Theorem 6874.2 (Real separation via uniformity NameCert obligations)**.** *For every accepted* $\mathsf{RealSeparationViaUniformity}^{\uparrow}$ *carrier* $E = (U, F, S, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealSeparationViaUniformity}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed Real-uniform entourage row, Cauchy-filter row, stream-window row, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *uniform separation, requiring every separated filter request to read the* $\mathsf{RealUniformStructure}^{\uparrow}$ *row* U *before the* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *is available;*
3. *finite Real readback, requiring* S *and* Q *to mediate every Real-facing read before* R *is consumed;*
4. *classifier stability, requiring componentwise* hsame *transport* H *and displayed* Cont *replay* C *to preserve the route* U, F, S, Q, R*;*
5. *ledger non-escape, requiring* P *and* N *to export no quotient filter, separated quotient completion, selected limit, trichotomy, open-cover compactness, countable choice, host real equality, or ambient Real completeness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6874.1. The accepted object exposes only $U, F, S, Q, R, H, C, P, N$.

Uniform separation follows from the displayed source order. The filter row F is available only after the Real-induced entourage row U has been read, so a consumer cannot separate Cauchy-filter evidence by an external quotient or host equality.

Finite Real readback is mediated by the stream and regular rational rows. The window row S is inspected first, Q reads the regular rational data, and R seals only the resulting Real-facing name.

Transport and replay preserve this same route. The row H supplies componentwise hsame stability, and C repeats the route U, F, S, Q, R under displayed continuation.

Finally, provenance is exhausted by P and N. Since the excluded quotient, selection, trichotomy, compactness, choice, host-equality, and ambient-completeness data are not rows of the carrier, the local NameCert surface cannot export them. □

Theorem 6874.3 (Real separation Cauchy-filter handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RealSeparationViaUniformity}^{\uparrow}$ *carrier reads separated Cauchy-filter evidence only through the displayed rows*

$$\mathsf{RealUniformStructure}^{\uparrow}, \mathsf{CauchyFilter}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

Consequently the handoff exports no quotient filters, separated quotient completion, selected limits, trichotomy, open-cover compactness, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a completion-facing consumer. By Definition 6874.1, the consumer can see the packet only through $U, F, S, Q, R, H, C, P, N$.

The separation route starts at U. The Real uniform structure supplies the displayed entourage surface, and the Cauchy-filter row F is read downstream of that surface.

The Real-facing handoff then passes through S, Q, R. Stream windows determine the finite observations, regular rational readback records them, and the Real row seals the result.

The structural rows H, C, P, N transport, replay, source, and name the same route. None of them adds a quotient filter, separated quotient completion, selected limit, trichotomy, compactness, choice, host equality, or ambient Real-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSeparationViaUniformity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSeparationViaUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6874.1, Definition 6874.2, and Definition 6874.3 seed the finite route from Real-induced uniform separation to Cauchy-filter readback and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSeparationViaUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, separated quotient completion, selected limits, trichotomy, open-cover compactness, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, uniform separation, finite Real readback, transport, replay, provenance, and local naming for BEDC.Derived.RealSeparationViaUniformityUp.

Constructive story: A $\mathsf{RealSeparationViaUniformity}^{\uparrow}$ packet is generated from one RealUniformStructure row, one CauchyFilter row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6875

A Concrete Naming Certificate for RegularCauchyFilterComparison$^{\uparrow}$

Following Bishop and Bridges and Bourbaki, the RegularCauchyFilterComparison$^{\uparrow}$ packet records the finite comparison surface between filter-style Cauchy data and regular-sequence completion data. It sits between the Cauchy-filter source of chapter 333, the Bishop regular Cauchy completion route of chapter 1639, the dyadic endpoint ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet compares displayed finite rows only; it does not quotient filters, select a limit, use countable choice, assert host equality of Real names, or invoke ambient Real$^{\uparrow}$ completeness.

Definition 6875.1 (Regular Cauchy filter comparison carrier)**.** *A* RegularCauchyFilterComparison$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, B, T, S, D, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* CauchyFilter$^{\uparrow}$ *base row, naming the finite basis requests and displayed refinements offered to the completion consumer.*
2. *B is the cofinal-base row, recording which displayed filter base refines the regular common-tail window.*
3. *T is the* RegSeqRat$^{\uparrow}$ *tail-window row exposed by the refined base.*
4. *S is the* StreamName$^{\uparrow}$ *finite-observation row read on that tail window.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row shared by the filter request and the regular-sequence readback.*
6. *R is the terminal* Real$^{\uparrow}$ *seal handoff, available only after F, B, T, S, D have been displayed.*
7. *H records componentwise* hsame *transport for the filter, refinement, tail-window, observation, tolerance, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a filter-base tolerance request through the refined regular tail route and into the terminal Real seal.*
9. *P is the* Pkg *provenance over* RegularCauchyFilterComparison$^{\uparrow}$, CauchyFilter$^{\uparrow}$, BishopRegularCauchyCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterComparison}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, B, T, S, D, R, H, C, P, N$. No coordinate stores quotient-filter equality, selected limits, countable-choice schedules, host equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyFilterComparisonUp.RegularCauchyFilterComparisonUp`
Lean4 (definition) `BEDC.Derived.RegularCauchyFilterComparisonUp.RegularCauchyFilterComparisonCarrier`
Lean4 ✓ `BEDC.Derived.RegularCauchyFilterComparisonUp.RegularCauchyFilterComparisonTasteGate`
`single carrier alignment`

Theorem 6875.2 (Regular Cauchy filter sequential handoff)**.** *Every accepted* $\mathsf{RegularCauchyFilterComparison}^{\uparrow}$ *packet that receives a* $\mathsf{CauchyFilter}^{\uparrow}$ *basis whose displayed base refines the packet's common-tail window hands the completion read to a* $\mathsf{RegSeqRat}^{\uparrow}$ *tail window with the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite observations,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The terminal* $\mathsf{Real}^{\uparrow}$ *seal is read only after that regular tail route has been displayed.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterComparisonUp.RegularCauchyFilterComparisonSequentialHandoff`

Proof. Project the carrier of Definition 6875.1. The incoming filter row is F, and the cofinal-base row B is the only place where a filter refinement may be read.

Use B to expose the finite regular tail window T. The stream observations S and dyadic tolerance ledger D are then read on the same displayed window, so the comparison has a sequence-facing route before any Real seal is consumed.

The structural rows preserve that route. Componentwise hsame transport in H and displayed Cont replay in C carry the same finite rows through provenance P and local naming N.

Finally read the terminal $\mathsf{Real}^{\uparrow}$ seal R. Since the carrier has no quotient-filter, selected-limit, choice, host-equality, or Real-completeness coordinate, the handoff is exactly the displayed finite sequential route. □

Theorem 6875.3 (Regular Cauchy filter comparison NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilterComparison}^{\uparrow}$ *carrier $K = (F, B, T, S, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterCompari}}$ *surface consists exactly of:*

1. *carrier admission for the CauchyFilter base, cofinal-base refinement, RegSeqRat tail window, StreamName observations, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *sequential handoff, requiring the refined filter base to expose T, S, D before R is available;*
3. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve the route F, B, T, S, D, R;*
4. *ledger non-escape, requiring P and N to export no quotient filters, selected limits, countable choice, host Real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is the projection of the tuple $K = (F, B, T, S, D, R, H, C, P, N)$. The listed rows exhaust the fields visible to a completion-facing consumer.

Sequential handoff is supplied by Definition 6875.2. The filter request is first refined by B, then read as the regular tail window T with observations S and tolerance ledger D before the terminal Real seal R is exposed.

Classifier stability is rowwise. The hsame row transports displayed coordinates, and the Cont row replays the same finite route without changing the classifier surface.

The ledger boundary follows from absence. Since no excluded object is a coordinate of the carrier, provenance and local naming cannot export quotient filters, selected limits, countable choice, host Real equality, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6875.1, Definition 6875.2, and Definition 6875.3 seed the finite comparison surface between CauchyFilter bases and RegSeqRat tail windows over DyadicRatCore, StreamName, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host Real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, sequential handoff, classifier stability, provenance, and local naming for BEDC.Derived.RegularCauchyFilterComparisonUp.

Constructive story: A comparison packet is generated from one CauchyFilter base row, one cofinal-base refinement row, one RegSeqRat tail window, StreamName observations, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6876

A Concrete Naming Certificate for $\mathsf{FiniteBetaClosednessIteration}^{\uparrow}$

Following Barendregt and Coquand on typed lambda calculi and structural closure arguments, the $\mathsf{FiniteBetaClosednessIteration}^{\uparrow}$ packet records the finite NameCert route behind the MetaCIC theorem `betaStarStep_preserves_closed`. It concretizes the closedness-preservation audit map of chapter 9381 beside the witness packet of chapter 3344 and the subject-reduction obstruction of chapter 731. The packet is a closedness-only object: it does not assert subject reduction, confluence, normalization, conversion preservation, or a typing transport theorem.

Definition 6876.1 (Finite beta closedness iteration carrier)**.** *A* $\mathsf{FiniteBetaClosednessIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (Z, B, O, S, L, H, C, P, N)$$

with the following displayed rows:

1. *Z is the zero-step row, recording that a term already closed at the displayed boundary remains closed without taking a beta step.*
2. *B is the one-step beta closedness row, read from the* `betaStep_preserves_closed` *route.*
3. *O is the finite order row listing the displayed beta steps of the accepted* `BetaStarStep` *chain.*
4. *S is the successor-step row, recording that B may be replayed at the head of the finite chain before the remaining tail is inspected.*
5. *L is the terminal* `ClosedAt` *ledger for the endpoint term.*
6. *H records componentwise* hsame *transport for the chain, closedness boundary, endpoint ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite induction from Z through repeated uses of B and S to L.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteBetaClosednessIteration}^{\uparrow}$, `BetaStep`, `BetaStarStep`, `ClosedAt`, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteBetaClosednessIteration}^{\uparrow}}$ *row.*

The carrier has no coordinate for a typing derivation, dependent-codomain transport, subject-reduction discharge, confluence diagram, normalization proof, or conversion rule.

Theorem 6876.2 (Finite beta closedness route)**.** *Every accepted* $\mathsf{FiniteBetaClosednessIteration}^{\uparrow}$ *packet routes a finite* `BetaStarStep` *chain through the zero-step row, repeated one-step beta closedness rows, the displayed finite order of the chain, and the terminal* `ClosedAt` *ledger. Thus a closed source term remains inside the displayed closedness classifier along the finite beta chain, without adding a subject-reduction, confluence, normalization, or conversion claim.*

Proof. Project the carrier of Definition 6876.1. A zero-length beta chain reads Z and immediately reaches the terminal closedness ledger L.

For a nonzero finite chain, read the displayed head step from O and apply the one-step row B. The successor row S records that the remaining finite tail is another accepted closedness-iteration request.

Iterate this finite route until the endpoint ledger L is reached. The replay row C records the induction as displayed continuation data, and H transports only the closedness and chain rows.

The route never reads a typing derivation or codomain transport. The subject-reduction obstruction remains outside the carrier, so the theorem is a closedness-preservation statement only. □

Theorem 6876.3 (Finite beta closedness iteration NameCert obligations)**.** *For every accepted* $\mathsf{FiniteBetaClosednessIteration}^{\uparrow}$ *carrier* $I = (Z, B, O, S, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteBetaClosednessIteration}^{\uparrow}}$ *surface consists exactly of carrier admission, zero-step closedness, one-step beta closedness, finite-chain ordering, successor replay, endpoint* `ClosedAt` *ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored for subject reduction, dependent-codomain transport, confluence, normalization, conversion preservation, or typing stability.*

Proof. Carrier admission is tuple projection. The only visible rows are $Z, B, O, S, L, H, C, P, N$, so the NameCert surface starts and ends with those displayed fields.

The zero-step and successor cases are the two finite-chain constructors. The zero case reads Z; the successor case reads B for the head beta step, then uses S and C to replay the same closedness route over the remaining finite tail.

The endpoint ledger L records the final `ClosedAt` claim. Transport by H is componentwise and cannot change the classifier from closedness to typing.

Finally, provenance and local naming do not enlarge the carrier. Since no subject-reduction, codomain-transport, confluence, normalization, conversion, or typing-stability coordinate exists, none can be exported as a local NameCert obligation. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteBetaClosednessIteration}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteBetaClosednessIteration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6876.1, Definition 6876.2, and Definition 6876.3 seed the finite ClosedAt-preservation route for BetaStarStep chains.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteBetaClosednessIteration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, dependent-codomain transport, confluence, normalization, conversion preservation, typing stability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked zero-step, one-step beta, finite-chain, successor replay, endpoint ClosedAt, transport, provenance, and local naming rows for BEDC.Derived.FiniteBetaClosednessIterationUp.

Constructive story: A finite beta closedness packet is generated from zero-step closedness, one-step beta closedness, a finite BetaStarStep order row, successor replay, a terminal ClosedAt ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6877

A Concrete Naming Certificate for $\mathsf{Wronskian}^{\uparrow}$

Following Sturm–Liouville theory and Bishop–Bridges constructive analysis, the $\mathsf{Wronskian}^{\uparrow}$ packet records the finite determinant-and-derivative surface used to inspect linear dependence before an ODE or real-analysis consumer may read a terminal real seal. It sits after the derivative rows of chapter 122, the continuous-map family surface of chapter 130, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance arithmetic of chapter 291, and the terminal real-name seal of chapter 38. The packet names a constructive Wronskian certificate as displayed BEDC rows; it does not import host function equality, classical limits, selected differentiability witnesses, quotient real names, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Falsifiable prediction: A consumer that reads a Wronskian determinant or linear-dependence verdict without the derivative, continuous-map, StreamName, RegSeqRat, DyadicRatCore, and Real-seal rows has left the $\mathsf{Wronskian}^{\uparrow}$ packet.

Independence witness: derivative, continuousmap, streamname, regseqrat, dyadicratcore, real: $\mathsf{Wronskian}^{\uparrow}$ is not bijective to any one sibling because it jointly carries derivative jets, determinant rows, rational readback, terminal real sealing, transport, replay, provenance, and local naming.

Definition 6877.1 (Wronskian carrier)**.** *A* $\mathsf{Wronskian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (F, D, J, \Omega, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{ContinuousMap}^{\uparrow}$ *finite family row for the inspected functions;*
2. *D is the* $\mathsf{Derivative}^{\uparrow}$ *derivative-admission row for the displayed derivative depths;*
3. *J is the finite jet table whose entries are read only through the same derivative and continuous-map rows;*
4. *Ω is the alternating determinant ledger over the displayed jet table;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-request section selecting the inspected windows;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the determinant values on those windows;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed Wronskian value rows;*

8. *H records componentwise* hsame *transport of the family, derivative, jet, determinant, window, readback, and seal rows;*
9. *C records displayed* Cont *replay from function-family requests through derivative jets, determinant assembly, StreamName windows, RegSeqRat readback, and the Real seal;*
10. *P is the* Pkg *provenance over* $\mathsf{Wronskian}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{Wronskian}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host function equality, a classical limit, a selected differentiability witness, quotient real equality, countable choice, or ambient real completeness.

Theorem 6877.2 (Wronskian NameCert obligations)**.** *For every accepted* $\mathsf{Wronskian}^{\uparrow}$ *carrier*

$$W = (F, D, J, \Omega, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Wronskian}^{\uparrow}}$ *surface consists exactly of continuous-family admission through F, derivative-row admission through D, finite jet exposure through J, determinant-ledger exposure through Ω, finite-window exposure through S, regular rational readback through R, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianNameCertObligations`

Proof. Project the carrier of Definition 6877.1. The family row, derivative row, jet table, determinant ledger, window row, readback row, and Real seal row are visible before the structural rows are read.

Read the analytic route in order. The row F supplies the continuous-map family surface, D supplies derivative admission, J records only the displayed finite derivative jets, and Ω assembles those jets into the Wronskian determinant ledger.

The value-facing route then passes through S, R, E. The $\mathsf{StreamName}^{\uparrow}$ row fixes the inspected finite requests, $\mathsf{RegSeqRat}^{\uparrow}$ reads the determinant values as regular rational data, and $\mathsf{Real}^{\uparrow}$ seals only that displayed readback.

The rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for the excluded host principles, the listed rows exhaust the local NameCert surface. □

Theorem 6877.3 (Wronskian determinant-ledger exactness)**.** *Every determinant or linear-dependence read of an accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet must expose the derivative row D, continuous-map family row F, finite jet table J, determinant ledger Ω,* $\mathsf{StreamName}^{\uparrow}$ *window row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance route, and terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The read is exact only as the displayed dependency route through chapter 122, chapter 130, chapter 126, chapter 301, chapter 291, and chapter 38; it exports no host function equality, selected differentiability witness, or quotient Real equality.*

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier determinant ledger exactness`

Proof. Project the carrier of Definition 6877.1. The determinant-facing rows are F, D, J, Ω, so determinant assembly can only inspect the displayed continuous-map family, derivative admission, jet table, and alternating ledger.

Route value reads through S, R, E. The finite window row fixes the requests, the regular rational row reads determinant values, and the Real seal exposes only those displayed values with the dyadic tolerance route named by the package row.

The structural rows H, C, P, N preserve this inventory under transport, replay, provenance, and local naming. Since none of these rows contains host function equality, a selected differentiability witness, or quotient Real equality, determinant-ledger exactness is confined to the displayed sibling route. □

Theorem 6877.4 (Wronskian regular Cauchy determinant handoff)**.** *Every accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet whose rows read derivative data,* $\mathsf{ContinuousMap}^{\uparrow}$ *moduli,* $\mathsf{Real}^{\uparrow}$ *seals,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readbacks,* $\mathsf{StreamName}^{\uparrow}$ *finite windows, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows exports a determinant handoff only through those displayed rows. In carrier notation, the determinant handoff is available only after the route*

$$F, D, J, \Omega, S, R, E, H, C, P, N$$

has exposed the continuous-map family row, derivative row, finite jet table, determinant ledger, stream-window row, regular readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming. $\mathsf{SturmSeparation}^{\uparrow}$ *and* $\mathsf{SturmRootCount}^{\uparrow}$ *consumers may cite this handoff, but they receive no hidden quotient Real equality, host determinant equality, selected differentiability witness, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier regular cauchy determinant handoff`

Proof. Project the carrier of Definition 6877.1. The derivative and continuous-map data are displayed as D and F, while the determinant ledger is assembled only from the finite jet table J and the alternating row Ω.

Route the value-facing read through S, R, E. The $\mathsf{StreamName}^{\uparrow}$ row fixes the finite windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row reads the determinant values as regular rational data, and the $\mathsf{Real}^{\uparrow}$ seal exposes only those displayed readbacks with the dyadic tolerance route named by P.

Apply componentwise transport and replay through H and C. Since the determinant ledger has already been tied to F, D, J, Ω, S, R, E, stability under hsame and Cont replay can only move the same displayed rows.

Finally pass through provenance and local naming. The Sturm consumers cited in the statement are downstream readers of this handoff, not additional coordinates of the $\mathsf{Wronskian}^{\uparrow}$ carrier, so they cannot import hidden quotient Real equality, host determinant equality, selected differentiability witnesses, or ambient completeness. □

Theorem 6877.5 (Wronskian RegSeqRat derivative-window dependency)**.** *Every accepted* $\mathsf{Wronskian}^{\uparrow}$ *derivative-read packet over* $\mathsf{Real}^{\uparrow}$ *consumes derivative rows only through the finite route*

$$F, D, J, \Omega, S, R, E, H, C, P, N.$$

The derivative rows are exposed as $\mathsf{StreamName}^{\uparrow}$ *windows from chapter 126,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback from chapter 301,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budgets from chapter 291, and* $\mathsf{ContinuousMap}^{\uparrow}$ *graph rows from chapter 130 before the* $\mathsf{SturmRootCount}^{\uparrow}$ *and* $\mathsf{SturmSeparation}^{\uparrow}$ *consumers of chapter 3612 and chapter 8378 may read a determinant or separation verdict. The packet exports no host derivative equality, selected differentiability witness, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier regseqrat window dependency`

Proof. Project the carrier of Definition 6877.1. The continuous-map row F, derivative row D, finite jet table J, and determinant ledger Ω expose the derivative-facing data before any value row is read.

Route each derivative value through the window and readback rows. The $\mathsf{StreamName}^{\uparrow}$ row S fixes the finite inspected windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies regular rational readback, and the dyadic tolerance route named by P is the only tolerance budget visible to the determinant ledger.

Apply the regular Cauchy determinant handoff of Definition 6877.4. It keeps the determinant route attached to the displayed continuous-map, derivative, stream-window, regular-readback, dyadic-tolerance, and Real-seal rows.

Finally use the Sturm separation handoff of Definition 6877.15. The Sturm consumers receive the same finite route as downstream input, so they cannot replace it by host derivative equality, selected differentiability data, quotient real equality, or ambient completeness. □

Theorem 6877.6 (Wronskian determinant-route stability)**.** *Let*

$$W = (F, D, J, \Omega, S, R, E, H, C, P, N)$$

and

$$W' = (F', D', J', \Omega', S', R', E', H', C', P', N')$$

be accepted $\mathsf{Wronskian}^{\uparrow}$ *packets. Suppose the displayed componentwise* hsame *transport rows identify the continuous-family rows* F, F'*, derivative rows* D, D'*, finite jet tables* J, J'*, determinant ledgers* Ω, Ω'*,* $\mathsf{StreamName}^{\uparrow}$ *window rows* S, S'*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* R, R'*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance routes named by* P, P'*, and terminal* $\mathsf{Real}^{\uparrow}$ *seals* E, E'*. Then every determinant or linear-dependence read of* W *and* W' *follows the same finite route through those rows. In particular, transport cannot replace the determinant route by host function equality, selected differentiability witnesses, quotient real equality, or ambient completeness.*

Proof. Project both carriers using Definition 6877.1. The hypotheses identify exactly the rows that the carrier exposes to determinant-facing and value-facing consumers: the continuous-family row, derivative row, jet table, determinant ledger, finite window row, regular readback row, dyadic tolerance route, and terminal Real seal.

Apply Definition 6877.3. Any determinant read must already pass through F, D, J, Ω, S, R, E and the named dyadic tolerance route. Since the corresponding primed rows are related componentwise by the displayed hsame transport, the read has no second route on which to switch representatives.

Use Definition 6877.7 for the linear-dependence consumer boundary. Linear-dependence reads are downstream of the same determinant ledger and value route, so the componentwise transport carries them through the same finite rows.

Finally apply Definition 6877.9. The terminal Real seal is reached only after the displayed route has been read. Host function equality, selected differentiability witnesses, quotient real equality, and ambient completeness are absent from both carriers, so transport cannot introduce them. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier determinant route stability`

Theorem 6877.7 (Wronskian linear-dependence boundary)**.** *Every linear-dependence or Sturm–Liouville-facing consumer of an accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet must pass through*

$$F, D, J, \Omega, S, R, E, H, C, P, N.$$

The consumer receives derivative jets, determinant rows, finite request windows, regular rational readback, dyadic tolerance arithmetic, and the terminal $\mathsf{Real}^{\uparrow}$ *seal. It receives no host function equality, selected basis relation, classical zero theorem, quotient real equality, countable-choice row, or ambient completeness principle.*

Proof. Start with Definition 6877.2. It identifies the displayed carrier rows as the whole local NameCert surface and gives no second source for derivative, determinant, readback, or seal data.

