control estimate.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational energy and norm-control observations.*
8. *Z is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the Sobolev, Poincare, dyadic, and rational readback rows have been displayed.*

9. *H records componentwise* hsame *transport for S, Q, D, W, Y, A, R, Z and their dependency rows.*
10. *C records displayed* Cont *replay from a finite energy request through Sobolev exposure, Poincare control, dyadic accounting, rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{PoincareInequality}^{\uparrow}$, ConstructiveSobolevEn $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}}$ *row.*

The carrier has no coordinate for host measure completion, quotient equality of functions, selected representatives, global compactness, Hahn–Banach separation, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6837.2 (Sobolev–Poincare finite-energy NameCert obligations)**.** *For every accepted* $\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}$ *carrier $E = (S, Q, D, W, Y, A, R, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SobolevPoincareFiniteEn}}$ *surface consists exactly of carrier admission, Sobolev weak-derivative exposure, Poincare control exposure, bounded-domain or finite-window admission, dyadic tolerance accounting, constructive energy readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.SobolevPoincareFiniteEnergyUp.TasteGate.SobolevPoincareFiniteEnergyTasteGate`
`single carrier alignment`

Proof. Project the carrier of Definition 6837.1. The analytic rows are S, Q, D, W, Y, A, R, Z, and the structural rows are H, C, P, N.

The Sobolev row S supplies only the displayed weak-derivative and magnitude surface of chapter 440. The Poincare row Q supplies only the bounded-domain or zero-mean control route of chapter 2329. Thus the energy-control handoff is read through displayed Sobolev and Poincare rows before any downstream energy consumer receives it.

The dyadic schedule W and accounting row A keep every tolerance comparison inside $\mathsf{DyadicRatCore}^{\uparrow}$. The constructive energy row Y and rational readback row R then route the observed bounds through chapter 5956 and chapter 301.

Finally the Real seal Z is downstream of those rows, and H, C, P, N preserve the same packet under transport, replay, provenance, and naming. Since the carrier omits measure completion, quotient equality, selected representatives, Hahn–Banach separation, and Real completeness, no accepted local NameCert route exports them. □

Theorem 6837.3 (Sobolev–Poincare finite-energy handoff)**.** *Every PDE, variational, trace, or metric consumer that reads an accepted* $\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}$ *packet must traverse*

$$\mathsf{Sobolev}^{\uparrow},\ \mathsf{PoincareInequality}^{\uparrow},\ \mathsf{ConstructiveSobolevEnergy}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $S, Q, D, W, Y, A, R, Z, H, C, P, N$. The handoff exports a finite energy-control route and nothing outside those rows.

Proof. Apply Definition 6837.2. It makes Sobolev exposure, Poincare control, bounded-window admission, dyadic accounting, constructive energy, rational readback, and the Real seal first-class obligations of one packet.

A downstream consumer can therefore read a finite energy-control datum only after these rows have been exposed in order. Omitting the Sobolev row loses the weak-derivative source; omitting the Poincare row loses the control estimate; omitting the dyadic and rational rows loses the finite numerical accounting; and omitting the seal loses the terminal Real boundary.

The structural rows H, C, P, N keep that route stable under transport, replay, provenance, and naming. Thus the exported handoff is exactly the displayed finite route, not a completed Sobolev space theorem or an external separation principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}}$.

Constructive story: A $\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}$ packet is generated from Sobolev weak-derivative rows, Poincare control rows, bounded-domain or finite-window rows, dyadic tolerance rows, constructive energy rows, rational readback rows, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6837.1, Definition 6837.2, and Definition 6837.3 seed the finite Sobolev–Poincare energy-control route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SobolevPoincareFiniteEnergy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hahn–Banach separation, measure completion, quotient equality of functions, selected representatives, global compactness, Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Sobolev exposure, Poincare control, bounded-window exactness, dyadic accounting, rational readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SobolevPoincareFiniteEnergyUp.

Chapter 6838

A Concrete Naming Certificate for $\mathsf{PartialityBoundary}^{\uparrow}$

Following the total-functional-language discipline of CIC, Coq, Agda, Lean, and Idris totality checking, the $\mathsf{PartialityBoundary}^{\uparrow}$ packet records the boundary between total host computation and explicitly marked partial escape as finite BEDC NameCert data. It concretizes the total-language analysis of chapter 9370, reads local channel termination through chapter 3996, and keeps refusal-to-decide separate through chapter 1197. The packet does not admit a partial-function surface inside BEDC; it records the attempted escape as a refusal row.

Definition 6838.1 (Partiality-boundary carrier)**.** *A* $\mathsf{PartialityBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, F, A, E, R, L, H, C, P, N)$$

with the following displayed rows:

1. *T is the total-host row, recording the typed BEDC term or certificate route whose reduction is accepted only as a finite total computation.*
2. *F is the step-indexed computation row, exposing finite fuel and the displayed result-or-timeout observation for the inspected route.*
3. *A is the attempted partial escape row, naming the external request for unrestricted recursion, a partial annotation, or a non-total host function.*
4. *E is the termination-boundary row, read through chapter 3996 when a local event endpoint is displayed.*
5. *R is the refusal ledger, read through chapter 1197 when the attempted escape has no admitted total route.*
6. *L is the totality classifier row, accepting only routes that remain in T, F, E or are recorded as refusal in R.*
7. *H records componentwise* hsame *transport for total-host rows, fuel rows, attempted escape rows, termination-boundary rows, refusal rows, classifier rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from a host computation request through total reduction, step-indexed fuel, local endpoint exposure, attempted escape inspection, and refusal.*
9. *P is the* Pkg *provenance over* $\mathsf{PartialityBoundary}^{\uparrow}$*, chapter 9370,* $\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}$*,* $\mathsf{TerminationRefusalBoundary}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{PartialityBoundary}^{\uparrow}}$ *row.*
The carrier has no coordinate for a BEDC partial function, unrestricted recursion, a divergence oracle, a total halting predicate, or a proof that a missing finite endpoint is nontermination.

Theorem 6838.2 (Partiality-boundary NameCert obligations)**.** *For every accepted* $\mathsf{PartialityBoundary}^{\uparrow}$ *carrier* $B = (T, F, A, E, R, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PartialityBoundary}^{\uparrow}}$ *surface consists exactly of total-host admission, step-indexed computation exposure, attempted-escape exposure, termination-boundary routing, refusal-ledger routing, totality classifier stability, componentwise transport, displayed replay, provenance, and local naming. The surface records the total-host versus partial-escape boundary but exports no partial BEDC function.*

Proof. Project the carrier of Definition 6838.1. The total computation rows are T, F, E, the attempted escape is A, the refusal boundary is R, and the structural rows are L, H, C, P, N.

The total-host row T and step-indexed row F keep every admitted computation finite. The termination-boundary row E may expose a local endpoint, but only through the channel termination boundary of chapter 3996.

If the request asks for unrestricted recursion or a partial annotation, the attempted escape row A is not converted into a BEDC function. It is routed to the refusal ledger R, whose role is the refusal-to-decide boundary of chapter 1197.

The classifier L accepts only those two outcomes: finite total exposure or displayed refusal. Transport, replay, provenance, and local naming preserve the same boundary, so no accepted route exports unrestricted recursion, a divergence oracle, a total halting predicate, or a nontermination proof. □

Theorem 6838.3 (Partiality-boundary total-host handoff)**.** *Every host-computation consumer that reads an accepted* $\mathsf{PartialityBoundary}^{\uparrow}$ *packet receives either a displayed total route through* T, F, E, L, H, C, P, N *or a displayed refusal route through* A, R, L, H, C, P, N*. These routes are disjoint at the local NameCert surface: the refusal route records the failed partial escape, while the total route records finite step-indexed computation.*

Proof. Use Definition 6838.2. The packet exposes the total-host rows, fuel row, termination-boundary row, attempted escape row, refusal row, classifier row, and structural rows as the whole local surface.

For a total route, the consumer reads T, F, E before the classifier L and the structural rows. This is a finite computation route in the total host.

For an attempted partial route, the consumer reads A and then R before the same classifier and structural rows. This is a refusal route, not a function definition.

Because no carrier row identifies A with a total endpoint or identifies R with divergence, the two handoffs stay separated inside the same finite NameCert packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PartialityBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PartialityBoundary}^{\uparrow}$ packet is generated from total-host rows, step-indexed fuel rows, attempted partial-escape rows, termination-boundary rows, refusal-ledger rows, totality classifier rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PartialityBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 6838.1, Definition 6838.2, and Definition 6838.3 seed the finite total-host versus partial-escape boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PartialityBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not admit partial BEDC functions, unrestricted recursion, divergence oracles, a total halting predicate, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked total-host admission, step-indexed exposure, attempted-escape routing, termination-boundary routing, refusal-ledger exactness, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.PartialityBoundaryUp.

Chapter 6839

Sierpinski Continuity Classifier NameCert Construction

Following Sierpinski and standard constructive topology, the $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$ packet records continuity through the finite observable-open classifier rather than through a host open-set predicate. It sits beside the Sierpinski observable truth carrier of chapter 1860, the finite observation topology of chapter 6831, the topology row discipline of chapter 88, and the continuous-map naming surface of chapter 130. The packet names the route by which a finite observation of an open predicate is read as a Sierpinski-valued classifier and transported through a continuous map; it does not install host open-set extensionality, quotient topology, open-cover compactness, or an ambient classical evaluator.

Definition 6839.1 (Sierpinski continuity classifier carrier)**.** *A* $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, F, O, S, W, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Topology}^{\uparrow}$ *row whose opens are inspected only through finite observation data.*
2. *Y is the target* $\mathsf{Topology}^{\uparrow}$ *row receiving the displayed open-predicate read.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, recording the map as a finite BEDC route from source observations to target observations.*
4. *O is the target open-predicate row under inspection.*
5. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *classifier row, turning the open-predicate read into displayed observable truth.*
6. *W is the* $\mathsf{FiniteObservationTopology}^{\uparrow}$ *window row, listing the finite observations through which O and S are tested.*
7. *H records componentwise* hsame *transport for source topology, target topology, continuous-map, open-predicate, Sierpinski classifier, finite-window, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a continuity-classifier request through X, Y, F, O, S, W, H.*
9. *P is the* Pkg *provenance over* $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{FiniteObservationTopology}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SierpinskiContinuityClassifier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, F, O, S, W, H, C, P, N$. It has no coordinate for a host open-set equality proof, a quotient topology on observations, an open-cover compactness principle, a hidden truth evaluator, or a detached classical continuity predicate.

Lean4 (definition) `BEDC.Derived.SierpinskiContinuityClassifierUp`

Theorem 6839.2 (Sierpinski continuity classifier NameCert obligations)**.** *For every accepted* $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$ *carrier*

$$K = (X, Y, F, O, S, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SierpinskiContinuityClassifier}^{\uparrow}}$ *surface consists exactly of source and target topology exposure through X, Y; continuous-map exposure through F; target open-predicate exposure through O; Sierpinski-valued observable truth through S; finite observation topology exposure through W; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier in Definition 6839.1. The public continuity-classifier rows are exactly $X, Y, F, O, S, W, H, C, P, N$.

The open-predicate read is represented by the Sierpinski-valued classifier row S. The finite observation row W determines which displayed windows may test the target open row O, and the continuous-map row F is the only route by which those observations are pulled back to the source topology row X.

Classifier stability is componentwise hsame transport through H. Transport preserves the topology rows, the continuous-map row, the open-predicate row, the Sierpinski classifier row, and the finite observation row before replay and provenance are consumed.

Since no row stores host open-set extensionality, quotient topology, open-cover compactness, hidden truth evaluation, or a detached classical continuity predicate, the listed rows exhaust the local NameCert obligations. □

Theorem 6839.3 (Finite observation route for Sierpinski continuity)**.** *Every finite-observation topology consumer of an accepted* $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$ *carrier must read the target open row O as a* $\mathsf{SierpinskiSpace}^{\uparrow}$ *classifier row S, test it only through the finite windows W, and replay the pullback route through F, C, P, N. The consumer receives a displayed finite-observation continuity classifier; it receives no host open-set extensionality principle, no quotient topology on unseen observations, and no classical open-cover compactness claim.*

Proof. Read the carrier rows from Definition 6839.1. The only open-predicate information available to a consumer is the pair O, S, with S exposing observable truth in the Sierpinski packet.

Apply the finite observation row W. It restricts the continuity test to displayed windows, so the consumer cannot quantify over unseen opens or replace the observed classifier by a host predicate.

Transport through H is componentwise. The topology rows, continuous-map row, open row, Sierpinski classifier row, and finite-window row are preserved before the route is replayed by C and sourced by P, N.

Thus the route exposes a finite-observation classifier for continuity and nothing stronger. Host open-set extensionality, quotient topology, and classical open-cover compactness are outside the carrier. □

Falsifiable prediction: No accepted $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$ consumer can cite continuity through finite observation topology unless it first exposes source and target topology rows, the

continuous-map row, the target open-predicate row, the Sierpinski classifier row, finite observation windows, transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: sierpinski-space, finite-observation-topology, topology, continuousmap: no listed sibling is bijective with $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$ because this carrier alone binds a continuous-map row, a target open-predicate row, Sierpinski-valued observable truth, finite observation windows, componentwise transport, replay, provenance, and local NameCert rows into one accepted continuity-classifier packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SierpinskiContinuityClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{SierpinskiContinuityClassifier}^{\uparrow}$ packet is generated from source and target Topology rows, a ContinuousMap row, a target open-predicate row, a SierpinskiSpace classifier row, finite observation topology windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SierpinskiContinuityClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6839.1, Definition 6839.2, and Definition 6839.3 seed the finite-observation route from displayed open-predicate reads to Sierpinski-valued continuity classifiers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SierpinskiContinuityClassifier}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SierpinskiContinuityClassifierUp`

Bridge status: none

Not claimed: This chapter does not close host open-set extensionality, quotient topology, open-cover compactness, selected limits, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Sierpinski classifier exactness, finite-window stability, continuous-map pullback replay, componentwise transport, provenance, and local naming for BEDC.Derived.SierpinskiContinuityClassifier

Chapter 6840

A Concrete Naming Certificate for $\mathsf{CauchyIntersectionPrinciple}^{\uparrow}$

Following Bishop and Bridges on nested intervals, regular Cauchy reals, and constructive real approximation, the $\mathsf{CauchyIntersectionPrinciple}^{\uparrow}$ packet records the finite intersection route by which a displayed family of nested dyadic windows reaches a Real-facing seal. It sits after the dyadic tolerance surface of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the Cauchy source discipline of chapter 3413, and the terminal real-name boundary of chapter 38. The packet names a finite common-window intersection principle for Real and Completion consumers; it does not select a completed limit, quotient Cauchy names, invoke countable choice, decide trichotomy, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6840.1 (Cauchy intersection principle carrier)**.** *A* $\mathsf{CauchyIntersectionPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the nested dyadic window row, recording finite left and right endpoint data over* $\mathsf{DyadicRatCore}^{\uparrow}$ *together with the displayed inclusion checks between successive windows.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row, recording the finite precision requests under which the displayed windows are certified Cauchy.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row exposing exactly the inspected window stages and no unseen tail.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite observations and dyadic tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, M, S, R have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic-window, modulus, stream-observation, regular-readback, Real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an intersection request through D, M, S, R, E, H and back to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyIntersectionPrinciple}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyIntersectionPrinciple}^{\uparrow}}$ *row.*
The carrier exports only this finite nested-window packet. It has no coordinate for selected limits, quotient equality of Cauchy names, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyIntersectionPrincipleUp.CauchyIntersectionPrincipleTasteGate single carrier alignment`

Theorem 6840.2 (Cauchy intersection principle NameCert obligations)**.** *For every accepted* CauchyIntersectionPrin *carrier $K = (D, M, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyIntersectionPrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission through the displayed nested dyadic windows, Cauchy modulus requests, StreamName finite observations, RegSeqRat readback, Real-seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6840.1. The rows $D, M, S, R, E, H, C, P, N$ are the complete public packet, so carrier admission can only admit data already displayed in those rows.

The analytic route first reads D and M. Thus every intersection-facing consumer sees the nested dyadic windows and the finite Cauchy modulus requests before any stream window, regular readback, or Real seal is available.

Next read S and R. The stream row names the inspected finite stages, while the regular rational row supplies readback from the same finite observations and dyadic tolerance ledger.

Finally use E, H, C, P, N. The Real seal is terminal in this packet, and the transport, replay, provenance, and local naming rows preserve the same displayed route. Since no carrier row stores selected limits, quotient equality, countable choice, trichotomy, host real equality, or ambient completeness, none of those principles can be exported by the local certificate. □

Theorem 6840.3 (Cauchy intersection window extraction)**.** *Every completion-facing read of an accepted* $\mathsf{CauchyIntersectionPrinciple}^{\uparrow}$ *carrier factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the finite rows $D, M, S, R, E, H, C, P, N$. The consumer receives a displayed nested-window intersection route and a terminal Real seal; it receives no selected limit, quotient equality of Cauchy names, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the obligation theorem. It forces every completion-facing consumer to expose the dyadic window row and the Cauchy modulus row before the inspected stream stages can be read.

The sibling route then supplies the finite readback. DyadicRatCore supplies the endpoint and tolerance rows, StreamName supplies the inspected window stages, RegSeqRat supplies the regular rational readback, and the Real chapter supplies only the terminal seal.

The structural rows do not enlarge the route. Componentwise hsame transport and displayed Cont replay preserve the same packet, while P and N source and name it. Therefore the extracted window remains a finite BEDC packet rather than a selected completed limit or an ambient completeness theorem. □

Falsifiable prediction: Every accepted CauchyIntersectionPrincipleUp consumer exposes nested DyadicRatCore windows, a finite CauchyModulus schedule, StreamName observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before it can cite the intersection route.

Independence witness: dyadicratcore, streamname, regseqrat, cauchy, real: removing any one of these sibling routes leaves the packet without the corresponding dyadic window, finite observation, regular readback, Cauchy modulus discipline, or terminal Real seal row.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyIntersectionPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyIntersectionPrinciple}^{\uparrow}$ packet is generated from nested DyadicRatCore windows, a finite CauchyModulus schedule, StreamName observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyIntersectionPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6840.1, Definition 6840.2, and Definition 6840.3 seed the finite nested-window intersection route from dyadic tolerance data to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyIntersectionPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy names, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-window exactness, Cauchy modulus discipline, finite-observation readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyIntersectionPrincipleUp.

Chapter 6841

A Concrete Naming Certificate for $\mathsf{RegularCauchyClamp}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyClamp}^{\uparrow}$ packet records the finite regular-Cauchy route for clamping a regular rational Cauchy name between two regular rational endpoint rows before the terminal $\mathsf{Real}^{\uparrow}$ seal is inspected. It sits below the Real-facing clamp of chapter 1810 and reads its source surface through chapter 301, the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the lower-bound factorization of chapter 1832, the upper-bound factorization of chapter 1833, and the terminal real seal of chapter 38. The packet gives completion-facing interval, oscillation, and boundedness consumers a pre-seal regular-Cauchy clamp route without host trichotomy, quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6841.1 (Regular Cauchy clamp carrier)**.** *A* $\mathsf{RegularCauchyClamp}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, L, U, W, D, M, N, R, E, H, C, P, A)$$

with the following displayed rows:

1. *X is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational Cauchy readback is being clamped.*
2. *L and U are the* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint rows for the displayed lower and upper bounds.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the precision requested by the clamp consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and readback ledger; it records the requested dyadic tolerance, the endpoint slack, and the comparison scale used by the two factorization rows.*
5. *M is the* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *factorization row implementing the lower projection* $\max(X, L)$ *on the displayed regular-Cauchy surface.*
6. *N is the* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *factorization row implementing the upper projection* $\min(M, U)$ *after the lower projection has been exposed.*
7. *R is the exported* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular-Cauchy clamp value.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R has been displayed.*
9. *H records componentwise* hsame *transport for the source, endpoints, windows, dyadic ledger, maximum row, minimum row, readback, seal, replay, provenance, and local name.*

10. *C records displayed* Cont *replay from a clamp request through* $X, L, U, W, D, M, N, R, E, H, P, A$.
11. *P records* Pkg *provenance over* $\mathsf{RegularCauchyClamp}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyMaximum}^{\uparrow}$, $\mathsf{RegularCauchyMinimum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *A is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyClamp}^{\uparrow}}$ *row.*

The classifier reads only the displayed tuple $K = (X, L, U, W, D, M, N, R, E, H, C, P, A)$. It has no coordinate for host order trichotomy, quotient stream equality, selected limit, countable-choice schedule, ambient real completeness, Lean verification, or bridge checking.

Theorem 6841.2 (Regular Cauchy clamp NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyClamp}^{\uparrow}$ *carrier*

$$K = (X, L, U, W, D, M, N, R, E, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyClamp}^{\uparrow}}$ *surface consists exactly of carrier admission for the source row, endpoint rows, finite-window row, dyadic tolerance ledger, maximum factorization row, minimum factorization row, exported readback row, Real seal, componentwise transport, displayed replay, provenance, and local naming. The certificate also requires factorization order: M must be read as the displayed* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *route for* $\max(X, L)$ *before N is read as the displayed* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *route for* $\min(M, U)$.

Proof. Project the carrier of Definition 6841.1. Its displayed rows are exactly the source regular-rational readback, two endpoint rows, the finite observation window, dyadic tolerance ledger, two factorization rows, exported readback, Real seal, and structural rows.

The factorization order is part of the row inventory. The maximum row M can inspect only X, L, W, D and the structural rows available at that stage; the minimum row N is downstream of M and the upper endpoint row U.

The exported readback R and seal E have no independent numeric source. They can therefore expose only the regular-Cauchy clamp route already displayed by M and N, transported by H and replayed by C. □

Theorem 6841.3 (Regular Cauchy clamp min–max factorization)**.** *Every accepted* $\mathsf{RegularCauchyClamp}^{\uparrow}$ *carrier $K = (X, L, U, W, D, M, N, R, E, H, C, P, A)$ presents its clamp value through the finite route*

$$\begin{aligned} X, L, U, W, D &\longmapsto M = \max(X, L), \\ M, U, D &\longmapsto N = \min(M, U), \\ N &\longmapsto R \longmapsto E. \end{aligned}$$

No consumer receives a direct host clamp operation, a trichotomy of the three regular Cauchy rows, quotient stream equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier and read the maximum row M. By Definition 6841.1, this row is the only lower-projection coordinate and it factors through the displayed $\mathsf{RegularCauchyMaximum}^{\uparrow}$ route.

Next read the minimum row N. It is downstream of M and U, so its only upper-projection source is the displayed $\mathsf{RegularCauchyMinimum}^{\uparrow}$ route applied to the lower-projected row and the upper endpoint.

Finally read R and then E. Since the carrier has no coordinate for any excluded host or quotient object, the exported route is exactly the displayed min–max factorization. □

Theorem 6841.4 (Regular Cauchy clamp Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyClamp}^{\uparrow}$ *packet must first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* X*, endpoint rows* L, U*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *row* M*,* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *row* N*, and exported* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*. The terminal seal* E *records only the displayed regular-Cauchy clamp boundary and cannot be used as an ambient Real-level clamp theorem.*

Proof. The Real seal row E is downstream of the exported readback row R in the carrier tuple. Thus a Real-facing consumer cannot inspect E until the regular-Cauchy readback has been displayed.

The readback row R is downstream of the two factorization rows. Those factorization rows force the route through $\mathsf{RegularCauchyMaximum}^{\uparrow}$ and $\mathsf{RegularCauchyMinimum}^{\uparrow}$ before any Real-facing seal is available.

The structural rows H, C, P, A transport, replay, source, and name only that route. Hence E seals the pre-seal regular-Cauchy clamp boundary and does not add host order, quotient equality, selected limits, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyClamp}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyClamp}^{\uparrow}$ packet is generated from one RegSeqRat source row, two RegSeqRat endpoint rows, StreamName windows, a DyadicRatCore tolerance ledger, RegularCauchyMaximum and RegularCauchyMinimum factorization rows, an exported RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyClamp}^{\uparrow}}$, seed)

Scope closed: Definition 6841.1, Definition 6841.2, Definition 6841.3, and Definition 6841.4 seed the finite regular-Cauchy clamp route below the Real-facing clamp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyClamp}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a checked Lean carrier, bridge checking, host clamp operations, trichotomy, quotient stream equality, selected limits, countable choice, chosen dense enumerations, or ambient Real completeness.

Upgrade path: Obligation closure requires explicit carrier admission, window coverage, dyadic tolerance exactness, min–max factorization exactness, Real seal handoff, transport, replay, provenance, and local NameCert obligations for BEDC.Derived.RegularCauchyClampUp.

Chapter 6842

A Concrete Naming Certificate for $\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy estimates over dyadic rational scales, the DyadicRadiusHalvingLadd packet records the finite radius ladder used by the L10 Real and Completion route. It sits between the dyadic arithmetic rows of chapter 291, the finite-window naming discipline of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet supplies monotone 2^{-n} radii as displayed NameCert data; it does not import completed real algebra, quotient-name equality, countable choice, selected limits, or an ambient completeness theorem.