The derivative and determinant rows supply the only linear-dependence-facing evidence. A consumer may inspect J and Ω, but those rows are already downstream of the continuous-map and derivative admissions F, D.

The value route is fixed by S, R, E. The finite window is read by $\mathsf{StreamName}^{\uparrow}$, the determinant value is read by $\mathsf{RegSeqRat}^{\uparrow}$ with $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance arithmetic, and the terminal endpoint is the displayed $\mathsf{Real}^{\uparrow}$ seal.

Therefore a linear-dependence consumer cannot replace the packet by host function equality, a selected basis relation, a classical zero theorem, quotient real equality, countable choice, or ambient completeness. Those objects are absent from the carrier and from the local classifier. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier linear dependence boundary`

Theorem 6877.8 (Wronskian linear-dependence witness route)**.** *A linear-dependence witness read for an accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet is admitted only when the finite jet table* J*, determinant ledger* Ω*,* $\mathsf{StreamName}^{\uparrow}$ *window row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance route named by* P*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *are all displayed. The witness is therefore a finite Wronskian readback route through the packet rows, not a host zero theorem, selected basis relation, quotient real equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 6877.1. A witness-facing read can inspect only the displayed family, derivative, jet, determinant, window, readback, seal, transport, replay, provenance, and local naming rows.

Invoke determinant-ledger exactness and determinant-route stability, Definition 6877.3 and Definition 6877.6. Exactness forces the read through J, Ω, S, R, E and the named dyadic tolerance route, while stability keeps that route fixed under componentwise transport.

The linear-dependence boundary then applies through Definition 6877.7. Since host zero theorems and selected basis relations are not carrier coordinates and are not supplied by the sibling rows, the admitted witness is only the displayed finite readback route. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier linear dependence witness`

Theorem 6877.9 (Wronskian Real-seal nonescape)**.** *Every Real-facing consumer of an accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed route*

$$F, D, J, \Omega, S, R, E, H, C, P, N$$

and through the sibling rows $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Derivative}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. The packet exports no quotient stream, host real equality, selected limit, selected differentiability witness, countable-choice row, ambient completeness theorem, or bridge row.*

Proof. Project the Real-facing rows from Definition 6877.1. The terminal seal row E is downstream of the family, derivative, jet, determinant, finite-window, and regular-readback rows.

Apply Definition 6877.2. It states that these rows, together with H, C, P, N, are the complete local NameCert surface for the accepted packet.

Use Definition 6877.7 for the consumer boundary. Any downstream read that wants a Wronskian value or a linear-dependence verdict must pass through the same finite route before it can inspect the Real seal.

The excluded objects are not carrier coordinates and are not supplied by the sibling rows. Hence the terminal $\mathsf{Real}^{\uparrow}$ seal cannot be reached through quotient streams, host equality, selected limits, selected differentiability witnesses, countable choice, ambient completeness, or bridge data. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier real seal nonescape`

Theorem 6877.10 (Wronskian carrier obligation)**.** *Every accepted* $\mathsf{Wronskian}^{\uparrow}$ *carrier exposes the obligation rows*

$$F, D, J, \Omega, S, R, E, H, C, P, N$$

before any determinant, linear-dependence, ODE, or Real-facing consumer reads the packet. The rows must include the continuous-map family, derivative admissions, finite jet table, determinant ledger, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance route named by provenance, terminal Real seal, componentwise transport, continuation replay, package provenance, and local NameCert naming.

Proof. Project the carrier of Definition 6877.1. Its analytic rows are F, D, J, Ω, S, R, E, and its structural rows are H, C, P, N.

Use the NameCert obligation theorem. It identifies continuous-family admission, derivative-row admission, finite jet exposure, determinant-ledger exposure, finite-window exposure, regular rational readback, Real sealing, transport, replay, provenance, and local naming as the complete local surface.

The determinant-ledger and Real-seal nonescape theorems then force every downstream consumer through the same row sequence. Thus the carrier obligation is row projection and route preservation, not determinant algebra over an ambient host field. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier obligation`

Theorem 6877.11 (Wronskian classifier stability)**.** *The* $\mathsf{Wronskian}^{\uparrow}$ *classifier is stable under componentwise* hsame *transport of the continuous-map family rows, derivative rows, finite jet tables, determinant ledgers, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance routes, Real seals, continuation rows, provenance rows, and local NameCert rows. Such transport preserves the finite Wronskian route and cannot substitute host function equality, selected differentiability witnesses, quotient real equality, countable choice, or ambient completeness.*

Proof. Start with determinant-route stability, Definition 6877.6. It already transports determinant and linear-dependence reads across componentwise identified rows without creating a second representative route.

Apply the carrier obligation theorem. Since each accepted read begins with the same displayed row inventory, classifier comparison may only inspect those rows and their componentwise transports.

Finally use Real-seal nonescape. The terminal seal is downstream of the displayed route through $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the classifier cannot switch to any excluded host or quotient principle. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier classifier stability`

Theorem 6877.12 (Wronskian ledger exactness)**.** *The Wronskian determinant ledger Ω is exact only as a displayed route through the derivative row D, continuous-map family row F, finite jet table J, StreamName window row S, RegSeqRat readback row R, DyadicRatCore tolerance route named by P, and Real seal E. Removing any one of these rows changes the ledger surface and prevents a consumer from reading the same* $\mathsf{Wronskian}^{\uparrow}$ *packet.*

Proof. Use determinant-ledger exactness. It requires determinant and linear-dependence reads to expose the derivative, continuous-map, finite-jet, determinant, StreamName, RegSeqRat, DyadicRatCore, and Real-seal route.

Apply carrier obligation and classifier stability. They keep the ledger tied to $F, D, J, \Omega, S, R, E, H, C, P, N$ under transport and route replay, so no host determinant equality or selected differentiability witness can replace a missing row.

If a listed row is removed, the continuation row C and provenance row P no longer replay the same dependency chain. The packet therefore fails to expose the exact Wronskian ledger claimed by the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier ledger exactness`

Theorem 6877.13 (Wronskian obligation closure scope)**.** *The carrier, NameCert obligations, determinant ledger, determinant-route stability, linear-dependence boundary, witness route, and Real-seal nonescape theorems form the visible* $\mathsf{Wronskian}^{\uparrow}$ *obligation surface over the* $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. Every accepted read of*

$$W = (F, D, J, \Omega, S, R, E, H, C, P, N)$$

therefore remains inside the finite route through continuous-map admission, derivative admission, jet display, determinant assembly, dyadic tolerance, finite request windows, regular rational readback, terminal Real sealing, hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming.*

Proof. Start with the carrier and NameCert obligations, Definition 6877.1 and Definition 6877.2. They expose exactly the rows $F, D, J, \Omega, S, R, E, H, C, P, N$ and no additional analytic coordinate.

Use determinant-ledger exactness and determinant-route stability, Definition 6877.3 and Definition 6877.6. These results keep determinant reads on the route through $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Finally apply the linear-dependence boundary, witness route, and Real-seal nonescape theorems, Definition 6877.7, Definition 6877.8, and Definition 6877.9. They show that every consumer-facing read remains within the displayed obligation surface and exports none of the excluded host or quotient principles. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier obligation closure scope`

Theorem 6877.14 (Wronskian differential-equation consumer handoff)**.** *Every ODE, Sturm–Liouville, or linear-dependence consumer of an accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet must enter through the determinant-ledger route of Definition 6877.13 before reading any* $\mathsf{Real}^{\uparrow}$*-seal conclusion. In particular, the consumer must expose $F, D, J, \Omega, S, R, E, H, C, P, N$ and the sibling rows* $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before it may use a Wronskian value or a linear-dependence verdict.*

Proof. Apply the obligation closure scope of Definition 6877.13. It identifies the determinant-ledger route as the visible surface for every accepted read.

Use the linear-dependence boundary and witness route, Definition 6877.7 and Definition 6877.8. These force ODE-facing and linear-dependence-facing consumers to read the derivative jets, determinant ledger, dyadic tolerance route, StreamName window, and RegSeqRat readback before any verdict is available.

Finally use Real-seal nonescape from Definition 6877.9. The terminal seal row is downstream of the same determinant-ledger route, so no consumer can reach a Real-seal conclusion through host function equality, selected bases, classical zero theorems, quotient real equality, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier differential equation consumer handoff`

Theorem 6877.15 (Wronskian Sturm separation handoff)**.** *Any* $\mathsf{SturmSeparation}^{\uparrow}$ *or* $\mathsf{SturmRootCount}^{\uparrow}$ *consumer that reads a* $\mathsf{Wronskian}^{\uparrow}$ *zero or nonzero separation must first expose the Wronskian carrier rows*

$$F, D, J, \Omega, S, R, E, H, C, P, N$$

together with the Sturm comparison and root-count sibling route. The handoff supplies only the displayed finite determinant-ledger route through $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*; it supplies no host zero theorem, selected basis relation, quotient real equality, countable choice, or ambient completeness.*

Proof. Project the Wronskian carrier of Definition 6877.1. The rows $F, D, J, \Omega, S, R, E, H, C, P, N$ display the function family, derivative admission, jet table, determinant ledger, finite request windows, regular rational readback, Real seal, transport, replay, provenance, and local naming before any consumer read is available.

Apply determinant-ledger exactness and determinant-route stability, Definition 6877.3 and Definition 6877.6. These keep zero and nonzero determinant reads attached to the same displayed route through continuous-map admission, derivative admission, finite windows, dyadic tolerance, regular rational readback, and the terminal Real seal.

Use the linear-dependence boundary and Real-seal nonescape results, Definition 6877.7 and Definition 6877.9. They prevent the consumer from replacing the displayed determinant ledger by host function equality, selected bases, quotient real equality, countable choice, or ambient completeness.

Finally route the zero-separation read through the existing Sturm sibling chapters as consumers. The $\mathsf{SturmSeparation}^{\uparrow}$ and $\mathsf{SturmRootCount}^{\uparrow}$ rows therefore receive a Wronskian handoff only after the determinant and Real-facing rows have been shown; they do not add new coordinates to the Wronskian packet. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier sturm separation handoff`

Theorem 6877.16 (Wronskian differential scope ledger)**.** *Every determinant, zero-separation, or linear-dependence consumer of an accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet must expose the* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{Derivative}^{\uparrow}$ *rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback rows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the* $\mathsf{SturmSeparation}^{\uparrow}$ *and* $\mathsf{SturmRootCount}^{\uparrow}$ *handoff rows before any local NameCert export is available. In carrier notation, the visible differential scope is the route*

$$F, D, J, \Omega, S, R, E, H, C, P, N$$

together with the Sturm handoff of Definition 6877.15. The ledger exports no host derivative equality, selected differentiability witness, selected basis relation, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or Sturm conclusion outside the displayed route.*

Proof. Project the Wronskian carrier of Definition 6877.1. The rows $F, D, J, \Omega, S, R, E, H, C, P, N$ are the only displayed continuous-map, derivative, jet, determinant, stream-window, regular-readback, Real-seal, transport, replay, provenance, and local naming coordinates.

Use determinant-ledger exactness and derivative-route stability through Definition 6877.3 and Definition 6877.6. These keep every determinant read attached to $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before a consumer can inspect the value.

Apply the linear-dependence boundary and Real-seal nonescape, Definition 6877.7 and Definition 6877.9. They keep zero and nonzero reads on the same finite route and prevent replacement by host derivative equality, selected differentiability witnesses, selected bases, quotient real equality, countable choice, or ambient completeness.

Finally use the Sturm separation handoff of Definition 6877.15. The $\mathsf{SturmSeparation}^{\uparrow}$ and $\mathsf{SturmRootCount}^{\uparrow}$ consumers receive only the displayed Wronskian route, so local NameCert export remains scoped to the differential ledger named in the statement. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier differential scope ledger`

Theorem 6877.17 (Wronskian L10 scope binding)**.** *Every accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet consumed by determinant, derivative, or Sturm-separation routes must expose the finite route through* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{Derivative}^{\uparrow}$ *rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *windows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Wronskian}^{\uparrow}}$ *row before any zero or nonzero determinant conclusion is public. The route exports no host differentiable function, selected representative, quotient stream, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier l10 scope binding`

Proof. Project the Wronskian carrier of Definition 6877.1. The carrier displays $F, D, J, \Omega, S, R, E, H, C, P, N$, so every determinant-facing consumer starts from continuous-map admission, derivative admission, the finite jet table, and the determinant ledger.

Apply determinant-ledger exactness and determinant-route stability, Definition 6877.3 and Definition 6877.6. These force determinant, zero, and nonzero reads through the visible $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route before any public conclusion is available.

Use Real-seal nonescape and the Sturm separation handoff, Definition 6877.9 and Definition 6877.15. The terminal seal and the Sturm-facing consumer both remain downstream of the same displayed route.

Finally apply the differential scope ledger of Definition 6877.16. Since host differentiable functions, selected representatives, quotient streams, trichotomy branches, and ambient completeness are absent from the carrier and classifier, the L10 public boundary is exactly the finite row route named in the statement. □

Theorem 6877.18 (Wronskian obligation-closure package)**.** *The carrier of Definition 6877.1, the NameCert obligations of Definition 6877.2, determinant-ledger exactness, determinant-route stability, the linear-dependence boundary, the witness route, and Real-seal nonescape assemble the* $\mathsf{Wronskian}^{\uparrow}$ *obligationClosure surface over* $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The assembled package exports*

no host function equality, selected differentiability witness, quotient Real equality, countable choice, ambient completeness, or bridge row.

Proof. Project the carrier rows $F, D, J, \Omega, S, R, E, H, C, P, N$ from Definition 6877.1. The NameCert obligation theorem reads these as continuous-map admission, derivative admission, finite jet exposure, determinant exposure, StreamName windowing, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Use determinant-ledger exactness and determinant-route stability. They bind determinant reads to the displayed finite route through $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ and keep the route invariant under componentwise hsame transport.

Apply the linear-dependence boundary, witness route, and Real-seal nonescape theorems. These force every ODE-facing or Real-facing consumer through the same rows and show that the excluded host principles are absent from the carrier, classifier, transport, replay, provenance, and local NameCert surfaces. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier obligation closure package`

Theorem 6877.19 (Wronskian public determinant export)**.** *Every accepted* $\mathsf{Wronskian}^{\uparrow}$ *packet exports exactly the finite determinant ledger route through* $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert. *The exported public surface is the displayed route*

$$F, D, J, \Omega, S, R, E, H, C, P, N,$$

with determinant, zero-separation, and linear-dependence reads confined to those rows. It exports no host function equality, selected differentiability witness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the Wronskian carrier of Definition 6877.1. The rows $F, D, J, \Omega, S, R, E, H, C, P, N$ are the only continuous-map, derivative, jet, determinant, finite-window, readback, Real-seal, transport, replay, provenance, and naming coordinates available to a public consumer.

Apply determinant-ledger exactness and determinant-route stability, Definition 6877.3 and Definition 6877.6. These force every determinant read through the same displayed route and keep that route fixed under componentwise hsame transport.

Use the linear-dependence boundary and Real-seal nonescape theorems, Definition 6877.7 and Definition 6877.9. They place zero-separation and linear-dependence reads downstream of the determinant ledger and terminal Real seal without adding host equality or a selected differentiability witness.

Finally apply the L10 scope binding of Definition 6877.17. The public export is therefore exactly the finite route named in the statement, and every excluded quotient, host, or ambient-completeness principle remains outside the packet. □

Lean4 ✓ `BEDC.Derived.WronskianUp.WronskianCarrier public determinant export`

Closure status for $\mathsf{NameCert}_{\mathsf{Wronskian}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Wronskian}^{\uparrow}$ packet is generated from a finite continuous-map family row, derivative-admission rows, a displayed jet table, an alternating determinant ledger, finite StreamName requests, regular rational readback, a terminal Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Wronskian}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 6877.1, Definition 6877.2, Definition 6877.3, Definition 6877.6, Definition 6877.7, Definition 6877.8, Definition 6877.9, Definition 6877.10, Definition 6877.11, Definition 6877.12, Definition 6877.17, and Definition 6877.18 bind the finite Wronskian carrier, determinant-ledger route, transport stability, linear-dependence boundary, witness route, Real-seal nonescape surface, carrier obligations, classifier stability, ledger exactness, L10 scope boundary, and obligation package.

Formal verification: FormalStatus(NameCert$_{\text{Wronskian}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, classical zero theorems, selected bases, selected differentiability witnesses, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Public export requires a checked Wronskian carrier theorem family, public consumer surface, and bridge discipline for BEDC.Derived.WronskianUp.

Chapter 6878

A Concrete Naming Certificate for $\mathsf{LandauKolmogorovInequality}^{\uparrow}$

Following Landau and Kolmogorov, the $\mathsf{LandauKolmogorovInequality}^{\uparrow}$ packet records the finite derivative-window route by which an intermediate derivative norm is bounded between a low-order norm ledger and a high-order derivative norm ledger. It sits beside the asymptotic comparison surface of chapter 2252, the finite-window interpolation route of chapter 6814, the norm carrier of chapter 89, and the terminal real-name seal of chapter 38. The packet names a constructive analysis inequality surface over displayed derivative and norm rows; it is not a host function equality principle, an unbounded differentiability tower, a measure completion theorem, or an ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 6878.1 (Landau–Kolmogorov inequality carrier)**.** *A* $\mathsf{LandauKolmogorovInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, N_0, N_k, N_m, A, W, R, E, H, C, P, Z)$$

with the following displayed rows:

1. *D is the derivative-window ledger, naming the finite orders $0 < k < m$ and the inspected derivative windows used by the estimate.*
2. *N_0, N_k, N_m are the* $\mathsf{Norm}^{\uparrow}$ *rows for the base function, the intermediate derivative, and the highest displayed derivative.*
3. *A is the interpolation-exponent row, storing the finite rational exponent data and coefficient budget used by the Landau–Kolmogorov comparison.*
4. *W is the* $\mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow}$ *handoff row that places the displayed derivative windows and norm ledgers in one finite interpolation packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational inequality budget and all finite tolerance requests.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after $D, N_0, N_k, N_m, A, W, R$ have been displayed.*
7. *H records componentwise* hsame *transport for the derivative-window, norm-ledger, exponent, interpolation, readback, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a derivative-window request through the norm ledgers, interpolation exponents, regular rational readback, and Real seal.*

9. *P is the* Pkg *provenance over* LandauKolmogorovInequality$^{\uparrow}$, LandauSymbol$^{\uparrow}$, GagliardoNirenbergFiniteWindow$^{\uparrow}$, Norm$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *Z is the local* NameCert$_{\text{LandauKolmogorovInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, N_0, N_k, N_m, A, W, R, E, H, C, P, Z$. The carrier has no coordinate for host function equality, a choice-selected derivative representative, an infinite differentiability tower, measure completion, quotient norm equality, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6878.2 (Landau–Kolmogorov inequality NameCert obligations)**.** *For every accepted* LandauKolmogorovInequality$^{\uparrow}$ *carrier*

$$K = (D, N_0, N_k, N_m, A, W, R, E, H, C, P, Z),$$

the local NameCert$_{\text{LandauKolmogorovInequality}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed derivative-window ledger, three norm ledgers, interpolation-exponent row, finite-window handoff, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *derivative-window exactness, requiring the intermediate derivative request and the highest derivative request to be read through the same finite row D before any norm comparison is exposed;*
3. *norm-ledger accountability, requiring N_0, N_k, N_m to be the only norm rows available to the inequality read;*
4. *interpolation-exponent exactness, requiring A and W to store the rational exponent data and finite interpolation budget before R may read the inequality as regular rational data;*
5. *Real-seal nonescape, requiring every Real-facing conclusion to pass through R and then E;*
6. *stability under componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row;*
7. *refusal of host function equality, selected derivative representatives, unbounded differentiability towers, measure completion, quotient norm equality, countable choice, and ambient* Real$^{\uparrow}$ *completeness as local certificate data.*

No Landau–Kolmogorov inequality obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6878.1. The accepted packet exposes only the derivative-window row, three norm rows, interpolation data, regular rational readback, the Real seal, and the structural rows.

The derivative and norm obligations are finite. The row D fixes the orders and inspected windows, while N_0, N_k, N_m are the only norm ledgers available to the comparison; no host derivative representative or quotient norm equality can be read outside them.

The interpolation step is routed through A and W. These rows store the rational exponent data and the finite-window handoff already associated with GagliardoNirenbergFiniteWindow$^{\uparrow}$, so the estimate reaches R only as displayed regular rational data.

Finally, E, H, C, P, Z seal and preserve the same route. Since the excluded host-function, choice, infinite-tower, measure-completion, quotient, and ambient-completeness objects are not carrier rows, the local NameCert surface cannot export them. □

Theorem 6878.3 (Landau–Kolmogorov derivative-norm handoff)**.** *Every derivative-norm consumer of an accepted* $\mathsf{LandauKolmogorovInequality}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{LandauSymbol}^{\uparrow},\ \mathsf{GagliardoNirenbergFiniteWindow}^{\uparrow},\ \mathsf{Norm}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCe}$$

The intermediate derivative norm is therefore read only after the derivative-window ledger, base and high-order norm ledgers, interpolation-exponent row, finite-window handoff, regular rational readback, and Real seal have all been displayed. The handoff exports no host function equality, selected derivative representative, infinite differentiability tower, measure completion, quotient norm equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $K = (D, N_0, N_k, N_m, A, W, R, E, H, C, P, Z)$. The derivative-norm request can inspect the intermediate row N_k only together with the derivative-window ledger D and the endpoint norm rows N_0, N_m.

The interpolation data then passes through A and W. The row W is the finite Gagliardo–Nirenberg-style handoff, and A supplies the rational exponent budget read by the estimate.

The Real-facing read is downstream of R and E. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming preserve the same finite chain, so the consumer never receives an external equality, selection, infinite tower, measure completion, quotient, choice, or ambient-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LandauKolmogorovInequality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LandauKolmogorovInequality}^{\uparrow}$ packet is generated from one derivative-window ledger, three NormUp ledgers, one rational interpolation-exponent row, one GagliardoNirenbergFiniteWindowUp handoff, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LandauKolmogorovInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6878.1, Definition 6878.2, and Definition 6878.3 seed the finite derivative-window interpolation route through norm ledgers, RegSeqRat readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LandauKolmogorovInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, selected derivative representatives, infinite differentiability towers, measure completion, quotient norm equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-window exactness, norm-ledger accountability, interpolation-exponent exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LandauKolmogorovInequalityUp.

Chapter 6879

A Concrete Naming Certificate for $\mathsf{CauchyNetDiagonal}^{\uparrow}$

Following Moore–Smith and Kelley on nets, the $\mathsf{CauchyNetDiagonal}^{\uparrow}$ packet names the finite diagonal extraction route by which a displayed Cauchy net is read through a cofinal schedule and handed to regular rational names. It sits over the Cauchy-net source of chapter 3794, the Moore–Smith net surface of chapter 2190, the stream-window naming surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance scale of chapter 1768, and the Real seal of chapter 38. The chapter records a finite diagonal packet only; it does not add a choice functional, quotient net equality, selected subnet, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 6879.1 (Cauchy-net diagonal carrier)**.** *A* $\mathsf{CauchyNetDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, M, K, T, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CauchyNet}^{\uparrow}$ *source row whose directed-domain and Cauchy evidence are displayed before any diagonal consumer reads the packet.*
2. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *source row, recording that the source is consumed as Moore–Smith net data rather than as an unordered family.*
3. *K is the finite cofinal diagonal schedule, listing the observed directed indices and the finite cofinality checks used by the packet.*
4. *T is the dyadic tolerance ledger, recording the requested error levels and the finite comparisons used to meet them.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row obtained by reading the scheduled observations in order.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to those stream windows.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational readback.*
8. *H records componentwise* hsame *transport for $A, M, K, T, S, Q, R, C, P, N$.*
9. *C records displayed* Cont *replay from the Cauchy-net source through the Moore–Smith row, finite schedule, dyadic ledger, stream window, regular rational readback, and Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyNet}^{\uparrow}$*,* $\mathsf{MooreSmithNet}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetDiagonal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, K, T, S, Q, R, H, C, P, N$. It has no coordinate for a choice functional, quotient net equality, selected subnet, selected representative, selected limit, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyNetDiagonalUp.CauchyNetDiagonalUp`

Theorem 6879.2 (Cauchy-net diagonal NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNetDiagonal}^{\uparrow}$ *carrier $D = (A, M, K, T, S, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyNetDiagonal}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed Cauchy-net source, Moore–Smith source, finite cofinal diagonal schedule, dyadic tolerance ledger, stream window, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *source visibility, requiring the rows A and M to remain available before any diagonal schedule or completion-facing read is consumed;*
3. *schedule exactness, requiring K to display the finite cofinal observations and T to display the dyadic tolerance ledger used by those observations;*
4. *readback routing, requiring S, Q, R to be consumed in order from stream windows to regular rational data and then to the Real seal;*
5. *structural stability, requiring H, C, P, N to preserve and name exactly the same finite route.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6879.1. The accepted packet exposes exactly the rows $A, M, K, T, S, Q, R, H, C, P, N$, so the local naming surface can read only those coordinates.

The source rows come first. The Cauchy-net row A supplies directed Cauchy evidence, while the Moore–Smith row M fixes the net interface through which the diagonal route is read.

The finite diagonal step is then local to K and T. The schedule lists the observed directed indices, and the dyadic ledger lists the tolerance comparisons that justify each observed window.

Finally the packet reads S, Q, R as stream windows, regular rational data, and a Real seal. Componentwise hsame, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row preserve this same route without adding any hidden selector or completion theorem. □

Lean4 ✓ `BEDC.Derived.CauchyNetDiagonalUp.CauchyNetDiagonalNameCertObligations`

Theorem 6879.3 (Cauchy-net diagonal RegSeqRat handoff)**.** *Every regular-rational or Real-facing consumer of an accepted* $\mathsf{CauchyNetDiagonal}^{\uparrow}$ *carrier reads the diagonal route only through*

$$\mathsf{CauchyNet}^{\uparrow}, \mathsf{MooreSmithNet}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The handoff exports no choice functional, quotient net equality, selected subnet, selected representative, selected limit, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier. The only source coordinates are the Cauchy-net row A and the Moore–Smith row M, so a consumer cannot read a detached family, selected subnet, or quotient net before the displayed source route is fixed.

The diagonal observations pass through K and T. These rows are finite data: the cofinal observation schedule and the dyadic tolerance ledger. They do not contain a choice operator or a global completion principle.

The handoff to regular rational names is exactly the route S, Q, R. The stream row supplies the windows, the regular rational row reads those windows, and the Real row seals the resulting name.

The remaining rows H, C, P, N transport, replay, source, and name the same packet. Since none of these rows is a selector, quotient equality, host equality, or ambient completeness theorem, the RegSeqRat and Real-facing handoff is exhausted by the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetDiagonal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNetDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6879.1, Definition 6879.2, and Definition 6879.3 seed the finite diagonal extraction route from Cauchy-net and Moore–Smith data to StreamName, RegSeqRat, and Real readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNetDiagonal}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyNetDiagonalUp.CauchyNetDiagonalNameCertObligations`

Bridge status: none

Not claimed: This chapter does not close a choice functional, quotient net equality, selected subnet, selected representative, selected limit, quotient stream equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, source visibility, finite cofinal schedule exactness, dyadic tolerance ledger exactness, readback routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyNetDiagonalUp.

Constructive story: A $\mathsf{CauchyNetDiagonal}^{\uparrow}$ packet is generated from a CauchyNet row, a MooreSmithNet source row, a finite cofinal diagonal schedule, a dyadic tolerance ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6880

A Concrete Naming Certificate for $\mathsf{PrueferGroup}^{\uparrow}$

Following Pruefer's p-primary torsion group construction, the $\mathsf{PrueferGroup}^{\uparrow}$ packet records the cyclic p^n-torsion windows and their coherent inclusions as finite BEDC NameCert data. It sits after the operation surface of chapter 41, the commutative specialization of chapter 42, the finite-code discipline of chapter 6390, and the separately topological Pruefer surface route of chapter 6799. The packet names a displayed torsion-window algebra and not an ambient quotient group, a choice-selected compatible root chain, or an infinite colimit object.

Definition 6880.1 (Pruefer group carrier)**.** *A* $\mathsf{PrueferGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (p, W, I, A, T, D, H, C, P, N)$$

with the following displayed rows:

1. *p is the prime-index row naming the fixed torsion prime and the visible arithmetic ledger for p-power exponents.*
2. *W is the finite window row, listing the cyclic torsion stages currently exposed to the packet as $p, p^2, \ldots, p^k$ windows.*
3. *I is the coherent inclusion row, recording the displayed stage-to-stage embeddings from the p^n window to the p^{n+1} window.*
4. *A is the* $\mathsf{AbGroup}^{\uparrow}$ *operation row for the displayed windows, retaining the group operation, unit, inverse, operation congruence, and commutativity read through the sibling abelian-group certificate.*
5. *T is the torsion-window classifier row, comparing accepted endpoints only by a common displayed p^m window and its inclusion ledger.*
6. *D is the divisibility handoff row: every displayed endpoint has a next-window predecessor only when the relevant inclusion row in I is present.*
7. *H records componentwise* hsame *transport for the prime, window, inclusion, abelian-operation, classifier, divisibility, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a torsion endpoint request through its finite window, inclusion route, abelian operation readback, classifier comparison, divisibility handoff, transport, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{PrueferGroup}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{PrueferSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PrueferGroup}^{\uparrow}}$ *row.*

The classifier has no coordinate for quotienting an external group, selecting roots outside the displayed inclusion ledger, or replacing the finite windows by an ambient infinite colimit.

Theorem 6880.2 (Pruefer group NameCert obligations)**.** *For every accepted* $\mathsf{PrueferGroup}^{\uparrow}$ *carrier*

$$G = (p, W, I, A, T, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrueferGroup}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the fixed-prime row, finite p-power torsion windows, coherent inclusion ledger, abelian operation row, transport, replay, provenance, and local naming;*
2. *p-power compatibility, requiring each operation and inverse read in A to remain inside a displayed window and to commute with the inclusion rows of I;*
3. *torsion-window classifier stability, requiring T to compare endpoints only after transporting them to a common displayed p^m window;*
4. *divisibility handoff, exposing a predecessor in the next torsion window exactly through the corresponding row of D and not through a global root selector;*
5. *ledger refusal excluding quotient groups, choice-selected roots, and ambient infinite colimits from the accepted packet.*

Proof. Project the carrier of Definition 6880.1. The tuple displays the prime row, finite torsion windows, coherent inclusions, abelian-group operation rows, torsion classifier, divisibility handoff, transport, replay, provenance, and local name as separate rows.

The carrier-admission row reads p, W, I, A, H, C, P, N before any classifier or divisibility claim is available. Since W is finite and I lists only displayed stage-to-stage inclusions, admission is a finite BHist read.

For compatibility, inspect A together with I. The operation, unit, inverse, congruence, and commutativity rows are inherited through chapter 42, while each operation endpoint is checked inside a visible p^n window and transported along the named inclusions.

The classifier row T compares two accepted endpoints only after a common displayed window has been named. The divisibility row D is then a next-window handoff for that displayed endpoint, not a selection principle over all roots.

Finally, H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. No row supplies quotient-group equality, a choice-selected root chain, or an ambient colimit carrier, so the five listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{PrueferGroup}^{\uparrow}$ read displays a fixed prime row, finite p-power torsion windows, coherent inclusion rows, abelian operation rows, torsion-window classifier stability, divisibility handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: group, abgroup, pruefer-sequence, pruefer-surface: $\mathsf{PrueferGroup}^{\uparrow}$ is not bijective to any listed sibling because it binds finite p-power torsion windows, coherent inclusions, abelian operation rows, torsion-window classifier stability, and divisibility handoff into one algebraic NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PrueferGroup}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrueferGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6880.1 and Definition 6880.2 seed the finite fixed-prime, torsion-window, coherent-inclusion, abelian-operation, classifier, divisibility, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrueferGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient-group construction, selected compatible root chains, ambient infinite colimits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, p-power compatibility, torsion-window classifier stability, divisibility handoff, and nonescape for BEDC.Derived.PrueferGroupUp.

Constructive story: A $\mathsf{PrueferGroup}^{\uparrow}$ packet is generated from a fixed prime row, finite p-power torsion windows, coherent inclusion rows, abelian operation rows, torsion-window classifier rows, divisibility handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6881

A Concrete Naming Certificate for $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$

Following Bishop and Bridges on diagonal Cauchy arguments, the $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$ packet records the finite evidence by which a family of regular rational Cauchy routes is read along one displayed diagonal schedule before a Real or Completion consumer receives a seal. It sits beside the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the completion-facing envelope of chapter 6864, and the diagonal filter route of chapter 6873. The certificate names a finite diagonal criterion only; it does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, or countable choice.

Definition 6881.1 (Cauchy diagonal criterion carrier)**.** *A* $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the finite precision request and comparison slack used by the diagonal read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *diagonal schedule row, naming the finitely inspected stream windows and the index route used for the diagonal passage.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback row obtained from the displayed windows and dyadic tolerance request.*
4. *R is the regular route row stating that the same D, S, Q packet answers the Cauchy request before any endpoint seal is read.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback is displayed.*
6. *H records componentwise* hsame *transport for the tolerance, schedule, readback, regular-route, seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a diagonal Cauchy request through D, S, Q, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host Cauchy-completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6881.2 (Cauchy diagonal criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$ *carrier* $K = (D, S, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, dyadic tolerance exposure through* D*, diagonal stream-window exposure through* S*, regular rational readback through* Q*, regular-route handoff through* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 6881.1. The only visible rows are $D, S, Q, R, E, H, C, P, N$, so the local NameCert surface has no extra coordinate from which to export a quotient stream, selected limit, or completeness principle.

Read the diagonal evidence through D, S, Q, R. The dyadic tolerance row fixes the precision request, the stream row fixes the finite windows and diagonal schedule, the regular rational row supplies readback, and the regular-route row records that these same data answer the Cauchy request.

Finally use E, H, C, P, N. The Real seal is downstream of the regular readback, and transport, replay, provenance, and local naming preserve the same displayed packet. Therefore the listed rows exhaust the NameCert obligations. □

Theorem 6881.3 (Cauchy diagonal criterion regular handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing consumer of an accepted* $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$ *packet reaches its endpoint only through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The diagonal criterion supplies Bishop-style finite Cauchy evidence for regular-Cauchy Real routes, while exporting no quotient stream equality, selected limit, countable-choice schedule, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start from the tolerance row D and the stream row S. Together they display the finite precision request, diagonal schedule, and stream windows used by the criterion.

Read the regular rational row Q and regular-route row R next. These rows are downstream of the same D, S data, so a consumer cannot obtain a regular Cauchy readback without first inspecting the displayed dyadic and stream evidence.

The terminal Real row E is available only after Q. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve that order. Thus the completion-facing handoff remains finite and does not import quotient streams, selected limits, countable choice, or Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$ endpoint read displays a DyadicRatCore tolerance request, StreamName diagonal windows, RegSeqRat regular readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any Real or Completion consumer may use the route.

Independence witness: dyadicratcore, streamname, regseqrat, real, fan-modulus-real-completion-boundary, cauchy-filter-diagonal: no listed sibling supplies the whole packet $K = (D, S, Q, R, E, H, C, P, N)$, because each sibling contributes only tolerance arithmetic, finite stream naming, regular rational

readback, endpoint sealing, completion-facing envelope data, or filter diagonal routing while this packet binds the Bishop-style diagonal criterion into one finite NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDiagonalCriterion}\uparrow}$.

Constructive story: A $\mathsf{CauchyDiagonalCriterion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance request, StreamName diagonal windows, RegSeqRat regular readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6881.1, Definition 6881.2, and Definition 6881.3 seed the finite diagonal Cauchy route from dyadic tolerance data and stream windows to regular rational readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, quotient streams, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal schedule exposure, dyadic tolerance exactness, regular readback stability, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyDiagonalCriterionUp.

Chapter 6882

A Concrete Naming Certificate for $\mathsf{EgorovTheorem}^{\uparrow}$

Following Egorov and Lebesgue, the $\mathsf{EgorovTheorem}^{\uparrow}$ packet records the theorem-level finite route from almost-uniform convergence data to measure-convergence consumers without adding a host measure-completion primitive. It sits after the finite measure and integration ledgers of chapter 92 and chapter 123, the lower-semicontinuity route of chapter 3447, the domination route of chapter 2340, the large-set continuous approximation route of chapter 4147, and the regular-rational and real-name seals of chapter 301 and chapter 38. The packet is a finite NameCert carrier for the theorem interface: it exports exceptional-set and uniform-window rows that later Fatou, dominated-convergence, and Lusin-style readers can consume, but it does not claim ambient measure completion, almost-everywhere quotient equality, selected representatives, countable choice, or the full host Egorov theorem.

Definition 6882.1 (Egorov theorem carrier)**.** *An* $\mathsf{EgorovTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, I, F, D, L, R, E, A, W, U, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite* $\mathsf{Measure}^{\uparrow}$ *row whose measurable-set ledger bounds every exceptional-set read.*
2. *I is the* $\mathsf{Integral}^{\uparrow}$ *row used by downstream integral consumers after the exceptional and uniform rows have been displayed.*
3. *F is the* $\mathsf{FatouLemma}^{\uparrow}$ *source row, exposed only as a lower-bound and liminf-facing consumer of the same finite measure ledger.*
4. *D is the* $\mathsf{DominatedConvergence}^{\uparrow}$ *source row, exposed only as a domination and integrability consumer of M, I, A, W, U.*
5. *L is the* $\mathsf{LusinApproximation}^{\uparrow}$ *source row, exposing large-set continuous approximation only after the exceptional-set budget is visible.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route for all displayed real-valued observations and tolerance comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by the regular-rational readback route, not by a host real-completeness argument.*

8. *A is the finite exceptional-set row, recording the measurable approximants, the finite measure budget, and containment checks used by the theorem packet.*
9. *W is the finite uniform-window row, recording the index threshold, precision requests, and observation sites on which the theorem route is uniform outside A.*
10. *U is the almost-uniform convergence row, asserting that the displayed R, E, W comparisons are uniform on the complement of the displayed exceptional budget.*
11. *Q is the theorem-handoff row, routing accepted reads from A, W, U into the Fatou, dominated-convergence, Lusin, and integral consumers without changing their carrier rows.*
12. *H records componentwise* hsame *transport for $M, I, F, D, L, R, E, A, W, U, Q$ and the structural rows.*
13. *C records displayed* Cont *replay of the finite route*
$$M, I, F, D, L, R, E, A, W, U, Q \longmapsto H, P, N.$$
14. *P is the* Pkg *provenance over* $\mathsf{EgorovTheorem}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{FatouLemma}^{\uparrow}$, $\mathsf{DominatedConvergence}^{\uparrow}$, $\mathsf{LusinApproximation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{EgorovTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, I, F, D, L, R, E, A, W, U, Q, H, C, P, N$. It has no coordinate for completed measure algebras, quotient almost-everywhere equality, selected representatives, countable exceptional unions, countable choice, or an ambient theorem object outside the finite carrier.

Theorem 6882.2 (Egorov theorem NameCert obligations)**.** *For every accepted* $\mathsf{EgorovTheorem}^{\uparrow}$ *carrier*
$$G = (M, I, F, D, L, R, E, A, W, U, Q, H, C, P, N),$$
the local $\mathsf{NameCert}_{\mathsf{EgorovTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite measure row, integral row, Fatou row, dominated-convergence row, Lusin row, regular-rational readback row, real-name seal, exceptional-set row, uniform-window row, almost-uniform convergence row, theorem-handoff row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every theorem-level public read must pass through A, W, U, Q before it can reach the Fatou, dominated-convergence, Lusin, or integral consumers.*

Proof. Project the carrier of Definition 6882.1. The theorem-facing rows are A, W, U, Q: they name the finite exceptional budget, the finite uniform window, the almost-uniform comparison, and the handoff to downstream consumers.

The rows M, I, F, D, L, R, E supply the measure, integral, Fatou, dominated-convergence, Lusin, regular-rational, and real-name dependency surface on which those four rows are interpreted. The structural rows H, C, P, N transport, replay, source, and name exactly the same finite route.

Since the carrier contains no completed measure algebra, quotient almost-everywhere equality, selected representative, countable exceptional union, countable choice row, or ambient theorem object, the listed rows exhaust the local NameCert obligations. □

Theorem 6882.3 (Egorov theorem finite handoff)**.** *For every accepted* $\mathsf{EgorovTheorem}^{\uparrow}$ *carrier G, any downstream almost-uniform convergence read by a Fatou, dominated-convergence, Lusin, or integral consumer factors through the finite route*
$$A, W, U, Q \longrightarrow F, D, L, I.$$

The handoff preserves the displayed $\mathsf{Measure}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows and does not replace them by selected exceptional sets, almost-everywhere quotient equality, selected representatives, countable choice, or ambient measure completion.*

Proof. Start with the theorem-handoff row Q. By carrier admission, Q is displayed only together with the exceptional-set row A, uniform-window row W, and almost-uniform convergence row U.

Read the downstream consumers next. The Fatou row F, dominated-convergence row D, Lusin row L, and integral row I receive the same finite measure ledger and the same regular-rational and real-name seals already named by M, R, E.

Transport and replay through H and C preserve those rows componentwise. Because no selected exceptional set, quotient almost-everywhere equality, selected representative, countable-choice row, or measure-completion row occurs in G, the handoff is exhausted by the displayed finite route. □

Theorem 6882.4 (Egorov theorem exceptional-window nonescape)**.** *Every accepted* $\mathsf{EgorovTheorem}^{\uparrow}$ *packet exposes its theorem-level convergence content only through the paired exceptional-set and uniform-window rows* A, W *together with the almost-uniform row* U*. A consumer may refine a finite observation schedule through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows, but it may not bypass* A, W, U *by invoking ambient measure completion, almost-everywhere quotient equality, selected representatives, countable choice, or the full host Egorov theorem.*

Proof. The finite observation schedule is read through W, and each precision comparison is evaluated through R and sealed by E. The exceptional-set budget is read through A, whose finite measure ledger is interpreted by M.

The almost-uniform row U binds these two reads together. Thus any refinement of observations that preserves the same A, W, U, R, E data gives the same public theorem-level verdict.

No other carrier coordinate can export the convergence content. In particular Q, H, C, P, N only hand off, transport, replay, source, and name the displayed rows, so the forbidden ambient objects have no projection from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{EgorovTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{EgorovTheorem}^{\uparrow}$ packet is generated from finite Measure and Integral rows, Fatou, DominatedConvergence, and Lusin consumer rows, RegSeqRat readbacks, Real seals, exceptional-set and uniform-window rows, almost-uniform handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EgorovTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6882.1, Definition 6882.2, Definition 6882.3, and Definition 6882.4 seed the finite theorem-level almost-uniform convergence route through exceptional-set, uniform-window, Fatou, dominated-convergence, Lusin, integral, regular-rational, real-name, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EgorovTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient measure completion, almost-everywhere quotient equality, selected representatives, countable choice, the full host Egorov theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exceptional-set budget exactness, uniform-window exactness, almost-uniform handoff, consumer routing, transport stability, and replay stability for BEDC.Derived.EgorovTheoremUp.

Chapter 6883

A Concrete Naming Certificate for PolymorphicInstantiationCoverage$^{\uparrow}$

The PolymorphicInstantiationCoverage$^{\uparrow}$ packet realizes the typed-example frontier of section 9386.6 as finite universe-instantiation and typed-window data. It sits beside the MetaCIC gallery of chapter 775, the typed-example matrix of chapter 923, the dependent-eliminator coverage packet of chapter 6650, the typed-conversion residual frontier of chapter 6069, and the proof-search frontier of chapter 4284. It records where polymorphic examples have been instantiated inside finite typed windows, while keeping eliminator coverage, conversion residuals, proof search, stream observation, and regular-rational readback as separate sibling routes through chapter 126 and chapter 301.

Definition 6883.1 (Polymorphic-instantiation coverage carrier)**.** *A* PolymorphicInstantiationCoverage$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (G, W, U, T, V, O, X, R, S, B, H, C, K, N)$$

with the following displayed rows:

1. *G is the finite typed-example gallery row whose polymorphic identity, type-application, and Church-encoded examples are being audited.*
2. *W is the typed-window row, recording the finite contexts, binders, sort levels, type arguments, and term endpoints inspected by the packet.*
3. *U is the universe-instantiation row, listing the concrete universe and sort substitutions accepted by the window.*
4. *T is the typed-instantiation row, pairing polymorphic source terms with displayed type arguments and typed target endpoints.*
5. *V is the conversion-boundary row, recording where beta, type application, and definitional conversion checks are required before an instantiated example is counted.*
6. *O is the omission-obstruction row, retaining any polymorphic example whose type argument, universe row, or conversion boundary is missing from W, U, T, V.*
7. *X is the transport row from the typed-example coverage matrix into the local polymorphic-instantiation packet.*
8. *R is the replay row, recording bounded re-checks of the accepted instantiation windows without claiming global coverage of all polymorphic programs.*

9. *S is the source-provenance row, separating gallery examples, dependent-eliminator siblings, conversion-frontier siblings, proof-search siblings, stream observations, and regular-rational readbacks.*
10. *B is the boundary row refusing dependent-eliminator coverage, unrestricted conversion residual closure, proof-search completeness, and semantic parametricity as consequences of this packet.*
11. *H records componentwise* hsame *transport for $G, W, U, T, V, O, X, R, S, B$ and the structural rows.*
12. *C records displayed* Cont *replay of the finite route*

$$G, W, U, T, V, O, X, R, S, B \longmapsto H, K, N.$$

13. *K is the* Pkg *provenance over* $\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}$, $\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}$, $\mathsf{TypedExampleCoverageMatrix}^{\uparrow}$, $\mathsf{DependentEliminatorCoverage}^{\uparrow}$, $\mathsf{MetaCICTypedConversionResidualFrontier}^{\uparrow}$, $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, W, U, T, V, O, X, R, S, B, H, C, K, N$. It has no coordinate for all dependent eliminators, a full conversion algorithm, a proof-search completeness theorem, semantic parametricity, quotient syntax equality, host universe polymorphism, or global MetaCIC consistency.