Definition 6842.1 (Dyadic radius halving ladder carrier)**.** *A* $\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Z, R, W, S, M, E, H, C, P, N)$$

with the following visible rows:

1. *Z is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *unit-radius row naming the initial scale 2^0 and its positive dyadic certificate.*
2. *R is the finite radius-list row, displaying the entries $r_i = 2^{-i}$ for every inspected index in the current request.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records exactly which indices of the ladder are inspected.*
4. *S is the successor-halving row, certifying $r_{i+1} + r_{i+1} = r_i$ on every displayed adjacent pair.*
5. *M is the monotonicity row, recording $r_{i+1} \leq r_i$ and the stronger scale comparison $r_{i+k} \leq r_i$ whenever both indices are in the displayed window.*
6. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *error-budget row consumed by regular Cauchy estimates and by the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
7. *H records componentwise* hsame *transport for unit scale, finite radius rows, stream windows, halving, monotonicity, error-budget, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request to a finite stream window, dyadic radius lookup, halving comparison, monotone-scale read, and regular Cauchy budget handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *unary-history window material,* BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}}$ *row.*

The classifier compares packets only through the displayed rows $Z, R, W, S, M, E, H, C, P, N$. It has no coordinate for a host exponential function, selected real limit, quotient real equality, countable choice, ambient real algebra, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6842.2 (Dyadic radius monotone scale)**.** *Let $D = (Z, R, W, S, M, E, H, C, P, N)$ be an accepted* $\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}$ *carrier. Every radius comparison exported to a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the same finite window W, the same displayed dyadic radius row R, and the same successor-halving row S. In particular the consumed scale is monotone on the displayed request:*

$$r_j \leq r_i$$

whenever $i \leq j$ and both indices are visible in W.

Proof. Project the carrier of Definition 6842.1. The only scale coordinates are the unit row Z, finite radius row R, stream window W, successor-halving row S, and monotonicity row M.

Read the adjacent comparisons first. The row S gives the displayed equality $r_{i+1} + r_{i+1} = r_i$ for every adjacent pair in W, and positivity is inherited from the $\mathsf{DyadicRatCore}^{\uparrow}$ row Z and the radius-list row R.

Now iterate inside the finite window. The monotonicity row M records the finite transitive closure of those adjacent comparisons for the same displayed indices, so a later radius can be consumed only as a smaller or equal dyadic budget.

Finally transport the result through H, C, P, N. These rows replay and name the same ladder before E is read by $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$, and they add no host exponential, selected limit, quotient equality, countable-choice row, real algebra, or completeness coordinate. □

Theorem 6842.3 (Dyadic radius refinement handoff)**.** *Every accepted* $\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}$ *packet supplies a refinement route from a requested finite stream window to a regular Cauchy error budget:*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer first displays the window W, then reads the dyadic radii R and adjacent-halving row S, then consumes the monotone-scale row M, and only then reaches the regular Cauchy budget row E and any terminal Real-facing seal.

Proof. Start with a precision request. The continuation row C routes that request to the finite $\mathsf{StreamName}^{\uparrow}$ window W before any radius value is inspected.

Within that window, the dyadic rows are explicit. The radius row R lists the inspected 2^{-i} entries and S records the halving relation between adjacent displayed entries, so the route stays inside $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic.

Apply Definition 6842.2. The monotone row M is the only bridge from the finite dyadic ladder to the regular Cauchy error ledger, and it is already attached to the same window and radius rows.

The handoff row E can therefore be consumed by $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ only after the finite ladder has been displayed. Provenance and local naming through P, N preserve this dependency and exclude a host exponential function, quotient-name equality, selected limit, countable choice, ambient real algebra, or completeness theorem. □

Theorem 6842.4 (Dyadic radius NameCert obligation surface)**.** *For the carrier of Definition 6842.1, the local* $\mathsf{NameCert}_{\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}}$ *surface consists of exactly five rows:*

1. *carrier admission for the displayed packet $D = (Z, R, W, S, M, E, H, C, P, N)$;*

2. *classifier locality for the* DyadicRatCore$^{\uparrow}$ *unit scale, finite radius list, and* StreamName$^{\uparrow}$ *inspected window;*
3. *stability through componentwise* hsame *transport H and displayed* Cont *replay C;*
4. *exactness through the successor-halving row S, monotone-scale row M, and regular Cauchy budget row E;*
5. *ledger control through* Pkg *provenance P and the local naming row N.*

No NameCert obligation may replace these rows by a host exponential map, selected real limit, quotient stream equality, arbitrary trichotomy, countable choice, ambient real algebra, or completeness of Real$^{\uparrow}$.

Proof. Carrier admission projects $Z, R, W, S, M, E, H, C, P, N$ from Definition 6842.1. No radius, window, halving, monotonicity, error-budget, transport, replay, provenance, or naming row is implicit.

Classifier locality reads only the dyadic unit scale, finite radius list, and inspected stream window. This prevents the ladder from ranging over an unbounded host sequence or an external exponential function.

Stability and exactness are supplied by the displayed structural rows. The hsame and Cont rows preserve the same finite packet, while S, M, E state the halving, monotone-scale, and regular-budget facts consumed downstream.

The package and naming rows close the ledger. Since every exported read must pass through P and N, the certificate surface is exhausted by the five listed rows. □

Falsifiable prediction: A regular Cauchy or Real-facing consumer refutes the DyadicRadiusHalvingLadderUp carrier if it reads a 2^{-n} budget without displaying the finite StreamNameUp window, DyadicRatCoreUp radius row, adjacent-halving row, monotone-scale row, regular Cauchy budget row, transport, replay, provenance, and local naming rows.

Independence witness: dyadicratcore, streamname, regseqrat, real, and unaryhistory-window material: none is bijective to DyadicRadiusHalvingLadder$^{\uparrow}$ because only this packet binds unit dyadic scale, finite radius list, inspected stream window, successor halving, monotone refinement, regular Cauchy budget, transport, replay, provenance, and local naming as one NameCert surface.

Closure status for NameCert$_{\text{DyadicRadiusHalvingLadder}\uparrow}$.

Constructive story: A DyadicRadiusHalvingLadder$^{\uparrow}$ packet is generated from a DyadicRatCore unit-radius row, finite dyadic radius rows, a StreamName inspected window, successor-halving rows, monotone-scale rows, a RegSeqRat error-budget handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{DyadicRadiusHalvingLadder}\uparrow}$, seed)

Scope closed: Definition 6842.1, Definition 6842.2, Definition 6842.3, and Definition 6842.4 seed the finite dyadic radius ladder required by regular Cauchy and Real-completion estimates.

Formal verification: FormalStatus(NameCert$_{\text{DyadicRadiusHalvingLadder}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host exponentiation, selected limits, quotient real equality, arbitrary trichotomy, countable choice, ambient real algebra, completeness of RealUp, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic radius exactness, stream-window locality, successor-halving exactness, monotone-scale refinement, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicRadiusHalvingLadderUp.

Chapter 6843

A Concrete Naming Certificate for $\mathsf{ArchimedeanCauchyTailModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ArchimedeanCauchyTailModulus}^{\uparrow}$ packet records the finite Archimedean extraction by which a Cauchy presentation yields an inspectable tail modulus before a Real-completion consumer reads a seal. It sits beside the Archimedean real source of chapter 430, the Cauchy carrier of chapter 3413, the dyadic tolerance ledger of chapter 291, the stream-name window surface of chapter 126, the regular rational readback of chapter 301, and the Real seal of chapter 38. The packet names the finite tail-modulus extraction route; it does not assert ambient completeness, select a quotient representative, or choose a limit outside the displayed rows.

Definition 6843.1 (Archimedean Cauchy tail modulus carrier)**.** *An* $\mathsf{ArchimedeanCauchyTailModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, Q, D, S, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *source row, exposing Archimedean comparison data only as finite named evidence.*
2. *Q is the* $\mathsf{Cauchy}^{\uparrow}$ *presentation row whose tail request is being interpreted.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the requested positive precision, slack conversion, and dyadic comparison budget.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *inspection row, recording the finite windows of the Cauchy presentation that have been read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from those windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after R and the tolerance row D have been displayed.*
7. *T is the tail-modulus row, recording the finite index after which the displayed Cauchy windows satisfy the requested dyadic tolerance.*
8. *H records componentwise* hsame *transport for A, Q, D, S, R, E, T and the structural rows.*
9. *C records displayed* Cont *replay from a tail request through source, Cauchy presentation, tolerance, windows, readback, Real seal, and tail-modulus rows.*

10. *P is the* Pkg *provenance over* ArchimedeanCauchyTailModulus$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, Cauchy$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* NameCert$_{\text{ArchimedeanCauchyTailModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed source, Cauchy, dyadic, stream, readback, Real-seal, tail-modulus, transport, replay, provenance, and local naming rows. It has no coordinate for quotient stream equality, selected limits, countable choice, hidden Archimedean search, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.ArchimedeanCauchyTailModulusUp`

Theorem 6843.2 (Archimedean Cauchy tail modulus NameCert obligations)**.** *For every accepted* ArchimedeanCauchyTailModulus$^{\uparrow}$ *carrier* $M = (A, Q, D, S, R, E, T, H, C, P, N)$*, the local* NameCert$_{\text{ArchimedeanCauchyTailModulus}^{\uparrow}}$ *surface consists exactly of carrier admission,* ArchimedeanReal$^{\uparrow}$ *source exposure,* Cauchy$^{\uparrow}$ *presentation exposure,* DyadicRatCore$^{\uparrow}$ *tolerance exactness,* StreamName$^{\uparrow}$ *finite-window inspection,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal non-escape, tail-modulus index exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6843.1. The source, Cauchy presentation, tolerance, stream-window, readback, Real-seal, tail-modulus, transport, replay, provenance, and local-name rows are precisely the displayed packet coordinates.

Read the Archimedean and Cauchy rows first. The source row supplies only finite comparison evidence, and the Cauchy row supplies only the named presentation whose tail is being inspected.

Use the dyadic tolerance row together with the stream window row. The requested precision is a DyadicRatCore$^{\uparrow}$ datum, and the inspected tail data are exactly the finite windows recorded by StreamName$^{\uparrow}$.

The regular rational readback and Real seal come after those rows. The tail-modulus row T then records the displayed index at which the same windows satisfy the same tolerance. Transport, replay, provenance, and local naming preserve this route, so there is no hidden coordinate for quotient equality, selected limits, choice, or ambient completeness. □

Theorem 6843.3 (Archimedean Cauchy tail modulus extraction route)**.** *Every Real-and-completion consumer of an accepted* ArchimedeanCauchyTailModulus$^{\uparrow}$ *packet reads the tail index only through*

$$\text{ArchimedeanReal}^{\uparrow},\quad \text{Cauchy}^{\uparrow},\quad \text{DyadicRatCore}^{\uparrow},\quad \text{StreamName}^{\uparrow},\quad \text{RegSeqRat}^{\uparrow},\quad \text{Real}^{\uparrow}.$$

The exported datum is a finite tail-modulus row for the displayed Cauchy presentation, not a quotient Real equality, selected representative, choice sequence, or ambient completeness theorem.

Proof. Start with the carrier route. The accepted packet stores the Archimedean source and Cauchy presentation as finite rows A and Q, so the consumer begins with displayed data rather than an external real object.

Next consume the tolerance and window rows. The requested precision is read from D, while S records the inspected finite tail windows. No tail index is exported before both rows are visible.

Then read R and E. The regular rational readback and Real seal are downstream of the same windows and tolerance, so they cannot add a selected limit or quotient representative.

Finally expose T through the structural rows H, C, P, N. Since the carrier contains no hidden search, choice, quotient, or completeness coordinate, the tail-modulus row is exactly the finite extraction route named in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyTailModulus}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanCauchyTailModulus}^{\uparrow}$ packet is generated from ArchimedeanReal source evidence, a Cauchy presentation, DyadicRatCore tolerance data, StreamName tail windows, RegSeqRat readback, a Real seal, a tail-modulus index row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyTailModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6843.1, Definition 6843.2, and Definition 6843.3 seed the finite Archimedean tail-modulus extraction surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanCauchyTailModulus}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient Real equality, selected representatives, countable choice, hidden Archimedean search, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, finite-window inspection, RegSeqRat readback, Real seal non-escape, tail-modulus index exposure, transport, replay, provenance, and local naming for BEDC.Derived.ArchimedeanCauchyTailModulusUp.

Chapter 6844

A Concrete Naming Certificate for ConsistencyObservationBudget$^{\uparrow}$

The ConsistencyObservationBudget$^{\uparrow}$ packet realizes the finite observation side of the computation-and-consistency vision in section 9364.10. It sits after the MetaCIC critical-path route of chapter 765, the stream-name observation surface of chapter 126, the regular rational readback of chapter 301, and the Real seal of chapter 38. The packet records bounded consistency observations as NameCert rows; it does not claim global consistency, semantic soundness for every host model, or an unbounded proof search oracle.

Definition 6844.1 (Consistency observation budget carrier)**.** *A* ConsistencyObservationBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, O, S, R, E, M, L, F, H, C, P, N)$$

with the following displayed rows:

1. *K is the* MetaCICCriticalPath$^{\uparrow}$ *kernel route row through which accepted declarations, reduction traces, and checker handoffs are observed.*
2. *O is the finite observation schedule row, listing the declarations, reductions, checker calls, and local contradiction probes admitted by the budget.*
3. *S is the* StreamName$^{\uparrow}$ *row naming the finite stream of observation windows.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row for numeric or ranked budget counters attached to those windows.*
5. *E is the* Real$^{\uparrow}$ *seal row for any Real-facing budget threshold used by an observation consumer.*
6. *M is the metatheoretic boundary row, recording that each observation is local to the displayed MetaCIC route.*
7. *L is the ledger row listing accepted observation outcomes, refused out-of-budget requests, and unresolved probes.*
8. *F is the field-faithfulness request row that later Lean TasteGate work must discharge with* Nontrivial *and* FieldFaithful *instances for the carrier.*
9. *H records componentwise* hsame *transport for K, O, S, R, E, M, L, F and the structural rows.*

10. *C records displayed* Cont *replay from observation request through kernel route, schedule, stream windows, readback, seal, boundary, ledger, field-faithfulness request, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{ConsistencyObservationBudget}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ConsistencyObservationBudget}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by these displayed rows. It has no coordinate for global consistency, hidden model identity, unbounded proof search, semantic soundness outside the inspected route, quotient proof equality, or a final contradiction oracle.

Lean4 (statement) `BEDC.Derived.ConsistencyObservationBudgetUp`

Theorem 6844.2 (Consistency observation budget NameCert obligations)**.** *For every accepted* $\mathsf{ConsistencyObservationBudget}^{\uparrow}$ *carrier* $B = (K, O, S, R, E, M, L, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConsistencyObservati}}$ *surface consists exactly of carrier admission,* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *route exposure, finite observation schedule exposure,* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *counter readback,* $\mathsf{Real}^{\uparrow}$ *threshold seal non-escape, metatheoretic boundary exposure, observation ledger exposure,* Nontrivial *and* FieldFaithful *TasteGate request exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6844.1. The kernel route, observation schedule, stream windows, readback counters, threshold seal, boundary row, ledger row, field-faithfulness request, and structural rows are exactly the displayed coordinates.

The observation route begins at $\mathsf{MetaCICCriticalPath}^{\uparrow}$. The packet can inspect accepted declarations, reductions, and checker handoffs only through the route row K and the finite schedule O.

The stream, readback, and seal rows bind the budget to finite observations. The ledger row L then records outcomes, refusals, and unresolved probes without turning any local observation into a global consistency theorem.

Finally the row F states the downstream Lean TasteGate obligation: Nontrivial and FieldFaithful instances must be supplied before the carrier can be read as a faithful field surface. Transport, replay, provenance, and local naming preserve the same finite packet, so no hidden model or unbounded oracle is exported. □

Theorem 6844.3 (Consistency observation finite-budget boundary)**.** *Every consistency-facing read exported by an accepted* $\mathsf{ConsistencyObservationBudget}^{\uparrow}$ *packet factors through the finite observation route*

$$\mathsf{MetaCICCriticalPath}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the boundary, ledger, field-faithfulness request, transport, replay, provenance, and local NameCert *rows. The read reports bounded observations only; it does not certify global consistency, hidden model identity, unbounded proof search, or semantic soundness outside the displayed MetaCIC route.*

Proof. Start with the kernel route and schedule rows K, O. They define which declarations, reductions, checker calls, and local contradiction probes are inside the observation budget.

Next read S, R, E. The stream windows, counter readbacks, and threshold seal keep the budget finite and inspectable before any consistency-facing report is consumed.

Use the boundary and ledger rows M, L. The boundary row states that the observation is local to the displayed MetaCIC route, and the ledger row records accepted outcomes, refused out-of-budget requests, and unresolved probes.

Finally keep F, H, C, P, N visible. The TasteGate request records the needed Nontrivial and FieldFaithful instances, while transport, replay, provenance, and naming preserve the same carrier. Therefore the exported read is a bounded observation packet, not a global consistency claim. □

Falsifiable prediction: A claimed $\mathsf{ConsistencyObservationBudget}^{\uparrow}$ consumer is refuted if it exports global consistency, hidden model identity, unbounded proof search, or semantic soundness outside a finite MetaCICCriticalPath observation schedule.

Independence witness: metaciccriticalpath, streamname, regseqrat, real: none is bijective with $\mathsf{ConsistencyObservationBudget}^{\uparrow}$, because the siblings supply kernel route, observation windows, counter readback, and threshold seal rows while this packet additionally binds observation schedule, metatheoretic boundary, ledger, TasteGate request, transport, replay, provenance, and local NameCert rows.

Lean TasteGate work for $\mathsf{ConsistencyObservationBudget}^{\uparrow}$ must provide Nontrivial and FieldFaithful instances before the budget can serve as a faithful carrier for downstream consistency-observation consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{ConsistencyObservationBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{ConsistencyObservationBudget}^{\uparrow}$ packet is generated from a MetaCICCriticalPath route, finite observation schedule, StreamName windows, RegSeqRat counters, Real threshold seal, metatheoretic boundary, observation ledger, TasteGate request, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConsistencyObservationBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6844.1, Definition 6844.2, and Definition 6844.3 seed the finite consistency-observation budget surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConsistencyObservationBudget}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close global consistency, hidden model identity, unbounded proof search, semantic soundness outside the displayed route, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, MetaCIC route exposure, finite schedule exposure, stream-window admission, counter readback, threshold seal non-escape, boundary and ledger exposure, TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.ConsistencyObservationBudgetUp.

Chapter 6845

A Concrete Naming Certificate for $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$ packet records a finite route from a displayed unary Archimedean bound to dyadic approximation data that can be handed to $\mathsf{Real}^{\uparrow}$ consumers. It sits beside the natural-number bound surface of chapter 28, the rational approximation rows of chapter 37, the dyadic precision ledger of chapter 291, the approximation packet of chapter 335, and the terminal real-name seal of chapter 38. The chapter names a finite BEDC witness for Archimedean dyadic approximation; it does not import host real equality, quotient cuts, selected Cauchy limits, trichotomy, countable choice, or ambient completeness.

Definition 6845.1 (ArchimedeanDyadicApproximation carrier)**.** *An* $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, Q, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the unary Archimedean bound row, read through the finite* $\mathsf{Nat}^{\uparrow}$ *naming surface.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *approximation row attached to the same bound request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row that records the dyadic denominator and tolerance ledger.*
4. *W is the* $\mathsf{DyadicApproximation}^{\uparrow}$ *bracket row, exposing the finite dyadic enclosure licensed by B, Q, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, available only after the bound, rational approximation, precision, and bracket rows have been displayed.*
6. *H records componentwise* hsame *transport for the bound, rational approximation, dyadic precision, bracket, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the Archimedean bound through rational approximation, dyadic precision, dyadic bracket, and then the real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicApproximation}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient cuts, host real equality, a selected Cauchy limit, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6845.2 (ArchimedeanDyadicApproximation NameCert obligations)**.** *For every accepted* $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$ *carrier* $A = (B, Q, D, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicApproxi}}$ *surface consists exactly of carrier admission for the displayed bound, rational approximation, dyadic precision, bracket, real seal, transport, replay, provenance, and local naming rows; Archimedean exactness requiring* B *to be read before* Q*; dyadic precision exactness requiring* D *before* W*; real handoff exactness requiring* W *before* E*; and ledger exhaustion excluding quotient cuts, host equality, selected limits, trichotomy, choice schedules, and ambient completeness.*

Proof. Project the carrier of Definition 6845.1. The rows $B, Q, D, W, E, H, C, P, N$ are displayed as separate coordinates, so none of the downstream rows can hide the bound or precision data.

The Archimedean and dyadic clauses are read in order. The rational approximation row Q is attached to the unary bound row B, while the bracket row W is downstream of the dyadic precision row D.

Finally, the real seal E is reached only after B, Q, D, W have been displayed. The structural rows H, C, P, N transport, replay, package, and name this same finite packet, so the excluded principles have no carrier coordinate from which they can be exported. □

Theorem 6845.3 (Archimedean dyadic approximation real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$ *packet receives the finite route*

$$B, Q, D, W \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer reads a unary Archimedean bound, a $\mathsf{Rat}^{\uparrow}$ *approximation row, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row, a* $\mathsf{DyadicApproximation}^{\uparrow}$ *bracket row, and the* $\mathsf{Real}^{\uparrow}$ *seal; it receives no host real equality, quotient cut, selected Cauchy limit, trichotomy row, choice schedule, or ambient completeness principle.*

Proof. Use Definition 6845.2. Its Archimedean exactness, dyadic precision exactness, and real handoff exactness clauses force the route B, Q, D, W, E before any real-facing read can occur.

After the seal is read, the only remaining coordinates are H, C, P, N. These rows preserve the same finite packet by componentwise transport, displayed replay, provenance, and local naming.

Therefore a $\mathsf{Real}^{\uparrow}$ consumer receives exactly the displayed bound-to-bracket route with the seal and structural rows. Since quotient cuts, host equality, selected limits, trichotomy, choice schedules, and ambient completeness are absent from the carrier and the obligation surface, the handoff cannot export them. □

Lean4 (statement) `BEDC.Derived.ArchimedeanDyadicApproximationUp.ArchimedeanDyadicApproximationUp`

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}}$, seed)

Scope closed: Definition 6845.1, Definition 6845.2, and Definition 6845.3 seed the finite Archimedean dyadic approximation route from unary bounds to the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.ArchimedeanDyadicApproximationUp.ArchimedeanDyadicApproximationUp`

Bridge status: none

Not claimed: This chapter does not close quotient cuts, host real equality, selected Cauchy limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, bound exactness, dyadic precision exactness, real handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.ArchimedeanDyadicApproximationUp.

Constructive story: An $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$ packet is generated from a unary Archimedean bound, a Rat approximation row, a DyadicRatCore precision row, a DyadicApproximation bracket row, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6846

A Concrete Naming Certificate for $\mathsf{CompactUniformMeshModulus}^{\uparrow}$

Following the finite-net proof of Heine–Cantor in Bishop and Bridges constructive metric analysis, the $\mathsf{CompactUniformMeshModulus}^{\uparrow}$ packet realizes the compact finite-mesh route of chapter 9237 as concrete NameCert data. It consumes the compact metric finite-net rows of chapter 129, the continuous-map pointwise-modulus rows of chapter 130, the rational lower-bound rows of chapter 37, the finite-net fold of chapter 619, and the tolerance-only consumer surface of chapter 369. The packet records a finite $\mathsf{ProbeBundle}$ mesh and a rational lower-bound fold; it does not import open-cover compactness, choice-selected centers, semantic continuity, an external modulus function, quotient metric equality, or target completeness.

Definition 6846.1 (Compact uniform mesh modulus carrier)**.** *A* $\mathsf{CompactUniformMeshModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, M, F, B, L, Q, T, R, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, tying the compact source to displayed mesh centers and coverage witnesses.*
2. *M is the source and target metric row shared by the compact carrier and the continuous map.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, exposing pointwise-modulus ledgers at displayed mesh centers.*
4. *B is the finite* $\mathsf{ProbeBundle}$ *mesh row, listing center names, membership rows, and source-distance coverage rows.*
5. *L is the local radius ledger that attaches a positive* $\mathsf{Rat}^{\uparrow}$ *precision radius to each displayed probe.*
6. *Q is the rational lower-bound fold row over the finite mesh.*
7. *T is the metric-triangle handoff row that converts source mesh proximity and pointwise target estimates into one uniform estimate.*
8. *R is the* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance-only output row consumed by downstream compact-continuity arguments.*

9. *H records componentwise* hsame *transport for compact metric data, continuous-map data, mesh rows, rational folds, triangle handoff, uniform-modulus output, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a tolerance request through finite mesh inspection, pointwise-radius readback, rational lower-bound folding, triangle handoff, and the uniform-modulus row.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformMeshModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, *finite-fold material,* BHist, hsame, Cont, Pkg, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformMeshModulus}^{\uparrow}}$ *row.*

The classifier compares packets only through $K, M, F, B, L, Q, T, R, H, C, P, N$. It has no coordinate for an ambient open-cover compactness theorem, externally selected finite subcover, selected subsequence, host modulus function, quotient metric equality, or completeness of the target metric.

Theorem 6846.2 (Compact uniform mesh finite-net handoff)**.** *Every accepted* $\mathsf{CompactUniformMeshModulus}^{\uparrow}$ *packet hands a* $\mathsf{UniformModulus}^{\uparrow}$ *consumer the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{ProbeBundle},\ \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

For $U = (K, M, F, B, L, Q, T, R, H, C, P, N)$, the output row R is readable only after the compact metric mesh K, B, the pointwise-radius ledger F, L, the rational lower-bound fold Q, and the metric-triangle handoff T have all been displayed in the same packet.

Proof. Project the carrier of Definition 6846.1. The compact metric row, metric ledger, continuous-map row, finite mesh, local radii, rational fold, triangle handoff, output row, transport, replay, provenance, and naming rows are the complete inventory.

Read the finite mesh first. The compact metric row K and ProbeBundle row B expose only displayed centers and coverage witnesses, so the proof route does not pass through a host open-cover theorem or an externally selected subcover.

Next read the pointwise data. The continuous-map row F supplies local modulus evidence only at the centers displayed by B, and the local-radius row L keeps those radii attached to the same finite mesh.

Now fold and hand off. The row Q is the finite rational lower bound over L, and T is the metric-triangle estimate that converts mesh proximity plus pointwise control into one uniform estimate.