Theorem 6883.2 (Polymorphic-instantiation coverage NameCert obligations)**.** *For every accepted* $\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}$ *carrier*

$$P = (G, W, U, T, V, O, X, R, S, B, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}}$ *surface consists exactly of carrier admission for the gallery row, typed-window row, universe-instantiation row, typed-instantiation row, conversion-boundary row, omission-obstruction row, coverage-matrix transport row, replay row, source-provenance row, boundary row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A polymorphic example is counted only when W, U, T, V are displayed together and the omission row O records no missing instantiation-window component for that example.*

Proof. Project the accepted carrier of Definition 6883.1. The polymorphic-instantiation surface is exactly W, U, T, V: the typed window, universe substitutions, term-level instantiations, and conversion boundary.

The gallery and coverage-matrix rows G, X identify the source examples being audited. The rows O, R, S, B record omissions, bounded replay, provenance, and the separation from dependent-eliminator, conversion, proof-search, stream, and regular-rational sibling routes.

Transport, replay, package provenance, and local naming through H, C, K, N preserve the same rows. Since no row stores total dependent-eliminator coverage, full conversion closure, proof-search completeness, semantic parametricity, quotient syntax equality, host universe polymorphism, or global consistency, the listed rows exhaust the NameCert obligations. □

Theorem 6883.3 (Polymorphic-instantiation omission refutation)**.** *If a proposed typed-example coverage packet counts a polymorphic example while omitting the corresponding type argument from T, universe entry from U, typed window from W, or conversion boundary from V, then it is not accepted as a* $\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}$ *carrier. The omitted component is retained in O as a refutation of the proposed coverage count.*

Proof. Acceptance is read from the carrier rows W, U, T, V, O. A counted example must display its typed window, universe substitution, typed instantiation endpoint, and conversion boundary in the same packet.

If any one of those components is absent, the omission-obstruction row O is the only available destination for the proposed count. The replay row R may re-check displayed windows, but it cannot manufacture a missing universe, type argument, typed endpoint, or conversion boundary.

Thus a packet with such an omission fails carrier admission for the counted example, and the omission itself becomes the local refutation. □

Theorem 6883.4 (Polymorphic-instantiation sibling separation)**.** *Every accepted* PolymorphicInstantiationCoverage *read separates polymorphic instantiation from dependent-eliminator coverage, typed-conversion residuals, proof-search frontiers, stream observation, and regular-rational readback. Those consumers may cite the provenance row S, but they cannot read this packet as their own carrier or as a proof of their closure obligations.*

Proof. The provenance row S names the sibling routes, while the boundary row B records that their obligations are not discharged by the polymorphic-instantiation rows. The local carrier counts only examples whose W, U, T, V rows are displayed.

Dependent eliminators require eliminator-family rows not present here. Typed-conversion residuals require residual-frontier and endpoint rows, proof search requires search-frontier evidence, and stream or regular-rational consumers require their own observation and readback carriers.

Therefore the local packet can route citations to those siblings but cannot replace their NameCert obligations. □

Falsifiable prediction: A claimed polymorphic-instantiation coverage count that omits an instantiation-window component from W, U, T, V is refuted by the omission-obstruction row O.

Independence witness: dependent-eliminator-coverage, metacic-typed-conversion-residual-frontier, metacic-proof-search-frontier, streamname, regseqrat: these siblings carry eliminator-family rows, residual-conversion rows, proof-search rows, stream-observation rows, or regular-rational readbacks, but none carries the combined universe-instantiation, typed-window, typed-instantiation, conversion-boundary, omission, transport, replay, provenance, and local NameCert surface of $\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}$.

The future Lean TasteGate file must provide $\mathsf{Nontrivial\ PolymorphicInstantiationCoverage}^{\uparrow}$ and $\mathsf{FieldFaithful\ PolymorphicInstantiationCoverage}^{\uparrow}$ instances for the displayed rows $G, W, U, T, V, O, X, R, S, B, H, C, K$, before any positive gate may count this packet as field-faithful.

Closure status for $\mathsf{NameCert}_{\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}}$.

Constructive story: A $\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}$ packet is generated from finite typed-example gallery rows, typed windows, universe-instantiation rows, typed-instantiation endpoints, conversion boundaries, omission obstructions, coverage-matrix transport, bounded replay, sibling provenance, boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6883.1, Definition 6883.2, Definition 6883.3, and Definition 6883.4 seed the finite typed-window, universe-instantiation, conversion-boundary, omission, transport, replay, provenance, and local naming surface for polymorphic-instantiation coverage.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolymorphicInstantiationCoverage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim dependent-eliminator coverage, full conversion residual closure, proof-search completeness, stream readback closure, regular-rational completeness, semantic parametricity, quotient syntax equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, instantiation-window exactness, omission-obstruction soundness, sibling separation, transport stability, replay stability, Nontrivial evidence, and FieldFaithful evidence for BEDC.Derived.PolymorphicInstantiationCoverageUp.

Chapter 6884

A Concrete Naming Certificate for $\mathsf{UniformlySmoothSpace}^{\uparrow}$

Following Clarkson and Day, the $\mathsf{UniformlySmoothSpace}^{\uparrow}$ packet records a constructive modulus-of-smoothness surface over the normed and Banach carriers of chapter 1950 and **??**. It reads Hilbert comparison rows through chapter 91, convex balancing rows through chapter 208, and scalar tolerance rows through chapter 38. The packet names finite smoothness data for future duality, Clarkson-inequality, and constructive fixed-point routes without importing Hahn–Banach separation, weak compactness, reflexivity, or host norm equality.

Definition 6884.1 (Uniformly smooth space carrier)**.** *A* $\mathsf{UniformlySmoothSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (N, B, R, H, K, \rho, E, T, C, P, L)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormedSpace}^{\uparrow}$ *row exposing vector addition, scalar action, the norm read, and the induced metric only through the normed-space NameCert surface.*
2. *B is the* $\mathsf{BanachSpace}^{\uparrow}$ *handoff row. It allows complete-norm consumers to read the same normed carrier but does not select a completed point or identify a host Banach norm.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *row carrying positive dyadic tolerances, norm comparisons, and the scalar budgets used by the smoothness request.*
4. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *comparison row. It records the quadratic-model sibling used as a downstream check, not a declaration that the source norm comes from an inner product.*
5. *K is the* $\mathsf{ConvexSet}^{\uparrow}$ *row naming the balanced unit-ball window in which the paired perturbations are displayed.*
6. *ρ is the modulus-of-smoothness row. For every displayed positive scalar request t it carries a Real budget $\rho(t)$ together with the row*

$$\frac{\|x + ty\| + \|x - ty\|}{2} - 1 \leq \rho(t)$$

   for displayed unit rows x, y admitted by N, K, R.
7. *E is the small-scale stability row requiring the displayed ratio $\rho(t)/t$ to be transported by the same Real tolerance ledger as t is refined toward the local smoothness window.*

8. *T records componentwise* hsame *transport for $N, B, R, H, K, \rho, E, C, P, L$.*
9. *C records displayed* Cont *replay from a smoothness request through*

$$N, B, R, H, K, \rho, E \longmapsto T, P, L.$$

10. *P is the* Pkg *provenance over* $\mathsf{UniformlySmoothSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{UniformlySmoothSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for Hahn–Banach separation, weak compactness, reflexivity, host norm equality, a quotient dual, selected supporting functionals, or an ambient differentiability theorem.

Theorem 6884.2 (Uniformly smooth modulus stability)**.** *For every accepted* $\mathsf{UniformlySmoothSpace}^{\uparrow}$ *carrier $S = (N, B, R, H, K, \rho, E, T, C, P, L)$, the modulus row ρ is stable under componentwise* hsame *transport of the normed-space, Banach handoff, Real tolerance, Hilbert comparison, and convex unit-ball rows. In particular, any accepted consumer that refines the displayed scalar request t must replay the same route*

$$N, B, R, H, K, \rho, E, T, C, P, L$$

before reading the inequality row for $\rho(t)$ or the local ratio row $\rho(t)/t$.

Proof. Start from carrier admission in Definition 6884.1. The normed-space row N, Real row R, and convex unit-ball row K determine the displayed unit vectors, scalar request, and norm comparisons used in the smoothness inequality.

Transport is then componentwise. The row T carries hsame for the normed, Banach, Real, Hilbert, convex, modulus, and small-scale rows, so replacing a displayed endpoint must replace the whole modulus route rather than only the value $\rho(t)$.

Finally replay the request through C. Since E ties $\rho(t)/t$ to the same Real tolerance ledger as t, scalar refinement cannot bypass the original rows. The absent Hahn–Banach, weak-compactness, reflexivity, quotient-dual, and host equality objects therefore have no carrier coordinate from which to alter the modulus read. □

Theorem 6884.3 (Uniformly smooth NameCert obligation)**.** *For every accepted* $\mathsf{UniformlySmoothSpace}^{\uparrow}$ *carrier $S = (N, B, R, H, K, \rho, E, T, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{UniformlySmoothSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, normed-space visibility, Banach handoff, Real tolerance readback, Hilbert comparison, convex unit-ball balancing, modulus-of-smoothness inequality, small-scale ratio stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $N, B, R, H, K, \rho, E, T, C, P, L$.*

Proof. Project the carrier. The analytic rows are N, B, R, H, K, ρ, E: normed-space data, complete-norm handoff, scalar tolerance, Hilbert comparison, balanced convex window, modulus inequality, and small-scale stability.

The structural rows T, C, P, L transport, replay, source, and name those analytic rows as one finite packet. They add no supporting functional, quotient dual, weak compactness, reflexivity theorem, Hahn–Banach separation, or host norm equality.

Thus a consumer receives a smoothness certificate only by displaying all listed rows. Since the classifier has no other coordinate, the local NameCert obligation surface is exactly the finite packet described above. □

Falsifiable prediction: An accepted $\mathsf{UniformlySmoothSpace}^{\uparrow}$ read is refuted if a consumer obtains a modulus-of-smoothness inequality or a $\rho(t)/t$ stability row without first displaying the $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, transport, replay, provenance, and local NameCert rows.

Independence witness: normedspace, banachspace, hilbert, convexset, real: $\mathsf{UniformlySmoothSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries normed-space data, Banach handoff, Real tolerance budgets, Hilbert comparison, convex unit-ball balancing, a modulus-of-smoothness row, small-scale stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlySmoothSpace}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{UniformlySmoothSpace}^{\uparrow}$ packet is generated from NormedSpace rows, BanachSpace handoff rows, Real tolerance rows, Hilbert comparison rows, ConvexSet unit-ball rows, a modulus-of-smoothness row, small-scale ratio stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlySmoothSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6884.1, Definition 6884.2, and Definition 6884.3 seed the finite modulus-of-smoothness route over normed-space, Banach, Real, Hilbert, and convex unit-ball rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlySmoothSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hahn–Banach separation, weak compactness, reflexivity, host norm equality, quotient-dual construction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus inequality exactness, small-scale ratio stability, transport, replay, provenance, and local naming for BEDC.Derived.UniformlySmoothSpaceUp.

Chapter 6885

A Concrete Naming Certificate for $\mathsf{PathConnectedSpace}^{\uparrow}$

Following Hausdorff and Bishop–Bridges topology, the $\mathsf{PathConnectedSpace}^{\uparrow}$ packet records path connectedness as a finite endpoint-pair and displayed-path route over topology and continuity data. It sits beside the connectedness carrier of chapter 2353, the local comparison surface of chapter 5809, the continuity route of chapter 59, and the interval-connectedness source of chapter 4369. The certificate names the finite means by which endpoint pairs, path families, endpoint evaluations, continuous replay, and connectedness consumers are exposed without importing host path spaces, quotient path components, or selected paths.

Definition 6885.1 (PathConnectedSpace carrier)**.** *A* $\mathsf{PathConnectedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, F, V, C, G, L, H, R, P, N)$$

with the following displayed rows:

1. *E is the endpoint-pair row. It records each displayed source and target point request through the ambient* $\mathsf{Topology}^{\uparrow}$ *and names the pair before any path witness may be read.*
2. *F is the displayed path-family row. For each accepted endpoint pair it stores the finite path name, interval parameter ledger, and source-to-target scheduling row visible to consumers.*
3. *V is the endpoint-evaluation ledger. It records that the displayed path reads the left endpoint as the first point in E and the right endpoint as the second point in E.*
4. *C is the* $\mathsf{Continuous}^{\uparrow}$ *replay row for each displayed path, including the inverse-image open rows and the finite continuity evidence used by downstream readers.*
5. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *consumer route. It records that a connectedness consumer may read the path route only after the endpoint, family, endpoint-evaluation, and continuity rows have been displayed.*
6. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *comparison row. It records local connectedness as a sibling comparison surface rather than as a source of path selection.*
7. *H records componentwise* hsame *transport for endpoint pairs, displayed path families, endpoint-evaluation ledgers, continuity replay, connectedness consumers, local comparison rows, provenance, and local naming rows.*

8. *R records displayed* Cont *replay from endpoint-pair requests through the displayed path family, endpoint evaluations, continuity replay, connectedness consumer route, and local comparison row.*

9. *P is the* Pkg *provenance over* $\mathsf{PathConnectedSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{IntervalConnectedness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PathConnectedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, F, V, C, G, L, H, R, P, N$. It has no coordinate for host path spaces, quotient path components, selected paths, excluded middle, open-cover compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.PathConnectedSpaceUp.PathConnectedSpaceTasteGate single carrier alignment`

Theorem 6885.2 (PathConnectedSpace NameCert obligations)**.** *For every accepted* $\mathsf{PathConnectedSpace}^{\uparrow}$ *carrier*

$$K = (E, F, V, C, G, L, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PathConnectedSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the endpoint-pair, displayed path-family, endpoint-evaluation, continuity replay, connectedness consumer, locally connected comparison, transport, replay, provenance, and naming rows; endpoint exactness through V; path-family stability through F and H; continuous-image handoff through C; connectedness consumer routing through G; and ledger nonescape from host path spaces, quotient path components, selected paths, excluded middle, open-cover compactness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 6885.1. The projection exposes exactly the rows $E, F, V, C, G, L, H, R, P, N$, so carrier admission is exhausted by those coordinates.

Endpoint exactness is read from V. The displayed path in F is not available to a consumer until V has tied its left and right endpoint evaluations back to the ordered endpoint pair in E.

Path-family stability is transported componentwise through H. The same endpoint pair, path-family name, endpoint ledger, continuity replay, connectedness route, and local comparison row are then replayed by R and sourced by P, N.

Finally, continuous-image and connectedness consumers can inspect only C and G. Since no carrier row stores a host path space, quotient component, selected path operator, excluded-middle split, or open-cover compactness principle, none of those objects can escape the local ledger. □

Theorem 6885.3 (PathConnectedSpace continuous image route)**.** *Every continuous-image consumer of an accepted* $\mathsf{PathConnectedSpace}^{\uparrow}$ *carrier*

$$K = (E, F, V, C, G, L, H, R, P, N)$$

reads the displayed path route E, F, V, C before any $\mathsf{ConnectedSpace}^{\uparrow}$ *consumer row or* $\mathsf{IntervalConnectedness}^{\uparrow}$ *interval consumer may use the packet. The exported image route is therefore a finite continuity-and-endpoint replay, not a host-space assertion that arbitrary path components have been selected.*

Proof. Start with a continuous-image request. Carrier admission exposes the endpoint row E and the displayed path-family row F before the request reaches any connectedness consumer.

The endpoint-evaluation ledger V is then forced into the route. It binds the left and right evaluations of the displayed path to the endpoint pair already named in E.

The continuity replay row C is read next. Its inverse-image open rows and finite continuity evidence are the only data made available to an image consumer before connectedness handoff.

Only after E, F, V, C have been read may the consumer pass through G or through an interval-connectedness handoff named in P. Thus $\mathsf{ConnectedSpace}^{\uparrow}$ and $\mathsf{IntervalConnectedness}^{\uparrow}$ consume the displayed path route; they do not create a separate selected path space or quotient path-component surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{PathConnectedSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PathConnectedSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6885.1, Definition 6885.2, and Definition 6885.3 seed the finite endpoint-pair, displayed-path, continuity, connectedness-consumer, and local-comparison route over topology and interval-connectedness neighbours.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PathConnectedSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PathConnectedSpaceUp.PathConnectedSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient path components, selected paths, excluded middle, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, path-family stability, continuous-image handoff, connectedness consumer routing, and ledger nonescape for BEDC.Derived.PathConnectedSpaceUp.

Constructive story: A $\mathsf{PathConnectedSpace}^{\uparrow}$ packet is generated from endpoint pairs, displayed path families, endpoint-evaluation ledgers, Continuous replay rows, ConnectedSpace consumer routes, LocallyConnected comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Chapter 6886

A Concrete Naming Certificate for $\mathsf{TubularNeighborhood}^{\uparrow}$

Following Whitney and Hirsch on tubular neighbourhoods, the $\mathsf{TubularNeighborhood}^{\uparrow}$ packet records the finite naming surface for a submanifold, its normal bundle, a metric-controlled exponential chart, and the resulting neighbourhood image. It reads the source manifold through chapter 96 and the smooth atlas boundary through chapter 4291; it reads the bundle row through chapter 97 and the vector-bundle carrier of chapter 210; it reads the metric and exponential-chart rows through chapter 133 and chapter 142; and it reads radius and image budgets through the Real seal of chapter 38. The certificate names the displayed finite tubular route without asserting a global collar, selected closest-point projection, quotient equality of normal vectors, or ambient completeness.

Definition 6886.1 (Tubular neighborhood carrier)**.** *A* $\mathsf{TubularNeighborhood}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, N, G, E, R, U, H, C, P, L)$$

with the following displayed rows:

1. *S is the submanifold and source-manifold row, read through* $\mathsf{Manifold}^{\uparrow}$ *and* $\mathsf{SmoothManifold}^{\uparrow}$*, including the displayed inclusion data and the finite atlas windows on which the construction is inspected.*
2. *N is the normal-bundle row, read through* $\mathsf{Bundle}^{\uparrow}$ *and* $\mathsf{VectorBundle}^{\uparrow}$*, carrying the displayed fibre complement and transition compatibility data for the source row.*
3. *G is the* $\mathsf{RiemannianMetric}^{\uparrow}$ *row, exposing the metric, orthogonality, and fibre-length comparisons used to choose the visible normal window.*
4. *E is the* $\mathsf{ExpMap}^{\uparrow}$ *row, recording the finite exponential-chart request from the normal-bundle window into the ambient manifold chart.*
5. *R is the radius ledger, a* $\mathsf{Real}^{\uparrow}$ *tolerance row that bounds the visible normal vectors and records the local injectivity budget used by the displayed chart.*
6. *U is the neighbourhood image row, naming the visible image of the radius-bounded normal vectors under the exponential-chart row.*
7. *H records componentwise* hsame *transport for $S, N, G, E, R, U, C, P, L$.*

8. *C records displayed* Cont *replay from submanifold reads through the normal-bundle, metric, exponential-chart, radius, and image rows.*
9. *P is the* Pkg *provenance over* $\mathsf{TubularNeighborhood}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, $\mathsf{ExpMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{TubularNeighborhood}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a global retraction, selected nearest point, quotient normal-vector equality, trichotomy of distances, or ambient manifold completeness.

Lean4 (statement) `BEDC.Derived.TubularNeighborhoodUp.TubularNeighborhoodUp`

Theorem 6886.2 (Tubular neighborhood NameCert obligations)**.** *For every accepted* $\mathsf{TubularNeighborhood}^{\uparrow}$ *carrier $T = (S, N, G, E, R, U, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{TubularNeighborhood}^{\uparrow}}$ *surface consists exactly of carrier admission, submanifold and source-manifold visibility, normal-bundle attachment, Riemannian metric readback, exponential-chart replay, radius-ledger boundedness, neighbourhood-image exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6886.1. The source row S supplies the displayed manifold and submanifold windows, while N attaches the normal-bundle data to those same windows.

Read the analytic rows next. The metric row G supplies the orthogonality and fibre-length comparisons, the exponential-chart row E records the visible chart request, and the radius row R bounds the normal vectors before the image row U is exposed.

The structural rows H, C, P, L transport, replay, source, and name the same finite packet. Since the carrier has no row for a global retraction, selected nearest point, quotient normal-vector equality, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 6886.3 (Tubular neighborhood normal-bundle handoff)**.** *Every* $\mathsf{TubularNeighborhood}^{\uparrow}$ *consumer of the neighbourhood image row must first read the finite handoff*

$$\mathsf{Manifold}^{\uparrow}, \mathsf{Bundle}^{\uparrow}, \mathsf{RiemannianMetric}^{\uparrow}, \mathsf{ExpMap}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto S, N, G, E, R, U, H, C, P, L.$$

In particular, the normal-bundle row and metric row are visible before the exponential-chart image is consumed, and the radius ledger is visible before the image is treated as a neighbourhood.

Proof. Start from the carrier rows $S, N, G, E, R, U, H, C, P, L$. The source manifold row and normal-bundle row determine which fibre windows are eligible for the tubular request.

The metric row then fixes the finite orthogonality and length comparisons used by the request. Only after those comparisons are displayed can the exponential-chart row E replay the normal vector into the ambient manifold chart.

The radius ledger R precedes the image row U, so a consumer cannot treat U as a neighbourhood without also reading the bounded normal-window evidence. Transport and replay through H and C, together with provenance P and local naming L, keep the handoff attached to the same packet.

Thus the handoff is a finite normal-bundle route through the cited manifold, bundle, metric, exponential-map, and Real rows. It does not export a selected nearest point, global retraction, quotient normal-vector equality, trichotomy of distances, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{TubularNeighborhood}^{\uparrow}$ read is refuted if a consumer obtains the neighbourhood image row without first displaying the source-manifold row, normal-bundle row, Riemannian metric row, exponential-chart row, radius ledger, transport, replay, provenance, and local NameCert rows.

Independence witness: manifold, bundle, riemannianmetric, expmap, real: $\mathsf{TubularNeighborhood}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source manifold data, normal-bundle attachment, metric comparison, exponential-chart replay, radius boundedness, image exposure, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TubularNeighborhood}^{\uparrow}}$.

Constructive story: A $\mathsf{TubularNeighborhood}^{\uparrow}$ packet is generated from submanifold and source-manifold rows, normal-bundle rows, Riemannian metric rows, exponential-chart rows, Real radius ledgers, neighbourhood image rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TubularNeighborhood}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6886.1, Definition 6886.2, and Definition 6886.3 seed the finite normal-bundle and exponential-chart route for tubular neighbourhood consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TubularNeighborhood}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close selected nearest-point projections, global retractions, quotient equality of normal vectors, trichotomy of distances, ambient manifold completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, normal-bundle attachment, metric-radius exactness, exponential-chart replay, image nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TubularNeighborhoodUp.

Chapter 6887

A Concrete Naming Certificate for KolmogorovThreeSeriesBoundary$^{\uparrow}$

Following Kolmogorov and Feller on convergence of independent random series, the KolmogorovThreeSeriesBoundary packet records the finite tail-boundary data that a BEDC probability consumer may inspect before asking for any classical three-series conclusion. It sits after the probability substrate of chapter 184, the measurable-preimage surface of chapter 185, the pushforward law row of chapter 186, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite tail ledger for truncated random-variable reads; it does not assert almost-sure convergence, close the full three-series theorem, invoke countable choice, identify quotient distribution equality, take host probability limits, or import ambient Real$^{\uparrow}$ completeness.

Definition 6887.1 (Kolmogorov three-series boundary carrier)**.** *A* KolmogorovThreeSeriesBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (\Omega, X, D, T, V, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* ProbSpace$^{\uparrow}$ *source row carrying the event algebra, probability measure, and total-mass endpoint.*
2. X *is the finite* RandomVar$^{\uparrow}$ *family row listing the random variables whose tails are currently exposed.*
3. D *is the* Distribution$^{\uparrow}$ *pushforward row for the displayed variables and their truncation events.*
4. T *is the finite tail-threshold row, naming the truncation windows and tail events inspected by the packet.*
5. V *is the truncated-variance ledger row, recording only the displayed second-moment windows attached to* T*.*
6. M *is the truncated-mean ledger row, recording only the displayed expectation windows attached to* T*.*
7. R *is the* RegSeqRat$^{\uparrow}$ *readback row for the finite probability, mean, and variance windows.*
8. E *is the terminal* Real$^{\uparrow}$ *seal row reached after the regular rational readbacks are displayed.*
9. H *records componentwise* hsame *transport for probability, random-variable, distribution, threshold, mean, variance, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a tail-boundary request through the finite threshold, readback, and seal rows.*
11. *P is the* Pkg *provenance over* $\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for almost-sure convergence, the full three-series theorem, countable choice, quotient equality of distributions, host probability limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6887.2 (Kolmogorov three-series boundary NameCert obligations)**.** *For every accepted* $\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}$ *carrier*

$$K = (\Omega, X, D, T, V, M, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed probability source, finite random-variable family, pushforward distribution rows, truncation-threshold ledger, truncated variance ledger, truncated mean ledger, regular rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming; threshold stability requiring T, V, M to remain attached to the same displayed variables and distributions under* hsame*; readback exactness requiring R, E to be consumed only after the finite tail windows have been displayed; and ledger refusal excluding almost-sure convergence, the full three-series theorem, countable choice, quotient distribution equality, host probability limits, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the accepted packet.*

Proof. Project the carrier of Definition 6887.1. The source probability row, finite random-variable family, pushforward distribution rows, truncation thresholds, truncated variance rows, truncated mean rows, readback, seal, transport, replay, provenance, and local name are separate finite rows of the same BHist packet.

Carrier admission reads Ω, X, D, T, V, M before any Real-facing endpoint is exposed. The sibling chapters named above supply only displayed probability, measurable-preimage, pushforward, regular-readback, and Real-seal rows, so the admission route remains finite.

Threshold stability is componentwise. Transport through H preserves the same variable family, distribution row, threshold window, mean ledger, and variance ledger before R repacks the visible numbers as $\mathsf{RegSeqRat}^{\uparrow}$ data.

Finally C, P, N replay, source, and name the same route. Since no row supplies convergence, a completed three-series theorem, countable choice, quotient distribution equality, host probability limits, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6887.3 (Kolmogorov three-series boundary finite tail route)**.** *Every probability-limit consumer of an accepted* $\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{ProbSpace}^{\uparrow} \longmapsto \mathsf{RandomVar}^{\uparrow} \longmapsto \mathsf{Distribution}^{\uparrow} \longmapsto T, V, M \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before treating a tail-boundary endpoint as public. The route exports exactly the displayed probability source, random-variable family, pushforward law, truncation thresholds, truncated mean and variance ledgers, regular rational readback, terminal Real seal, componentwise transport, continuation replay, provenance, and local naming; it exports no almost-sure convergence theorem, no full three-series theorem closure, no countable-choice schedule, no quotient distribution equality, no host probability limit, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations above. They force every accepted read through $\Omega, X, D, T, V, M, R, E, H, C, P, N$ before a consumer may inspect a Real-facing tail endpoint.

Use the sibling dependency route. The $\mathsf{ProbSpace}^{\uparrow}$ row supplies the source measure, $\mathsf{RandomVar}^{\uparrow}$ supplies measurable preimages for the displayed variables, $\mathsf{Distribution}^{\uparrow}$ supplies the pushforward law row, $\mathsf{RegSeqRat}^{\uparrow}$ supplies finite numerical readback, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal.

The finite tail route is therefore just row projection and dependency composition. A consumer can pass from the probability source to the Real-facing endpoint only through the displayed truncation, mean, and variance ledgers, and no carrier coordinate remains for the refused convergence, choice, quotient, host-limit, or completeness objects. □

Falsifiable prediction: Every accepted $\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}$ read displays a ProbSpace source row, finite RandomVar family row, Distribution pushforward row, finite tail-threshold row, truncated variance and mean ledgers, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: probspace, randomvar, distribution, regseqrat, real: $\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}$ is not bijective to any listed sibling because it binds probability source data, finite random-variable tails, pushforward distribution rows, truncation thresholds, truncated mean and variance ledgers, regular rational readback, and a terminal Real seal into one finite tail-boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6887.1, Definition 6887.2, and Definition 6887.3 seed the finite probability-source, random-variable, distribution, truncation-threshold, truncated-mean, truncated-variance, readback, Real-seal, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure convergence, the full three-series theorem, countable choice, quotient distribution equality, host probability limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold stability, truncated mean and variance readback, finite tail-route exactness, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KolmogorovThreeSeriesBou

Constructive story: A $\mathsf{KolmogorovThreeSeriesBoundary}^{\uparrow}$ packet is generated from a probability source row, finite random-variable family row, pushforward distribution row, finite tail-threshold row, truncated variance and mean ledgers, regular rational readback, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6888

A Concrete Naming Certificate for $\mathsf{AumannIntegralBoundary}^{\uparrow}$

Following Aumann on integrals of set-valued maps, the $\mathsf{AumannIntegralBoundary}^{\uparrow}$ packet records the finite NameCert boundary at which a set-valued integral can be read without importing a host measurable-selection principle. It sits after the measurable ledger of chapter 92, the scalar readback surface of chapter 123, the convex-value carrier of chapter 208, the observable random input surface of chapter 185, and the target normed carrier of chapter 90. The packet names a finite boundary for downstream probability and optimization readers: it exposes displayed selection rows and their integrals, but it does not claim a global measurable-selection theorem, quotient equality of selections, countable choice, or ambient measure completion.

Definition 6888.1 (Aumann integral boundary carrier)**.** *An* $\mathsf{AumannIntegralBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, R, X, V, G, S, K, L, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row whose measurable-event ledger bounds every domain-side read.*
2. *R is the* $\mathsf{RandomVar}^{\uparrow}$ *observation row carrying the displayed random input, measurable preimage tests, and observable classifier.*
3. *X is the source measurable-space row on which the set-valued map is inspected.*
4. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *value row, recording nonempty convex fibres and their finite membership tests.*
5. *G is the measurable graph row, displaying the finite graph tests that relate source observations in X, R to value candidates in V.*
6. *S is the displayed finite selection ledger. Its entries are finite rows*

   $$(s_i, \gamma_i, \mu_i, \iota_i)_{i \in I}$$

   where each s_i is a named selection candidate, γ_i is its graph-admission witness through G, μ_i is its measurable-read witness through M, R, X, and ι_i is its integral-read token.
7. *K is the convex-value stability row, recording that every displayed selection value remains inside the named convex fibre of V and that finite convex combinations preserve the same value boundary.*

8. *L is the integral readback row, reducing each ι_i to the finite scalar or vector integral data already accepted by* $\mathsf{Integral}^{\uparrow}$.
9. *B is the* $\mathsf{Banach}^{\uparrow}$ *target row in which the displayed integral endpoints and norm comparisons are read.*
10. *H records componentwise* hsame *transport for $M, R, X, V, G, S, K, L, B$ and the structural rows.*
11. *C records displayed* Cont *replay of the route*

$$M, R, X, V, G \longmapsto S \longmapsto K, L \longmapsto B.$$

12. *P is the* Pkg *provenance over* $\mathsf{AumannIntegralBoundary}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{AumannIntegralBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed measure, random-variable, source, convex-value, measurable-graph, finite-selection, convex-stability, integral-readback, Banach-target, transport, replay, provenance, and local naming rows.

Theorem 6888.2 (Aumann integral boundary NameCert obligations)**.** *For every accepted* AumannIntegralBoundary *carrier*

$$A = (M, R, X, V, G, S, K, L, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AumannIntegralBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure row, random-variable row, source row, convex-value row, measurable graph row, displayed finite selection ledger, convex-value stability row, integral readback row, Banach target row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through N. Every public set-valued integral read must pass through G, S, K, L, B before it names an endpoint or boundary verdict.*

Proof. Project the carrier of Definition 6888.1. The dependency rows M, R, X, V provide the measure, random-variable, source, and convex-value data on which the boundary is interpreted.

The theorem-facing rows are G, S, K, L, B. The graph row G admits only displayed graph tests, the finite ledger S lists the selection candidates that are actually inspected, the convex row K keeps their values inside the displayed fibres, the integral row L reads their accepted integrals, and the Banach row B names the endpoint and norm comparisons.

Transport and replay do not add analytic content. The rows H, C, P, N preserve, replay, source, and name exactly the same finite route, so the local certificate has no projection to a global measurable-selection theorem, quotient equality of selections, countable choice, or ambient measure completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{AumannIntegralBoundary}^{\uparrow}}$.

Constructive story: An $\mathsf{AumannIntegralBoundary}^{\uparrow}$ packet is generated from displayed measure, random-variable, source, convex-value, measurable-graph, finite-selection, convex-stability, integral-readback, Banach-target, transport, replay, provenance, and local naming rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AumannIntegralBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 6888.1 and Definition 6888.2 seed the finite set-valued integral boundary through displayed selection ledgers and Banach integral readbacks.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AumannIntegralBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a global measurable-selection theorem, quotient equality of selections, countable choice, ambient measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, measurable graph exactness, finite selection ledger exactness, convex-value stability, integral readback, Banach target preservation, transport stability, and replay stability for BEDC.Derived.AumannIntegralBoundaryUp.

Chapter 6889

A Concrete Naming Certificate for $\mathsf{CompactRegularRealFunction}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CompactRegularRealFunction}^{\uparrow}$ packet names a real-valued function on a displayed compact metric source by a finite regular approximation surface rather than by a host function quotient. It sits after the compact metric carrier of chapter 129, the continuous-map carrier of chapter 130, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the locally convex functional-analysis source route of chapter 3386. The packet gives compact/continuous and completion-facing routes a finite real-function carrier; it does not assert open-cover compactness, choice of covers, quotient real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6889.1 (Compact regular real-function carrier)**.** *A* $\mathsf{CompactRegularRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, C, W, R, E, L, H, Q, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *and naming only the compact carrier data visible to chapter 129.*
2. *C is the continuous-map row, read through* $\mathsf{ContinuousMap}^{\uparrow}$ *and exposing the domain, codomain, continuity witness, and modulus-facing data used by the packet.*
3. *W is the finite stream-window row, read through* $\mathsf{StreamName}^{\uparrow}$ *and recording the inspected source windows and output-name windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *output readback row for the regular rational approximants attached to those windows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W and R have displayed the regular output name.*
6. *L is the local regularity ledger, recording the compact-window tolerance request, the displayed regular schedule, and the refusal to choose an open-cover subcover or a quotient representative of the function.*
7. *H records componentwise* hsame *transport for K, C, W, R, E, L and the structural rows.*
8. *Q records displayed* Cont *replay from compact-window requests through the stream windows, regular readbacks, Real seal, and local regularity ledger.*

9. *P records* Pkg *provenance over* $\mathsf{CompactRegularRealFunction}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRegularRealFunction}^{\uparrow}}$ *row.*

The classifier compares packets only through $K, C, W, R, E, L, H, Q, P, N$. It has no coordinate for open-cover compactness, selected finite subcovers, quotient equality of real functions, countable choice, a hidden function-space completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6889.2 (Compact regular real-function NameCert obligations)**.** *For every accepted* $\mathsf{CompactRegularRealFunction}^{\uparrow}$ *carrier $F = (K, C, W, R, E, L, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactRegularRealFunction}^{\uparrow}}$ *surface consists exactly of compact metric source exposure, continuous-map exposure, stream-window exposure, regular rational output readback, Real seal routing, local regularity-ledger visibility, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6889.1. The compact source row K and continuous-map row C determine the displayed domain and continuity surface, while W, R, E are the only path from a requested output window to a sealed real name.

The local regularity ledger L records the compact-window tolerance schedule inspected by the packet. It is a displayed finite row, so it cannot choose an open cover, select a hidden subcover, or replace regular output names by quotient real equality.

Transport, replay, provenance, and local naming through H, Q, P, N preserve the same rows. Since no other coordinate is present, the listed rows exhaust the NameCert obligations. □

Theorem 6889.3 (Compact regular real-function Real-seal handoff)**.** *Every Real-facing read from an accepted* $\mathsf{CompactRegularRealFunction}^{\uparrow}$ *packet must pass through the stream-window row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *output readback row R, and the* $\mathsf{Real}^{\uparrow}$ *seal row E before it is visible to compact/continuous or functional-analysis consumers. The handoff exports only the sealed output route for displayed compact windows; it does not assert* $\mathsf{Real}^{\uparrow}$ *completeness or quotient equality of real-valued functions.*

Proof. The carrier presents W, R, E in that order. A consumer asking for real output data first receives the finite stream windows named by $\mathsf{StreamName}^{\uparrow}$, then the regular rational readback named by $\mathsf{RegSeqRat}^{\uparrow}$, and only then the terminal $\mathsf{Real}^{\uparrow}$ seal.

The compact metric and continuous-map rows K, C identify the source of the request, but they do not supply a real output by themselves. The regularity ledger L records the displayed schedule connecting the compact window to the output route.

Thus every Real-facing handoff is mediated by W, R, E, L and then preserved through H, Q, P, N. No row supplies ambient completeness of $\mathsf{Real}^{\uparrow}$, a selected limit, or quotient equality of functions. □

Falsifiable prediction: Every accepted $\mathsf{CompactRegularRealFunction}^{\uparrow}$ read exposes compact metric source data, continuous-map data, stream windows, RegSeqRat output readback, RealUp seal, local regularity ledger, transport, replay, provenance, and local naming before any compact real-function value is public.

Independence witness: compactmetric, continuousmap, streamname, regseqrat, real, locally-convex-space: these siblings carry compact source data, continuous-map data, stream windows, regular rational readbacks, Real seals, or locally convex functional-analysis routes, but none carries the combined compact source, regular real-output, local regularity, transport, replay, provenance, and local NameCert surface of $\mathsf{CompactRegularRealFunction}^{\uparrow}$.

The Lean follow-up in `lean4/BEDC/Derived/CompactRegularRealFunctionUp.lean` should expose `BEDC.Derived.CompactRegularRealFunctionUp` without adding open-cover compactness, countable choice, quotient real equality, selected function representatives, or ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRegularRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRegularRealFunction}^{\uparrow}$ packet is generated from compact metric source rows, continuous-map rows, stream windows, regular rational output readbacks, a RealUp seal, a local regularity ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRegularRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6889.1, Definition 6889.2, and Definition 6889.3 seed the finite compact regular real-function route over compact source, continuous-map, stream-window, regular-readback, Real-seal, regularity-ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRegularRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected finite subcovers, quotient equality of real-valued functions, countable choice, Lean verification, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, continuous-map exposure, stream-window exposure, regular-rational readback, Real-seal routing, local regularity-ledger stability, transport, replay, provenance, Nontrivial evidence, and FieldFaithful evidence for BEDC.Derived.CompactRegularRealFunctionUp.

Chapter 6890

A Concrete Naming Certificate for $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$

The $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$ packet realizes the decidability frontier of chapter 9386 as a finite closed-term fragment rather than as an unrestricted conversion theorem. It reads the positive checker surface of chapter 9379, the candidate-mediated normalization route of chapter 9383, the typed-normalization audit of chapter 3539, the typed-examples gallery of chapter 775, the bounded normal-conversion bridge of chapter 3439, and the typed-conversion residual frontier of chapter 6069. The packet keeps closed-term typing, bounded-normal endpoints, finished-normal witnesses, and obstruction rows visible before any local decidability read is accepted.

Definition 6890.1 (MetaCIC closed typing fragment carrier)**.** *A* $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, J, B, F, O, X, R, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed-term row, listing the finite closed MetaCIC terms and contexts inspected by the packet.*
2. *J is the type-checker row, recording the option-valued typing or rejection judgement accepted at the decidability audit interface.*
3. *B is the bounded-normal endpoint row, exposing the bounded normalizer output and fuel boundary used by the local check.*
4. *F is the finished-normal witness row, present only when the bounded endpoint has been sealed as a finished closed normal form.*
5. *O is the obstruction row, retaining missing closedness evidence, missing finished-normal evidence, subject-reduction boundaries, confluence residuals, and conversion-frontier failures.*
6. *X is the transport row from the decidability audit map, normalization audit map, typed-normalization packet, typed-examples gallery, bounded bridge, and residual frontier into the local fragment.*
7. *R is the replay row, recording bounded re-checks of T, J, B, F, O without claiming an unrestricted closed-term beta-conversion decider.*
8. *S is the provenance row separating the checker, normalization, gallery, endpoint-bridge, residual-frontier, and open-problem sources.*

9. *H records componentwise* hsame *transport for T, J, B, F, O, X, R, S and the structural rows.*
10. *C records displayed* Cont *replay from a local closed-typing request through the checker, endpoint, obstruction, transport, replay, provenance, and naming rows.*
11. *P records* Pkg *provenance over* $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$, $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$, $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$, $\mathsf{MetaCICTypedConversionResidualFrontier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetacicClosedTypingFragment}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, J, B, F, O, X, R, S, H, C, P, N$. It has no coordinate for a global closedness decider, unrestricted beta-conversion decidability, unconditional normalization, unconditional confluence, erased subject-reduction discharge, quotient syntax equality, or host consistency.

Theorem 6890.2 (MetaCIC closed typing fragment NameCert obligations)**.** *For every accepted* $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$ *carrier $M = (T, J, B, F, O, X, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetacicClosedTypingF}}$ *surface consists exactly of closed-term exposure, type-checker exposure, bounded-normal endpoint exposure, finished-normal witness exposure when present, obstruction retention, audit-map transport, bounded replay, provenance separation, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6890.1. The rows T and J are the closed-term and checker-facing surface, while B and F name the bounded endpoint and finished-normal evidence that the decidability frontier requires.

The obstruction row O is retained in the same packet. It records when closedness, finished-normal evidence, subject reduction, confluence residuals, or conversion endpoints are not available, so the checker rows cannot be read as a global conversion theorem.

Rows X, R, S, H, C, P, N transport, replay, source, preserve, and name the same finite surface. Since no coordinate stores global closedness decision, unrestricted beta-conversion, unconditional normalization, unconditional confluence, quotient syntax equality, or host consistency, the listed rows exhaust the NameCert obligations. □

Theorem 6890.3 (MetaCIC closed typing fragment decidable boundary)**.** *Every accepted* MetacicClosedTypingFrag *read separates the local closed-typing checker result from unrestricted closed-term beta-conversion decidability. A local positive typing row may be consumed only together with its bounded-normal endpoint, finished-normal witness status, obstruction row, transport, replay, provenance, and local naming rows.*

Proof. The checker row J is local to the displayed closed-term row T. It does not contain a theorem deciding closedness for arbitrary terms or beta-conversion for all closed typed inputs.

The endpoint rows B, F show exactly where bounded normal computation has reached a finished normal form. If that evidence is absent or blocked, the obstruction row O remains visible and prevents promotion to an unrestricted conversion result.

Transport and replay through X, R, H, C, P, N preserve this boundary. Therefore the packet can expose a finite decidability fragment while refusing global closedness, conversion, normalization, confluence, subject-reduction, quotient-syntax, or consistency claims. □

Falsifiable prediction: Every accepted $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$ read exposes closed-term typing, bounded-normal endpoint, finished-normal witness, obstruction, transport, replay, provenance, and local naming rows before any decidability claim.

Independence witness: metacic-open-problem-ledger, bounded-normal-conversion-bridge, metacic-conversion-endpoint-seal, metacic-typed-conversion-residual-frontier: these routes carry the open ledger, endpoint bridge, endpoint seal, or residual frontier, but none carries the combined closed-term, checker, bounded endpoint, finished-normal, obstruction, transport, replay, provenance, and local NameCert surface of $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$.

The Lean follow-up in `lean4/BEDC/Derived/MetacicClosedTypingFragmentUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ MetacicClosedTypingFragment}^{\uparrow}$ and $\mathsf{FieldFaithful\ MetacicClosedTypingFragment}^{\uparrow}$ instances preserving $T, J, B, F, O, X, R, S, H, C, P, N$ before any positive gate may treat this packet as field-faithful.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicClosedTypingFragment}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicClosedTypingFragment}^{\uparrow}$ packet is generated from finite closed-term rows, checker rows, bounded-normal endpoints, finished-normal witnesses, obstruction rows, audit-map transport, bounded replay, provenance separation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicClosedTypingFragment}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6890.1, Definition 6890.2, and Definition 6890.3 seed the finite closed-typing fragment route over closed terms, checker output, bounded endpoints, finished-normal witnesses, obstructions, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicClosedTypingFragment}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global closedness decider, unrestricted closed-term beta-conversion decidability, unconditional normalization, unconditional confluence, erased subject-reduction discharge, quotient syntax equality, Lean verification, host consistency, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-term exposure, checker exposure, bounded-normal endpoint exposure, finished-normal witness stability, obstruction retention, transport, replay, provenance, Nontrivial evidence, and FieldFaithful evidence for BEDC.Derived.MetacicClosedTypingFragmentUp.

Chapter 6891

A Concrete Naming Certificate for $\mathsf{HitMissConvergence}^{\uparrow}$

Following Kelley and Kuratowski on hit–miss hyperspace convergence, the $\mathsf{HitMissConvergence}^{\uparrow}$ packet records the finite BEDC surface by which a hyperspace or cluster-set consumer reads hit and miss convergence data without importing an ambient host hyperspace topology. It sits between the hit–miss classifier of chapter 1660, the Vietoris route of chapter 2375, the Kuratowski convergence consumer of chapter 6591, the compact-metric support of chapter 129, the metric source of chapter 57, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence interface only; it is not a selected closed-set limit, a quotient hyperspace equality, a host Vietoris topology, or a compactness theorem.

Definition 6891.1 (Hit–miss convergence carrier)**.** *A* $\mathsf{HitMissConvergence}^{\uparrow}$ *carrier is a tuple*

$$H = (L, M, V, K, D, R, E, T, C, P, N)$$

with the following finite rows.