Finally expose R through H, C, P, N. These structural rows transport, replay, source, and name the same finite route, so no selected center, selected subsequence, external modulus, quotient equality, semantic continuity theorem, or target-completeness row can be exported. □

Theorem 6846.3 (Compact uniform mesh obligation surface)**.** *For the carrier of Definition 6846.1, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformMeshModulus}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission for $U = (K, M, F, B, L, Q, T, R, H, C, P, N)$;*

2. *classifier locality for the* $\mathsf{CompactMetric}^{\uparrow}$ *source,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph, finite* ProbeBundle *mesh, and* $\mathsf{Rat}^{\uparrow}$ *radius histories;*

3. *stability through componentwise* hsame *transport H and displayed* Cont *replay C;*

4. *exactness through the local-radius row L, rational lower-bound fold Q, metric-triangle handoff T, and* $\mathsf{UniformModulus}^{\uparrow}$ *output row R;*

5. *ledger control through* Pkg *provenance P and the local naming row N.*

No NameCert obligation may replace these rows by open-cover compactness, a choice-selected mesh, semantic continuity, an external modulus function, quotient metric equality, selected subsequence data, or target completeness.

Proof. Carrier admission is projection from Definition 6846.1. The rows $K, M, F, B, L, Q, T, R, H, C, P, N$ are all explicit, and no compact, continuous, mesh, fold, triangle, output, transport, replay, provenance, or naming row is implicit.

Classifier locality reads only the compact metric source, continuous graph, finite mesh, and rational radius histories. This keeps the mesh-to-modulus route inside displayed NameCert data.

Stability and exactness are then separated. The rows H and C preserve the same packet under transport and replay, while L, Q, T, R state the finite lower-bound and uniform-modulus handoff consumed downstream.

The package and naming rows close the ledger. Since every exported read must pass through P and N, the certificate surface is exactly the five listed rows and contains no coordinate for the excluded host principles. □

Falsifiable prediction: A UniformModulusUp consumer refutes CompactUniformMeshModulusUp if it reaches the tolerance-only row without displaying the CompactMetricUp finite mesh, ContinuousMapUp pointwise-radius rows, finite ProbeBundle mesh, RatUp lower-bound fold, metric-triangle handoff, transport, replay, provenance, and local naming rows.

Independence witness: compactmetric, continuousmap, uniformmodulus, rat, finitenetminimumfold, and compact-uniform-ladder siblings: none is bijective to $\mathsf{CompactUniformMeshModulus}^{\uparrow}$ because only this packet binds compact finite-mesh coverage, pointwise radii, rational lower-bound folding, metric-triangle handoff, uniform-modulus output, transport, replay, provenance, and local naming as one NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformMeshModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformMeshModulus}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise-modulus rows, finite ProbeBundle mesh rows, Rat lower-bound folds, metric-triangle handoff rows, UniformModulus output rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformMeshModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6846.1, Definition 6846.2, and Definition 6846.3 seed the finite mesh-to-uniform-modulus route for compact continuous maps.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformMeshModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected meshes, selected subsequences, semantic continuity, external modulus functions, quotient metric equality, target completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact mesh exposure, pointwise-radius attachment, rational lower-bound fold exactness, metric-triangle handoff, UniformModulusUp output, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformMeshModulusUp.

Chapter 6847

A Concrete Naming Certificate for $\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}$

Following Hausdorff and Bishop–Bridges constructive metric analysis, the $\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}$ packet records the finite-net approximation surface used when compact metric names are compared through displayed Hausdorff tolerances. It sits over the metric carrier of chapter 57, the compact-metric row of chapter 129, the total-bounded finite-net source of chapter 127, the finite epsilon-net handoff of chapter 1767, the Hausdorff metric boundary of chapter 2086, and the dyadic, regular-rational, and real-name readbacks of chapter 291, chapter 301, and chapter 38. The packet names a finite approximation object for completion-facing consumers without importing open-cover compactness, selected dense subsets, countable choice, quotient completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6847.1 (Finite Hausdorff metric approximation carrier)**.** *A* $\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, K, \varepsilon, E_A, E_B, D, H, R, S, T, P, N)$$

with the following displayed rows:

1. *X is the shared* $\mathsf{Met}^{\uparrow}$ *row, carrying the point classifier and distance rows used by the approximation.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net field read at the displayed tolerance.*
3. *ε is the positive tolerance row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and, when a Real-facing bound is requested, through the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal route.*
4. *E_A and E_B are two finite* $\mathsf{ProbeBundle}$ *net rows for the compact names being compared, including center membership and coverage witnesses exposed by the finite-net handoff.*
5. *D is the directed Hausdorff comparison ledger: every center of E_A has a displayed distance row to an admitted center of E_B, and every center of E_B has a displayed distance row to an admitted center of E_A, all bounded by the same tolerance budget.*
6. *H records componentwise* hsame *transport for the metric source, compact-metric row, tolerance row, the two finite nets, directed comparison ledger, readback row, seal row, replay, provenance, and local naming rows.*

7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for any rational or dyadic Hausdorff bound exposed to a completion-facing consumer.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite nets, directed distance ledger, and regular-rational readback have been displayed.*
9. *T records displayed* Cont *replay of the route*

$$X, K, \varepsilon, E_A, E_B \longmapsto D \longmapsto R \longmapsto S.$$

10. *P is the* Pkg *provenance over* $\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient finite subset, selected dense set, open cover, selected subcover, quotient completion, countable-choice schedule, host hyperspace equality, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 6847.2 (Finite Hausdorff metric approximation NameCert obligations)**.** *For every accepted* $\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}$ *carrier* $F = (X, K, \varepsilon, E_A, E_B, D, H, R, S, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, compact-metric row, tolerance, two finite nets, directed Hausdorff comparison ledger, componentwise transport, regular-rational readback, terminal Real seal, replay, provenance, and local naming rows. Every approximation read must expose E_A, E_B, D before R or S is consumed, and the ledger exports no open-cover compactness, selected subcover, quotient completion, countable choice, selected limit, host hyperspace equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 6847.1. The metric and compact rows are X, K, the tolerance row is ε, and the finite approximation data are exactly the two net rows E_A, E_B together with the directed comparison ledger D.

The finite-net rows are prerequisite data. A center can be used in the directed Hausdorff ledger only after it is visible in the relevant $\mathsf{ProbeBundle}$ and admitted through the compact-metric and total-bounded source rows.

The directed comparison ledger is then forced by D. It records both directions of the finite Hausdorff estimate under the same tolerance budget, so a consumer cannot replace the row by an open cover, a selected dense subset, or a host hyperspace construction.

The readback and seal rows are downstream. The $\mathsf{RegSeqRat}^{\uparrow}$ row R and terminal $\mathsf{Real}^{\uparrow}$ seal S expose only the finite bound already produced by E_A, E_B, D, while H, T, P, N transport, replay, source, and name that same packet. □

Theorem 6847.3 (Finite-net Hausdorff handoff)**.** *Every compact-metric, Hausdorff-metric, or completion-facing consumer of an accepted* $\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{TotallyBounded}^{\uparrow},\ E_A, E_B \longmapsto \mathsf{DyadicRatCore}^{\uparrow},\ D \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the consumer receives finite net centers, coverage rows, dyadic tolerance comparisons, regular-rational readback, and the terminal Real seal as displayed rows. It receives no open-cover compactness theorem, selected subcover, quotient completion, selected limit, countable choice, host hyperspace equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of the accepted packet. By carrier admission, the only metric entry point is the shared $\mathsf{Met}^{\uparrow}$ row X, and the compact data are read through the $\mathsf{CompactMetric}^{\uparrow}$ row K together with its $\mathsf{TotallyBounded}^{\uparrow}$ finite-net field.

Open the finite nets next. The rows E_A and E_B provide the displayed center bundles and coverage witnesses at the tolerance ε, and the dyadic tolerance row keeps the scale comparison inside $\mathsf{DyadicRatCore}^{\uparrow}$.

Apply the directed ledger D. It supplies the two finite Hausdorff comparison directions before any rational or Real-facing bound can be exported, so the handoff remains a finite-net route rather than an open-cover or host-hyperspace argument.

Finally read R and S. The $\mathsf{RegSeqRat}^{\uparrow}$ readback packages the bound for completion-facing consumers, and the $\mathsf{Real}^{\uparrow}$ seal is reached only after the finite nets and dyadic comparison ledger have been displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6847.1, Definition 6847.2, and Definition 6847.3 seed the finite-net Hausdorff approximation route over compact metric data, dyadic tolerance rows, regular-rational readback, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host hyperspaces, selected dense subsets, selected subcovers, quotient completion, countable choice, selected limits, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-net visibility, directed Hausdorff ledger exactness, dyadic tolerance transport, RegSeqRat readback, Real seal nonescape, replay, provenance, and local naming for BEDC.Derived.FiniteHausdorffMetricApproximationUp.

Constructive story: A $\mathsf{FiniteHausdorffMetricApproximation}^{\uparrow}$ packet is generated from a shared MetricSpaceUp row, a CompactMetricUp source, a positive DyadicRatCoreUp tolerance, two finite ProbeBundle nets, a directed Hausdorff comparison ledger, componentwise hsame transport, RegSeqRat readback, a terminal RealUp seal, displayed Cont replay, Pkg provenance, and local naming.

Chapter 6848

A Concrete Naming Certificate for $\mathsf{BishopIntervalSelection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface by which a Real and Completion consumer may pass from displayed closed bounded intervals to a bisection-driven real-name handoff. It sits after the closed interval carrier of chapter 1591, the located bisection route of chapter 1711, the regular rational readback of chapter 301, and the terminal real-name certificate of chapter 38. The packet names the constructive choice of a displayed interval branch at finite precision; it does not select a host point, invoke countable choice, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6848.1 (Bishop interval-selection carrier)**.** *A* $\mathsf{BishopIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, L, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, recording the left endpoint, right endpoint, and boundedness ledger available to the selection request.*
2. *L is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *branch row, recording the finite bisection decisions and located side tests already accepted by the packet.*
3. *Q is the rational tolerance row, naming the requested precision and the side condition that the displayed interval length is within that request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite sequence of selected interval endpoints.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, L, Q, R have been displayed.*
6. *H records componentwise* hsame *transport for interval endpoints, bisection rows, tolerances, regular readbacks, real seals, replay data, provenance, and local naming.*
7. *C records displayed* Cont *replay from interval requests through bisection, rational tolerance, regular readback, and real sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalSelection}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, Q, R, E, H, C, P, N$. It has no coordinate for a selected real point, host interval compactness, quotient real equality, countable-choice branch schedule, or ambient completeness theorem.

Theorem 6848.2 (Bishop interval-selection NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalSelection}^{\uparrow}$ *carrier* $I = (B, L, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, closed bounded interval exposure, located bisection branch exposure, tolerance coverage, regular rational readback, terminal real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6848.1. The analytic rows are B, L, Q, R, E, and they are ordered from displayed closed interval data to located bisection, tolerance, regular readback, and real sealing.

Use the sibling interval chapters. chapter 1591 supplies the closed bounded interval row, and chapter 1711 supplies the finite branch row whose side tests are already displayed.

Now read the completion-facing rows. The $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ chapters, chapter 301 and chapter 38, are reached only through R and E after the tolerance row Q has been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 6848.3 (Bishop interval-selection nested interval handoff)**.** *Every completion-facing read of an accepted* $\mathsf{BishopIntervalSelection}^{\uparrow}$ *carrier must read the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row B, the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *branch row L, the tolerance row Q, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before it consumes the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E. Thus nested interval data enter the Real and Completion chain as a displayed finite handoff, not as a hidden point selector.*

Proof. Start with the carrier row order in Definition 6848.1. The interval source and bisection branch are the only rows that can determine which closed subinterval is selected at a finite stage.

Apply Definition 6848.2. It requires tolerance coverage and regular rational readback to be part of the same local certificate before the real seal is available.

The structural rows H, C, P, N preserve that route without adding a branch selector. Therefore a consumer that reaches E has already consumed the displayed rows B, L, Q, R, and a consumer that bypasses those rows leaves the accepted $\mathsf{BishopIntervalSelection}^{\uparrow}$ packet. □

Falsifiable prediction: Every accepted BishopIntervalSelectionUp completion-facing read displays a ClosedBoundedIntervalUp source row, a LocatedIntervalBisectionUp branch row, tolerance coverage, RegSeqRatUp readback, RealUp sealing, transport, replay, provenance, and local NameCert naming.

Independence witness: closedboundedinterval, located-interval-bisection, regseqrat, real: $\mathsf{BishopIntervalSelection}$ is not bijective to any listed sibling because it jointly carries a closed interval source, located branch decisions, tolerance coverage, regular readback, terminal real sealing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalSelection}^{\uparrow}$ packet is generated from closed bounded interval rows, located bisection rows, tolerance rows, regular rational readback, real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6848.1, Definition 6848.2, and Definition 6848.3 seed the finite interval-selection handoff for the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host point selection, countable choice, quotient real equality, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval exposure, bisection branch exposure, tolerance coverage, regular readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalSelectionUp.

Chapter 6849

A Concrete Naming Certificate for $\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}$

The $\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}$ packet realizes the Cook compile-frontier budget named in section 9390.5 as finite NameCert data. It combines the cellular automaton substrate of chapter 934, the Rule 110 trust substrate of chapter 6517, the coordinate packet of chapter 949, the Cook compile-frontier witness of chapter 952, and the compile-frontier witness of chapter 954. The packet records a budget surface rather than a proof of universality: it displays production counts, tape-symbol counts, step budgets, closed round trips, and obstruction rows as inspectable finite data.

Definition 6849.1 (Rule 110 Cook frontier-budget carrier)**.** *A* $\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, U, K, C, P, T, S, R, O, H, D, G, N)$$

with the following visible rows:

1. *A is the* $\mathsf{CellularAutomaton}^{\uparrow}$ *substrate row naming the local cellular rule and finite orbit interface.*
2. *U is the* $\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}$ *row naming the Rule 110 manifest, evaluator, classifier, and audit-route surface.*
3. *K is the* $\mathsf{CookFrontierCoordinate}^{\uparrow}$ *coordinate row for production-count, tape-symbol-count, and step-budget entries.*
4. *C is the* $\mathsf{CookCompileFrontierWitness}^{\uparrow}$ *row recording the Cook compile-frontier witness consumed by the budget.*
5. *P is the* $\mathsf{CompileFrontierWitness}^{\uparrow}$ *row recording the general compile-frontier witness aligned with C.*
6. *T is the production-count row.*
7. *S is the tape-symbol-count row.*
8. *R is the step-budget and closed-round-trip row.*
9. *O is the obstruction row, recording why a larger requested compile-frontier instance is outside the displayed budget.*

10. *H records componentwise* hsame *transport for substrate, coordinate, witness, count, round-trip, obstruction, replay, provenance, and local naming rows.*
11. *D records displayed* Cont *replay for the same rows.*
12. *G is the* Pkg *provenance over the substrate, coordinate, witness, budget, transport, replay, and local naming rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an unstated universality theorem, hidden evaluator, unbounded tape oracle, external complexity claim, or closed-round-trip result not displayed by the packet.

Theorem 6849.2 (Rule 110 Cook frontier-budget NameCert obligations)**.** *For every accepted* $\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}$ *carrier $F = (A, U, K, C, P, T, S, R, O, H, D, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenCoo}}$ *surface consists exactly of carrier admission, cellular substrate exposure, Rule 110 trust-substrate exposure, Cook coordinate exposure, Cook compile-frontier witness exposure, compile-frontier witness exposure, production-count coverage, tape-symbol-count coverage, step-budget and closed-round-trip coverage, obstruction-row exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6849.1. The substrate and witness rows are A, U, K, C, P, while the concrete budget rows are T, S, R, O.

Read the sibling packets in order. The cellular automaton and Rule 110 trust-substrate chapters provide the local-rule and manifest surface; the Cook coordinate and frontier-witness chapters provide the rows that interpret production counts, tape symbols, step budgets, round trips, and obstruction data.

The rows H, D, G, N transport, replay, source, and name exactly those displayed entries. Since no hidden evaluator, unbounded tape oracle, external complexity claim, or unstated universality proof is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6849.3 (Rule 110 Cook frontier-budget closed observation)**.** *Recomputing the displayed* $\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}$ *packet returns the same production-count row T, tape-symbol-count row S, step-budget and closed-round-trip row R, and obstruction row O whenever the substrate, coordinate, and witness rows A, U, K, C, P are unchanged. Thus the Cook compile-frontier budget is a closed observational packet over displayed rows, not a detached complexity estimate.*

Proof. Start with the substrate rows A and U. They fix the local cellular rule, manifest surface, evaluator route, classifier route, and audit readback available to the packet.

Use the coordinate and witness rows K, C, P. They determine which production-count, tape-symbol-count, step-budget, closed-round-trip, and obstruction entries are being measured.

Now replay the budget through H, D, G, N. Componentwise transport and displayed continuation preserve the same count and obstruction rows, while provenance and local naming prevent replacement by an external estimate. Therefore recomputation over unchanged substrate and witness rows returns the same displayed budget packet. □

Falsifiable prediction: Recomputing the displayed RuleOneTenCookFrontierBudgetUp packet returns the same production-count, tape-symbol-count, step-budget, closed-round-trip, and obstruction rows.

Independence witness: cellularautomaton, rule110-cellular-trust-substrate, cookfrontiercoordinate, cookcompilefrontierwitness, compilefrontierwitness: none is bijective to the combined budget

packet because RuleOneTenCookFrontierBudgetUp simultaneously carries substrate rows, coordinate rows, compile-frontier witnesses, production counts, tape-symbol counts, step budgets, closed round trips, obstruction rows, transport, replay, provenance, and local NameCert naming.

Theorem 6849.4 (Rule 110 Cook frontier-budget TasteGate handoff)**.** *The Lean follow-up site* lean4/BEDC/Derived/RuleOneTenCookFrontierBudgetUp/TasteGate.lean *must include explicit* Nontrivial RuleOneTen *and* FieldFaithful RuleOneTenCookFrontierBudget$^{\uparrow}$ *instances. The nontriviality instance must expose at least one accepted displayed budget packet, and the field-faithfulness instance must keep substrate, coordinate, witness, production-count, tape-symbol-count, step-budget, closed-round-trip, obstruction, transport, replay, provenance, and local naming rows distinct.*

Proof. The carrier is not a terminal tag: it has separate substrate, coordinate, witness, count, round-trip, obstruction, transport, replay, provenance, and naming rows.

Nontriviality therefore has to exhibit an accepted budget packet over those rows. Field faithfulness has to prevent the count rows from replacing the witness rows, the closed-round-trip row from replacing the obstruction row, or the local NameCert row from replacing provenance.

Thus the named TasteGate file is the correct follow-up site for the same displayed budget carrier. □

Closure status for NameCert$_{\text{RuleOneTenCookFrontierBudget}^{\uparrow}}$.

Constructive story: A RuleOneTenCookFrontierBudget$^{\uparrow}$ packet is generated from cellular substrate rows, Rule 110 trust-substrate rows, Cook coordinate rows, compile-frontier witness rows, production-count rows, tape-symbol-count rows, step-budget rows, closed-round-trip rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{RuleOneTenCookFrontierBudget}^{\uparrow}}$, seed)

Scope closed: Definition 6849.1, Definition 6849.2, and Definition 6849.3 seed the finite budget packet for the Rule 110 Cook compile-frontier surface.

Formal verification: FormalStatus(NameCert$_{\text{RuleOneTenCookFrontierBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a new universality theorem, an unbounded tape oracle, an external complexity bound, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, substrate exposure, coordinate exposure, witness exposure, production-count coverage, tape-symbol-count coverage, step-budget coverage, closed-round-trip coverage, obstruction exactness, nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenCookFrontier

Chapter 6850

A Concrete Naming Certificate for $\mathsf{LinearlyOrderedReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LinearlyOrderedReal}^{\uparrow}$ packet records the finite order-facing route by which real-name consumers may read located comparison data without importing a host real line, quotient equality, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. It sits after the located line interface of chapter 3395, the located real-name surface of chapter 1933, the order rows of chapter 1378, the finite comparison discipline of $\mathsf{TotalOrder}^{\uparrow}$, the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a constructive order boundary for L10 Real and Completion routes, not a classical ordered field of reals.

Definition 6850.1 (LinearlyOrderedReal carrier)**.** *A* $\mathsf{LinearlyOrderedReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Lambda = (R, L, A, O, T, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after the located and order comparison rows have been displayed.*
2. *L is the* $\mathsf{LocatedRealLine}^{\uparrow}$ *row presenting the shared located line interface for order-facing real consumers.*
3. *A is the* $\mathsf{LocatedReal}^{\uparrow}$ *row presenting the point-facing located real-name surface and its finite apartness-ready windows.*
4. *O is the* $\mathsf{Order}^{\uparrow}$ *comparison row, carrying the displayed preorder or order request read from L, A, D, S, Q.*
5. *T is the* $\mathsf{TotalOrder}^{\uparrow}$ *comparison row, recording only the finite comparison branch exposed by the located line and order rows; it is not a trichotomy oracle outside the displayed request.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and tolerance ledger used to compare the located windows named by L, A, O, T.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by each order-facing comparison request.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows and dyadic tolerances.*

9. *H records componentwise* hsame *transport for the real seal, located line, located real, order rows, dyadic ledger, stream windows, regular readback, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an order-facing request through L, A, O, T, D, S, Q and then to the* $\mathsf{Real}^{\uparrow}$ *seal R.*
11. *P is the* Pkg *provenance over* $\mathsf{LinearlyOrderedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealLine}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LinearlyOrderedReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient real equality, a chosen representative of a real name, unrestricted trichotomy, host real-line completeness, selected limits, countable choice, or a public bridge.

Theorem 6850.2 (LinearlyOrderedReal NameCert obligations)**.** *For every accepted* $\mathsf{LinearlyOrderedReal}^{\uparrow}$ *carrier $\Lambda = (R, L, A, O, T, D, S, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LinearlyOrderedReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed* $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealLine}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *transport, replay, provenance, and local naming rows;*
2. *displayed comparison stability, requiring every comparison read to transport componentwise through H and to replay through the same continuation route C;*
3. *located-order handoff, requiring every order-facing consumer to pass through L, A, D, S, Q, O, T before the* $\mathsf{Real}^{\uparrow}$ *seal R is exposed;*
4. *ledger nonescape, excluding quotient real equality, selected representatives, unrestricted trichotomy, selected limits, countable choice, bridge data, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local data;*
5. *Real-seal routing, requiring the terminal seal R to preserve the same located line, located real, dyadic tolerance, stream-window, regular readback, and order rows already displayed by the carrier.*

No $\mathsf{LinearlyOrderedReal}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 6850.1. The analytic rows are exactly the located line row L, located real row A, order rows O, T, dyadic ledger D, stream windows S, regular readback Q, and terminal real seal R.

Displayed comparison stability is componentwise. The transport row H relates the displayed rows one by one, while the replay row C preserves the route from located line and located real data through the dyadic, stream, regular, and order rows.

The located-order handoff follows because R is terminal. An order-facing consumer reaches it only after the located line and located real rows have supplied the finite windows, the dyadic ledger has supplied the tolerance cells, and the order rows have recorded the displayed comparison.

Finally, P and N source and name the same finite packet. Since the excluded principles are not coordinates of the carrier or clauses of the obligation surface, the ledger cannot export them. □

Theorem 6850.3 (LinearlyOrderedReal located-order handoff)**.** *Every order-facing* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LinearlyOrderedReal}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{LocatedRealLine}^{\uparrow},\ \mathsf{LocatedReal}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Order}^{\uparrow},\ \mathsf{TotalOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Equivalently, the consumer must read the located line row L, located real row A, dyadic tolerance row D, finite window row S, regular readback row Q, order row O, and displayed total-order comparison row T before it may use the Real seal R.

Proof. Start with an accepted carrier $\Lambda = (R, L, A, O, T, D, S, Q, H, C, P, N)$. By Definition 6850.2, the only order-facing comparison rows are O and T, and both are downstream of the located line, located real, dyadic, stream, and regular readback rows.

The sibling located-line interface of chapter 3395 supplies the line-facing entry point L, while chapter 1933 supplies the point-facing located row A. The dyadic, stream, and regular readback rows are exactly the finite comparison data named by chapter 291, chapter 126, and chapter 301.

After these rows are displayed, the order request may read O and the displayed comparison branch T. The terminal seal R is then the same $\mathsf{Real}^{\uparrow}$ route cited by chapter 38, repacked through H, C, P, N.

Thus every order-facing Real consumer passes through the located line, dyadic tolerance, finite window, regular readback, and order rows before the Real seal. The handoff exports no quotient equality, selected representative, unrestricted trichotomy, selected limit, countable choice, bridge component, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{LinearlyOrderedReal}^{\uparrow}}$.

Constructive story: A $\mathsf{LinearlyOrderedReal}^{\uparrow}$ packet is generated from a RealUp seal, LocatedRealLineUp row, LocatedRealUp row, OrderUp and TotalOrderUp comparison rows, DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LinearlyOrderedReal}^{\uparrow}}$, seed)

Scope closed: Definition 6850.1, Definition 6850.2, and Definition 6850.3 seed the finite located-order route for Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LinearlyOrderedReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, unrestricted trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displayed comparison stability, located-order handoff, ledger nonescape, Real-seal routing, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.LinearlyOrderedRealUp.

Chapter 6851

A Concrete Naming Certificate for $\mathsf{WeakCompactness}^{\uparrow}$

Following Bourbaki and Schaefer on locally convex functional analysis, the $\mathsf{WeakCompactness}^{\uparrow}$ packet records the finite weak-topology compactness interface that a functional-analysis consumer may inspect before any host weak compactness theorem is available. It sits after the finite weak-star dual-ball route of chapter 3420 and chapter 6401, beside the compact carrier of chapter 60, and over bounded functional-analysis source data. The chapter names weak compactness only as finite NameCert data: a source row, weak-observation window, bounded-set row, compactness evidence, scalar readback, transport, replay, provenance, and local naming.

Definition 6851.1 (Weak compactness carrier)**.** *A* $\mathsf{WeakCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (F, T, B, A, C, R, H, Q, P, N)$$

with the following displayed rows:

1. *F is the functional-analysis source row, read through the finite vector, topology, continuity, and bounded-linear-functional surfaces made available to the consumer.*
2. *T is the weak-topology observation window, listing only the finitely many bounded-linear-functional probes and scalar tolerances visible in the present read.*
3. *B is the bounded set row, exposing the displayed boundedness ledger before any compactness-facing read is allowed.*
4. *A is the Banach–Alaoglu and weak-star compactness handoff row, consumed only through the finite windows of chapter 3420 and chapter 6401.*
5. *C is the* $\mathsf{Compact}^{\uparrow}$ *compactness evidence row for the displayed weak-observation window, not an unrestricted open-cover compactness theorem over a host weak topology.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for functional values, bounds, and comparison tolerances.*
7. *H records componentwise* hsame *transport for the functional-analysis source, weak observation window, bounded row, handoff row, compactness evidence, scalar readback, replay, provenance, and local naming rows.*
8. *Q records displayed* Cont *replay from a weak compactness request through $F, T, B, A, C, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{WeakCompactness}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{WeakStarCompactness}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{WeakCompactness}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $F, T, B, A, C, R, H, Q, P, N$. It has no coordinate for a selected weak cluster point, ultrafilter argument, unrestricted product compactness, quotient equality of functionals, host weak topology, or ambient reflexivity theorem.

Lean4 (statement) `BEDC.Derived.WeakCompactnessUp`

Theorem 6851.2 (Weak compactness NameCert obligations)**.** *For every accepted* $\mathsf{WeakCompactness}^{\uparrow}$ *carrier*

$$W = (F, T, B, A, C, R, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeakCompactness}^{\uparrow}}$ *surface consists exactly of functional-analysis source admission through F, finite weak-observation admission through T, bounded-set admission through B, Banach–Alaoglu and weak-star compactness handoff through A, compactness evidence through C, scalar readback through R, componentwise transport through H, displayed replay through Q, provenance through P, and local naming through N.*

Proof. Project the accepted carrier in Definition 6851.1. The displayed rows $F, T, B, A, C, R, H, Q, P, N$ are the complete inventory available to the certificate.

The analytic source is read first. Row F fixes the functional-analysis surface, row T restricts the weak topology to a finite observation window, and row B supplies the boundedness ledger before compactness evidence is inspected.

The compactness-facing part is then routed through A, C, R. The handoff row A cites only the finite Banach–Alaoglu and weak-star compactness windows, C records the compact evidence for the displayed window, and R keeps scalar values and tolerances inside the Real readback surface.

Finally the structural rows H, Q, P, N transport, replay, source, and name the same finite packet. Since no selected cluster point, ultrafilter, quotient functional equality, unrestricted product compactness, host weak topology, or reflexivity row is present, the listed obligations exhaust the local NameCert surface. □

Theorem 6851.3 (Weak compactness functional-analysis handoff)**.** *Every functional-analysis consumer of an accepted* $\mathsf{WeakCompactness}^{\uparrow}$ *packet must read the finite route*

$$F, T, B, A, C, R, H, Q, P, N$$

before exporting weak compactness data. Thus the consumer sees a functional-analysis source, a finite weak-topology observation window, a bounded-set row, the Banach–Alaoglu and weak-star compactness handoff, $\mathsf{Compact}^{\uparrow}$ *evidence,* $\mathsf{Real}^{\uparrow}$ *scalar readback, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows. The export carries no selected weak cluster point, ultrafilter argument, unrestricted product compactness, quotient functional equality, host weak topology, ambient reflexivity theorem, or open-cover compactness principle.*

Proof. Begin with a functional-analysis consumer request. By Definition 6851.2, the request must expose F, T, B before any compactness-facing data can be read.

Next use the handoff row A. It points only to the finite dual-ball and weak-star compactness windows already displayed by the sibling chapters, so the consumer cannot replace the handoff with an unrestricted compactness theorem.

The compactness and scalar data then pass through C and R. Row C is the local $\mathsf{Compact}^{\uparrow}$ evidence for the displayed window, while R keeps functional values, bounds, and tolerances inside the scalar readback surface.

The structural rows H, Q, P, N preserve the same route for transport, replay, provenance, and naming. Since the carrier has no row for any refused host principle, the exported functional-analysis handoff is exactly the finite weak compactness route stated above. □

Falsifiable prediction: Every public $\mathsf{WeakCompactness}^{\uparrow}$ read factors through a functional-analysis source row, a finite weak-topology observation window, a bounded-set row, a Banach–Alaoglu and $\mathsf{WeakStarCompactness}^{\uparrow}$ handoff, $\mathsf{Compact}^{\uparrow}$ evidence, $\mathsf{Real}^{\uparrow}$ scalar readback, componentwise hsame, displayed Cont, Pkg, and local NameCert naming. A read that exports selected weak cluster points, ultrafilters, quotient functional equality, unrestricted product compactness, host weak topology, ambient reflexivity, or open-cover compactness from this packet refutes the carrier boundary.

Independence witness: banachalaoglu, weakstarcompactness, compact: none is bijective with $\mathsf{WeakCompactness}^{\uparrow}$ because this carrier binds the functional-analysis source, weak-observation window, bounded-set row, finite dual-ball handoff, compactness evidence, scalar readback, transport, replay, provenance, and local NameCert rows while refusing selection and unrestricted compactness coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{WeakCompactness}^{\uparrow}$ packet is generated from a functional-analysis source row, a finite weak-topology observation window, a bounded-set row, a Banach–Alaoglu and weak-star compactness handoff, compactness evidence, scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WeakCompactness}^{\uparrow}}$, seed)

Scope closed: Definition 6851.1, Definition 6851.2, and Definition 6851.3 seed the finite weak compactness interface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WeakCompactness}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close selected weak cluster points, ultrafilter arguments, quotient functional equality, unrestricted product compactness, host weak topology, ambient reflexivity, open-cover compactness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak-observation-window admission, bounded-set admission, finite dual-ball handoff exactness, compactness-row handoff, scalar readback, transport, replay, provenance, and local naming for BEDC.Derived.WeakCompactnessUp.

Chapter 6852

A Concrete Naming Certificate for $\mathsf{KleeneRecursionTheorem}^{\uparrow}$

Kleene's recursion theorem in computability theory records the finite self-reference mechanism by which a computable transformation of program indices admits an index naming its own transformed behavior. The $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ packet reconstructs only the BEDC naming surface of that mechanism: finite program syntax, finite quotation of indices, a self-application window, a fixed-index witness row, transport, replay, provenance, and local naming. It sits after the computability carrier of chapter 199, the syntax and self-application surface of chapter 200, the first-order coding surface of chapter 197, and the NameCert transport discipline exemplified by chapter 481.

The packet is not a host partial-recursive semantics theorem. It does not identify programs by quotient extensional equality, does not choose representatives of partial functions, and does not import Rice-style semantic classification or Myhill-style global minimization.

Definition 6852.1 (Kleene recursion theorem carrier)**.** *A* $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, Q, W, F, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Computable}^{\uparrow}$ *program row, naming a displayed computable transformer on program indices;*
2. *Q is the finite syntax and index-quotation row, read through* $\mathsf{LambdaCalc}^{\uparrow}$ *and* $\mathsf{FirstOrder}^{\uparrow}$ *coding surfaces rather than through a host numbering theorem;*
3. *W is the self-application window, recording the finite route by which a quoted index is fed to the displayed transformer;*
4. *F is the fixed-index witness row, naming the finite index window whose transformed program is re-read through the same quotation route;*
5. *H records componentwise* hsame *transport for E, Q, W, F and the structural rows;*
6. *C records displayed* Cont *replay of the transformer, quotation, self-application, and fixed-index windows;*
7. *P is the* Pkg *provenance over* $\mathsf{KleeneRecursionTheorem}^{\uparrow}$, $\mathsf{Computable}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{KleeneRecursionTheorem}^{\uparrow}}$ *row.*

The carrier exports only a finite recursion-theorem naming certificate. It has no coordinate for host semantic equality of partial functions, unrestricted partiality, quotient program equality, oracle choice, Rice classification, or a Myhill minimization theorem.

Theorem 6852.2 (Kleene recursion theorem NameCert obligations)**.** *For every accepted* $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ *carrier* $K = (E, Q, W, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KleeneRecursionTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed computable transformer row* E*, finite syntax and index quotation through* Q*, self-application exposure through* W*, fixed-index witnessing through* F*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6852.1. The only computability-facing row is E, the only quotation row is Q, and the only self-reference rows are W and F.

The structural rows do not add semantic content. Transport through H compares the displayed rows componentwise, while replay through C exposes the same finite transformer, quotation, self-application, and witness route to consumers.

Finally P and N source and name the packet. Since no carrier coordinate stores host partial-function equality, quotient program equality, oracle choice, Rice classification, or Myhill minimization, the NameCert surface is exhausted by the listed rows. □

Theorem 6852.3 (Kleene recursion theorem fixed-index window)**.** *Every fixed-index read from an accepted* $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ *packet must expose the finite route*

$$E \longmapsto Q \longmapsto W \longmapsto F$$

before the witness is consumed. The route reads the $\mathsf{Computable}^{\uparrow}$ *transformer, the* $\mathsf{LambdaCalc}^{\uparrow}$ *and* $\mathsf{FirstOrder}^{\uparrow}$ *quotation row, the self-application window, and the fixed-index witness as one* BHist *packet. It cannot be cited as semantic equality of partial functions, quotient equality of program indices, unrestricted partiality, oracle choice, Rice theorem, or Myhill theorem.*

Proof. Start with the obligation surface of Definition 6852.2. It makes E, Q, W, F the consumer-visible recursion-theorem rows and keeps H, C, P, N structural.

The witness row F is therefore not detached from the transformer. It is read only after the finite quotation row Q and self-application window W have been displayed over the same computable transformer row E.

The exclusions follow by coordinate exhaustion. The carrier contains no row for host semantic equality, quotient program equality, unrestricted partiality, oracle selection, Rice classification, or Myhill minimization, so none of those endpoints can be exported by the fixed-index window. □

Theorem 6852.4 (Kleene recursion theorem computable handoff)**.** *Any* $\mathsf{Computable}^{\uparrow}$*,* $\mathsf{LambdaCalc}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*, or NameCert consumer citing an accepted* $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ *packet receives only the finite handoff* E, Q, W, F, H, C, P, N*. The handoff permits the consumer to read a displayed computable transformer together with its quotation, self-application, fixed-index witness, transport, replay, provenance, and local name. It supplies no host semantic equality, unrestricted partiality, quotient program equality, selected oracle, Rice-style nontrivial semantic classifier, or Myhill-style global identification theorem.*

Proof. Read the carrier inventory of Definition 6852.1. The rows E, Q, W, F form the computability and self-reference surface, while H, C, P, N preserve, replay, source, and name that surface.

Apply the NameCert obligation theorem. A downstream consumer must see all eight rows before it can cite the packet as a recursion-theorem handoff, and the fixed-index window theorem keeps the witness attached to the displayed quotation and self-application route.

Thus the handoff is finite BEDC data. Because the refused semantic objects are absent from the carrier and from the structural rows, the consumer cannot recover them by citing the packet. □

Falsifiable prediction: A computability packet that omits the quotation row Q or self-application window W cannot satisfy the $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ NameCert obligation surface.

Independence witness: Computable, LambdaCalc, FirstOrder, NameCertMorphism: these siblings supply computability, syntax, coding, and transport rows, but none carries the eight-row self-reference packet E, Q, W, F, H, C, P, N, so none is bijective to $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ under the displayed NameCert obligations.

Closure status for $\mathsf{NameCert}_{\mathsf{KleeneRecursionTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{KleeneRecursionTheorem}^{\uparrow}$ packet is generated from a displayed computable transformer row, finite syntax and index quotation, a self-application window, a fixed-index witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KleeneRecursionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6852.1, Definition 6852.2, Definition 6852.3, and Definition 6852.4 seed the finite recursion-theorem naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KleeneRecursionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host semantic equality, unrestricted partiality, quotient program equality, oracle choice, Rice theorem, Myhill theorem, Lean verification, or bridge checking for $\mathsf{KleeneRecursionTheorem}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, quotation exactness, self-application window stability, fixed-index witness routing, computable handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KleeneRecursionTheoremUp.

Chapter 6853

A Concrete Naming Certificate for $\mathsf{BaireCategoryDenseReflector}^{\uparrow}$

Following Baire, Oxtoby, and Bishop–Bridges, the $\mathsf{BaireCategoryDenseReflector}^{\uparrow}$ packet records the constructive dense-reflector route behind complete-metric Baire arguments as finite NameCert data. It sits after the theorem-level dense-open schedule of chapter 3570, the complete-metric inspection surface of chapter 3535, the dense-reflector completion route of chapter 3786, the indexed density row of chapter 1566, the finite StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, the DyadicRatCore tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet names the finite route used by complete-metric Baire consumers; it does not assert a host generic point, countable-choice selector, quotient completion equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6853.1 (BaireCategoryDenseReflector carrier)**.** *A* $\mathsf{BaireCategoryDenseReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, U, R, A, W, Q, T, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *dense-open schedule row, carrying the theorem-level finite route for complete-metric Baire reads.*
2. *U is the* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *inspection row, exposing complete-metric Cauchy service, metric comparison, and finite Baire surface data before any dense-reflector read.*
3. *R is the* $\mathsf{CauchyCompletionDenseReflector}^{\uparrow}$ *route row, supplying the dense-reflector completion handoff used by completion-facing consumers.*
4. *A is the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *indexed density row, naming the countable dense source only through displayed finite windows and tolerance data.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the dense-open schedule, indexed density requests, and completion readback.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the retained regular rational windows.*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for dense-open refinements, countable-density requests, Cauchy-completion tolerances, and real-seal comparisons.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, U, R, A, W, Q, T have been displayed.*

9. *H records componentwise* hsame *transport for the theorem route, complete-metric surface, dense-reflector route, indexed density row, windows, readbacks, tolerances, Real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from dense-open schedules through complete-metric inspection, dense-reflector handoff, indexed density, finite windows, tolerance accounting, readback, and Real sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{BaireCategoryDenseReflector}^{\uparrow}$, $\mathsf{BaireCategoryTheorem}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurface}$ $\mathsf{CauchyCompletionDenseReflector}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryDenseReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host intersections, selected generic points, quotient completion representatives, countable-choice schedules, open-cover compactness, or ambient completeness.

Theorem 6853.2 (BaireCategoryDenseReflector NameCert obligations)**.** *For every accepted* BaireCategoryDenseRe *carrier $D = (B, U, R, A, W, Q, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryDenseReflector}^{\uparrow}}$ *surface consists exactly of carrier admission for the theorem-level dense-open schedule, complete-metric Baire inspection, Cauchy completion dense-reflector handoff, countable dense source, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance accounting, RealUp sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every complete-metric Baire consumer that asks for a dense-reflector route must inspect those rows before reading the Real-facing seal.*

Proof. Project the carrier of Definition 6853.1. The rows B, U, R, A are the only rows that introduce the Baire theorem route, complete-metric inspection surface, dense-reflector completion route, and countable dense source.

The finite observation and tolerance stage is W, Q, T, E. StreamName windows expose the retained dense-open and density requests, RegSeqRat supplies regular rational readback, DyadicRatCore records the tolerance ledger, and the terminal Real seal is reached only after those rows are displayed.

Finally read H, C, P, N. These rows preserve the same finite route under componentwise transport, replay, provenance, and local naming. Since the carrier has no coordinate for a host intersection, selected generic point, quotient completion representative, countable-choice schedule, open-cover compactness theorem, or ambient completeness witness, no accepted packet can export one. □

Theorem 6853.3 (BaireCategoryDenseReflector handoff)**.** *Every complete-metric Baire read that consumes an accepted* $\mathsf{BaireCategoryDenseReflector}^{\uparrow}$ *packet factors through*

$$\mathsf{BaireCategoryTheorem}^{\uparrow} \longmapsto \mathsf{CompleteMetricBaireSurface}^{\uparrow} \longmapsto \mathsf{CauchyCompletionDenseReflector}^{\uparrow} \longmapsto \mathsf{CountableDens}$$

The handoff exports the finite dense-reflector route needed by downstream complete-metric Baire arguments, not a selected generic point, quotient completion equality, host intersection object, countable-choice selector, open-cover compactness theorem, or ambient completeness principle.

Proof. Start with the theorem route B and the complete-metric inspection row U. These rows make the dense-open schedule and complete-metric Cauchy service visible before a consumer can ask for dense-reflector data.

Next consume R and A. The Cauchy completion dense-reflector row supplies the completion-facing handoff, while the countable dense source row supplies indexed density data through the displayed finite packet rather than through a selected dense set.

The read then passes through W, Q, T, E and is transported by H, C, P, N. Thus every exported route is the displayed chain through BaireCategoryTheorem, CompleteMetricBaireSurface, CauchyCompletionDenseReflector, CountableDenseSubset, StreamName, RegSeqRat, DyadicRatCore, and Real rows. The excluded host and choice objects are not carrier fields and cannot be recovered from the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireCategoryDenseReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireCategoryDenseReflector}^{\uparrow}$ packet is generated from a BaireCategoryTheorem dense-open schedule, a CompleteMetricBaireSurface inspection row, a CauchyCompletionDenseReflector handoff, a CountableDenseSubset indexed density row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireCategoryDenseReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6853.1, Definition 6853.2, and Definition 6853.3 seed the finite dense-reflector route behind complete-metric Baire arguments over theorem-level, complete-metric, dense-reflector, countable-density, window, readback, tolerance, Real, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireCategoryDenseReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host generic point, quotient completion equality, selected dense set, countable-choice schedule, open-cover compactness theorem, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exposure, complete-metric inspection, dense-reflector handoff, indexed density exposure, finite-window readback, tolerance accounting, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BaireCategoryDenseReflectorUp.

Chapter 6854

A Concrete Naming Certificate for $\mathsf{LocatedCutApartness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCutApartness}^{\uparrow}$ packet records the finite route by which apartness evidence can be read from located-cut data before any real-name seal or comparison consumer receives it. It sits beside the located-cut carrier of chapter 404, the located-real comparison surface of **??**, the apartness-real evidence route of chapter 304, the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite L10 boundary for reading apartness from located cuts; it does not import quotient cuts, trichotomy, selected representatives, countable choice, host real equality, or ambient Real completeness.

Definition 6854.1 (LocatedCutApartness carrier)**.** *A* $\mathsf{LocatedCutApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, U, G, D, S, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower located-cut row read from* $\mathsf{LocatedCut}^{\uparrow}$*, exposing finite rational evidence below the cut.*
2. *U is the upper located-cut row read from* $\mathsf{LocatedCut}^{\uparrow}$*, exposing finite rational evidence above the same cut.*
3. *G is the positive gap row read through* $\mathsf{ApartnessReal}^{\uparrow}$*, recording the apartness witness that separates the displayed lower and upper observations.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the lower and upper observations at the requested precision.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the located-cut observations are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback extracted from those windows.*
7. *Q is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row attached to the same located-cut request.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after the located-cut, apartness, dyadic, stream, readback, and located-real rows have been displayed.*
9. *H records componentwise* hsame *transport for L, U, G, D, S, R, Q, E and the structural rows.*

10. *C records displayed* Cont *replay from a located-cut apartness request through the same finite route.*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedCutApartness}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCutApartness}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient cuts, host real equality, trichotomy, selected cut representatives, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6854.2 (LocatedCutApartness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCutApartness}^{\uparrow}$ *carrier $A = (L, U, G, D, S, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCutApartness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed lower located-cut row, upper located-cut row, apartness gap row, dyadic tolerance ledger, finite stream windows, regular rational readback, located-real comparison row, Real seal, componentwise transport, displayed replay, provenance, and local naming; lower-upper exactness requiring L, U to remain attached to the same located-cut request; gap exactness requiring G before any apartness consumer can read Q or E; regular readback exactness requiring D, S, R before the seal; and ledger exhaustion excluding quotient cuts, trichotomy, selected representatives, countable choice, host equality, and ambient completeness.*

Proof. Project the carrier of Definition 6854.1. The rows $L, U, G, D, S, R, Q, E, H, C, P, N$ are the complete displayed packet, so carrier admission is a finite coordinate read.

Lower-upper exactness is forced by the shared $\mathsf{LocatedCut}^{\uparrow}$ source. The lower and upper rows cannot be separated from the same located-cut request because the apartness row G reads them as one finite gap witness.

The readback and seal clauses follow the route D, S, R, Q, E. The dyadic ledger fixes the requested precision, the stream row records the inspected windows, the regular rational row records the Cauchy-facing handoff, and the located-real comparison row is displayed before the terminal Real seal.

The structural rows H, C, P, N transport, replay, package, and name only this packet. Since the excluded principles are not carrier coordinates, no local NameCert obligation can export them. □

Theorem 6854.3 (LocatedCutApartness gap handoff)**.** *Let $A = (L, U, G, D, S, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedCutApartness}^{\uparrow}$ *packet. Every apartness consumer of A reads the positive gap evidence through*

$$L, U \longmapsto G \longmapsto D, S, R, Q.$$

Thus the consumer sees lower and upper located-cut observations, a displayed $\mathsf{ApartnessReal}^{\uparrow}$ *gap witness, the dyadic precision ledger, finite stream windows, regular rational readback, and located-real comparison data before any terminal seal is available.*

Proof. Start from the NameCert obligations of Definition 6854.2. The gap exactness clause places G downstream of the common lower and upper located-cut rows L, U.

Read the finite observation rows next. The dyadic ledger D supplies the tolerance, the stream row S supplies the inspected windows, and the regular rational row R supplies the Cauchy-facing readback.

The located-real comparison row Q is reached only after that finite route. Therefore an apartness consumer receives the route displayed in the statement and cannot replace it by trichotomy, host real equality, quotient cuts, selected representatives, countable choice, or ambient completeness. □

Theorem 6854.4 (LocatedCutApartness Real seal non-escape)**.** *Let* $A = (L, U, G, D, S, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedCutApartness}^{\uparrow}$ *packet. Every* $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal receives only*

$$L, U, G, D, S, R, Q, E, H, C, P, N.$$

The seal exports no quotient cut, trichotomy branch, selected representative, countable-choice schedule, host equality row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply the gap handoff of Definition 6854.3. A consumer cannot reach the located-real comparison row Q until the lower and upper located-cut rows, apartness gap, dyadic ledger, stream windows, and regular readback have been displayed.

The terminal Real seal E is downstream of the same route by Definition 6854.2. After E is read, the only remaining coordinates are H, C, P, N.

Those structural rows preserve the displayed packet by componentwise transport, replay, provenance, and local naming. Since the excluded principles are absent from both the carrier and the obligation surface, no seal-facing consumer can obtain them from $\mathsf{LocatedCutApartness}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCutApartness}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCutApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6854.1, Definition 6854.2, Definition 6854.3, and Definition 6854.4 seed the finite route reading apartness evidence from located-cut data through dyadic, stream, RegSeqRat, LocatedReal, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCutApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient cuts, trichotomy, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-upper exactness, gap handoff, regular readback discipline, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCutApartnessUp.

Constructive story: A $\mathsf{LocatedCutApartness}^{\uparrow}$ packet is generated from lower and upper LocatedCut rows, an ApartnessReal positive gap witness, DyadicRatCore tolerance data, StreamName windows, RegSeqRat readback, a LocatedReal comparison row, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6855

A Concrete Naming Certificate for $\mathsf{CauchyFilterCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Kelley on filter convergence, the packet records Cauchy filters as objects and refinement/limit-compatible maps as morphisms. It sits after the Cauchy-filter carrier of chapter 333, the uniform-completion interface of chapter 1473, the metric-completion route of chapter 1506, the regular rational readback of chapter 301, the finite stream-name windows of chapter 126, and the terminal real-name seal of chapter 38. The category packet is a finite interface for Cauchy-filter transport; it is not a quotient completion, a selected limit operation, countable choice, or an ambient complete object.

Definition 6855.1 (Cauchy filter category carrier)**.** *A* $\mathsf{CauchyFilterCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, M, I, A, H, C, P, N)$$

with the following displayed rows:

1. *O is the object row, listing accepted* $\mathsf{CauchyFilter}^{\uparrow}$ *packets and their finite basis, refinement, compatibility, and endpoint windows.*
2. *M is the morphism row, listing refinement maps and limit-compatible handoff maps between displayed Cauchy-filter objects.*
3. *I is the identity row, assigning to each displayed object its local refinement identity over the same basis and compatibility surface.*
4. *A is the composition row, composing two compatible morphism rows only when their middle Cauchy-filter object is displayed.*
5. *H records componentwise* hsame *transport for objects, morphisms, identities, composition, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from object admission through refinement maps, identity, composition, transport, provenance, and the local name.*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterCategory}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through O, M, I, A, H, C, P, N. It has no coordinate for quotient filter equality, selected limits, countable-choice schedules, ambient complete objects, quotient real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.CauchyFilterCategoryUp`

Theorem 6855.2 (Cauchy filter category NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterCategory}^{\uparrow}$ *carrier $K = (O, M, I, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCategory}^{\uparrow}}$ *surface consists exactly of Cauchy-filter object exposure through O, refinement and limit-compatible morphism exposure through M, identity exposure through I, composition exposure through A, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6855.1. The accepted packet displays exactly the rows O, M, I, A, H, C, P, N.

The object row keeps the $\mathsf{CauchyFilter}^{\uparrow}$ data visible before any categorical read. The morphism row then records only refinement and limit-compatible maps between displayed objects; it does not create a quotient object or choose a limit.