1. *L is the finite hit ledger, listing the displayed source cells, target neighbourhood probes, and witnessed hits used by the convergence read.*
2. *M is the finite miss ledger, listing the displayed closed or compact avoidance probes and their witnessed exclusions.*
3. *V is the* $\mathsf{VietorisTopology}^{\uparrow}$ *route through which hit and miss rows are interpreted before any hyperspace-facing consumer can read them.*
4. *K is the* $\mathsf{KuratowskiConvergence}^{\uparrow}$ *route that consumes the same hit and miss rows as finite convergence evidence.*
5. *D records compact and metric support from* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$*, including the finite ball or compact-source names on which the hit and miss ledgers are checked.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback row for displayed radius and stage bounds.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal for real-valued tolerance endpoints reached only after R has been displayed.*
8. *T is componentwise* hsame *transport through L, M, V, K, D, R, E.*
9. *C is displayed* Cont *replay for the same finite route.*

10. *P is* Pkg *provenance over* $\mathsf{HitMissConvergence}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{KuratowskiConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HitMissConvergence}^{\uparrow}}$ *row naming exactly this carrier surface.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host powerset, selected closed-set limit, quotient equality of hyperspace points, open-cover compactness object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 (statement) `BEDC.Derived.HitMissConvergenceUp`

Theorem 6891.2 (Hit–miss convergence NameCert obligations)**.** *For every accepted* $\mathsf{HitMissConvergence}^{\uparrow}$ *carrier $H = (L, M, V, K, D, R, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HitMissConvergence}^{\uparrow}}$ *surface consists exactly of finite hit-ledger admission through L; finite miss-ledger admission through M; Vietoris routing through V; Kuratowski convergence routing through K; compact and metric support through D; regular-rational tolerance readback through R; real tolerance sealing through E; componentwise* hsame *transport through T; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6891.1. The rows $L, M, V, K, D, R, E, T, C, P, N$ are exactly the hit, miss, Vietoris, Kuratowski, support, tolerance, transport, replay, provenance, and naming coordinates.

The hit and miss ledgers are finite before either route can be read. The Vietoris route V supplies the hyperspace-facing interpretation, while the Kuratowski route K consumes the same finite evidence as convergence data.

The support and tolerance rows D, R, E keep the route inside compact-metric, metric, regular-rational, and real-seal data already displayed in the packet. Transport, replay, provenance, and local naming preserve that same finite route, so the listed rows exhaust the local certificate surface. □

Theorem 6891.3 (Hit–miss convergence Kuratowski route)**.** *Every* $\mathsf{KuratowskiConvergence}^{\uparrow}$ *or Kuratowski cluster-set consumer that reads an accepted* $\mathsf{HitMissConvergence}^{\uparrow}$ *packet must first expose the finite hit ledger L, the finite miss ledger M, the* $\mathsf{VietorisTopology}^{\uparrow}$ *route V, the compact and metric support row D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback R, the* $\mathsf{Real}^{\uparrow}$ *seal E, and the structural rows T, C, P, N. The consumer receives a finite hit–miss convergence route and not a host hyperspace topology, selected closed-set limit, quotient equality, open-cover compactness proof, or ambient real completeness principle.*

Proof. Begin with Definition 6891.2. It fixes the accepted read to the displayed finite rows and leaves no coordinate for a host hyperspace object or selected limit.

The Kuratowski route K can consume hit–miss data only after L and M have been displayed and interpreted through V. The compact-metric and metric support row D supplies the named source cells, while R and E seal the tolerance endpoints.

Finally the structural rows T, C, P, N transport, replay, source, and name the same route. Thus every Kuratowski-facing read factors through the finite hit–miss interface and cannot export any of the refused host, quotient, compactness, or completeness endpoints. □

Falsifiable prediction: Every accepted $\mathsf{HitMissConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{KuratowskiConvergence}^{\uparrow}$ read without first exposing the finite hit ledger, finite miss ledger, Vietoris route, compact/metric support, tolerance readback, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: hyperspace, vietoris, kuratowski, compactmetric, metric, regseqrat, real: none is bijective with $\mathsf{HitMissConvergence}^{\uparrow}$ because this carrier alone binds finite hit and miss ledgers to the Kuratowski-facing convergence route while retaining the support, tolerance, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HitMissConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{HitMissConvergence}^{\uparrow}$ packet is generated from finite hit ledgers, finite miss ledgers, a Vietoris route, a Kuratowski convergence route, compact and metric support, RegSeqRat tolerance readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HitMissConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6891.1, Definition 6891.2, and Definition 6891.3 seed the finite hit–miss convergence interface for hyperspace and Kuratowski consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HitMissConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected closed-set limits, quotient hyperspace equality, host Vietoris topology, open-cover compactness, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite hit and miss ledger exactness, Vietoris route preservation, Kuratowski route preservation, compact/metric support exactness, RegSeqRat and Real tolerance sealing, transport, replay, provenance, and local naming for BEDC.Derived.HitMissConvergenceUp.

Chapter 6892

A Concrete Naming Certificate for $\mathsf{IntervalBisectionSearch}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{IntervalBisectionSearch}^{\uparrow}$ packet records the finite bisection-search surface for a located real interval whose endpoint signs, apartness data, dyadic midpoint rows, and shrinking brackets are inspected before a regular Cauchy readback or terminal real seal is consumed. It sits beside the dyadic rational carrier of chapter 291, the finite stream-window source of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located endpoint ledger of chapter 394. The packet names constructive interval bisection search as displayed BEDC rows; it is not host real trichotomy, not a selected root, not quotient real equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6892.1 (Interval bisection search carrier)**.** *An* $\mathsf{IntervalBisectionSearch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, M, A, L, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row, exposing located lower and upper endpoint names, endpoint comparison budgets, and interval membership rows.*
2. *M is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint row, recording the dyadic midpoint request, its endpoint placement witnesses, and the finite tolerance ledger used to split the current bracket.*
3. *A is the sign and apartness witness row. It records the finite sign-read or apartness-read data used to retain one child bracket without invoking real trichotomy.*
4. *L is the shrinking bracket ledger, listing the retained located interval at each inspected bisection stage together with the displayed diameter or tolerance decrease row.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row obtained from the retained bracket endpoints at the requested precisions.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the midpoint or retained-endpoint schedule selected by the finite ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, M, A, L, S, R have been displayed.*
8. *H stores componentwise* hsame *transport for located endpoints, midpoint rows, sign or apartness witnesses, bracket ledgers, stream windows, regular readback, Real seal, replay, provenance, and local naming.*

9. *C stores displayed* Cont *replay of the bisection-search request through* $I, M, A, L, S, R, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{IntervalBisectionSearch}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalBisectionSearch}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite bisection-search history. It has no coordinate for a host root selector, unrestricted sign trichotomy, quotient equality of real names, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6892.2 (Interval bisection search NameCert obligations)**.** *For every accepted* $\mathsf{IntervalBisectionSearch}^{\uparrow}$ *carrier* $B = (I, M, A, L, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntervalBisectionSearch}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the located interval row, dyadic midpoint row, sign or apartness witness row, shrinking bracket ledger, stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming;*
2. *classifier stability under componentwise* hsame *transport of* I, M, A, L, S, R, E*;*
3. *midpoint exactness, requiring every retained child bracket to cite the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint row before it is inspected;*
4. *sign and apartness locality, requiring every branch decision to be read from A and not from host trichotomy of real values;*
5. *bracket shrinkage, requiring the ledger L to expose a smaller located interval or tighter tolerance row at each accepted stage;*
6. $\mathsf{StreamName}^{\uparrow}$ *window exposure using only retained endpoint windows from L;*
7. $\mathsf{RegSeqRat}^{\uparrow}$ *readback from the same retained windows or midpoint schedule;*
8. $\mathsf{Real}^{\uparrow}$ *seal nonescape through* S, R, E*;*
9. *displayed* Cont *replay and* Pkg *provenance for the whole route;*
10. *ledger refusal for any consumer that omits a located endpoint, midpoint, sign or apartness, shrinking bracket, stream window, regular readback, Real seal, transport, replay, provenance, or local naming row.*

Proof. Project the carrier of Definition 6892.1. The visible rows are exactly $I, M, A, L, S, R, E, H, C, P, N$, and the packet has no hidden coordinate for a host root selector, real trichotomy, quotient equality, selected limit, or completeness theorem.

The classifier is rowwise. Componentwise hsame transport preserves the located interval, midpoint, sign or apartness, bracket ledger, stream, readback, and seal rows together, so a transported bisection-search read remains inside the same finite route.

Midpoint exactness and branch locality are read from M and A. The midpoint row is the only split source, and the sign or apartness row is the only branch-retention source, so the carrier cannot replace them by a host comparison of real values.

The readback obligations follow from L, S, R, E. The shrinking bracket ledger fixes the retained windows, the stream row exposes finite endpoint observations, the regular rational row repacks the same observations, and the Real seal is terminal. Repacking with H, C, P, N gives the stated local NameCert surface. □

Theorem 6892.3 (Interval bisection search L10 handoff)**.** *Every Real-and-Completion consumer reading an accepted* $\mathsf{IntervalBisectionSearch}^{\uparrow}$ *carrier must pass through the finite L10 route*

$$\mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Concretely, the consumer first reads the located endpoint row I, then the dyadic midpoint and sign-apartness rows M, A, then the shrinking bracket ledger L, then the stream and regular rational readback rows S, R, and only then the terminal Real seal E. The handoff exports no host real equality, selected root, quotient stream equality, unrestricted sign trichotomy, chosen limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier $B = (I, M, A, L, S, R, E, H, C, P, N)$. The source interval is displayed by I, so every endpoint or membership read begins in the $\mathsf{LocatedInterval}^{\uparrow}$ row.

Next read the bisection rows. The dyadic midpoint row M and the sign or apartness row A determine the retained child bracket as finite BEDC evidence, while L records the shrinking bracket history that downstream consumers may inspect.

Then pass to L10 readback. The finite windows S and regular rational row R are built only from the retained bracket ledger, and the terminal seal E is read only after those rows are present.

Finally replay the route through H, C, P, N. These structural rows transport, replay, source, and name the same finite packet, so none of the refused host-level or completion-level claims can be exported by the bisection-search handoff. □

Falsifiable prediction: Every accepted $\mathsf{IntervalBisectionSearch}^{\uparrow}$ consumer must expose located endpoints, dyadic midpoint data, sign or apartness witnesses, shrinking bracket rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert naming before using a bisection-search result.

Independence witness: locatedinterval, dyadicratcore, streamname, regseqrat, real: no listed sibling alone supplies the joint packet containing located endpoint rows, dyadic midpoint splitting, sign or apartness branch retention, shrinking bracket ledger, finite windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalBisectionSearch}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalBisectionSearch}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6892.1, Definition 6892.2, and Definition 6892.3 seed the finite bisection-search route over located interval endpoints, dyadic midpoint rows, sign or apartness witnesses, shrinking brackets, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalBisectionSearch}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close root existence, root uniqueness, host real trichotomy, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint exactness, sign and apartness locality, bracket shrinkage, L10 readback, transport, replay, provenance, and local naming for BEDC.Derived.IntervalBisectionSearchUp.

Constructive story: An $\mathsf{IntervalBisectionSearch}^{\uparrow}$ packet is generated from a located interval source, dyadic midpoint rows, sign or apartness branch witnesses, a shrinking bracket ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6893

A Concrete Naming Certificate for $\mathsf{OstrowskiCompletion}^{\uparrow}$

Following Bourbaki and Artin on valuations and absolute-value completions, the $\mathsf{OstrowskiCompletion}^{\uparrow}$ packet records the finite boundary at which a displayed field source may be routed to an Archimedean or non-Archimedean completion-facing certificate. It sits between the prime-scale p-adic row of chapter 100, the local-field boundary of chapter 173, the dyadic valuation row of chapter 2106, the completion-functor surface of chapter 423, and the terminal real-name seal of chapter 38. The packet names only displayed absolute-value, valuation-choice, Cauchy-window, seal, transport, replay, provenance, and local naming rows; it does not quotient completions, select limits, identify host fields, invoke trichotomy beyond the displayed branch row, or import choice.

Definition 6893.1 (Ostrowski completion carrier)**.** *An* $\mathsf{OstrowskiCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (F, A, V, B, W, S, H, C, P, N)$$

with the following displayed rows:

1. *F is the source field row, including the finite arithmetic operations and equality classifier visible to the completion request.*
2. *A is the absolute-value row, displaying positivity, multiplicativity, and triangle-control data only as BEDC history.*
3. *V is the valuation-facing branch row, distinguishing the Archimedean route from the non-Archimedean route without exporting a host dichotomy.*
4. *B records the boundary handoff to the* $\mathsf{Padic}^{\uparrow}$*,* $\mathsf{LocalField}^{\uparrow}$*, and* $\mathsf{DyadicValuation}^{\uparrow}$ *siblings when the displayed branch is non-Archimedean.*
5. *W is the finite Cauchy-window ledger consumed before any completion-facing read may inspect the source.*
6. *S is the completion seal row, routed through* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *or local-field seal already displayed by the packet.*
7. *H records componentwise* hsame *transport for the source, absolute-value row, branch row, boundary handoff, Cauchy-window ledger, completion seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a completion request through $F, A, V, B, W, S, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{OstrowskiCompletion}^{\uparrow}$, $\mathsf{Padic}^{\uparrow}$, $\mathsf{LocalField}^{\uparrow}$, $\mathsf{DyadicValuation}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{OstrowskiCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient Cauchy classes, selected representatives, a completed host field, a global classification theorem, countable choice, or equality between Archimedean and non-Archimedean models.

Theorem 6893.2 (Ostrowski completion NameCert obligations)**.** *For every accepted* $\mathsf{OstrowskiCompletion}^{\uparrow}$ *carrier*

$$O = (F, A, V, B, W, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OstrowskiCompletion}^{\uparrow}}$ *surface consists exactly of source-field exposure, absolute-value row exposure, valuation-branch exposure, non-Archimedean sibling handoff, finite Cauchy-window admission, completion-seal routing, componentwise transport, displayed continuation replay, package provenance, and local naming. Every completion-facing consumer must display F, A, V, W before it may read the seal row S, and any non-Archimedean read of S must also display the sibling boundary row B.*

Proof. Project the carrier of Definition 6893.1. The displayed rows are precisely the source field, absolute-value row, valuation branch, sibling handoff, Cauchy-window ledger, completion seal, and structural rows.

The absolute-value and branch obligations are supplied by A and V. The row A records the finite algebraic and triangle-control data read by a completion request, while V records which completion route is visible without adding an external classification principle.

The completion handoff is then bounded by B, W, S. The non-Archimedean route must pass through the displayed $\mathsf{Padic}^{\uparrow}$, $\mathsf{LocalField}^{\uparrow}$, and $\mathsf{DyadicValuation}^{\uparrow}$ boundary row B; every route must pass through the finite Cauchy-window ledger W before the seal row S can be consumed through $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ and the relevant terminal seal.

Finally H, C, P, N preserve, replay, source, and name the same finite packet. Since no quotient completion, selected limit, host-field equality, global classification theorem, or choice coordinate occurs in the carrier, the stated rows exhaust the NameCert obligation surface. □

Falsifiable prediction: An accepted $\mathsf{OstrowskiCompletion}^{\uparrow}$ replay must expose the same source field row, absolute-value row, valuation branch, Cauchy-window ledger, completion seal, transport, replay, provenance, and local naming before any consumer reads a completion-facing endpoint. A replay that reaches a quotient completion, selected representative, host completed field, hidden branch choice, or unrecorded limit rejects this NameCert instance.

Independence witness: The packet is independent of quotient completion carriers, selected Cauchy representatives, ambient field equality, and global classification theorems because its completion-facing read is mediated only by the displayed BHist, hsame, Cont, Pkg, and NameCert rows. The Archimedean and non-Archimedean branches are visible as packet data, not as an external case split supplied by choice.

Closure status for $\mathsf{NameCert}_{\mathsf{OstrowskiCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{OstrowskiCompletion}^{\uparrow}$ packet is generated from a source field row, an absolute-value row, a valuation-branch row, non-Archimedean sibling handoff data, finite Cauchy-window rows, a completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OstrowskiCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 6893.1 and Definition 6893.2 seed the absolute-value completion boundary between Archimedean, p-adic, local-field, dyadic-valuation, Cauchy-completion, and Real-facing rows.

Formal verification: FormalStatus(NameCert$_{\text{OstrowskiCompletion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Ostrowski classification, quotient completions, selected Cauchy limits, host completed fields, branch trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, absolute-value row exposure, branch-row determinacy, sibling handoff exactness, Cauchy-window routing, completion-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.OstrowskiCompletionUp.

Chapter 6894

A Concrete Naming Certificate for $\mathsf{BishopSplineSpace}^{\uparrow}$

Following de Boor and Bishop–Bridges, the $\mathsf{BishopSplineSpace}^{\uparrow}$ packet records a constructive finite spline carrier over dyadic knot data, polynomial pieces, regular rational readback, and compact-uniform modulus routes. It sits after the dyadic rational core of chapter 291, the polynomial row of chapter 50, the Real seal of chapter 38, the regular sequence readback of chapter 301, and the compact-uniform handoff of chapter 2299. The packet names only the finite knot-and-piece data needed by later compact-uniform and Real approximation readers.

Definition 6894.1 (Bishop spline space carrier)**.** *A* $\mathsf{BishopSplineSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, C, P, R, E, H, T, Q, N)$$

with the following displayed rows:

1. *G is the knot-grid row. It contains a finite increasing dyadic list, its endpoint order tests, adjacent-cell membership tests, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *evidence used to replay each comparison without a hidden real cut.*

2. *C is the coefficient row family. For every displayed cell of G it stores the finite rational or dyadic coefficient tuple that determines the local polynomial piece.*

3. *P is the piecewise-polynomial row. It reads each coefficient tuple through the* $\mathsf{Poly}^{\uparrow}$ *carrier and records the cell-local polynomial value, degree bound, and endpoint trace requested by the finite knot grid.*

4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It turns each displayed local value and endpoint trace into the regular rational sequence data used by the surrounding constructive real layer.*

5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records the finite Real comparison and tolerance tokens produced from R and keeps them attached to the same knot cell and polynomial piece.*

6. *H records componentwise* hsame *transport for G, C, P, R, E, T, Q, N and for the finite cell index used to select a piece.*

7. *T records displayed* Cont *replay of the route*

$$G, C \longmapsto P \longmapsto R \longmapsto E.$$

8. *Q is the* Pkg *provenance over* $\mathsf{BishopSplineSpace}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSplineSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed knot grid, coefficient rows, piecewise-polynomial rows, regular rational readback, Real seal, componentwise transport, displayed replay, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.BishopSplineSpaceUp.BishopSplineSpaceTasteGate single carrier alignment`

Theorem 6894.2 (Bishop spline space NameCert obligations)**.** *For every accepted* $\mathsf{BishopSplineSpace}^{\uparrow}$ *carrier*

$$K = (G, C, P, R, E, H, T, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopSplineSpace}^{\uparrow}}$ *surface consists exactly of knot-grid admission, coefficient-row admission, piecewise-polynomial interpretation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public spline read must pass through the finite rows $G, C, P, R, E, H, T, Q, N$ before it names a cell value, endpoint trace, or compact-uniform approximation datum.*

Proof. Project the carrier of Definition 6894.1. The analytic rows are G, C, P, R, E: the finite knot grid, finite coefficient family, polynomial interpretation, regular rational readback, and Real seal.

The structural rows then keep that analytic route finite. The transport row H moves the grid, coefficients, cell index, polynomial piece, readback, and seal together, while T replays the route from knot-and-coefficient data to Real-sealed local values.

Finally the provenance and local naming rows Q, N certify that the public object is exactly this finite packet. Since the classifier has no coordinate for a selected interpolation theorem, quotient function equality, ambient completion, or global approximation claim, those objects cannot be read from the local NameCert surface. □

Theorem 6894.3 (Bishop spline finite knot replay)**.** *For every accepted* $\mathsf{BishopSplineSpace}^{\uparrow}$ *carrier $K = (G, C, P, R, E, H, T, Q, N)$ and every displayed cell of the finite knot grid G, the spline value route is obtained by finite recursion over the knot list: select the adjacent cell row, read its coefficient tuple through C, interpret it through the corresponding polynomial row of P, pass the resulting local value through R, and seal the read in E. The replay exposes no open-ended node choice, quotient equality of functions, or ambient completeness witness.*

Proof. Induct over the finite knot list in G. The endpoint row supplies the base comparison, and each adjacent-pair step either identifies the displayed cell or passes to the next finite grid edge with the same $\mathsf{DyadicRatCore}^{\uparrow}$ comparison evidence.

Once the cell is identified, project the matching coefficient tuple from C and the matching polynomial row from P. The regular rational readback R and Real seal E are attached to that same cell by the componentwise transport row H.

Replay the route through T and record it through Q, N. The construction never asks for an interpolation-node selector, a quotient equality of global functions, an ambient completion point, or any infinitary compactness object beyond the displayed compact-uniform handoff named in the package provenance. □

Falsifiable prediction: An accepted $\mathsf{BishopSplineSpace}^{\uparrow}$ read is refuted if a consumer obtains a spline value, endpoint trace, or compact-uniform approximation datum without first displaying

the knot-grid, coefficient, polynomial, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, transport, replay, provenance, and local NameCert rows.

Independence witness: dyadicratcore, polynomial, real, regseqrat, compactuniformmodulus: $\mathsf{BishopSplineSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite knot-grid data, coefficient rows, piecewise-polynomial rows, regular rational readback, Real sealing, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSplineSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopSplineSpace}^{\uparrow}$ packet is generated from finite dyadic knot-grid rows, coefficient rows, piecewise-polynomial rows, RegSeqRat readback rows, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSplineSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6894.1, Definition 6894.2, and Definition 6894.3 seed the finite spline-space route over dyadic knots, polynomial pieces, regular rational readback, Real sealing, and compact-uniform package provenance.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSplineSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an approximation theorem, selected interpolation nodes, quotient function equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite knot recursion, piecewise-polynomial readback, Real sealing, compact-uniform handoff preservation, transport stability, replay stability, and local naming for BEDC.Derived.BishopSplineSpaceUp.

Chapter 6895

A Concrete Naming Certificate for $\mathsf{FiniteSupportingHyperplane}^{\uparrow}$

Following Rockafellar and Bishop–Bridges, the $\mathsf{FiniteSupportingHyperplane}^{\uparrow}$ packet records the finite-dimensional supporting-hyperplane data used by convex-analysis consumers before any separation principle is available. It sits beside the convex carrier of chapter 208, the vector-space carrier of chapter 47, the linear-map row of chapter 48, and the scalar seal of chapter 38. The packet names only displayed finite-dimensional rows; it does not claim Hahn–Banach, arbitrary Banach separation, selected minimizers, quotient dual spaces, ambient $\mathsf{Real}^{\uparrow}$ completeness, or choice.

Definition 6895.1 (Finite supporting hyperplane packet)**.** *A* $\mathsf{FiniteSupportingHyperplane}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, C, p, \ell, \alpha, W, H, R, P, N)$$

with the following displayed rows:

1. *V is the finite-dimensional* $\mathsf{VecSpace}^{\uparrow}$ *row over the displayed* $\mathsf{Real}^{\uparrow}$ *scalar seal;*
2. *C is the* $\mathsf{ConvexSet}^{\uparrow}$ *row whose finite convex-combination operations are visible to the packet;*
3. *p is the boundary point row, recorded only as a point already admitted by the finite-dimensional carrier;*
4. *ℓ is the* $\mathsf{LinMap}^{\uparrow}$ *functional row;*
5. *α is the displayed* $\mathsf{Real}^{\uparrow}$ *scalar level row;*
6. *W is the finite witness ledger saying that the inspected convex rows lie on one side of the displayed affine hyperplane and that p lies on its boundary;*
7. *H records componentwise* hsame *transport for the vector, convex, point, functional, scalar, witness, replay, package, and naming rows;*
8. *R records displayed* Cont *replay routes by which downstream optimization or convexity consumers inspect the same finite rows;*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteSupportingHyperplane}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSupportingHyperplane}^{\uparrow}}$ *row.*

The carrier is finite-dimensional by construction. It has no coordinate for Hahn–Banach, arbitrary Banach separation, selected minimizers, quotient dual equality, open-cover compactness, or choice-selected witnesses.