The identity and composition rows are local BEDC rows over the same displayed objects. Transport, replay, provenance, and naming preserve that packet surface, so the listed rows exhaust the local certificate. □

Theorem 6855.3 (Cauchy filter category composition nonescape)**.** *Every composition read in an accepted* $\mathsf{CauchyFilterCategory}^{\uparrow}$ *packet factors through two displayed morphism rows and their shared middle* $\mathsf{CauchyFilter}^{\uparrow}$ *object before the composed row A is readable. The composition may be consumed by* $\mathsf{UniformCompletion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *routes as a finite refinement interface, but it exports no quotient completion, selected limit, countable choice, ambient complete object, quotient real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Read the morphism row M and the composition row A in Definition 6855.1. The composition row is available only after the source, middle, and target Cauchy-filter objects are displayed in O.

Use the NameCert obligations of Definition 6855.2. They force the object, morphism, identity, and composition rows to be exposed before transport, replay, provenance, and local naming.

The completion-facing siblings may consume this interface as finite refinement data. Since the carrier has no row for quotient filter equality, selected limits, choice schedules, ambient complete objects, quotient real equality, or Real completeness, composition cannot export any of those claims. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterCategory}^{\uparrow}$ consumer that composes Cauchy-filter maps must display the two morphism rows, the shared middle CauchyFilterUp object, transport, replay, provenance, and local NameCert row before any completion-facing read is named.

Independence witness: cauchyfilter, uniformcompletion, metriccompletion, regseqrat, streamname, real: none is bijective with $\mathsf{CauchyFilterCategory}^{\uparrow}$ because this packet jointly carries Cauchy-filter objects, refinement morphisms, identities, composition, transport, replay, provenance, and local naming rows, while each sibling supplies only one source or consumer surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterCategory}^{\uparrow}$ packet is generated from CauchyFilter objects, refinement and limit-compatible morphisms, identity rows, composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyFilterCategory}^{\uparrow}}$, seed)

Scope closed: Definition 6855.1, Definition 6855.2, and Definition 6855.3 seed the categorical finite-data interface for Cauchy filters over object, morphism, identity, composition, transport, replay, provenance, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyFilterCategory}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.CauchyFilterCategoryUp`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, ambient complete objects, quotient real equality, Real$^{\uparrow}$ completeness, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, object exposure, refinement-morphism exposure, identity exposure, composition nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterCategoryUp.

Chapter 6856

A Concrete Naming Certificate for $\mathsf{JordanNormalForm}^{\uparrow}$

Following Horn–Johnson and standard finite-dimensional linear algebra, the $\mathsf{JordanNormalForm}^{\uparrow}$ packet records the finite matrix-block normal-form certificate read from a linear endomorphism over a displayed field source. It sits beside the matrix carrier of chapter 49, the linear-map surface of chapter 48, the vector-space source of chapter 47, the scalar field carrier of chapter 45, and the polynomial rows of chapter 50. The packet names only the finite block layout, nilpotent-chain ledger, and similarity-transport rows needed by a Jordan-form consumer; it does not import algebraic closure, quotient eigenspace equality, selected eigenvectors from a host theorem, or an ambient spectral theorem.

Definition 6856.1 (Jordan normal form carrier)**.** *A* $\mathsf{JordanNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, L, V, F, Q, B, N, S, H, C, P, A)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *row, recording the finite matrix entries, row-column index windows, and matrix multiplication requests used by the block read.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row, recording the endomorphism surface whose matrix presentation is inspected.*
3. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row, recording the displayed finite-dimensional vector-space basis and scalar-action windows.*
4. *F is the* $\mathsf{Field}^{\uparrow}$ *row, recording the scalar carrier through which the displayed entries and polynomial coefficients are read.*
5. *Q is the* $\mathsf{Poly}^{\uparrow}$ *row, recording the characteristic-polynomial and minimal-polynomial ledgers visible to the block scheduler.*
6. *B is the Jordan-block ledger, a finite list of block sizes, eigenvalue-name rows, and superdiagonal-one positions.*
7. *N is the nilpotent-chain ledger, recording the finite chain-length checks and kernel-power windows attached to each displayed block.*
8. *S is the similarity-transport row, recording the source presentation, target block presentation, and matrix-change rows used for the displayed conjugacy read.*

9. *H records componentwise* hsame *transport for M, L, V, F, Q, B, N, S and the local certificate rows.*

10. *C records displayed* Cont *replay along the route*

$$M, L, V, F, Q, B, N, S \longmapsto H, C, P, A.$$

11. *P is the* Pkg *provenance over* $\mathsf{JordanNormalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *A is the local* $\mathsf{NameCert}_{\mathsf{JordanNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, V, F, Q, B, N, S, H, C, P, A$. It has no coordinate for an algebraic-closure theorem, quotient eigenspace equality, a selected host basis, canonical uniqueness of the block order, or an ambient spectral theorem.

Theorem 6856.2 (Jordan normal form NameCert obligations)**.** *For every accepted* $\mathsf{JordanNormalForm}^{\uparrow}$ *carrier $J = (M, L, V, F, Q, B, N, S, H, C, P, A)$, the local* $\mathsf{NameCert}_{\mathsf{JordanNormalForm}^{\uparrow}}$ *surface consists exactly of carrier admission, matrix exposure through M, linear-map exposure through L, vector-space basis exposure through V, field-scalar exposure through F, polynomial-ledger exposure through Q, Jordan-block ledger exposure through B, nilpotent-chain exposure through N, similarity-transport exposure through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through A.*

Proof. Project the carrier of Definition 6856.1. Its mathematical rows are exactly M, L, V, F, Q, B, N, S: the matrix presentation, the linear map, the finite vector-space source, the scalar field source, the polynomial ledgers, the block ledger, the nilpotent-chain ledger, and the similarity-transport row.

The block rows are not independent host algebra. The Jordan-block ledger B is read only through the matrix, field, and polynomial rows M, F, Q, while the nilpotent-chain ledger N records finite chain checks rather than quotient eigenspace equality or selected generalized eigenspaces.

Finally attach H, C, P, A. Transport and replay preserve the displayed rows componentwise, provenance names the sibling sources, and the local NameCert row adds no algebraic-closure or spectral-theorem coordinate. Thus the listed rows exhaust the NameCert obligations for the finite Jordan-form packet. □

Theorem 6856.3 (Jordan block similarity boundary)**.** *Every normal-form consumer of an accepted* $\mathsf{JordanNormalForm}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Mat}^{\uparrow},\ \mathsf{LinMap}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow},\ \mathsf{Field}^{\uparrow},\ \mathsf{Poly}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

through $M, L, V, F, Q, B, N, S, H, C, P, A$ before treating the displayed block matrix as a Jordan-form certificate. The route exports only finite matrix entries, linear-map presentation data, vector-space basis rows, scalar and polynomial ledgers, block sizes, nilpotent-chain checks, similarity transport, replay, provenance, and local naming.

Proof. Start from Definition 6856.2. Any accepted read must expose the matrix, linear-map, vector-space, field, polynomial, block, nilpotent-chain, and similarity rows before the local NameCert row can be consumed.

The similarity transport remains finite. Row S records only the displayed source and target matrix presentations and the change-of-presentation rows needed for that read; it does not certify algebraic closure or provide quotient eigenspace equality.

The structural rows H, C, P, A preserve and name the same finite route. Since none of those rows contains a host spectral theorem, a selected eigenbasis outside the packet, or canonical uniqueness of block order, the exported boundary is exactly the displayed finite certificate. □

Falsifiable prediction: Every accepted $\mathsf{JordanNormalForm}^{\uparrow}$ consumer must display Matrix, LinearMap, VecSpace, Field, Polynomial, Jordan-block, nilpotent-chain, similarity-transport, hsame, Cont, Pkg, and local NameCert rows before reading a Jordan normal-form certificate.

Independence witness: matrix, linearmap, vecspace, field, polynomial: $\mathsf{JordanNormalForm}^{\uparrow}$ is not bijective to any listed sibling because this packet alone binds matrix entries, linear-map presentation, vector-space basis data, scalar-field rows, polynomial ledgers, finite Jordan-block layout, nilpotent-chain checks, similarity transport, replay, provenance, and local naming into one finite normal-form certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{JordanNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{JordanNormalForm}^{\uparrow}$ packet is generated from Matrix rows, LinearMap rows, VecSpace basis windows, Field scalar rows, Polynomial ledgers, a finite Jordan-block layout, nilpotent-chain checks, similarity-transport rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6856.1, Definition 6856.2, and Definition 6856.3 seed the finite Jordan normal-form certificate over matrix, linear-map, vector-space, field, polynomial, block, nilpotent-chain, similarity, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim algebraic closure, quotient eigenspace equality, selected host eigenvectors, canonical uniqueness of Jordan-block order, ambient spectral theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, block-ledger exactness, nilpotent-chain projection, similarity-transport non-escape, componentwise transport, provenance, and local NameCert exactness for BEDC.Derived.JordanNormalFo

Chapter 6857

A Concrete Naming Certificate for $\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$

The $\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$ packet realizes the residual-substitution confluence frontier of section 9386.3 as finite NameCert data. It sits beside the confluence inventory of chapter 6802, the residual-substitution boundary of chapter 2181, the bounded residual frontier of chapter 3808, the critical-path ledger of chapter 765, and the stream and regular-readback surfaces of chapter 126 and chapter 301. The packet schedules local diamond reads only through displayed residual-frontier and bounded-checker rows; it does not promote those reads to global confluence, arbitrary closed Church–Rosser, or a discharged substitution-compatibility theorem.

Definition 6857.1 (MetaCIC residual diamond scheduler carrier)**.** *A* $\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, R, E, J, L, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, recording the closed source, target type, and finite reduction-window data inspected by the scheduler.*
2. *R is the residual-frontier row, recording the residual-substitution boundary retained before any local diamond read is accepted.*
3. *E is the candidate-SN evidence row, recording the finite candidate-mediated strong-normalization evidence used only to bound inspected branches.*
4. *J is the bounded local-join checker row, recording the finite peak, branch fuel, and accepted common-reduct witness for the inspected window.*
5. *L is the L10 source row, recording the source chapter, audit-map, and dependency route from which the scheduler reads its confluence-facing frontier.*
6. *O is the obstruction row, retaining the reason a requested global diamond or Church–Rosser endpoint is outside the packet.*
7. *H records componentwise* hsame *transport for T, R, E, J, L, O and the local certificate rows.*
8. *C records displayed* Cont *replay along the route*

$$T, R, E, J, L, O \longmapsto H, C, P, N.$$

9. *P is the* Pkg *provenance over* MetacicResidualDiamondScheduler$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert, *together with the sibling confluence-inventory, residual-frontier, critical-path, stream, and regular-readback sources named above.*

10. *N is the local* NameCert$_{\text{MetacicResidualDiamondScheduler}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, E, J, L, O, H, C, P, N$. It has no coordinate for full residual-substitution compatibility, an unrestricted parallel diamond, global Church–Rosser, evaluator equality, quotient equality of terms, subject-reduction closure, or kernel consistency.

Theorem 6857.2 (MetaCIC residual diamond scheduler NameCert obligations)**.** *For every accepted* MetacicResidualDiamondScheduler$^{\uparrow}$ *carrier $D = (T, R, E, J, L, O, H, C, P, N)$, the local* NameCert$_{\text{MetacicResidual}}$ *surface consists exactly of carrier admission for the typed-window row, residual-frontier row, candidate-SN evidence row, bounded local-join checker row, L10 source row, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The Lean-side plan requires* Nontrivial MetacicResidualDiamondScheduler$^{\uparrow}$ *and* FieldFaithful MetacicResidualDiamondScheduler$^{\uparrow}$ *instances in* `TasteGate.lean`*, with the field-faithfulness witness preserving $T, R, E, J, L, O, H, C, P, N$ as distinct rows.*

Proof. Project the carrier of Definition 6857.1. The rows T, R, E, J, L, O expose the typed source window, residual frontier, candidate evidence, bounded checker, source route, and retained obstruction before any local diamond read can be consumed.

The join checker is bounded by construction. Row J records only the inspected peak, finite branch fuel, and displayed common-reduct witness, while R keeps the residual-substitution frontier visible and O records the refused global endpoint.

Finally H, C, P, N transport, replay, source, and name that same route. Nontrivial and FieldFaithful TasteGate instances must read the same row order, so a checked scheduler cannot erase the residual frontier, bounded checker, obstruction, or L10 source when presenting a diamond read. □

Theorem 6857.3 (MetaCIC residual diamond scheduler boundary)**.** *Every accepted local diamond read exported by a* MetacicResidualDiamondScheduler$^{\uparrow}$ *packet must expose*

$$T, R, E, J, L, O, H, C, P, N$$

before the read is consumed by a confluence-facing client. The scheduler may route a bounded residual-frontier peak to a displayed local join, but it exports no full BetaParallelSubstitutionCompatibility *proof, no arbitrary closed parallel diamond, no global closed Church–Rosser theorem, no evaluator equality, and no quotient equality of terms.*

Proof. Start from Definition 6857.2. The accepted packet exposes the typed window, residual frontier, candidate evidence, local checker, L10 source, and obstruction rows as separate fields.

The scheduler route is therefore local. A consumer can read a bounded common-reduct witness from J only after the frontier R and the source row L are displayed, and the obstruction row O remains attached to any stronger confluence request.

The structural rows preserve the same route. Since H, C, P, N do not add substitution compatibility, subject reduction, evaluator equality, or quotient term equality, the local diamond read cannot escape into a global confluence claim. □

Falsifiable prediction: Any accepted scheduler that exports a diamond read without residual-frontier, bounded-checker, obstruction, and L10-source rows refutes the $\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$ packet.

Independence witness: metaciccriticalpath, metacicclosuretrace, metacicnormalizationcertificaterouter, streamname, regseqrat: no listed sibling is bijective with $\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$, because this packet alone binds typed windows, residual-frontier rows, candidate-SN evidence, bounded local-join checks, L10 source routing, obstruction retention, transport, replay, provenance, and local naming into one residual-diamond scheduler.

The Lean-side plan for `lean4/BEDC/Derived/MetacicResidualDiamondSchedulerUp/TasteGate.lean` must provide $\mathsf{Nontrivial}\ \mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$ instances before any checked carrier-alignment theorem is cited for the packet. The nontrivial witness must separate an accepted bounded scheduler from a packet missing the residual frontier, and the field-faithfulness witness must preserve the typed-window, residual-frontier, candidate-SN, bounded-checker, L10-source, obstruction, transport, replay, provenance, and local-name rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$ packet is generated from a typed-window row, residual-frontier row, candidate-SN evidence row, bounded local-join checker row, L10 source row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6857.1, Definition 6857.2, and Definition 6857.3 seed the finite residual-diamond scheduler route over typed windows, residual-frontier evidence, candidate-SN bounds, local joins, L10 source routing, obstruction, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, full residual-substitution compatibility, arbitrary closed parallel diamond, global closed Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, kernel consistency, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-frontier retention, candidate-SN evidence exposure, bounded local-join checking, L10 source routing, obstruction non-escape, componentwise transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetacicResidualDiamondSch

Chapter 6858

A Concrete Naming Certificate for $\mathsf{LocalEmpiricalResidue}^{\uparrow}$

The $\mathsf{LocalEmpiricalResidue}^{\uparrow}$ packet realizes the local empirical residue branch of section 9414.25 as finite NameCert data. It sits beside the open-fit source of chapter 1132, the local closure gate of chapter 1312, the finite refutation surface of chapter 1169, the physical-induction gate of chapter 6534, and the predictive-descent packet of chapter 1182. Those siblings expose fit, local settlement, defeat, continuation stability, and descent; this packet names the residual finite data that remains visible when a locally settled empirical claim is still not final.

Definition 6858.1 (Local empirical residue carrier)**.** *A* $\mathsf{LocalEmpiricalResidue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (H, K, F, J, D, O, L, T, C, P, N)$$

with the following displayed rows:

1. *H is the finite observation-history row, naming the trace, probe bundle, observed signature, and model signature under inspection;*
2. *K is the classifier row used to judge agreement on the displayed trace;*
3. *F is the local fit or finite-failure row, recording the current empirical comparison under K;*
4. *J is the local closure row, read through* $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$*, stating that the current finite inquiry has been settled;*
5. *D is the failure-surface residue row, listing the displayed continuations or refinements that would defeat the present fit;*
6. *O is the open-observation row, recording that the packet does not enumerate all future histories;*
7. *L is the nonfinality ledger, naming the refused final-fit, final-induction-oracle, hidden-continuation, and total-confirmation reads;*
8. *T records componentwise* hsame *transport for H, K, F, J, D, O, L and the structural rows;*
9. *C records displayed* Cont *replay of the finite observation history, classifier, fit or failure judgment, local closure, residue surface, openness row, and nonfinality ledger;*
10. *P is the* Pkg *provenance over* $\mathsf{LocalEmpiricalResidue}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$, $\mathsf{FiniteObservationRefutation}^{\uparrow}$, $\mathsf{PhysicalInductionGate}^{\uparrow}$, $\mathsf{PredictiveDescent}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalEmpiricalResidue}^{\uparrow}}$ *row.*
The carrier has no coordinate for unrestricted empirical confirmation, selected future histories, total continuation enumeration, host physical-trajectory equality, or a final induction oracle.

Theorem 6858.2 (Local empirical residue NameCert obligations)**.** *For every accepted* $\mathsf{LocalEmpiricalResidue}^{\uparrow}$ *carrier $R = (H, K, F, J, D, O, L, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocalEmpiricalResidue}^{\uparrow}}$ *surface consists exactly of finite observation-history exposure through H, classifier exposure through K, local fit or finite-failure reading through F, local closure exposure through J, failure-surface residue through D, open-observation retention through O, nonfinality refusal through L, componentwise transport through T, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 6858.1. The empirical rows are precisely H, K, F, J, D, O, L: a finite trace, a classifier, a local fit or failure judgment, a local closure row, a residue failure surface, an openness row, and a nonfinality ledger.

The rows D, O, L keep the local judgment from becoming final. The failure-surface residue records displayed ways the present fit could be defeated; the openness row refuses an enumeration of all future histories; and the nonfinality ledger records the refused oracle reads.

Finally T, C, P, N transport, replay, source, and name the same finite packet. Since none of these structural rows adds a selected continuation, a total confirmation judgment, host trajectory equality, or a final induction oracle, the listed rows exhaust the NameCert obligation surface. □

Theorem 6858.3 (Local empirical residue nonfinality)**.** *Every consumer of an accepted* $\mathsf{LocalEmpiricalResidue}^{\uparrow}$ *packet that reads the local closure row J must also read the failure-surface residue D, open-observation row O, and nonfinality ledger L. Thus local empirical settlement may be used as finite evidence, but it cannot be exported as unrestricted future fit, total empirical confirmation, or a final induction oracle.*

Proof. Use the local closure boundary of Definition 9414.356. A finite inquiry may settle the displayed trace without settling all admissible future histories.

The carrier records this separation in the same packet. The row J is paired with D, O, L, so any accepted read of local closure exposes the remaining failure surface, the open-observation boundary, and the refused finality claims.

Transport, replay, provenance, and naming preserve that packet without adding new empirical coordinates. Therefore a downstream consumer can cite local empirical residue only as finite nonfinal evidence, not as a total confirmation or final induction principle. □

Falsifiable prediction: A consumer that reads local empirical closure from H, K, F, J, T, C, P, N while omitting the failure-surface residue D, open-observation row O, and nonfinality ledger L refutes the $\mathsf{LocalEmpiricalResidue}^{\uparrow}$ carrier.

Independence witness: realityconstrainedopenfit, localempiricalclosuregate, finiteobservationrefutation, physicalinductiongate, predictivedescent: none is bijective to $\mathsf{LocalEmpiricalResidue}^{\uparrow}$ because this packet alone binds finite observation history, classifier, local fit or failure, local closure, residue failure surface, open observation, nonfinality, transport, replay, provenance, and local naming as one NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalEmpiricalResidue}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocalEmpiricalResidue}^{\uparrow}$ packet is generated from finite observation history, classifier, local fit or finite failure, local closure, failure-surface residue, open-observation, nonfinality, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalEmpiricalResidue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6858.1, Definition 6858.2, and Definition 6858.3 seed the finite local empirical residue packet and its nonfinality boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocalEmpiricalResidue}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted empirical confirmation, selected future histories, total continuation enumeration, host physical-trajectory equality, or a final induction oracle for LocalEmpiricalResidue$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, failure-surface residue exactness, open-observation retention, nonfinality refusal, transport, replay, provenance, and local naming for BEDC.Derived.LocalEmpiricalResidueU

Chapter 6859

A Concrete Naming Certificate for $\mathsf{MengerCurvature}^{\uparrow}$

Following Menger's metric curvature tradition, the $\mathsf{MengerCurvature}^{\uparrow}$ packet records the finite three-point curvature readout as BEDC NameCert data. It sits after the metric carrier of chapter 57, the dyadic rational ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite metric-geometry object for downstream comparison and completion routes; it does not claim global curvature bounds, quotient metric geometry, selected circumcentres, trichotomy of distances, or completeness.

Definition 6859.1 (Menger curvature carrier)**.** *A* $\mathsf{MengerCurvature}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, D, Q, R, E, H, C, P, N)$$

with the following rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *carrier and distance classifier.*
2. *T is a displayed ordered triple of carried metric points.*
3. *D is the finite distance ledger for the three pairwise distances of T.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger recording rational triangle-window tests for the three distances.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the reciprocal perimeter and area-budget approximants used by the curvature numerator and denominator.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal of the named curvature value.*
7. *H is componentwise* hsame *transport for the source points, distance rows, rational ledgers, readback rows, and seal.*
8. *C is displayed* Cont *replay for the finite curvature computation.*
9. *P is the* Pkg *provenance over* $\mathsf{MengerCurvature}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MengerCurvature}^{\uparrow}}$ *row.*

Theorem 6859.2 (Menger curvature NameCert obligations)**.** *For every accepted* $\mathsf{MengerCurvature}^{\uparrow}$ *carrier* $K = (M, T, D, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MengerCurvature}^{\uparrow}}$ *surface consists exactly of metric source exposure through* M*; finite triple exposure through* T*; three-distance ledger exposure through* D*; dyadic triangle-window comparison through* Q*; regular rational readback through* R*; terminal Real sealing through* E*; componentwise* hsame *transport through* H*; displayed* Cont *replay through* C*;* Pkg *provenance through* P*; and local naming through* N*.*

Proof. Project the accepted carrier. The metric source row supplies only carried points and displayed distances, while the triple row selects the three finite endpoints that the curvature packet may inspect.

The dyadic and regular rational rows keep the computation finite. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger records triangle-window comparisons for the three distances, and the $\mathsf{RegSeqRat}^{\uparrow}$ row records the reciprocal perimeter and area-budget readbacks before the $\mathsf{Real}^{\uparrow}$ seal is formed.

Transport and replay preserve these same rows componentwise. Provenance and local naming therefore certify exactly the displayed curvature packet and do not add quotient equality, selected circumcentres, distance trichotomy, global curvature bounds, or completeness. □

Theorem 6859.3 (Menger curvature dyadic triangle handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MengerCurvature}^{\uparrow}$ *packet must read the finite route*

$$M, T, D, Q, R, E$$

in order: first the metric source and carried triple, then the three-distance ledger, then the dyadic triangle-window ledger, then the regular rational readback, and finally the Real seal. No consumer can bypass Q *and recover a curvature value directly from* M *and* E*.*

Proof. The distance ledger D is indexed by the displayed triple T, so the metric source M is only a source of finite carried distances. It does not by itself name a curvature row.

The handoff to Q records the triangle-window checks in the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger. These checks are the finite rational boundary that precedes the reciprocal perimeter and area-budget readbacks.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads those budgets before the $\mathsf{Real}^{\uparrow}$ seal E is admitted. Hence any downstream consumer that reaches E has already crossed the dyadic triangle handoff, and the packet provides no alternate route through quotient metric geometry, chosen circumcentres, trichotomy, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{MengerCurvature}^{\uparrow}$ consumer that reads a $\mathsf{Real}^{\uparrow}$ curvature seal exposes the $\mathsf{Met}^{\uparrow}$ source, carried triple, three-distance ledger, $\mathsf{DyadicRatCore}^{\uparrow}$ triangle-window comparisons, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before using the curvature value.

Independence witness: metric, dyadicratcore, regseqrat, real: $\mathsf{MengerCurvature}^{\uparrow}$ is not bijective to any listed sibling because this packet binds a three-point metric distance ledger, dyadic triangle-window comparisons, regular rational curvature readback, Real sealing, transport, replay, provenance, and local naming into one finite metric-curvature certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MengerCurvature}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MengerCurvature}^{\uparrow}$ packet is generated from a MetricUp source row, a finite carried triple, a three-distance ledger, DyadicRatCoreUp triangle-window comparisons, RegSeqRatUp reciprocal perimeter and area-budget readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MengerCurvature}\uparrow}$, seed)

Scope closed: Definition 6859.1, Definition 6859.2, and Definition 6859.3 seed the finite metric-curvature boundary for dyadic, regular-rational, and Real consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{MengerCurvature}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim global curvature bounds, quotient metric geometry, selected circumcentres, distance trichotomy, metric completion, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite triple exposure, three-distance ledger exposure, dyadic triangle-window comparison, regular rational readback, Real sealing, transport, replay, provenance, and local naming for the displayed metric-curvature packet.

Chapter 6860

A Concrete Naming Certificate for $\mathsf{DualBasis}^{\uparrow}$

Following Bourbaki and Axler, the $\mathsf{DualBasis}^{\uparrow}$ packet records the finite-dimensional dual-basis surface by displaying a finite basis, its coordinate functionals, the scalar field, the vector-space carrier, the linear-map rows, and the matrix-coordinate readback before any linear-algebra consumer can use dual coordinates. It sits over the vector-space carrier of chapter 47, the linear-map interface of chapter 48, and the matrix-coordinate table of chapter 49. The packet is a NameCert object for finite coordinate evaluation; it is not a host algebraic dual, a choice-selected basis, a quotient of functionals, or an ambient finite-dimensionality theorem.

Definition 6860.1 (Dual-basis carrier)**.** *A* $\mathsf{DualBasis}^{\uparrow}$ *carrier over a displayed scalar field row* F *and finite vector-space row* V *is a finite* BHist *packet*

$$D = (F, V, B, \Lambda, L, M, H, C, P, N)$$

with the following rows:

1. F *is the scalar* $\mathsf{Field}^{\uparrow}$ *row. It supplies the carried scalar endpoints, scalar classifier, zero and one endpoints, addition, multiplication, and classifier transport used by coordinate equations.*
2. V *is the* $\mathsf{VecSpace}^{\uparrow}$ *carrier row over* F*. It supplies vector addition, scalar action, the vector classifier, and the carried endpoint predicate for the listed basis vectors and reconstructed vectors.*
3. B *is the finite basis row. It records a displayed natural number* n*, carried vectors* b_i *for* $i : \mathsf{Fin}(n)$*, and a finite coordinate-reconstruction ledger saying that every listed carried vector in the packet is classified with the finite sum of its displayed coordinates against the* b_i *rows.*
4. Λ *is the coordinate-functional row. It records carried maps* $\lambda_i : V \to F$ *for* $i : \mathsf{Fin}(n)$ *and the evaluation table* $\lambda_i(b_j) \sim_F \delta_{ij}$*.*
5. L *is the* $\mathsf{LinMap}^{\uparrow}$ *row for the coordinate functionals. Each* λ_i *is admitted as a linear map from* V *to the one-dimensional scalar target read through* F*, with additivity and scalar-compatibility rows displayed in the same packet.*
6. M *is the* $\mathsf{Mat}^{\uparrow}$ *coordinate row. It records the finite table whose* (i, j) *entry is the carried scalar comparison of* $\lambda_i(b_j)$ *with* δ_{ij}*, together with coordinate-column readback for every listed vector.*
7. H *records componentwise* hsame *transport for scalar rows, vector rows, basis entries, coordinate functionals, linear-map rows, matrix-coordinate entries, and local classifiers.*

8. *C records displayed* Cont *replay from basis inspection through coordinate evaluation, linear-map admission, matrix readback, reconstruction, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{DualBasis}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DualBasis}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite basis and its coordinate-functional table. It has no coordinate for a host algebraic dual, a choice-selected basis, quotient functionals, arbitrary linear forms outside the listed rows, or ambient finite-dimensionality.

Theorem 6860.2 (Dual-basis NameCert obligations)**.** *For every accepted* $\mathsf{DualBasis}^{\uparrow}$ *carrier*

$$D = (F, V, B, \Lambda, L, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DualBasis}^{\uparrow}}$ *surface consists exactly of scalar admission through F, vector-space admission through V, finite basis admission through B, coordinate-functional admission through Λ, linear-map admission through L, matrix-coordinate readback through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier rows of Definition 6860.1. The scalar row F and vector-space row V are displayed before the basis row is read, so every basis vector and every reconstructed vector is carried inside the same vector-space classifier.

Next read the coordinate-functional row Λ together with the $\mathsf{LinMap}^{\uparrow}$ row L. The row L supplies the additivity and scalar-compatibility obligations for each λ_i, while Λ supplies the evaluations on the displayed basis vectors.

Now inspect the $\mathsf{Mat}^{\uparrow}$ row M. Its entries are the finite coordinate table $\lambda_i(b_j) \sim_F \delta_{ij}$, and its column readback is attached to the same basis row B. Thus a coordinate consumer receives the basis, the functionals, and the table as one finite packet.

Finally H, C, P, N transport, replay, source, and name exactly these rows. Since no carrier coordinate names a host algebraic dual, a choice-selected basis, quotient functionals, arbitrary outside linear forms, or an ambient finite-dimensionality theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6860.3 (Dual-basis coordinate readback)**.** *Every coordinate consumer accepted by a* $\mathsf{DualBasis}^{\uparrow}$ *packet must factor through*

$$F, V, B, \Lambda, L, M, H, C, P, N.$$

The consumer first reads the scalar $\mathsf{Field}^{\uparrow}$ *and vector-space* $\mathsf{VecSpace}^{\uparrow}$ *rows, then the finite basis row, then the* $\mathsf{LinMap}^{\uparrow}$ *rows for the coordinate functionals, and then the* $\mathsf{Mat}^{\uparrow}$ *coordinate table. It receives coordinate values only through the displayed evaluation table and reconstruction ledger, not through a host dual space, an arbitrary functional oracle, quotient functional equality, or a selected basis outside the packet.*

Proof. Use Definition 6860.2. It places B, Λ, L, M after the scalar and vector-space rows and before any coordinate read is exported.

For a basis vector b_j, the coordinate value is read from the matrix entry in M that records $\lambda_i(b_j) \sim_F \delta_{ij}$. For a listed carried vector, the reconstruction ledger in B supplies the displayed

finite coordinate column, and the same matrix readback identifies which scalar rows are being consumed.

Therefore the coordinate route is finite and packet-local. The carrier never exposes a separate algebraic dual endpoint, a selector for a basis, or a quotient of functionals, so no consumer can bypass the displayed rows. □

Theorem 6860.4 (Dual-basis nonescape)**.** *No accepted* $\mathsf{DualBasis}^{\uparrow}$ *consumer can obtain a coordinate functional, coordinate matrix entry, or reconstruction coefficient without reading the scalar field row, vector-space row, finite basis row, linear-map row, matrix-coordinate row, transport row, replay row, provenance row, and local naming row displayed in Definition 6860.1.*

Proof. Assume a consumer asks for coordinate data from an accepted packet. By Definition 6860.2, the only coordinate-functional source is Λ, the only linearity source is L, and the only coordinate table is M.

The finite basis row B is the support on which Λ and M are interpreted. Without B, the expressions $\lambda_i(b_j)$ and the reconstruction column have no row in the packet; without F and V, their scalar and vector classifiers are not available.

The structural rows H, C, P, N are the only transport, replay, provenance, and naming routes. Hence any coordinate read that omits one of $F, V, B, \Lambda, L, M, H, C, P, N$ has no carrier coordinate from which to escape into host duality, arbitrary functional choice, quotient equality, or ambient finite-dimensionality. □

Falsifiable prediction: Every accepted $\mathsf{DualBasis}^{\uparrow}$ coordinate read factors through the displayed scalar field row, vector-space row, finite basis row, coordinate-functional row, linear-map row, matrix-coordinate row, transport, replay, provenance, and local naming rows; a request that supplies only a host algebraic dual or a selected basis is rejected by this certificate.

Independence witness: field, vecspace, linearmap, matrix: $\mathsf{DualBasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries scalar field data, finite vector-space basis data, coordinate functionals, linear-map obligations, matrix-coordinate readback, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{DualBasis}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DualBasis}^{\uparrow}$ packet is generated from FieldUp scalar rows, VecSpaceUp carrier rows, finite basis rows, coordinate-functional rows, LinearMapUp admission rows, MatrixUp coordinate readback rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DualBasis}^{\uparrow}}$, seed)

Scope closed: Definition 6860.1, Definition 6860.2, Definition 6860.3, and Definition 6860.4 seed the finite dual-basis coordinate surface over field, vector-space, linear-map, and matrix rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DualBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host algebraic duals, arbitrary functional choice, quotient functional equality, selected bases outside the packet, norm equivalence, or ambient finite-dimensionality.

Upgrade path: Obligation closure requires binding the displayed scalar, vector-space, finite basis, coordinate-functional, linear-map, matrix-coordinate, transport, replay, provenance, and local naming rows against their BEDC primitive scope.

Chapter 6861

A Concrete Naming Certificate for $\mathsf{SequentialCoreflection}^{\uparrow}$

Following Franklin and Kelley on sequential spaces and coreflective topology, the $\mathsf{SequentialCoreflection}^{\uparrow}$ packet records the sequentially generated readback of a displayed space as finite BEDC NameCert data. It sits between the first-countable handoff of chapter 2157, the sequential closure route of chapter 1571, the cofinite-tail filter of chapter 1564, the finite stream windows of chapter 126, the regular rational sequence route of chapter 301, and the terminal real-name boundary of chapter 38. The certificate exposes the countable-name tests through which later closure and Real-facing consumers may inspect sequential reachability, without importing a host topological coreflection or a completed quotient space.

Definition 6861.1 (Sequential coreflection carrier)**.** *A* $\mathsf{SequentialCoreflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, Q, L, F, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source space row whose original open or closure observations are read only through displayed BEDC packet coordinates.*
2. *Q is the sequential-coreflection classifier row, recording that a point-name is tested by finite sequence windows and their eventual tail behaviour rather than by arbitrary host neighbourhoods.*
3. *L is the* $\mathsf{SequentialClosure}^{\uparrow}$ *row naming the sequence-closure test consumed by the carrier.*
4. *F is the* $\mathsf{FrechetFilter}^{\uparrow}$ *row recording cofinite-tail admission for the inspected sequence windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row displaying the finite prefixes and tail requests used by the test.*
6. *T is the first-countable handoff row, read through* $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$ *when a countable neighbourhood base is displayed.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row used when the inspected sequence data is passed to rational or metric readbacks.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, F, L, T, R have been displayed.*
9. *H records componentwise* hsame *transport for the source row, classifier row, closure row, tail filter, stream windows, first-countable handoff, rational handoff, real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay along the route*

$$X, Q, L, F, W, T, R, E \longmapsto H, C, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{SequentialCoreflection}^{\uparrow}$, $\mathsf{FirstCountableSequentialClosure}^{\uparrow}$, $\mathsf{SequentialClosure}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCoreflection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host topological coreflection, quotient point equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6861.2 (Sequential coreflection NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCoreflection}^{\uparrow}$ *carrier*

$$S = (X, Q, L, F, W, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialCoreflection}^{\uparrow}}$ *surface consists exactly of carrier admission, source-space exposure through X, sequential-coreflection classifier exposure through Q, sequential-closure exposure through L, cofinite-tail exposure through F, finite stream-window exposure through W, first-countable handoff exposure through T, regular rational handoff through R, real-name sealing through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6861.1. Its mathematical rows are exactly the source row X, classifier row Q, sequential-closure row L, Frechet-tail row F, stream-window row W, first-countable handoff row T, regular rational handoff R, and Real seal E.

The sequential classifier is therefore read through displayed countable-name tests. Row W exposes only finite stream windows, row F supplies only cofinite-tail discipline, and row L records the sequence-closure test visible to the packet.

The first-countable and Real-facing routes remain downstream. Row T is consumed only when a countable base handoff has already been displayed, while R and E pass inspected sequence data to regular rational and Real consumers without selecting a subsequence or identifying quotient points.

Finally attach H, C, P, N. These structural rows transport, replay, source, and name the same finite dependency route, so the listed rows exhaust the local NameCert obligations. □

Theorem 6861.3 (Sequential coreflection first-countable handoff)**.** *Every accepted* FirstCountableSequentialClosure *read consumed by a* $\mathsf{SequentialCoreflection}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{FrechetFilter}^{\uparrow},\ \mathsf{SequentialClosure}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as exposed by W, F, L, R, E and transported by H, C, P, N. The handoff lets a first-countable consumer replay the same finite sequence windows as a sequential-coreflection read, but it exports no host topology coreflection, quotient point equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the first-countable row T in Definition 6861.1. A consumer may use it only after the source row X and sequential classifier row Q have exposed the sequence test being replayed.

The countable-name data is then read through W, F, L. Finite prefixes and tail requests come from the $\mathsf{StreamName}^{\uparrow}$ window row W, eventual-tail discipline comes from $\mathsf{FrechetFilter}^{\uparrow}$ row F, and the closure test itself is the displayed $\mathsf{SequentialClosure}^{\uparrow}$ row L.

The Real-facing handoff is downstream from the same windows. Row R repacks the inspected sequence observations as regular rational data when such a readback is requested, and row E seals the resulting Real-facing boundary.

Thus the first-countable handoff is a replay of the displayed sequence route, not a separate topology theorem. The structural rows H, C, P, N preserve that route and add no selected subsequence, quotient point equality, countable-choice schedule, or ambient completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{SequentialCoreflection}^{\uparrow}$ read factors through source-space, sequential-classifier, SequentialClosure, FrechetFilter, StreamName, FirstCountableSequentialClosure, RegSeqRat, Real, hsame, Cont, Pkg, and local NameCert rows before exporting a sequentially generated closure read.

Independence witness: first-countable-sequential-closure, sequentialclosure, frechetfilter, streamname, regseqrat, real: $\mathsf{SequentialCoreflection}^{\uparrow}$ is not bijective to any listed sibling because this packet alone binds the source row, sequential-coreflection classifier, sequence-closure route, cofinite-tail filter, finite stream windows, first-countable handoff, regular rational readback, Real seal, transport, replay, provenance, and local naming into one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCoreflection}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCoreflection}^{\uparrow}$ packet is generated from a source-space row, a sequential-coreflection classifier row, SequentialClosure rows, FrechetFilter tail rows, StreamName windows, a FirstCountableSequentialClosure handoff, RegSeqRat readback rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCoreflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6861.1, Definition 6861.2, and Definition 6861.3 seed the finite sequential-coreflection certificate over countable-name sequence tests, closure rows, tail filters, first-countable handoff rows, rational readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCoreflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host topology coreflection, quotient point equality, selected subsequences, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequential-classifier exposure, SequentialClosure exactness, FrechetFilter tail discipline, StreamName window replay, first-countable handoff, RegSeqRat and Real non-escape, transport, provenance, and local naming for BEDC.Derived.SequentialCoreflectionUp.

Chapter 6862

A Concrete Naming Certificate for $\mathsf{GromovHyperbolicMetric}^{\uparrow}$

Following Gromov's hyperbolic metric spaces and the four-point formulation of coarse negative curvature, the $\mathsf{GromovHyperbolicMetric}^{\uparrow}$ packet records a finite metric carrier whose hyperbolicity is read through displayed distance comparisons and bounded four-point slack. It sits after the metric source of chapter 57, the length-space route of chapter 2082, the geodesic metric surface of chapter 2213, and the existing hyperbolic metric packet of chapter 3474; its boundary-facing consumers include chapter 3645, chapter 3732, and chapter 6470. The packet names only finite four-point, geodesic, and boundary-handoff rows, not a host geodesic space, selected boundary compactification, quotient of rays, or ambient completion theorem.

Definition 6862.1 (Gromov hyperbolic metric carrier)**.** *A* $\mathsf{GromovHyperbolicMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, L, E, \Delta, Q, S, B, H, C, P, N)$$

with displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *distance-observation row.*
2. *L is the* $\mathsf{LengthSpace}^{\uparrow}$ *path-length readback row when a length route is present.*
3. *E is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *geodesic witness row when geodesic segments are displayed.*
4. *Δ is the nonnegative hyperbolicity-bound row used by the four-point comparisons.*
5. *Q is the four-point comparison ledger over displayed quadruples.*
6. *S is the stability row recording that enlarging the displayed bound keeps the same accepted metric source.*
7. *B is the boundary-handoff row available to* $\mathsf{BusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, *and* $\mathsf{GromovBoundary}^{\uparrow}$ *consumers.*
8. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{GromovHyperbolicMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, E, \Delta, Q, S, B, H, C, P, N$. It has no coordinate for a selected geodesic model, quotient ideal boundary, host compactification, or ambient completion principle.

Theorem 6862.2 (Gromov hyperbolic metric NameCert obligations)**.** *For every accepted* $\mathsf{GromovHyperbolicMetric}^{\uparrow}$ *carrier* $G = (M, L, E, \Delta, Q, S, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GromovHyperbolicMetric}^{\uparrow}}$ *surface consists exactly of metric-source admission, optional length-space readback, optional geodesic witness exposure, hyperbolicity-bound admission, four-point comparison exposure, bound-stability reading, boundary-handoff exposure, componentwise transport, displayed replay, package provenance, and local naming. Every downstream consumer must factor through*

$$M, L, E, \Delta, Q, S, B, H, C, P, N$$

before it reads a hyperbolic metric datum.

Proof. Project the carrier of Definition 6862.1. The metric source M is visible before any four-point comparison is inspected, and the length and geodesic rows L, E are displayed as route data rather than as a host geodesic space.

The bound row Δ and comparison ledger Q provide the Gromov-hyperbolic content. They inspect only finite quadruples and the displayed distance observations, so the packet records hyperbolicity as BEDC comparison data.

The stability and boundary rows S, B then route the same accepted metric surface to boundary consumers. The structural rows H, C, P, N transport, replay, source, and name only those displayed rows, leaving no coordinate for selected geodesic models, quotient boundaries, host compactifications, or ambient completion theorems. □

Theorem 6862.3 (Gromov hyperbolic metric four-point stability)**.** *Every accepted* $\mathsf{GromovHyperbolicMetric}^{\uparrow}$ *carrier remains accepted when a consumer replaces the displayed hyperbolicity-bound row* Δ *by a transported row* Δ' *whose finite comparison ledger dominates the same quadruple reads. The accepted route is still*

$$M, L, E, \Delta', Q, S, B, H, C, P, N,$$

and the replacement does not add a host proof of global curvature, a selected geodesic realization, a quotient boundary, or ambient metric completion.

Proof. Start from the four-point ledger Q. It is indexed only by displayed metric observations from M, with optional length and geodesic support read through L and E.

The stability row S records the admissible transport from Δ to Δ' for those same finite quadruple reads. Since the row changes only the displayed bound, the metric source and the comparison ledger remain the same BEDC route.

Finally apply the structural rows H, C, P, N. They replay the transported bound and preserve the boundary handoff B, but they do not introduce a host curvature theorem, selected geodesic model, quotient boundary, or completion object. □

Theorem 6862.4 (Gromov hyperbolic metric geodesic boundary route)**.** *Every boundary-facing consumer of an accepted* $\mathsf{GromovHyperbolicMetric}^{\uparrow}$ *carrier must read the* $\mathsf{Met}^{\uparrow}$ *source row* M*, the length or geodesic rows* L, E *when present, the hyperbolicity bound* Δ*, the four-point ledger* Q*, and the boundary-handoff row* B *before it can use the packet in* $\mathsf{BusemannBoundary}^{\uparrow}$*,* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$*, or* $\mathsf{GromovBoundary}^{\uparrow}$*. The handoff exports finite metric and comparison rows, not a completed ideal boundary, quotient of rays, selected geodesic representative, or host compactification.*

Proof. Read the metric source through chapter 57, then the length and geodesic support through chapter 2082 and chapter 2213 when those rows are present.

Next expose Δ and Q. These rows are the only hyperbolicity evidence available to the packet, so a boundary consumer cannot bypass the finite four-point comparison surface.

The boundary handoff B is then consumed by the Busemann and Gromov boundary chapters named above. Because B is transported only through H, C, P, N, the export remains a finite metric comparison route and not a completed ideal boundary, quotient of rays, selected geodesic representative, or host compactification. □

Closure status for $\mathsf{NameCert}_{\mathsf{GromovHyperbolicMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{GromovHyperbolicMetric}^{\uparrow}$ packet is generated from MetricUp distance rows, optional LengthSpaceUp and GeodesicMetricUp support rows, a displayed hyperbolicity-bound row, a finite four-point comparison ledger, bound-stability rows, boundary-handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GromovHyperbolicMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6862.1, Definition 6862.2, Definition 6862.3, and Definition 6862.4 seed the finite four-point metric packet over metric, length-space, geodesic, stability, and boundary-handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GromovHyperbolicMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host geodesic space, selected boundary compactification, quotient of rays, global curvature theorem, ambient completion theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four-point ledger exactness, bound stability, metric and geodesic handoff, boundary route exactness, transport, replay, provenance, and local naming for BEDC.Derived.GromovHyperbolicMetricUp.

Chapter 6863

A Concrete Naming Certificate for $\mathsf{BrentSalaminPi}^{\uparrow}$

Following Brent and Salamin, the $\mathsf{BrentSalaminPi}^{\uparrow}$ packet records the finite Brent–Salamin arithmetic-geometric-mean route for a named value of π as an L10 Real and Completion computation object. It consumes the iteration discipline of chapter 1973, the terminal real-name seal of chapter 38, the dyadic arithmetic and budget carrier of chapter 291, the finite observation windows of chapter 126, and the regular rational readback route of chapter 301. The packet names only displayed AGM iteration rows, Real seals, dyadic error ledgers, finite windows, regular readback, transport, replay, provenance, and local naming; it does not export ambient completeness, quotient stream equality, selected limits, trichotomy, Lean verification, or bridge data.

Definition 6863.1 (Brent-Salamin pi carrier)**.** *A* $\mathsf{BrentSalaminPi}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, R, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ *iteration row, recording the finite Brent–Salamin recurrence windows used for the current precision request.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposing only the Real-name seals for the current approximation, correction term, and exported π read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row, storing the dyadic arithmetic cells, error radii, rounding slack, and precision ledger consumed by A, R, S, Q.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the requested AGM iterates, correction rows, and terminal approximation reads.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed stream windows and dyadic budgets.*
6. *H records componentwise* hsame *transport for the AGM row, Real seals, dyadic ledger, windows, readback, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of each accepted precision request through*

$$A \longmapsto D \longmapsto S \longmapsto Q \longmapsto R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{BrentSalaminPi}^{\uparrow}$, $\mathsf{ArithmeticGeometricMean}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BrentSalaminPi}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, R, D, S, Q, H, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, trichotomy, unrestricted analytic convergence, Lean evidence, or standard-bridge data.*

Theorem 6863.2 (Brent-Salamin pi NameCert obligations)**.** *For every accepted* $\mathsf{BrentSalaminPi}^{\uparrow}$ *carrier*

$$B = (A, R, D, S, Q, H, C, P, N),$$

the visible $\mathsf{NameCert}_{\mathsf{BrentSalaminPi}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the* $\mathsf{ArithmeticGeometricMean}^{\uparrow}$ *iteration row A, the* $\mathsf{Real}^{\uparrow}$ *seal row R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row D, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, and the structural rows H, C, P, N;*

2. *recurrence routing, requiring each public Brent–Salamin precision read to pass through the displayed AGM row A before any Real seal is consumed;*

3. *dyadic accounting, requiring D to store exactly the dyadic arithmetic cells, error radii, rounding slack, and precision ledger used by A, R, S, Q;*

4. *finite-window readback, requiring S and Q to mediate every exported approximation before the terminal Real-facing row R is visible;*

5. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*

6. *non-escape for ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, trichotomy, unrestricted analytic convergence, Lean verification, and standard-bridge data.*

No Brent–Salamin pi obligation is stored outside these rows.

Proof. Project the carrier of Definition 6863.1. The AGM row, Real seal row, dyadic budget, finite windows, and regular readback are the only computation-facing coordinates, while H, C, P, N are the only structural coordinates.

The recurrence route is forced by the displayed tuple. A public approximation request first reads A, then uses the dyadic cells and error radii in D to select the finite windows S and the regular readback Q before reaching R.

Transport, replay, provenance, and local naming are confined to H, C, P, N. Since none of the excluded completeness, quotient, limit-selection, order-decision, analytic-convergence, verification, or bridge objects appears as a carrier coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 6863.3 (Brent-Salamin pi dyadic error ledger)**.** *For every accepted* $\mathsf{BrentSalaminPi}^{\uparrow}$ *carrier*

$$B = (A, R, D, S, Q, H, C, P, N),$$

every public error claim about the exported π approximation factors through the displayed dyadic budget row D and the finite-window rows S, Q. Equivalently, a consumer can read an error assertion only along the route

$$A \longmapsto D \longmapsto S \longmapsto Q \longmapsto R \longmapsto H, C, P, N.$$

The packet therefore exports no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, quotient stream equality, selected limit, trichotomy witness, or hidden analytic convergence theorem.*

Proof. Start with the accepted carrier $B = (A, R, D, S, Q, H, C, P, N)$. The AGM row A names the finite recurrence data, but it does not by itself expose an error claim; the dyadic row D is the only coordinate carrying radii, rounding slack, and precision cells.

The public observation rows are S and Q. The finite stream windows in S select the visible recurrence and correction entries, and the regular rational readback in Q is the only handoff from those windows to the terminal Real-facing row R.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Because the carrier has no coordinate for ambient completeness, quotient stream equality, selected limits, trichotomy, or hidden analytic convergence, every public error claim factors through D, S, Q before the Real seal is read. □

Falsifiable prediction: Every accepted $\mathsf{BrentSalaminPi}^{\uparrow}$ precision read that exposes an error claim also exposes an ArithmeticGeometricMeanUp iteration row, a DyadicRatCore budget row, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: arithmetic-geometric-mean, real, dyadicratcore, streamname, regseqrat: $\mathsf{BrentSalaminPi}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Brent–Salamin AGM iteration rows, dyadic error budgets, finite windows, regular readback, Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BrentSalaminPi}^{\uparrow}}$.

Constructive story: A $\mathsf{BrentSalaminPi}^{\uparrow}$ packet is generated from one ArithmeticGeometricMeanUp iteration row, one RealUp seal row, one DyadicRatCore budget row, finite StreamName windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BrentSalaminPi}^{\uparrow}}$, seed)

Scope closed: Definition 6863.1, Definition 6863.2, and Definition 6863.3 seed the finite Brent–Salamin pi computation certificate surface for L10 Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BrentSalaminPi}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.BrentSalaminPiUp`

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, trichotomy, unrestricted analytic convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, recurrence routing, dyadic accounting, finite-window readback, Real-seal non-escape, transport/replay/provenance coverage, and local naming for BEDC.Derived.BrentSalaminPiUp.