Theorem 6895.2 (Finite supporting hyperplane NameCert obligations)**.** *For every accepted* FiniteSupportingHyper *carrier* $K = (V, C, p, \ell, \alpha, W, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteSupportingHyperplane}^{\uparrow}}$ *surface consists exactly of finite-dimensional vector-space admission, convex-set admission, boundary-point display, linear-functional display, scalar-level display, one-sided witness ledger exactness, componentwise transport, displayed replay, package provenance, and local naming. The certificate exports no Hahn–Banach principle, arbitrary Banach separation theorem, selected minimizer, quotient dual-space equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or choice principle.*

Proof. Project the packet rows. The finite-dimensional vector-space row V, convex row C, boundary-point row p, functional row ℓ, scalar row α, and witness row W provide the entire supporting-hyperplane surface.

Read the local certificate through the structural rows. The transport row H preserves the displayed coordinates componentwise, the replay row R exposes only the same finite route to consumers, and P, N record provenance and the local name.

Since no carrier coordinate stores Hahn–Banach separation, arbitrary Banach separation, selected minimizers, quotient dual equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or choice, the NameCert obligations cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSupportingHyperplane}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteSupportingHyperplane}^{\uparrow}$ packet is generated from finite-dimensional vector-space data, a displayed convex-set row, a boundary point, a linear functional, a scalar level, a finite one-sided witness ledger, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteSupportingHyperplane}^{\uparrow}}$, obligation)

Scope closed: Definition 6895.1 and Definition 6895.2 specify the finite-dimensional carrier rows and local NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteSupportingHyperplane}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Hahn–Banach, arbitrary Banach separation, selected minimizers, quotient dual-space equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: A checked closure requires Lean carrier admission, witness-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSupportingHyperplaneUp.

Chapter 6896

A Concrete Naming Certificate for $\mathsf{WeakConvergenceHilbert}^{\uparrow}$

Following Hilbert space weak convergence theory, the $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ packet records weak convergence only through finite scalar-test rows over a displayed Hilbert source. It sits over the Hilbert carrier of chapter 91, the finite weak-topology window of chapter 3597, the norm comparison surface of chapter 89, the regular rational readback surface of chapter 301, and the scalar seal of chapter 38. The chapter names the finite observation certificate used by weak-convergence consumers; it does not select a countable dual, assert compactness, identify a quotient sequence space, or import ambient completeness beyond the displayed sibling rows.

Definition 6896.1 (Weak convergence in Hilbert carrier)**.** *A* $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (H, W, N, R, S, T, C, P, L)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row. It records the carrier endpoint, inner-product readback surface, and Hilbert-facing provenance used by the scalar tests.*
2. *W is the sibling* $\mathsf{WeakTopology}^{\uparrow}$ *finite-window row, reused as the weak-neighbourhood interface for the displayed Hilbert source.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *comparison row. It records norm bounds and norm-facing tolerance data without replacing weak convergence by norm convergence.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for indexed scalar-test tolerances and finite convergence budgets.*
5. *S is the scalar-test row. Each entry displays a Hilbert source point, a test vector or functional row already accepted by H, W, and the scalar observation sent to the* $\mathsf{Real}^{\uparrow}$ *seal.*
6. *T records componentwise* hsame *transport for the Hilbert source, weak-window row, norm comparison, regular rational readback, scalar-test row, replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay from a weak-convergence request through*

$$H, W, N, R, S \longmapsto T, P, L.$$

8. *P is the* Pkg *provenance over* $\mathsf{WeakConvergenceHilbert}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{WeakConvergenceHilbert}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $H, W, N, R, S, T, C, P, L$. It has no coordinate for a selected dual basis, countable choice, compactness, quotient sequence equality, norm convergence, weak-star compactness, or an ambient host theorem.

Theorem 6896.2 (Weak convergence in Hilbert NameCert obligations)**.** *For every accepted* WeakConvergenceHilbe *carrier $Q = (H, W, N, R, S, T, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{WeakConvergenceHilbert}^{\uparrow}}$ *surface consists exactly of Hilbert source exposure through H, finite weak-topology window exposure through W, norm comparison through N, regular rational tolerance readback through R, scalar-test exposure through S, componentwise transport through T, displayed replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 6896.1. The only source row is H, the only weak-neighbourhood interface is W, and the only norm-facing data are the comparison budgets in N.

The convergence evidence is finite. The regular rational row R records the inspected tolerance budgets, and the scalar-test row S records the finitely many Hilbert observations sent to the $\mathsf{Real}^{\uparrow}$ seal.

The remaining rows are structural. Transport through T, replay through C, provenance through P, and local naming through L keep the same finite packet visible to every consumer. Since the carrier has no selected dual basis, choice schedule, compactness row, quotient sequence equality, norm-convergence coordinate, weak-star compactness row, or ambient host theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6896.3 (Weak convergence in Hilbert scalar readback route)**.** *Every scalar readback consumed from an accepted* $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ *packet factors through the displayed route*

$$H, W, N, R, S, T, C, P, L.$$

Thus a weak-convergence consumer may read only finite Hilbert scalar tests, regular rational tolerance budgets, norm-comparison boundaries, $\mathsf{Real}^{\uparrow}$ *scalar seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The route exports no selected dual sequence, no quotient function-space equality, no norm-convergence theorem, no compactness theorem, and no countable-choice principle.*

Proof. Begin with a scalar observation in S. Its Hilbert source is the same row H admitted by the carrier, and its weak-neighbourhood meaning is read through the same finite window W.

Read the tolerance data next. The row R supplies the regular rational budget for the observation, while N records the norm-facing comparison boundary without turning the weak read into a norm-convergence claim.

Finally send the scalar value to the $\mathsf{Real}^{\uparrow}$ seal and replay the route through T, C, P, L. Componentwise transport and displayed replay preserve the same observation window for consumers, so no selected dual sequence, quotient equality, norm-convergence theorem, compactness theorem, or choice principle can be obtained from the scalar readback. □

Theorem 6896.4 (Weak convergence in Hilbert finite-window nonescape)**.** *Any public read of an accepted* $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ *packet is exhausted by the finite Hilbert source row, weak-topology window, norm comparison, regular rational tolerance row, scalar-test row, transport, replay, provenance, and local naming data. In carrier notation the public route is*

$$H, W, N, R, S, T, C, P, L.$$

The packet does not export Banach–Alaoglu compactness, Mazur convex-block convergence, Kadec–Klee norm recovery, selected subsequences, a countable total test family, quotient sequence equality, or ambient Hilbert-space weak compactness.

Proof. Use the NameCert obligations theorem to expose the carrier rows. A public read must display H, W, N, R, S before it reaches any structural row.

Apply the scalar readback route. It sends every finite test through regular rational tolerances and the scalar seal before transport, replay, provenance, and local naming are consumed.

The refused analytic conclusions are not carrier coordinates. Since compactness, convex-block convergence, norm recovery, subsequence selection, countable test families, quotient equality, and ambient weak compactness are absent from $H, W, N, R, S, T, C, P, L$, no public read can export them. □

Falsifiable prediction: Every accepted $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ read must expose the $\mathsf{Hilbert}^{\uparrow}$ source, $\mathsf{WeakTopology}^{\uparrow}$ finite window, $\mathsf{Norm}^{\uparrow}$ comparison boundary, $\mathsf{RegSeqRat}^{\uparrow}$ tolerance row, scalar-test row, $\mathsf{Real}^{\uparrow}$ seal, BHist transport, hsame, Cont, Pkg, and local NameCert rows before any weak-convergence conclusion is public.

Independence witness: hilbert, weaktopology, norm, regseqrat, real: $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Hilbert source data, weak finite-window observations, norm comparison, regular rational tolerance readback, scalar-test rows, transport, replay, provenance, and local naming while refusing compactness, norm recovery, selected dual bases, and quotient sequence equality.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakConvergenceHilbert}^{\uparrow}}$.

Constructive story: A $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ packet is generated from a Hilbert source row, a WeakTopology finite-window row, a Norm comparison row, RegSeqRat tolerance readback, finite Real scalar-test rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakConvergenceHilbert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6896.1, Definition 6896.2, Definition 6896.3, and Definition 6896.4 seed the finite weak-convergence certificate over Hilbert scalar-test rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakConvergenceHilbert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close compactness, Mazur convex-block convergence, Kadec–Klee norm recovery, selected subsequences, countable total test families, quotient sequence equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite scalar-test stability, regular rational readback exactness, scalar nonescape, transport, replay, provenance, and local naming for BEDC.Derived.WeakConvergenceHilbertUp.

Chapter 6897

A Concrete Naming Certificate for CarlemanInequality$^{\uparrow}$

Following Hardy–Littlewood–Polya's treatment of inequalities, the CarlemanInequality$^{\uparrow}$ packet records the finite row surface by which a positive real-series source may expose partial-sum, geometric-mean, and summable-majorant control before a downstream inequality consumer reads the endpoint. It sits beside the real-series carrier of chapter 1581, the Cauchy majorant route of chapter 1774, the Young inequality packet of chapter 2358, and the Poincare inequality boundary of chapter 2329. The packet names a displayed Carleman inequality certificate; it does not choose an infinite sum, import host measure theory, quotient a sequence space, or assert a bridge-checked classical theorem.

Definition 6897.1 (Carleman inequality carrier)**.** *A* CarlemanInequality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, G, M, R, B, H, C, P, N)$$

with the following visible rows:

1. *S is the partial-sum row, recording the finite initial-segment sums of the displayed nonnegative real series source.*
2. *G is the geometric-mean row, recording the finite products and root reads used for the Carleman mean at each displayed index.*
3. *M is the summable-majorant row, carrying the majorant schedule and tail budget that bound the accumulated geometric means.*
4. *R is the* RealSeries$^{\uparrow}$ *readback row, exposing the source series only through the finite real-series packet.*
5. *B is the boundary comparison row, recording the displayed Carleman constant, endpoint budget, and comparison with the majorant route.*
6. *H records componentwise* hsame *transport for the partial-sum, geometric-mean, majorant, RealSeries readback, boundary comparison, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Carleman read through S, G, M, R, B, H, P, N.*
8. *P is the* Pkg *provenance over* CarlemanInequality$^{\uparrow}$, RealSeries$^{\uparrow}$, CauchyMajorantSeries$^{\uparrow}$, YoungInequality$^{\uparrow}$, PoincareInequality$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CarlemanInequality}^{\uparrow}}$ *row.*
The carrier predicate asserts exactly that these rows form one finite Carleman inequality packet. It has no coordinate for selected infinite sums, quotient sequence equality, ambient integral theory, host convexity, or a standard bridge.

Theorem 6897.2 (Carleman inequality NameCert obligations)**.** *For every accepted* $\mathsf{CarlemanInequality}^{\uparrow}$ *carrier* $K = (S, G, M, R, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CarlemanInequality}^{\uparrow}}$ *surface consists exactly of partial-sum exposure, geometric-mean exposure, summable-majorant exposure,* $\mathsf{RealSeries}^{\uparrow}$ *readback, boundary-comparison exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted Carleman inequality request is classified only by those finite rows.*

Proof. Project the carrier of Definition 6897.1. The analytic rows are the partial-sum row S, the geometric-mean row G, the summable-majorant row M, the real-series readback row R, and the boundary comparison row B.

The partial-sum and geometric-mean rows display the finite source of the inequality read. The summable-majorant row then supplies the tail budget and comparison schedule, while the real-series readback row keeps the source inside the finite $\mathsf{RealSeries}^{\uparrow}$ packet.

The boundary row B records the Carleman constant and endpoint comparison as packet data. It does not add an infinite-sum choice, quotient equality, host integral theorem, or convexity theorem.

Finally H, C, P, N transport, replay, source, and name the same displayed packet. Hence the local $\mathsf{NameCert}_{\mathsf{CarlemanInequality}^{\uparrow}}$ row exhausts the obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{CarlemanInequality}^{\uparrow}$ read factors through partial-sum rows, geometric-mean rows, a summable-majorant row, a RealSeriesUp readback row, a boundary-comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: realseries, cauchy-majorant-series, young-inequality, poincare-inequality: $\mathsf{CarlemanInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries partial-sum rows, geometric-mean rows, a summable-majorant route, RealSeries readback, boundary comparison, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CarlemanInequality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CarlemanInequality}^{\uparrow}$ packet is generated from partial-sum rows, geometric-mean rows, a summable-majorant row, a RealSeries readback row, a boundary-comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CarlemanInequality}^{\uparrow}}$, seed)

Scope closed: Definition 6897.1 and Definition 6897.2 seed the finite Carleman inequality route from displayed real-series data through geometric-mean and majorant comparison rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CarlemanInequality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, quotient sequence equality, ambient integral theory, host convexity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partial-sum exposure, geometric-mean exposure, summable-majorant exactness, RealSeries readback, boundary comparison, transport, replay, provenance, and local naming for BEDC.Derived.CarlemanInequalityUp.

Chapter 6898

A Concrete Naming Certificate for $\mathsf{CauchySchwarzCompletion}^{\uparrow}$

Following Riesz and Bishop–Bridges constructive analysis, the $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ packet records the finite completion-stable route by which a Cauchy–Schwarz estimate is carried from displayed real-vector inequality data into Cauchy-window and complete-metric handoff rows. It sits after the finite inequality certificate of chapter 1684, the Cauchy-window surface of chapter 406, the complete-metric boundary of chapter 128, and the terminal real-name seal of chapter 38. The packet names only the displayed finite route through regular rational readback, stream schedules, completion handoff, transport, replay, provenance, and local naming; it does not import a host Hilbert completion, quotient stream equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6898.1 (Cauchy–Schwarz completion carrier)**.** *A* $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, W, M, Q, S, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *inequality row, including the displayed finite-vector source, inner-product read, norm-square rows, and dyadic square comparison already sealed for real-analysis consumers.*
2. *W is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *Cauchy-window row, carrying the common finite windows through which the inequality row is inspected as a completion-facing sequence of estimates.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row, recording the displayed completeness request and the finite nonescape boundary for the estimate route.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the Cauchy-window observations and the dyadic tolerance comparisons attached to R.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row that exposes the finite observation windows shared by R, W, Q, and M.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the estimate value after the Cauchy-window and complete-metric handoff rows have been displayed.*
7. *H records componentwise* hsame *transport for $R, W, M, Q, S, E, C, P, N$.*

8. *C records displayed* Cont *replay from the finite Cauchy–Schwarz inequality row through the Cauchy-window, regular-readback, stream-schedule, complete-metric, and Real-seal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySchwarzCompletion}^{\uparrow}$, $\mathsf{CauchySchwarzReal}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Hilbert completion, quotient equality of Cauchy names, selected completed representatives, countable choice, detached real limits, or ambient completeness.

Theorem 6898.2 (Cauchy–Schwarz completion NameCert obligations)**.** *For every accepted* CauchySchwarzComple *carrier $K = (R, W, M, Q, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy–Schwarz real-inequality exposure through R, Cauchy-window exposure through W, complete-metric handoff exposure through M, regular rational readback through Q, shared stream scheduling through S, terminal Real seal non-escape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6898.1. The only inequality source is the displayed $\mathsf{CauchySchwarzReal}^{\uparrow}$ row R, whose finite vector, inner-product, norm-square, and dyadic square-comparison data are already part of the accepted packet.

The completion-facing route is then forced by W, M, Q, S, E. The Cauchy-window row W exposes the common finite windows, the complete-metric row M records the displayed handoff request, the regular rational row Q reads the finite observations, the stream row S schedules those observations, and the terminal Real row E seals the same route.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no row for host Hilbert completion, quotient Cauchy-name equality, selected completed representatives, countable choice, detached real limits, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 6898.3 (Cauchy–Schwarz completion limit handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{CauchySchwarzReal}^{\uparrow}, \mathsf{CauchySequenceSpace}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow} \longmapsto R, W, M, Q, S, E, H, C, P, N.$$

In particular, the Cauchy–Schwarz estimate is available at a completion boundary only after the Cauchy-window row, complete-metric handoff row, regular rational readback, stream schedule, terminal Real seal, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Start from an accepted packet $K = (R, W, M, Q, S, E, H, C, P, N)$. The estimate source is R, so every inequality read already factors through the finite real-vector and dyadic comparison rows named by chapter 1684.

The estimate can then enter completion only through the visible Cauchy-window route. The row W supplies the inspected Cauchy windows, S schedules the finite observations, and Q records the regular rational readback attached to those windows.

The handoff row M is the only complete-metric coordinate, and the Real seal E is downstream of R, W, M, Q, S. Thus a consumer cannot read a completion-stable estimate without first displaying the Cauchy-window, complete-metric, readback, schedule, and seal rows.

Finally, H, C, P, N keep the handoff attached to the same packet by transport, replay, provenance, and local naming. The route exports a finite completion-stable estimate boundary, not a

host Hilbert completion, quotient stream equality, selected limit, countable choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Falsifiable prediction: An accepted $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ read is refuted if a completion-facing consumer obtains the estimate boundary without first displaying the CauchySchwarzRealUp inequality row, CauchySequenceSpaceUp window row, CompleteMetricUp handoff row, RegSeqRatUp readback, StreamNameUp schedule, RealUp seal, transport, replay, provenance, and local NameCert rows.

Independence witness: cauchy-schwarz-real, cauchysequence-space, completemetric, regseqrat, streamname, real: $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an inequality row, Cauchy-window row, complete-metric handoff row, regular readback, stream schedule, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ packet is generated from a CauchySchwarzRealUp inequality row, CauchySequenceSpaceUp windows, a CompleteMetricUp handoff row, RegSeqRatUp readback, StreamNameUp schedules, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6898.1, Definition 6898.2, and Definition 6898.3 seed the finite completion-stable Cauchy–Schwarz estimate route over displayed Cauchy windows and complete-metric handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hilbert completion, quotient equality of Cauchy names, selected completed representatives, countable choice, detached real limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy–Schwarz inequality exposure, Cauchy-window exposure, complete-metric handoff, regular rational readback, stream scheduling, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySchwarzCompletionUp.

Chapter 6899

A Concrete Naming Certificate for $\mathsf{ArtinRees}^{\uparrow}$

Following Atiyah–Macdonald on the Artin–Rees lemma, the $\mathsf{ArtinRees}^{\uparrow}$ packet records the finite filtration interface by which an ideal-adic filtration on a displayed module is compared with the induced filtration on a displayed submodule. It sits after the ring carrier of chapter 43, the ideal carrier of chapter 81, the module carrier of chapter 46, and the Noetherian module surface of chapter 3648. The packet names only carrier rows, filtration rows, stabilization bounds, transport, replay, provenance, and local naming; it does not import quotient-module classification, selected generators, ambient Noetherian induction, or host equality of filtrations.

Definition 6899.1 (Artin–Rees carrier)**.** *An* $\mathsf{ArtinRees}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{ArtinRees}(R, I, M, L, F, A, H, Q, P, N).$$

The row R is the $\mathsf{Ring}^{\uparrow}$ *source surface, I is the* $\mathsf{Ideal}^{\uparrow}$ *row over that ring, M is the ambient* $\mathsf{Module}^{\uparrow}$ *row, and L is the displayed submodule row read inside the same module classifier. The row F records the finite ideal-adic filtration windows $I^n M$ and $I^n M \cap L$ visible to the packet. The row A is the Artin–Rees stabilization bound, asserting that after a displayed finite stage the induced filtration on L is read through the same ideal power route. The row H is componentwise* hsame *transport for the ring, ideal, module, submodule, filtration, and stabilization rows; Q is displayed* Cont *replay; P is* Pkg *provenance; and N is the local* $\mathsf{NameCert}_{\mathsf{ArtinRees}^{\uparrow}}$ *row.*

Theorem 6899.2 (Artin–Rees NameCert obligations)**.** *For every accepted* $\mathsf{ArtinRees}^{\uparrow}$ *carrier* $\mathsf{ArtinRees}(R, I, M, L, F, A, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArtinRees}^{\uparrow}}$ *surface consists exactly of source exposure for* $\mathsf{Ring}^{\uparrow}$*,* $\mathsf{Ideal}^{\uparrow}$*,* $\mathsf{Module}^{\uparrow}$*, and* $\mathsf{NoetherianModule}^{\uparrow}$*; submodule exposure through L; ideal-adic filtration exposure through F; finite stabilization access through A; componentwise transport through H; displayed replay through Q; provenance through P; and local naming through N.*

Proof. Project the displayed packet of Definition 6899.1. The rows R, I, M, L fix the algebraic sources before any filtration comparison is read.

The filtration row F exposes only the finite windows named by the packet, and the stabilization row A gives the finite stage at which the induced filtration on the submodule is read through the same ideal power route. This is the Artin–Rees obligation surface, not a quotient-module classifier or selected generator list.

Transport H and replay Q preserve those rows componentwise. Provenance P and local naming N then repack the same finite inventory as the local certificate, so no hidden Noetherian induction or host filtration equality enters the obligations. □

Theorem 6899.3 (Artin–Rees module-ideal consumer)**.** *Every downstream algebraic consumer that cites* $\mathsf{ArtinRees}^{\uparrow}$ *must first read the same ring row* R*, ideal row* I*, module row* M*, submodule row* L*, filtration row* F*, stabilization row* A*, transport row* H*, replay row* Q*, provenance row* P*, and local naming row* N*. The consumer may use the packet as a finite module–ideal stabilization certificate, but it receives no selected basis, quotient-module classification, maximal-submodule choice, or ambient equality of filtrations.*

Proof. Begin with the NameCert obligations of Definition 6899.2. They force every read to expose the ring, ideal, module, Noetherian module, and submodule sources before the filtration rows are available.

The rows F and A provide the only stabilization data available to a module–ideal consumer. Since they are displayed rows inside the same packet, the consumer cannot bypass them through a host Artin–Rees theorem or through quotient-module classification.

Finally, H, Q, P, N preserve the route as transport, replay, provenance, and local naming. Thus the downstream consumer receives exactly the finite stabilization certificate and nothing outside the displayed carrier. □

Falsifiable prediction: Any accepted $\mathsf{ArtinRees}^{\uparrow}$ consumer that cites ideal-adic stabilization without first exposing $R, I, M, L, F, A, H, Q, P, N$ refutes the carrier surface of Definition 6899.1.

Independence witness: ring, ideal, module, noetherian-module: no listed sibling is bijective to $\mathsf{ArtinRees}^{\uparrow}$, because this packet jointly binds ideal-adic filtration windows, a displayed submodule route, finite stabilization, componentwise transport, replay, provenance, and local NameCert rows into one Artin–Rees carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ArtinRees}^{\uparrow}}$.

Constructive story: An $\mathsf{ArtinRees}^{\uparrow}$ packet is generated from a ring source, ideal source, module source, submodule row, ideal-adic filtration windows, a finite stabilization bound, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ArtinRees}^{\uparrow}}$, seed)

Scope closed: Definition 6899.1, Definition 6899.2, and Definition 6899.3 seed the finite Artin–Rees module–ideal filtration interface over RingUp, IdealUp, ModuleUp, NoetherianModuleUp, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ArtinRees}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient-module classification, selected generators, ambient Noetherian induction, full Artin–Rees theorem strength, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, ideal-adic filtration exposure, finite stabilization access, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.ArtinReesUp.