Chapter 6864

A Concrete Naming Certificate for $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$

Following Bishop and Bridges and Troelstra on fan bars, regular sequences, and constructive real completion, the $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$ packet records the finite point where a fan-modulus depth ledger becomes a Real-completion boundary certificate. It sits after the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the fan/bar sibling route of chapter 1707. The packet names only finite windows, bar-depth bounds, dyadic tolerances, regular readbacks, Real seals, structural transport, replay, provenance, and local naming.

Definition 6864.1 (Fan-modulus Real-completion boundary carrier)**.** *A* $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, D, S, Q, R, W, H, C, P, N)$$

with the following displayed rows:

1. *F is the fan/bar modulus row, read through* $\mathsf{FanTheorem}^{\uparrow}$ *and* $\mathsf{BishopFanModulus}^{\uparrow}$*, recording the finite branch-depth bound available to the boundary.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to that same depth.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule whose entries are inspected only up to the displayed finite depth.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback obtained from those windows.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached after F, D, S, Q have been displayed.*
6. *W is the Real-completion boundary row, recording which downstream completion consumer may read the sealed finite window without selecting a limit.*
7. *H records componentwise* hsame *transport for the fan/bar, dyadic, stream, regular-readback, Real-seal, boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a consumer request through $F, D, S, Q, R, W, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BishopFanModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, D, S, Q, R, W, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, selected branches, selected limits, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6864.2 (Fan-modulus Real-completion boundary stability)**.** *Let $B = (F, D, S, Q, R, W, H, C, P, N)$ and $B' = (F', D', S', Q', R', W', H', C', P', N')$ be accepted* $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$ *carriers related by the componentwise* hsame *transport recorded in H and H'. Then every Real-completion boundary read through B is transported to the corresponding read through B' with the same finite fan/bar depth, dyadic tolerance ledger, StreamName window schedule, RegSeqRat readback, Real seal, and boundary row.*

Proof. Project the two accepted carriers. Their analytic rows are exactly F, D, S, Q, R, W and F', D', S', Q', R', W'.

The componentwise hsame rows H and H' identify the fan/bar depth, dyadic tolerances, stream windows, regular rational readbacks, Real seals, and boundary rows coordinate by coordinate. Displayed Cont replay then preserves the same route for any downstream completion consumer.

The provenance and local naming rows P, N and P', N' record the same finite dependency list. Hence transport cannot introduce selected limits, quotient streams, countable-choice schedules, open-cover compactness, or ambient Real completeness. □

Theorem 6864.3 (Fan-modulus Real-completion boundary NameCert obligations)**.** *For every accepted* $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$ *carrier $B = (F, D, S, Q, R, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, fan/bar depth admission through F, dyadic tolerance admission through D, finite StreamName window admission through S, RegSeqRat readback through Q, Real seal admission through R, Real-completion boundary admission through W, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 6864.1. The projected packet contains exactly $F, D, S, Q, R, W, H, C, P, N$.

The fan/bar row F bounds the branch-depth surface before any analytic read occurs. The dyadic, stream, and regular rational rows D, S, Q then give the finite tolerance and readback data that the Real seal may inspect.

The terminal rows R and W expose only the sealed Real boundary and the downstream completion boundary. Finally H, C, P, N transport, replay, source, and name that same finite route, so the listed obligations exhaust the local NameCert surface. □

Theorem 6864.4 (Fan-modulus Real-completion boundary L10 consumption)**.** *Every L10 Real-completion consumer of an accepted* $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$ *carrier factors through*

$$\mathsf{FanTheorem}^{\uparrow}, \mathsf{BishopFanModulus}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto W.$$

The consumer therefore receives a finite fan/bar modulus, dyadic tolerances, finite stream windows, regular rational readback, a terminal Real seal, and a displayed completion boundary row before any completion-facing read is exported.

Proof. Start from the carrier of Definition 6864.1. The consumer can inspect the boundary row W only after the preceding rows F, D, S, Q, R have been displayed.

The fan/bar row F supplies the finite modulus through the sibling route of chapter 1707. The tolerance and observation rows D, S, Q then pass through chapter 291, chapter 126, and chapter 301.

Only after those finite windows are visible may the Real seal of chapter 38 and the boundary row W be read. Since no carrier coordinate stores open-cover compactness, selected limits, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the L10 consumer receives only the displayed finite boundary. □

Falsifiable prediction: Every accepted FanModulusRealCompletionBoundaryUp L10 read displays fan/bar depth, DyadicRatCore tolerance, StreamName windows, RegSeqRat readback, a Real seal, Real-completion boundary, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: bishop-fan-modulus, dyadicratcore, streamname, regseqrat, real: FanModulusRealComple is not bijective to any listed sibling because it jointly carries fan/bar depth, dyadic tolerance, finite stream scheduling, regular rational readback, Real sealing, and a Real-completion boundary row while refusing compactness, choice, selected limits, quotient equality, host equality, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6864.1, Definition 6864.2, Definition 6864.3, and Definition 6864.4 seed the finite fan-modulus Real-completion boundary through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and fan/bar sibling rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, open-cover compactness, countable choice, quotient stream equality, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan/bar depth exactness, dyadic tolerance coverage, stream-window coverage, regular-readback coverage, Real seal admission, completion-boundary admission, transport, replay, provenance, and local naming for BEDC.Derived.FanModulusRealCompletionBoundaryUp.

Constructive story: A $\mathsf{FanModulusRealCompletionBoundary}^{\uparrow}$ packet is generated from a finite fan/bar modulus row, a DyadicRatCore tolerance row, StreamName windows, RegSeqRat readback, a Real seal, a Real-completion boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Chapter 6865

A Concrete Naming Certificate for $\mathsf{BishopIntervalChoice}^{\uparrow}$

Following Bishop and Bridges on nested interval arguments, the $\mathsf{BishopIntervalChoice}^{\uparrow}$ packet records the finite induction surface used when a closed bounded interval route is refined through lawlike dyadic windows. It sits over the interval carrier of chapter 1591, the dyadic arithmetic core of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. It differs from the finite token extraction of chapter 6054 and the compact finite-net surface of chapter 5208: the named object is the stepwise nested-window induction route, not a selected finite subcover, a chosen interval point, or an appeal to ambient compactness.

Definition 6865.1 (Bishop interval choice carrier)**.** *A* $\mathsf{BishopIntervalChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, including the lower endpoint, upper endpoint, endpoint-order, containment, stream, readback, and Real-seal data available from that packet.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *halving and containment ledger used to refine one closed bounded interval window to its next nested subwindow.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records exactly the finite name coordinates inspected at each displayed induction step.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those window coordinates.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the closed interval, dyadic, stream, and regular-rational rows have been displayed.*
6. *H records componentwise* hsame *transport for the interval source, dyadic ledger, stream windows, regular readbacks, Real seal, replay route, provenance row, and local naming row.*
7. *C records displayed* Cont *replay of each nested-window induction step through I, D, S, Q, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalChoice}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalChoice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, Q, R, H, C, P, N$. It has no coordinate for Heine–Borel compactness, trichotomy, selected points, quotient real equality, countable choice, or ambient Real completeness.

Theorem 6865.2 (Bishop interval choice NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalChoice}^{\uparrow}$ *carrier*

$$B = (I, D, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalChoice}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, dyadic nested-window refinement,* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obligation consumed by the certificate is read from $I, D, S, Q, R, H, C, P, N$.*

Proof. Project the carrier of Definition 6865.1. Its only visible rows are the closed bounded interval source, dyadic refinement ledger, stream windows, regular rational readbacks, Real seal, and the structural rows H, C, P, N.

The NameCert obligation surface is therefore row exact. Carrier admission reads I, nested-window refinement reads D, stream and regular-rational exposure read S and Q, and the terminal real-name boundary reads R only after those rows have been displayed.

The transport, replay, provenance, and local naming clauses are supplied by H, C, P, N. Since no row stores Heine–Borel compactness, trichotomy, selected points, quotient real equality, countable choice, or ambient completeness, none of those objects can become a certificate obligation. □

Theorem 6865.3 (Bishop interval choice nested-window induction)**.** *Every accepted* $\mathsf{BishopIntervalChoice}^{\uparrow}$ *carrier supports induction over its displayed nested-window route: the base step reads the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row I, and each successor step refines the current closed window using the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D before exposing the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window row S and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q. The induction state remains inside I, D, S, Q, H, C, P, N and does not select an interval point, finite subcover, quotient representative, trichotomy branch, countable-choice family, or ambient completion coordinate.*

Proof. The base step is the source projection. It reads the displayed closed bounded interval row I and no downstream seal or selected point.

For the successor step, use the dyadic ledger D. The ledger names the finite halving and containment data needed to pass from one displayed closed window to the next nested window.

The stream and readback rows then expose the successor window. The row S records the inspected finite name coordinates, and Q records the corresponding regular rational readback before any Real-facing consumer may inspect a seal.

The structural rows H, C, P, N transport, replay, source, and name the same induction route. Thus the induction is a finite nested-window recursion inside the packet, not an invocation of finite subcover selection, quotient equality, trichotomy, countable choice, or Real completeness. □

Theorem 6865.4 (Bishop interval choice Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{BishopIntervalChoice}^{\uparrow}$ *carrier factors through the closed interval source I, dyadic nested-window ledger D,* $\mathsf{StreamName}^{\uparrow}$ *window row S, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q before reading the terminal Real seal R. The seal exports only the displayed nested-window induction boundary and no Heine–Borel compactness, open-cover compactness, selected finite subcover, selected real point, trichotomy, quotient real equality, countable choice, or ambient Real completeness.*

Proof. Start with the NameCert obligations of Definition 6865.2. They force every accepted consumer read to begin from the same finite rows $I, D, S, Q, R, H, C, P, N$.

Apply nested-window induction. The consumer route reaches S and Q only by following the source interval and dyadic refinement rows step by step, so the Real seal cannot be detached from the displayed induction boundary.

The seal row R is therefore downstream of closed interval source, dyadic refinement, stream exposure, and regular-rational readback. The rows H, C, P, N preserve this boundary as transport, replay, provenance, and local naming.

Since the carrier contains no coordinate for compactness selection, selected points, trichotomy, quotient equality, countable choice, or ambient completeness, the Real and Completion consumer receives exactly the displayed nested-window seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalChoice}\uparrow}$.

Constructive story: A $\mathsf{BishopIntervalChoice}^{\uparrow}$ packet is generated from ClosedBoundedInterval, DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalChoice}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6865.1, Definition 6865.2, Definition 6865.3, and Definition 6865.4 seed the choice-free nested-window induction route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalChoice}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, Heine–Borel compactness, open-cover compactness, selected finite subcovers, selected interval points, trichotomy, quotient real equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic nested-window induction, StreamName and RegSeqRat readback exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalChoiceUp.

Chapter 6866

A Concrete Naming Certificate for $\mathsf{PathMetric}^{\uparrow}$

Following Burago–Burago–Ivanov on intrinsic metrics and Gromov on metric structures read through finite chains, the $\mathsf{PathMetric}^{\uparrow}$ packet records the path-distance surface obtained from a displayed metric carrier and finite curve-fragment rows. It sits between the metric source of chapter 57, the pointwise and modulus rows of chapter 130, the length-space consumer of chapter 2082, the segment-witness refinement of chapter 2213, and circle-source consumers such as chapter 58. The packet names path-distance data without assuming selected geodesics, quotient path spaces, host curve equality, or completion of the ambient metric carrier.

Definition 6866.1 (PathMetric carrier)**.** *A* $\mathsf{PathMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, F, L, D, B, H, C, Q, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *source row, carrying the endpoint classifier and the distance observations used by every path-fragment read.*
2. *F is a finite family of displayed curve-fragment rows, read through* $\mathsf{ContinuousMap}^{\uparrow}$ *when a fragment is presented by a finite graph or modulus ledger.*
3. *L is the fragment-length ledger, assigning each displayed fragment a finite length budget over the same metric source.*
4. *D is the path-distance row, recording the requested endpoint distance as the infimum-facing finite lower-envelope surface generated by the listed fragments.*
5. *B is the boundary handoff row for* $\mathsf{LengthSpace}^{\uparrow}$*,* $\mathsf{GeodesicMetric}^{\uparrow}$*, and* $\mathsf{S}^{1\uparrow}$ *consumers: it records which endpoint, fragment, and circle-source reads are visible before a downstream path-distance claim is used.*
6. *H records componentwise* hsame *transport for the metric source, fragment family, length ledger, path-distance row, boundary handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from endpoint reads through fragment inspection, length-budget comparison, path-distance exposure, and downstream handoff.*
8. *Q is the* Pkg *provenance over* $\mathsf{PathMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{LengthSpace}^{\uparrow}$*,* $\mathsf{GeodesicMetric}^{\uparrow}$*,* $\mathsf{S}^{1\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{PathMetric}^\uparrow}$ *row.*

The classifier compares accepted packets only through $M, F, L, D, B, H, C, Q, N$. It has no coordinate for selected geodesics, quotient path spaces, host equality of curves, unlisted path families, or ambient metric completion.

Theorem 6866.2 (PathMetric NameCert obligations)**.** *For every accepted* $\mathsf{PathMetric}^\uparrow$ *carrier $P = (M, F, L, D, B, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{PathMetric}^\uparrow}$ *surface consists exactly of carrier admission for the displayed metric source, curve-fragment family, fragment-length ledger, path-distance row, boundary handoff, componentwise transport, displayed replay, package provenance, and local naming. Every path-distance read must expose $M, F, L, D, B, H, C, Q, N$ before a downstream consumer may use it.*

Proof. Project the carrier of Definition 6866.1. The metric source M, the fragment family F, the fragment-length ledger L, the path-distance row D, and the handoff row B are all displayed before transport and naming are read.

The fragment route is finite. If a fragment is supplied by a graph or modulus row, it is read through the $\mathsf{ContinuousMap}^\uparrow$ boundary of chapter 130; its length is then recorded by L over the same metric source.

The path-distance row D is therefore not a quotient of all paths. It is the finite lower-envelope surface generated by the displayed fragment ledger and transported by H and C.

Finally Q and N source and name exactly this route. Since selected geodesics, quotient path spaces, host curve equality, unlisted path families, and ambient completion are absent from the carrier, no NameCert obligation can export them. □

Theorem 6866.3 (PathMetric length-space handoff)**.** *Every* $\mathsf{LengthSpace}^\uparrow$*,* $\mathsf{GeodesicMetric}^\uparrow$*, or* $\mathsf{S}^{1\uparrow}$ *consumer of an accepted* $\mathsf{PathMetric}^\uparrow$ *packet must read the finite route*

$$M, F, L, D \longmapsto B \longmapsto H, C, Q, N$$

before treating the path-distance row as usable data. The handoff supplies the displayed metric source, curve-fragment rows, length budgets, path-distance exposure, boundary handoff, transport, replay, provenance, and local naming; it supplies no selected geodesic, quotient path space, host curve equality, unlisted path family, or completed metric carrier.

Proof. Begin with the consumer boundary. A $\mathsf{LengthSpace}^\uparrow$ read uses the length ledger L and the path-distance row D, a $\mathsf{GeodesicMetric}^\uparrow$ read may compare a segment witness with the same rows, and an $\mathsf{S}^{1\uparrow}$ read may use only the circle-source rows exposed through the boundary handoff B.

The handoff row B is therefore the only downstream exit. It records which endpoint, fragment, length, and circle-source reads are visible before the consumer uses the path-distance claim.

Transport and replay remain componentwise through H and C, while Q and N preserve provenance and local naming. Hence the downstream surface is exactly the displayed route and cannot be replaced by selected geodesics, quotient path spaces, host curve equality, unlisted path families, or completion of the ambient metric carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{PathMetric}^\uparrow}$**.**

Constructive story: A $\mathsf{PathMetric}^\uparrow$ packet is generated from a displayed metric source, a finite family of curve-fragment rows, fragment-length ledgers, a path-distance row, a LengthSpace/GeodesicMetric/SOne boundary handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PathMetric}^\uparrow}$, seed)

Scope closed: Definition 6866.1, Definition 6866.2, and Definition 6866.3 seed the finite path-distance surface between MetricSpace, ContinuousMap, LengthSpace, GeodesicMetric, and SOne consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{PathMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected geodesics, quotient path spaces, host curve equality, unlisted path families, ambient metric completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fragment-family exactness, length-budget stability, path-distance boundary handoff, downstream consumer nonescape, transport stability, replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.PathMetricUp.

Chapter 6867

A Concrete Naming Certificate for $\mathsf{LocatedRange}^{\uparrow}$

Following Bishop and Bridges on located subsets and compact metric images, the $\mathsf{LocatedRange}^{\uparrow}$ packet records the finite data by which the range of a displayed compact-continuous map is read as located range data. It sits after the compact source of chapter 129, the graph and pointwise route of chapter 130, the tolerance handoff of chapter 369, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The carrier names compact-continuous range reads through displayed finite rows; it does not import open-cover compactness, selected image points, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6867.1 (LocatedRange carrier)**.** *A* $\mathsf{LocatedRange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (K_0, F, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. K_0 *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact domain only through displayed finite-net and coverage data.*
2. F *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, recording the finite graph and pointwise-continuity history available to range consumers.*
3. U *is the* $\mathsf{UniformModulus}^{\uparrow}$ *row that binds compact-source requests to one tolerance route before image windows are read.*
4. W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *image-window row, listing only the displayed windows inspected by downstream range queries.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same image windows and tolerance requests.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* W *and* R *have both been displayed.*
7. H *records componentwise* hsame *transport for the compact source, graph, modulus, windows, readback, seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a located-range request through* $K_0, F, U, W, R, E, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{LocatedRange}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRange}^\uparrow}$ *row.*

The classifier compares accepted packets only through $K_0, F, U, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, a choice-selected image point, quotient equality of maps, a countable-choice schedule, host real equality, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 6867.2 (LocatedRange NameCert obligations)**.** *For an accepted carrier $K = (K_0, F, U, W, R, E, H, C, P,$ the local* $\mathsf{NameCert}_{\mathsf{LocatedRange}^\uparrow}$ *surface consists exactly of five rows:*

1. *carrier admission for the finite packet K;*
2. *classifier locality for the* $\mathsf{CompactMetric}^\uparrow$ *source,* $\mathsf{ContinuousMap}^\uparrow$ *graph,* $\mathsf{UniformModulus}^\uparrow$ *tolerance route, finite* $\mathsf{StreamName}^\uparrow$ *windows,* $\mathsf{RegSeqRat}^\uparrow$ *readback, and* $\mathsf{Real}^\uparrow$ *seal;*
3. *stability through componentwise* hsame *transport H and displayed* Cont *replay C;*
4. *exactness through the ordered compact-source, continuous-graph, uniform-modulus, window, readback, and seal route K_0, F, U, W, R, E;*
5. *ledger control through* Pkg *provenance P and the local naming row N.*

No obligation may replace these rows by open-cover compactness, selected image points, quotient function equality, countable choice, host real equality, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 6867.1. The compact source, graph, modulus, window, readback, seal, transport, replay, provenance, and naming rows are exactly $K_0, F, U, W, R, E, H, C, P, N$.

Classifier locality is read through the same finite rows. The compact-source row supplies only displayed compact metric data, the graph row supplies only the continuous-map history, and the modulus row supplies only the tolerance route that is visible before windows are inspected.

Exactness then follows from the ordered route K_0, F, U, W, R, E. The image windows are admitted through W, the regular rational readback is downstream of those windows through R, and the real seal E is reached only after the readback row is displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier row stores open-cover compactness, selected image points, quotient function equality, countable choice, host real equality, or ambient completeness, the five listed rows exhaust the local NameCert surface. □

Theorem 6867.3 (LocatedRange compact-continuous handoff)**.** *Every range read from an accepted* $\mathsf{LocatedRange}^\uparrow$ *carrier factors through the finite compact-continuous route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{ContinuousMap}^\uparrow,\ \mathsf{UniformModulus}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{Real}^\uparrow.$$

In particular, a consumer may reach the range seal only after reading the compact source K_0, the continuous graph F, the uniform modulus U, the finite image windows W, the regular rational readback R, and the terminal real seal E in that order, with H, C, P, N preserving the same route.

Proof. Start with the compact source row K_0 and continuous graph row F. They expose the domain and image graph as displayed NameCert data, not as an open-cover compactness theorem or a host function object.

Read the uniform-modulus row U before any image window is consumed. This keeps every range query behind the compact-continuous tolerance route supplied by the source and graph rows.

The finite image windows W are then the only stream route available to the consumer. The readback row R attaches the same windows to the regular rational surface, and the seal row E is downstream of that readback.

The structural rows H, C, P, N preserve this order under transport, replay, provenance, and local naming. Hence no range read can fork into selected image points, quotient function equality, countable-choice schedules, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{LocatedRange}^{\uparrow}$ range read factors through compact source data, continuous graph data, a uniform-modulus row, finite StreamName image windows, RegSeqRat readback, Real seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Independence witness: compactmetric, continuousmap, uniformmodulus, streamname, regseqrat, real: no listed sibling supplies the whole ten-row packet $K = (K_0, F, U, W, R, E, H, C, P, N)$, because each sibling contributes only the compact source, graph, tolerance route, finite windows, regular readback, or terminal seal while this packet binds them into one located range certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRange}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRange}^{\uparrow}$ packet is generated from compact metric source rows, continuous graph rows, uniform-modulus tolerance rows, finite StreamName image windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRange}^{\uparrow}}$, seed)

Scope closed: Definition 6867.1, Definition 6867.2, and Definition 6867.3 seed the finite compact-continuous route from source data to located range reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRange}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected image points, quotient function equality, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact source exposure, continuous graph exposure, uniform-modulus exactness, finite window coverage, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRangeUp.

Chapter 6868

A Concrete Naming Certificate for $\mathsf{BishopCauchyTailModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyTailModulus}^{\uparrow}$ packet records the finite tail-threshold service by which a regular rational Cauchy stream answers a displayed tolerance request before any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reads the name. It sits over the dyadic tolerance ledger of chapter 291, the finite stream window of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the bidirectional Cauchy criterion route of chapter 1913. The certificate names the tail modulus as displayed finite data; it does not select a limit, quotient streams, invoke countable choice, or import ambient completeness.

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyTailModulus}^{\uparrow}$ read exposes a dyadic tolerance request, a finite tail threshold, a StreamName observation window, a RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: Nearest siblings include $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{BolzanoCauchy}^{\uparrow}$. None is bijective to $\mathsf{BishopCauchyTailModulus}^{\uparrow}$ because the dyadic packet stores tolerances, the stream packet stores finite observation names, the regular-sequence packet stores rational readback, the real packet stores a seal, and the Bolzano-Cauchy packet stores a bidirectional criterion rather than the finite tail-threshold service for one displayed request.

Definition 6868.1 (Bishop Cauchy tail modulus carrier)**.** *A* $\mathsf{BishopCauchyTailModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-request row, carrying the requested dyadic radius, comparison slack, and rational cells used by the tail test.*
2. *M is the tail-threshold row assigning the request in Q a finite index after which the displayed Cauchy tail is accepted.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, naming the observations inspected at and beyond the threshold.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window and tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after Q, M, S, R have been replayed.*

6. *H records componentwise* hsame *transport for the tolerance request, tail threshold, stream window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$Q, M, S, R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyTailModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BolzanoCauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyTailModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, S, R, E, H, C, P, N$. It has no coordinate for host Cauchy convergence, selected limits, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6868.2 (Bishop Cauchy tail modulus NameCert obligations)**.** *For every accepted* BishopCauchyTailModu *carrier*

$$T = (Q, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyTailModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tolerance request, finite tail threshold, StreamName window, RegSeqRat readback, Real seal, componentwise transport, continuation replay, provenance, and local naming rows. Every accepted consumer must read the tail-threshold row M after the tolerance row Q and before the readback route S, R, E.*

Proof. Carrier admission is projection from Definition 6868.1. The accepted packet displays exactly the tolerance request, threshold, stream window, regular readback, seal, transport, replay, provenance, and local naming rows.

The analytic route begins with Q and M. The dyadic row fixes the requested tolerance, and the threshold row is the only coordinate that answers that request with a finite tail index.

The readback route is downstream of the threshold. The window row S names the inspected observations, the regular rational row R reads those observations under the same tolerance, and the seal row E consumes that readback without adding a host limit.

Finally H, C, P, N transport, replay, source, and name only the same displayed route. Since no remaining coordinate stores quotient stream equality, selected limits, countable choice, trichotomy, or ambient completeness, the local NameCert obligations are exactly the listed rows. □

Theorem 6868.3 (Bishop Cauchy tail modulus finite tail exactness)**.** *Let*

$$T = (Q, M, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyTailModulus}^{\uparrow}$ *carrier. Every* $\mathsf{BolzanoCauchy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing read that consumes the displayed tail modulus factors through the finite route*

$$Q \longmapsto M \longmapsto S, R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives the same dyadic request, tail threshold, finite observation window, regular rational readback, Real seal, transport, replay, provenance, and local naming data, and receives no selected host limit, quotient stream equality, countable-choice schedule, trichotomy, or ambient completeness theorem.

Proof. Start from the accepted carrier and project the rows $Q, M, S, R, E, H, C, P, N$. The only row that can answer the tolerance request is the displayed threshold row M.

Read the downstream observations next. The stream window S and regular readback R are attached to the same request-threshold pair, so a consumer cannot inspect the readback before the finite tail index has been exposed.

The Real-facing seal E is reached only after that readback. Thus a $\mathsf{BolzanoCauchy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or completion-facing consumer sees a finite tail route rather than a selected limit or ambient completeness principle.

The structural rows preserve the route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row carry no extra analytic coordinate, so the listed route is exact for every accepted tail-modulus read. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyTailModulus}\uparrow}$.

Constructive story: A $\mathsf{BishopCauchyTailModulus}^{\uparrow}$ packet is generated from a dyadic tolerance request, finite tail threshold, StreamName finite window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyTailModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6868.1, Definition 6868.2, and Definition 6868.3 seed the finite tail-threshold route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyTailModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy streams, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-to-threshold routing, finite-window exactness, Real seal nonescape, and structural stability for BEDC.Derived.BishopCauchyTailModulusUp.

Chapter 6869

A Concrete Naming Certificate for $\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}$ packet records the finite diagonal uniform-modulus surface used when a family of regular Cauchy rational names is read through one displayed diagonal schedule before a Real or Completion consumer receives a seal. It sits beside the dyadic tolerance core of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the diagonal source route of chapter 372, and the selector surface of chapter 393. The packet is a Bishop-style finite modulus witness: it does not choose limits, quotient streams, countably many moduli, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6869.1 (Cauchy diagonal uniform modulus carrier)**.** *A* $\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, U, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the diagonal schedule row, read through* $\mathsf{StreamDiagonalSelector}^{\uparrow}$ *and naming the finite precision-to-window assignments consumed by the diagonal read.*
2. *U is the uniform modulus row, assigning each displayed tolerance request one finite bound that serves all selected regular Cauchy rows visible to the schedule.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget row, recording the dyadic request, slack conversion, radius ledger, and comparison cells used by U.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, displaying the regular rational readbacks inspected by the diagonal schedule.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, U, D, R and the* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *source route have been displayed.*
6. *H records componentwise* hsame *transport for the schedule, uniform modulus, dyadic budget, regular readback, Real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real or Completion tolerance request through S, U, D, R, E and the structural rows.*

8. *P records* Pkg *provenance over* $\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}$, $\mathsf{StreamDiagonalSelector}^{\uparrow}$, $\mathsf{RegularCauchyDiagon}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose consumer-visible route is $S, U, D, R, E, H, C, P, N$. It has no coordinate for a countable-choice selector, a family of hidden moduli, quotient stream equality, a selected completed limit, host real equality, or ambient Real completeness.

Theorem 6869.2 (Cauchy diagonal uniform modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}$ *packet $M = (S, U, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalUniformModul}}$ *surface consists exactly of carrier admission, diagonal schedule exposure through S, uniform modulus exposure through U, dyadic tolerance-budget visibility through D, RegSeqRat source readback through R, Real seal routing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 6869.1. The packet displays one diagonal schedule, one uniform modulus row, one dyadic tolerance ledger, the regular rational readbacks inspected by that schedule, and the terminal Real seal.

The diagonal schedule is read first. It fixes the finite StreamName windows and selector coordinates supplied by $\mathsf{StreamDiagonalSelector}^{\uparrow}$ and $\mathsf{RegularCauchyDiagonal}^{\uparrow}$. The uniform row U then answers a displayed tolerance request by a single bound over those scheduled reads rather than by choosing a separate hidden modulus for each source.

The dyadic budget D and regular readback row R make the bound auditable. They display the precision, slack, comparison, and rational readback data consumed before the Real seal E is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no countable-choice selector, quotient-stream equality, selected completed limit, host equality, or ambient completeness coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted CauchyDiagonalUniformModulusUp consumer displays the diagonal schedule, uniform modulus, DyadicRatCore tolerance budget, RegSeqRat source readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and NameCert rows before any Real-facing diagonal read is public.

Independence witness: dyadicratcore, streamname, regseqrat, real, regularcauchydiagonal, stream-diagonal-selector: no listed sibling supplies the whole nine-row packet $M = (S, U, D, R, E, H, C, P, N)$, because each sibling contributes only dyadic tolerance, finite window, regular readback, terminal seal, diagonal source, or selector data while this packet binds them under one uniform modulus row.

The future Lean file `lean4/BEDC/Derived/CauchyDiagonalUniformModulusUp.lean` should expose the carrier and NameCert-obligation surface for `BEDC.Derived.CauchyDiagonalUniformModulusUp` without adding quotient streams, selected limits, countable choice, or ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}$ packet is generated from a diagonal schedule, a uniform modulus row, a DyadicRatCore tolerance budget, RegSeqRat source readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyDiagonalUniformModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6869.1 and Definition 6869.2 seed the finite diagonal uniform-modulus route over schedule, tolerance, readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyDiagonalUniformModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, countable choice, quotient stream equality, selected completed limits, host real equality, ambient Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule exposure, uniform modulus exposure, dyadic tolerance-budget visibility, regular readback stability, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyDiagonalUniformModulusUp.

Chapter 6870

A Concrete Naming Certificate for $\mathsf{DyadicDecimalComparison}^{\uparrow}$

Following Bishop and Bridges on constructive decimal expansions and regular Cauchy real names, the $\mathsf{DyadicDecimalComparison}^{\uparrow}$ packet records the finite comparison surface by which inspected decimal prefixes are read against dyadic tolerances before any regular rational or real seal is consumed. It sits after the finite decimal-prefix carrier of chapter 1417, the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a finite L10 comparison route; it does not choose an infinite decimal stream, quotient a Cauchy sequence, decide trichotomy, select an endpoint convention, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6870.1 (Dyadic decimal comparison carrier)**.** *A* $\mathsf{DyadicDecimalComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DecimalExpansion}^{\uparrow}$ *finite-prefix row, displaying the inspected digit block, its place-value ledger, and the decimal window from which the comparison is read.*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic comparison radius, slack budget, and finite rational normalization used for the displayed prefix.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the prefix positions and tolerance requests inspected by the comparison.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same decimal prefix and dyadic tolerance data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, Q, W, R have all been displayed.*
6. *H records componentwise* hsame *transport for D, Q, W, R, E and for the replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a comparison request through the decimal prefix, dyadic tolerance, finite window, regular readback, and real seal rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicDecimalComparison}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicDecimalComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, Q, W, R, E, H, C, P, N$. It has no coordinate for an infinite decimal expansion, quotient real equality, endpoint selection, host trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6870.2 (Dyadic decimal comparison NameCert obligations)**.** *For every accepted* DyadicDecimalComparis *carrier $K = (D, Q, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicDecimalComparison}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the finite packet K;*
2. *classifier locality for the* $\mathsf{DecimalExpansion}^{\uparrow}$ *prefix row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, finite* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row;*
3. *stability under componentwise* hsame *transport H and displayed* Cont *replay C;*
4. *exactness of the ordered route D, Q, W, R, E from decimal prefix to dyadic tolerance, finite window, regular readback, and real seal;*
5. *ledger control through* Pkg *provenance P and the local naming row N.*

No obligation may replace these rows by an infinite decimal stream, quotient Cauchy equality, endpoint convention selection, host trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6870.1. The analytic rows are D, Q, W, R, E, and the structural rows are H, C, P, N.

The locality obligation reads only displayed finite data. The decimal row D exposes the inspected finite prefix, the dyadic row Q fixes the tolerance and normalization budget, the window row W records which prefix positions are inspected, and the readback and seal rows R, E are downstream of those rows.

The stability obligation is structural. Componentwise transport H preserves each displayed row, and replay C repeats the same route from a comparison request to the terminal seal.

The exactness and ledger obligations are then exhausted by D, Q, W, R, E, P, N. Since the carrier has no row for infinite streams, quotient equality, endpoint selection, trichotomy, countable choice, or ambient completeness, the five listed rows are the whole local NameCert surface. □

Theorem 6870.3 (Dyadic decimal comparison readback boundary)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicDecimalComparison}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, a consumer cannot reach the regular rational readback R or terminal seal E without first reading the decimal prefix row D, dyadic tolerance row Q, finite window row W, and structural rows H, C, P, N that preserve the same route.

Proof. Begin with an accepted packet $K = (D, Q, W, R, E, H, C, P, N)$. The carrier definition orders the decimal prefix, dyadic tolerance, and finite window rows before the regular readback and real seal.

Apply Definition 6870.2. The exactness row requires the route D, Q, W, R, E, while the stability and ledger rows require H, C, P, N to preserve and name that route.

Thus every readback or real-seal consumer sees the displayed finite comparison route before it sees R or E. The packet exports no separate route through an infinite decimal stream, quotient real representative, endpoint selector, host trichotomy, countable-choice schedule, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{DyadicDecimalComparison}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without reading the displayed decimal prefix, dyadic tolerance, finite StreamName window, componentwise transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: decimalexpansion, dyadicratcore, streamname, regseqrat, real: no listed sibling supplies the whole packet $K = (D, Q, W, R, E, H, C, P, N)$, because each sibling contributes only decimal prefixes, dyadic tolerance, finite windows, regular readback, or terminal seal while this packet binds them into one comparison certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicDecimalComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicDecimalComparison}^{\uparrow}$ packet is generated from a DecimalExpansion finite-prefix row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicDecimalComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6870.1, Definition 6870.2, and Definition 6870.3 seed the finite comparison route from decimal prefixes to dyadic tolerance and regular rational readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicDecimalComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite decimal stream selection, quotient real equality, endpoint convention selection, host trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, decimal-prefix exposure, dyadic tolerance exactness, finite window coverage, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicDecimalComparisonUp.

Chapter 6871

A Concrete Naming Certificate for $\mathsf{PringsheimDoubleSequence}^{\uparrow}$

Following Pringsheim and Hardy on double sequences and double series, the $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ packet records rectangular-window convergence as finite NameCert data rather than as an ambient selected double limit. It sits after the finite stream rows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the real seal of chapter 38, the Cauchy sequence-space route of chapter 406, and the diagonal cofinal-tail route of chapter 632. The carrier is the traditional Pringsheim rectangular-window object reconstructed over the Phase Real and completion route; it does not assert quotient streams, selected double limits, host real equality, countable choice, a general iterated-limit interchange theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6871.1 (Pringsheim double-sequence carrier)**.** *A* $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, J, W, T, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I and J are unary index schedules for the two Pringsheim directions.*
2. *W is the rectangular finite* $\mathsf{StreamName}^{\uparrow}$ *window row, displaying exactly the pairs inspected below a requested rectangle.*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the displayed side bounds, dyadic slack, and rectangle-tail budget.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rectangular observations and tolerance requests.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after the schedules, window, tolerance, and regular readback rows have been displayed.*
6. *H is componentwise* hsame *transport for the schedules, windows, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. *C is displayed* Cont *replay from index requests to rectangular windows, from windows to dyadic tolerances, and from tolerances to regular readbacks and the real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{PringsheimDoubleSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{DiagonalCofinalTail}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PringsheimDoubleSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, J, W, T, Q, E, H, C, P, N$. It contains no coordinate for quotient streams, selected double limits, host real equality, countable choice, general iterated-limit interchange, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PringsheimDoubleSequenceUp.PringsheimDoubleSequenceTasteGate single carrier alignment`

Theorem 6871.2 (Pringsheim double-sequence NameCert obligations)**.** *For every accepted* $\mathsf{PringsheimDoubleSeque}$ *carrier $D = (I, J, W, T, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PringsheimDoubleSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the two unary schedules, rectangular window, dyadic tolerance, regular readback, real seal, transport, replay, provenance, and local naming rows; rectangular-window exactness through I, J, W; tolerance exactness through T; regular readback through Q; real-seal nonescape through E; and structural preservation through H, C, P, N.*

Proof. Project the carrier in Definition 6871.1. The tuple lists all rows available to a certificate consumer, so carrier admission is componentwise over the displayed schedules, rectangular windows, tolerances, readbacks, seal, and structural rows.

The dependency order is exhausted from left to right. A request first exposes I and J, then the finite rectangle W, then the dyadic budget T, and only then the regular rational readback Q and real seal E.

The structural rows preserve that route. Componentwise transport, continuation replay, provenance, and local naming cannot introduce quotient streams, selected double limits, host real equality, choice, iterated-limit interchange, or ambient completeness because no such row is present in D. □

Theorem 6871.3 (Pringsheim double-sequence rectangular-window exactness)**.** *Every accepted rectangular-window read from $D = (I, J, W, T, Q, E, H, C, P, N)$ factors through the two unary schedules I, J and the finite* $\mathsf{StreamName}^{\uparrow}$ *rectangle W before it can consume a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, or a* $\mathsf{Real}^{\uparrow}$ *seal. The read exports the displayed rectangle route and not a quotient stream, selected double limit, host real equality, countable-choice selector, or general iterated-limit interchange theorem.*

Proof. Start with a rectangular-window read. The only index data available are the unary schedules I and J, so the read cannot inspect a pair before both one-dimensional schedules have been displayed.

The window row W then fixes the finite rectangle. The tolerance row T may be read only for that displayed rectangle, and Q repacks the same observations as regular rational data.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no quotient, selector, host-equality, choice, interchange, or completeness coordinate, the rectangular-window route is exact at the finite packet boundary. □

Theorem 6871.4 (Pringsheim double-sequence Real-seal handoff)**.** *For every accepted* $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ *packet $D = (I, J, W, T, Q, E, H, C, P, N)$, any completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer may cite only the finite route*

$$I, J, W \longmapsto T \longmapsto Q \longmapsto E, H, C, P, N.$$

The handoff records a rectangular-window Pringsheim seal for the Phase Real and completion route; it does not supply ambient Real completeness, selected double limits, quotient stream equality, host real equality, countable choice, or a general iterated-limit interchange theorem.

Proof. Apply Definition 6871.2. It identifies the seal as downstream of the schedules, rectangular window, tolerance row, and regular readback.

Apply Definition 6871.3. The completion-facing route remains tied to the same finite rectangle and dyadic budget before the regular handoff and seal are read.

Thus every Real-facing consumer receives the displayed finite route through E, H, C, P, N. The refused analytic and quotient objects have no carrier coordinate and cannot be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ completion-facing read exposes two unary index schedules and a rectangular finite StreamName window before any DyadicRatCore tolerance row, RegSeqRat readback, or RealUp seal is consumed.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchysequencespace, diagonalcofinaltail: $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two unary schedules, rectangular windows, dyadic tolerance rows, regular readbacks, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PringsheimDoubleSequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PringsheimDoubleSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6871.1, Definition 6871.2, Definition 6871.3, and Definition 6871.4 seed the finite rectangular-window double-sequence route over schedules, StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PringsheimDoubleSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected double limits, host real equality, countable choice, general iterated-limit interchange, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rectangular-window exactness, dyadic tolerance handoff, RegSeqRat readback, Real seal nonescape, and structural transport for BEDC.Derived.PringsheimDoubleSequenceUp.

Constructive story: A $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ packet is generated from two unary index schedules, rectangular StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6872

A Concrete Naming Certificate for GroundCompilerAuditMapClosure$^{\uparrow}$

The GroundCompilerAuditMapClosure$^{\uparrow}$ packet realizes the compiler audit-map methodology of chapter 9407 as finite NameCert data. It packages event-flow rows, source-channel rows, recognizer rows, certificate-gate rows, metric-report rows, non-evidence rows, transport, replay, provenance, and local naming so that a self-compilation consumer can inspect the compiler channel boundary without reading reports, motifs, host packages, or generated code as proof evidence. The downstream consumer is the MetaCIC critical-path packet of chapter 765, which reads those event-flow, source-channel, recognizer, certificate-gate, metric-report, and non-evidence rows before using compiler-channel audit data inside a finite critical-path route.

Definition 6872.1 (GroundCompiler audit-map closure carrier)**.** *A* GroundCompilerAuditMapClosure$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, S, R, K, M, O, H, C, P, N)$$

with the following displayed rows:

1. *F is the compiler event-flow row.*
2. *S is the legal source-channel row, including the channel by which a displayed event flow may be read.*
3. *R is the generated recognizer row for packages, NameCert data, derivation certificates, theorem codes, and chapter codes.*
4. *K is the certificate-gate row, exposed only after the legal source channel and recognizer rows are displayed.*
5. *M is the metric-report row, recording counts and adequacy reports as reports rather than certificate evidence.*
6. *O is the non-evidence row, retaining the boundary around motifs, reports, host packages, readable code, and hidden compiler input.*
7. *H records componentwise* hsame *transport for event-flow, source-channel, recognizer, gate, metric, non-evidence, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from event flow to source channel, from source channel to recognizer and certificate-gate checks, and from those rows to metric and non-evidence reports.*

9. *P is the* Pkg *provenance over* $\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, R, K, M, O, H, C, P, N$. It has no coordinate for treating motif similarity, metric counts, generated source text, host packages, or hidden compiler state as proof or certificate evidence.

Theorem 6872.2 (GroundCompiler audit-map closure obligations)**.** *For every accepted* GroundCompilerAuditMapC *packet $G = (F, S, R, K, M, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}}$ *surface consists exactly of event-flow exposure through F, legal source-channel exposure through S, generated recognizer exposure through R, certificate-gate exposure through K, metric-report exposure through M, non-evidence retention through O, and structural preservation through H, C, P, N.*

Proof. Project the carrier in Definition 6872.1. The compiler-facing rows are precisely F, S, R, K, M, O, and the structural rows are H, C, P, N.

Read the rows in audit order. Event flow is displayed first, the legal source channel is displayed before recognizer and certificate-gate export, and metric reports remain downstream reports rather than evidence rows.

The non-evidence row is retained through transport, replay, provenance, and naming. Since the carrier has no coordinate for report-as-proof, code-as-proof, motif-as-identity, host package input, or hidden compiler state, those readings are refused by exhaustion. □

Theorem 6872.3 (GroundCompiler audit-map legal-channel gate)**.** *Every accepted* GroundCompilerAuditMapClosu *export exposes the legal source-channel row S before the certificate-gate row K can be consumed. Recognizers, metric reports, and non-evidence ledgers may be cited only along the displayed route*

$$F, S \longmapsto R, K \longmapsto M, O, H, C, P, N.$$

The export does not promote readable code, motif reports, metric counts, hidden compiler input, or host package structure into proof or certificate evidence.

Proof. Apply Definition 6872.2. It makes S a first-class row of the accepted packet and places certificate-gate exposure among the rows that must remain visible to a consumer.

The replay row C preserves the channel order. A consumer moves from event flow through the legal channel before recognizer and certificate-gate rows are available, and metric or non-evidence reports are read only after that gate.

Thus the legal-channel gate is finite and local to the packet. The refused compiler artifacts have no carrier coordinate from which they could be retyped as evidence. □

Theorem 6872.4 (GroundCompiler audit-map metric non-evidence boundary)**.** *In every accepted* $\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}$ *carrier, metric reports and motif counts remain in M and the explicit non-evidence boundary remains in O through H, C, P, N. A self-compilation consumer may use these rows to audit coverage and reporting, but not as proof evidence, certificate evidence, theorem-code equality, chapter-code equality, or hidden input authorization.*

Proof. Project M and O from the carrier. The metric row records reports, and the non-evidence row records the boundaries around motifs, readable code, host packages, and hidden compiler state.

Apply the legal-channel gate theorem. Since M and O are downstream of the displayed event-flow, source-channel, recognizer, and certificate-gate rows, they cannot replace those rows.

The structural rows transport and replay the same boundary. Therefore report and motif data remain audit metadata rather than proof or certificate evidence. □

Falsifiable prediction: Every accepted $\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}$ packet exposes the legal source-channel row before certificate-gate export.

Independence witness: metacic-confluence-audit-packet, metaciccriticalpath, conceptregistry-surface, failurecertificate: $\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compiler event-flow, source-channel, recognizer, certificate-gate, metric-report, non-evidence, transport, replay, provenance, and local naming rows.

The Lean TasteGate route for this packet must provide Nontrivial and FieldFaithful instances by separating accepted compiler-channel audit packets from refused report-as-proof and hidden-input packets.

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6872.1, Definition 6872.2, Definition 6872.3, and Definition 6872.4 seed the finite compiler-channel audit-map closure over event-flow, source-channel, recognizer, certificate-gate, metric-report, non-evidence, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close proof evidence from reports, certificate evidence from motifs, theorem equality from code, chapter equality from topics, hidden compiler input authorization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, legal source-channel exposure, recognizer generatedness, certificate-gate ordering, metric-report non-evidence, non-evidence retention, TasteGate nontriviality, FieldFaithful coverage, and structural transport for BEDC.Derived.GroundCompilerAuditMapClosureUp.

Constructive story: A $\mathsf{GroundCompilerAuditMapClosure}^{\uparrow}$ packet is generated from compiler event-flow rows, legal source-channel rows, recognizer rows, certificate-gate rows, metric-report rows, non-evidence rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6873

A Concrete Naming Certificate for $\mathsf{CauchyFilterDiagonal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyFilterDiagonal}^{\uparrow}$ packet records the finite diagonal read by which a displayed Cauchy-filter completion route is handed to regular rational names and then to the terminal Real seal. It sits over the Cauchy-filter source of chapter 333, the completion-facing row of chapter 1569, the metric-completion boundary of chapter 1506, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the completed real-name seal of chapter 38. The chapter names a finite diagonal route only; it does not quotient filters, choose representatives, select completed limits, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6873.1 (Cauchy-filter diagonal carrier)**.** *A* $\mathsf{CauchyFilterDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, K, M, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row whose base requests and finite Cauchy evidence are available before any completion consumer reads the packet.*
2. *K is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *handoff row, recording the completion-facing use of the displayed filter source.*
3. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *boundary row, visible only after F and K have exposed the diagonal request.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that supplies the diagonal observation schedule.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to the stream windows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational readback.*
7. *H records componentwise* hsame *transport for $F, K, M, S, Q, R, C, P, N$.*
8. *C records displayed* Cont *replay from a finite Cauchy-filter request through the completion handoff, the metric-completion boundary, the diagonal stream window, the regular rational readback, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterDiagonal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, K, M, S, Q, R, H, C, P, N$. The carrier has no coordinate for quotient filters, selected representatives, chosen limits, countable-choice schedules, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6873.2 (Cauchy-filter diagonal NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterDiagonal}^{\uparrow}$ *carrier $D = (F, K, M, S, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterDiagonal}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed Cauchy-filter source, Cauchy-filter completion handoff, metric-completion boundary, stream-window schedule, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *diagonal source routing, requiring every completion-facing request to read the same F row before the rows K and M are available;*
3. *finite-window diagonalization, requiring the stream row S to supply the observed diagonal windows before any regular rational row Q or Real seal row R is consumed;*
4. *classifier stability, requiring componentwise* hsame *transport H and displayed* Cont *replay C to preserve the route F, K, M, S, Q, R;*
5. *ledger non-escape, requiring P and N to export no quotient filter, selected representative, chosen limit, countable-choice schedule, quotient stream equality, host real equality, or ambient Real completeness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6873.1. The accepted packet exposes exactly the rows $F, K, M, S, Q, R, H, C, P, N$, so every local obligation must be read from those rows.

The diagonal source route is forced by the carrier order. A completion-facing request cannot reach K or M without first reading the displayed Cauchy-filter source F.

The finite-window part then uses the diagonal observation schedule. The stream row S supplies the inspected windows, Q reads them as regular rational data, and R seals only the resulting Real-facing name.

Transport and replay are structural. Componentwise hsame in H preserves each displayed coordinate, while Cont replay in C repeats the same route F, K, M, S, Q, R for each accepted request.

Finally, the provenance rows are exhausted by P and N. Since quotient filters, selected representatives, chosen limits, countable choice, quotient stream equality, host real equality, and ambient Real completeness are not carrier rows, the local NameCert surface cannot export them. □

Theorem 6873.3 (Cauchy-filter diagonal Real-completion handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{CauchyFilterDiagonal}^{\uparrow}$ *carrier reads the completion route only through the displayed rows*

$$\mathsf{CauchyFilter}^{\uparrow}, \mathsf{CauchyFilterCompletion}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pk}$$

Consequently the handoff exports no quotient-filter equality, selected representative, selected limit, countable choice, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Real-facing completion consumer. Carrier admission gives access only to the rows $F, K, M, S, Q, R, H, C, P, N$ of Definition 6873.1.

The completion side is read first through F, K, M. The filter source F exposes finite Cauchy evidence, K records the Cauchy-filter completion handoff, and M records the metric-completion boundary available to the consumer.

The Real-facing side is then read through S, Q, R. The stream windows supply the diagonal observations, the regular rational row reads those windows, and the Real row seals the resulting name.

The rows H, C, P, N add transport, replay, provenance, and local naming only. They do not add a quotient, selector, choice, stream-equality, host-equality, or ambient-completeness coordinate, so the handoff remains inside the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterDiagonal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6873.1, Definition 6873.2, and Definition 6873.3 seed the finite diagonal route from Cauchy-filter completion data to regular rational readback and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected representatives, selected limits, countable choice, quotient stream equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, diagonal source routing, finite-window diagonalization, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterDiagonalUp.

Constructive story: A $\mathsf{CauchyFilterDiagonal}^{\uparrow}$ packet is generated from one CauchyFilter row, one CauchyFilterCompletion handoff row, one MetricCompletion boundary row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6874

A Concrete Naming Certificate for $\mathsf{RealSeparationViaUniformity}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces, the $\mathsf{RealSeparationViaUniformity}^{\uparrow}$ packet records the finite route by which Real-induced uniform entourage data separates a Cauchy-filter read before a regular rational or Real seal is consumed. It concretizes the compact-uniform-continuity context of chapter 9237 through the Real uniform-structure packet of chapter 1624, the Cauchy-filter source of chapter 333, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The chapter names a separated finite route only; it does not assert Hausdorff completion, quotient filters, selected limits, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6874.1 (Real separation via uniformity carrier)**.** *A* $\mathsf{RealSeparationViaUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (U, F, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *row whose Real-induced entourages supply the separation test.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row whose finite filter requests are read only through the displayed entourage surface.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected after the separated filter request is displayed.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback reached from those windows.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint and seal row consumed after the regular rational readback.*
6. *H records componentwise* hsame *transport for U, F, S, Q, R, C, P, N.*
7. *C records displayed* Cont *replay from a Real uniform entourage request through Cauchy-filter separation, finite stream windows, regular rational readback, and the Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSeparationViaUniformity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, S, Q, R, H, C, P, N$. The carrier has no coordinate for quotient filters, separated quotient completion, selected limits, trichotomy, open-cover compactness, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*