Chapter 6900

A Concrete Naming Certificate for $\mathsf{FloorFunction}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{FloorFunction}^{\uparrow}$ packet records the ordinary floor-function read as a finite certificate route rather than as a primitive operation on host real numbers. It consumes the real-name source of chapter 38, the integer bracket supplied by chapter 1479, the Real-facing integer-part handoff of chapter 1784, the residual row of chapter 1648, the dyadic tolerance core of chapter 291, the finite window surface of chapter 126, and the regular rational readback route of chapter 301. The packet names the displayed lower-integer value attached to a real name; it is not host floor, trichotomy, quotient real equality, selected representatives, countable choice, or ambient Real completeness.

Definition 6900.1 (FloorFunction carrier)**.** *A* $\mathsf{FloorFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, B, Z, F, D, S, G, I, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{Real}^{\uparrow}$ *row whose floor read is being requested.*
2. *B is the* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket row attached to the same source real.*
3. *Z is the* $\mathsf{Int}^{\uparrow}$ *candidate exposed by the bracket as the lower integer endpoint.*
4. *F is the* $\mathsf{FractionalPart}^{\uparrow}$ *residual row tied to the same source real and integer candidate.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row recording the finite tolerances used to inspect the source, bracket, and residual rows.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened for the finite real-name and residual observations.*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that interprets the displayed windows before the floor value is exported.*
8. *I is the* $\mathsf{RealIntegerPart}^{\uparrow}$ *handoff row that packages the same source, bracket, integer candidate, residual, dyadic scale, window, and readback route for Real-facing consumers.*
9. *H records componentwise* hsame *transport for the source real, bracket, integer candidate, residual, dyadic scale, window, readback, RealIntegerPart handoff, continuation, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from every floor request through R, B, Z, F, D, S, G, I without inserting another integer search.*

11. *P is the* Pkg *provenance over* $\mathsf{FloorFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{FractionalPart}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealIntegerPart}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FloorFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for host floor, trichotomy over arbitrary real names, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6900.2 (FloorFunction NameCert obligations)**.** *For every accepted* $\mathsf{FloorFunction}^{\uparrow}$ *carrier $K = (R, B, Z, F, D, S, G, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FloorFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure for the source* $\mathsf{Real}^{\uparrow}$ *row,* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket row,* $\mathsf{Int}^{\uparrow}$ *candidate row,* $\mathsf{FractionalPart}^{\uparrow}$ *residual row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{RealIntegerPart}^{\uparrow}$ *handoff row, and structural rows H, C, P, N;*

2. *bracket exactness, requiring the integer candidate Z to be read only as the lower endpoint of the displayed* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket B for the same source row R;*

3. *residual compatibility, requiring F to bind the same R, B, Z route before any fractional residual observation is exposed;*

4. *handoff compatibility, requiring the* $\mathsf{RealIntegerPart}^{\uparrow}$ *row I to consume exactly the displayed bracket, residual, dyadic, window, and readback rows;*

5. *transport and replay stability, requiring H and C to preserve the rows componentwise and to send each floor request back through R, B, Z, F, D, S, G, I;*

6. *ledger refusal, excluding host floor, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, and ambient Real completeness from the certificate surface.*

No FloorFunction obligation is stored outside these rows.

Proof. Project the accepted packet $K = (R, B, Z, F, D, S, G, I, H, C, P, N)$. The projection exposes exactly the real source, bracket, integer candidate, residual, dyadic scale, stream window, regular readback, RealIntegerPart handoff, transport, replay, provenance, and naming rows.

Bracket exactness is read from chapter 1479. The row B binds the source real to a finite lower endpoint and successor comparison, and Z is available only as the displayed integer candidate of that bracket.

Residual compatibility is read from chapter 1648. The residual row F attaches to the same source real and integer candidate, so it cannot provide an independent floor selector.

The Real-facing handoff is read through chapter 1784. The row I packages the same bracket route together with the dyadic scale, finite window, and regular readback rows.

Finally H, C, P, N transport, replay, source, and name the displayed packet. Since no excluded object appears as a carrier coordinate or classifier clause, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{FloorFunction}^{\uparrow}}$ obligation surface. □

Theorem 6900.3 (FloorFunction RealIntegerPart handoff)**.** *Every consumer that reads a floor value from an accepted* $\mathsf{FloorFunction}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{ArchimedeanIntegerPart}^{\uparrow} \longmapsto \mathsf{Int}^{\uparrow} \longmapsto \mathsf{FractionalPart}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeq}$$

In particular, every such read passes through chapter 1479 and chapter 1784. It receives no host floor function, trichotomy service, quotient real equality, selected representative, countable-choice row, or ambient Real completeness theorem.

Proof. Let a downstream consumer request the floor value. The replay row C sends the request first to the source $\mathsf{Real}^{\uparrow}$ row R, so the route starts from a displayed real name rather than from a host real.

The bracket row B then supplies the $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ certificate named by chapter 1479. The integer candidate Z is the lower endpoint exported by that finite bracket.

The residual and readback rows keep the endpoint attached to the same real-name route. The row F records the $\mathsf{FractionalPart}^{\uparrow}$ residual, while D, S, G expose only finite dyadic tolerances, finite windows, and regular rational readbacks.

The handoff row I is exactly the $\mathsf{RealIntegerPart}^{\uparrow}$ consumer surface of chapter 1784. Transport by H preserves the same rows componentwise, and P, N record no additional operation. Therefore every exported floor read factors through the stated route. □

Falsifiable prediction: Every $\mathsf{FloorFunction}^{\uparrow}$ read factors through one $\mathsf{Real}^{\uparrow}$ source row, one $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ bracket row, one $\mathsf{Int}^{\uparrow}$ candidate row, one $\mathsf{FractionalPart}^{\uparrow}$ residual row, one $\mathsf{DyadicRatCore}^{\uparrow}$ scale row, one $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{RealIntegerPart}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, archimedean-integer-part, int, fractional-part, dyadicratcore, streamname, regseqrat, real-integer-part: no listed sibling is bijective to $\mathsf{FloorFunction}^{\uparrow}$ because this packet jointly binds the floor-facing name, bracket endpoint, residual, finite tolerance scale, window read, regular readback, RealIntegerPart handoff, transport, replay, provenance, and local naming for the same real source.

Closure status for $\mathsf{NameCert}_{\mathsf{FloorFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FloorFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6900.1, Definition 6900.2, and Definition 6900.3 seed the finite floor-function certificate route from a displayed Real source through ArchimedeanIntegerPart bracket, Int candidate, FractionalPart residual, DyadicRatCore scale, StreamName window, RegSeqRat readback, RealIntegerPart handoff, and structural rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FloorFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host floor, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, bracket exactness, residual compatibility, RealIntegerPart handoff compatibility, transport replay stability, and ledger refusal for BEDC.Derived.FloorFunctionUp.

Constructive story: A $\mathsf{FloorFunction}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ source row, an $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ bracket row, an $\mathsf{Int}^{\uparrow}$ candidate row, a $\mathsf{FractionalPart}^{\uparrow}$ residual row, a $\mathsf{DyadicRatCore}^{\uparrow}$ scale row, a $\mathsf{StreamName}^{\uparrow}$ window row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{RealIntegerPart}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6901

A Concrete Naming Certificate for $\mathsf{CeilingFunction}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CeilingFunction}^{\uparrow}$ packet records the ordinary upper-integer read as a finite certificate route rather than as a primitive operation on host real numbers. It is the upper-integer dual of the lower endpoint route in chapter 6900; it consumes the upper dyadic enclosure discipline of chapter 1690, the integer bracket supplied by chapter 1479, the residual row of chapter 1648, and the real-name source of chapter 38. The packet names the displayed upper integer attached to a real name; it is not host ceiling, order trichotomy, quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6901.1 (CeilingFunction carrier)**.** *A* $\mathsf{CeilingFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, B, Z, U, F, D, Y, I, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{Real}^{\uparrow}$ *row whose upper-integer read is being requested.*
2. *B is the* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket row attached to the same source real.*
3. *Z is the* $\mathsf{Int}^{\uparrow}$ *lower endpoint exposed by the bracket.*
4. *U is the* $\mathsf{Int}^{\uparrow}$ *upper endpoint exposed by the same bracket, read as the successor-side integer when the residual row is nonzero and as Z on the exact-integer branch.*
5. *F is the* $\mathsf{FractionalPart}^{\uparrow}$ *residual row tied to the same source real and lower endpoint.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row recording the finite tolerances used to inspect the source, bracket, and residual rows.*
7. *Y is the* $\mathsf{DyadicCeiling}^{\uparrow}$ *upper-grid row used to compare the real-name window with the displayed upper endpoint.*
8. *I is the* $\mathsf{RealIntegerPart}^{\uparrow}$ *handoff row that packages the same source, bracket, lower endpoint, residual, dyadic scale, dyadic ceiling row, and upper-integer export for Real-facing consumers.*
9. *H records componentwise* hsame *transport for the source real, bracket, lower endpoint, upper endpoint, residual, dyadic scale, dyadic ceiling, RealIntegerPart handoff, continuation, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from every ceiling request through R, B, Z, U, F, D, Y, I without inserting another integer search.*

11. *P is the* Pkg *provenance over* $\mathsf{CeilingFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{FractionalPart}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicCeiling}^{\uparrow}$, $\mathsf{RealIntegerPart}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CeilingFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for host ceiling, trichotomy over arbitrary real names, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6901.2 (CeilingFunction NameCert obligations)**.** *For every accepted* $\mathsf{CeilingFunction}^{\uparrow}$ *carrier $K = (R, B, Z, U, F, D, Y, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CeilingFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure for the source* $\mathsf{Real}^{\uparrow}$ *row,* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket row, lower and upper* $\mathsf{Int}^{\uparrow}$ *endpoint rows,* $\mathsf{FractionalPart}^{\uparrow}$ *residual row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row,* $\mathsf{DyadicCeiling}^{\uparrow}$ *upper-grid row,* $\mathsf{RealIntegerPart}^{\uparrow}$ *handoff row, and structural rows H, C, P, N;*

2. *bracket exactness, requiring Z and U to be read only as the lower and upper endpoint rows of the displayed* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *bracket B for the same source row R;*

3. *residual compatibility, requiring F to bind the same R, B, Z route before the exact-integer and successor-side branches for U are exposed;*

4. *upper-grid compatibility, requiring Y to read the finite dyadic ceiling route through the scale row D before any upper-integer export is public;*

5. *handoff compatibility, requiring the* $\mathsf{RealIntegerPart}^{\uparrow}$ *row I to consume exactly the displayed bracket, residual, dyadic scale, dyadic ceiling, and upper-endpoint rows;*

6. *transport and replay stability, requiring H and C to preserve the rows componentwise and to send each ceiling request back through R, B, Z, U, F, D, Y, I;*

7. *ledger refusal, excluding host ceiling, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, and ambient Real completeness from the certificate surface.*

No CeilingFunction obligation is stored outside these rows.

Proof. Project the accepted packet $K = (R, B, Z, U, F, D, Y, I, H, C, P, N)$. The projection exposes exactly the real source, bracket, lower endpoint, upper endpoint, residual, dyadic scale, dyadic ceiling, RealIntegerPart handoff, transport, replay, provenance, and naming rows.

Bracket exactness is read from chapter 1479. The row B binds the source real to a finite lower endpoint and successor-side comparison, so Z and U are available only as the displayed endpoint rows of that bracket.

Residual compatibility is read from chapter 1648. The residual row F attaches to the same source real and lower endpoint, which fixes the exact-integer branch and the successor-side branch before U can be exported.

The upper dyadic comparison is read through chapter 1690. The row Y is inspected at the scale recorded by D, so the upper-integer read uses a finite upper-grid route rather than a host ceiling operation.

Finally I, H, C, P, N hand off, transport, replay, source, and name the displayed packet. Since no excluded object appears as a carrier coordinate or classifier clause, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{CeilingFunction}^{\uparrow}}$ obligation surface. □

Theorem 6901.3 (CeilingFunction floor-dual handoff)**.** *Every consumer that reads a ceiling value from an accepted* $\mathsf{CeilingFunction}^{\uparrow}$ *carrier receives the upper-integer dual of the floor route of chapter 6900. The lower endpoint Z is read through the same bracket and residual route used by* $\mathsf{FloorFunction}^{\uparrow}$*, while the exported endpoint U is constrained by the displayed upper branch and the* $\mathsf{DyadicCeiling}^{\uparrow}$ *upper-grid row Y. Thus the consumer obtains a finite upper-integer handoff, not host ceiling, trichotomy, quotient real equality, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier of Definition 6901.1. The rows $R, B, Z, F, D, I, H, C, P, N$ mirror the lower-endpoint rows used by chapter 6900, so the lower bracket read is shared with the floor route.

The extra endpoint row U records the upper side of the same finite bracket. Its exact-integer branch and successor-side branch are fixed only after the residual row F is tied to the same source and lower endpoint.

The row Y supplies the upper-grid comparison through chapter 1690. Consequently the exported endpoint is constrained by a displayed dyadic-ceiling read before the Real-facing handoff row I can be consumed.

The carrier has no coordinate for a host ceiling function or an ambient completeness theorem. Therefore the ceiling consumer receives only the finite upper-integer dual of the existing floor handoff. □

Theorem 6901.4 (CeilingFunction RealIntegerPart handoff)**.** *Every consumer that reads a ceiling value from an accepted* $\mathsf{CeilingFunction}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{ArchimedeanIntegerPart}^{\uparrow} \longmapsto \mathsf{Int}^{\uparrow} \longmapsto \mathsf{FractionalPart}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{DyadicCeiling}^{\uparrow} \longmapsto \mathsf{RealInt}$$

In particular, every such read passes through chapter 1479, chapter 1690, and chapter 1784. It receives no host ceiling function, trichotomy service, quotient real equality, selected representative, countable-choice row, hidden Archimedean search, or ambient Real completeness theorem.

Proof. Let a downstream consumer request the ceiling value. The replay row C sends the request first to the source $\mathsf{Real}^{\uparrow}$ row R, so the route starts from a displayed real name rather than from a host real.

The bracket row B then supplies the $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ certificate named by chapter 1479. The endpoint rows Z and U are the lower and upper integer rows exported by that finite bracket.

The residual and dyadic rows keep the endpoint attached to the same real-name route. The row F records the $\mathsf{FractionalPart}^{\uparrow}$ residual, while D and Y expose only finite dyadic tolerances and a displayed upper-grid read.

The handoff row I is the $\mathsf{RealIntegerPart}^{\uparrow}$ consumer surface. Transport by H preserves the same rows componentwise, and P, N record no additional operation. Therefore every exported ceiling read factors through the stated route. □

Falsifiable prediction: Every $\mathsf{CeilingFunction}^{\uparrow}$ read factors through one $\mathsf{Real}^{\uparrow}$ source row, one $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ bracket row, lower and upper $\mathsf{Int}^{\uparrow}$ endpoint rows, one $\mathsf{FractionalPart}^{\uparrow}$ residual row, one $\mathsf{DyadicRatCore}^{\uparrow}$ scale row, one $\mathsf{DyadicCeiling}^{\uparrow}$ upper-grid row, one $\mathsf{RealIntegerPart}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, archimedean-integer-part, int, fractional-part, dyadicratcore, dyadic-ceiling, real-integer-part: no listed sibling is bijective to $\mathsf{CeilingFunction}^{\uparrow}$ because this packet jointly binds the ceiling-facing name, lower and upper bracket endpoints, residual branch, finite tolerance scale, upper dyadic grid read, RealIntegerPart handoff, transport, replay, provenance, and local naming for the same real source.

Closure status for $\mathsf{NameCert}_{\mathsf{CeilingFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CeilingFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6901.1, Definition 6901.2, Definition 6901.3, and Definition 6901.4 seed the finite ceiling-function certificate route from a displayed Real source through ArchimedeanIntegerPart bracket, Int endpoint rows, FractionalPart residual, DyadicRatCore scale, DyadicCeiling upper-grid row, RealIntegerPart handoff, and structural rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CeilingFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host ceiling, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, unbounded stream reads, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, bracket exactness, residual compatibility, upper-grid compatibility, RealIntegerPart handoff compatibility, transport replay stability, and ledger refusal for BEDC.Derived.CeilingFunctionUp.

Constructive story: A $\mathsf{CeilingFunction}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ source row, an $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ bracket row, lower and upper $\mathsf{Int}^{\uparrow}$ endpoint rows, a $\mathsf{FractionalPart}^{\uparrow}$ residual row, a $\mathsf{DyadicRatCore}^{\uparrow}$ scale row, a $\mathsf{DyadicCeiling}^{\uparrow}$ upper-grid row, a $\mathsf{RealIntegerPart}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6902

A Concrete Naming Certificate for $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive analysis, the $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$ packet records the finite route by which a contraction on a displayed complete metric carrier produces a fixed-point endpoint surface. It sits over the complete-metric carrier of chapter 128, the contraction graph of chapter 1418, the finite Picard orbit of chapter 2359, the Banach endpoint discipline of chapter 396, the regular-rational handoff of chapter 301, and the real-name seal of chapter 38. The packet names a constructive fixed-point route only through displayed BEDC data; it does not import selected host fixed points, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6902.1 (CompleteMetricFixedPoint carrier)**.** *A* $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, T, I, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row, including the metric carrier, distance readback, regular Cauchy limit service, and local complete-metric naming route.*
2. *T is the* $\mathsf{ContractionMapping}^{\uparrow}$ *graph row, with a displayed self-map route, graph admission, rational contraction ledger, and strict unit-bound row.*
3. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *finite orbit row generated from an initial point by repeated reads of T.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *tail budget extracted from the residual distances carried by I and the contraction ledger of T.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reading the Picard orbit as a regular rational tail route before any endpoint-facing seal is consumed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after X, M, R have displayed the complete-metric limit request and the regular readback route.*
7. *H records componentwise* hsame *transport for the complete metric source, contraction graph, finite orbit, modulus, regular handoff, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from metric-distance requests through contraction application, finite Picard iteration, Cauchy-tail budgeting, regular handoff, and endpoint sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a host fixed-point object, quotient equality of functions, a countable-choice selector for iterates, or an ambient real-completeness oracle outside the carried $\mathsf{CompleteMetric}^{\uparrow}$ *source.*

Theorem 6902.2 (CompleteMetricFixedPoint NameCert obligations)**.** *For every accepted* CompleteMetricFixedPoi *carrier $F = (X, T, I, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricFixedPoint}^{\uparrow}}$ *surface consists exactly of complete-metric source admission, contraction-graph admission, Picard-orbit visibility, Cauchy-modulus tail budgeting,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff visibility,* $\mathsf{Real}^{\uparrow}$ *seal separation, component-wise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the carrier of Definition 6902.1.*

Proof. Project the carrier of Definition 6902.1. The displayed tuple exposes $X, T, I, M, R, E, H, C, P, N$ before any endpoint-facing consumer may read the packet.

Use the sibling interfaces. The $\mathsf{CompleteMetric}^{\uparrow}$ row supplies the carried limit-service surface, the $\mathsf{ContractionMapping}^{\uparrow}$ row supplies the graph and contraction-bound data, and the $\mathsf{PicardIteration}^{\uparrow}$ row supplies the finite orbit and residual-distance ledger.

The rows M, R, E form the completion-facing tail. The Cauchy-modulus row packages the finite tail budget, the regular-rational row packages the readback route, and the real seal remains downstream of both.

Finally attach H, C, P, N. Transport, replay, provenance, and local naming preserve the same carrier, so the NameCert surface contains exactly the listed rows and none of the excluded host fixed-point, quotient, choice, or ambient-completeness coordinates. □

Theorem 6902.3 (CompleteMetricFixedPoint Picard route)**.** *Every public fixed-point read of an accepted* $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may then be consumed by the $\mathsf{BanachFixedPoint}^{\uparrow}$ *endpoint discipline, but only after the finite orbit, tail budget, regular readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows have been displayed. It exports no selected host fixed point, quotient function equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the complete metric and contraction rows. The source row X is the only complete-metric surface available to the packet, and the graph row T is the only route for applying the contraction.

Read the Picard orbit next. The row I is finite and is generated by repeated visible applications of T, so it records a displayed orbit rather than a chosen infinite sequence or a selected endpoint.

Use the tail budget and handoff rows. The row M records the Cauchy modulus extracted from the orbit and contraction ledger, R records the regular rational readback route, and E is reached only after those rows have been exposed.

The Banach fixed-point sibling can consume this endpoint route as a fixed-point discipline, but it receives only $X, T, I, M, R, E, H, C, P, N$. Since the carrier has no additional coordinate, the public Picard route cannot be read as host fixed-point equality, quotient function equality, countable choice, or ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$ read factors through one CompleteMetricUp source, one ContractionMappingUp graph, one PicardIterationUp finite orbit, one CauchyModulusUp tail budget, one RegSeqRatUp handoff, one RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any fixed-point endpoint is consumed.

Independence witness: completemetric, contractionmapping, picarditeration, banachfixedpoint, regseqrat, real: none is bijective with $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$ because the packet jointly stores the complete metric source, contraction graph, Picard orbit, Cauchy tail budget, regular handoff, real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricFixedPoint}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6902.1, Definition 6902.2, and Definition 6902.3 seed the complete-metric fixed-point packet over displayed contraction, Picard, modulus, regular-rational, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected host fixed points, quotient function equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, contraction-graph admission, Picard-orbit visibility, Cauchy-modulus tail budgeting, RegSeqRat handoff visibility, Real seal separation, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{CompleteMetricFixedPoint}^{\uparrow}$ packet is generated from a CompleteMetricUp source row, ContractionMappingUp graph row, PicardIterationUp finite orbit, CauchyModulusUp tail budget, RegSeqRatUp handoff, RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6903

A Concrete Naming Certificate for $\mathsf{UniformBar}^{\uparrow}$

Following Bishop and Brouwer, the $\mathsf{UniformBar}^{\uparrow}$ packet records the finite-depth bar extraction used when a compact-uniform-continuity argument turns pointwise inspection into one shared modulus. It sits between the finite fan rows of chapter 400, the compact source rows of chapter 129, the metric and continuity surfaces of $\mathsf{Met}^{\uparrow}$ and $\mathsf{Continuous}^{\uparrow}$, and the rational precision rows of chapter 37. The packet is a finite certificate over displayed bar decisions, compact probes, pointwise modulus reads, rational tolerances, BHist histories, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

It is not Brouwer bar induction, not open-cover compactness, not a selected infinite branch, and not a host modulus function. A downstream L10 compact-uniform-continuity or real-completion consumer reads only the finite depth, the inspected witness window, and the rational precision ledger named by the packet.

Definition 6903.1 (UniformBar carrier)**.** *A* $\mathsf{UniformBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, K, M, A, R, D, W, H, C, P, N)$$

with the following visible rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite fan row supplying a decidable bar and unary branch-depth ledger;*
2. *K is the* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite probes are inspected by the bar;*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *source-distance row used to compare neighbouring compact probes;*
4. *A is the* $\mathsf{Continuous}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to each displayed probe;*
5. *R is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance request whose response is the extracted uniform depth;*
6. *D is the accepted finite depth row, read as a unary bound common to all displayed probe branches;*
7. *W is the finite witness window listing exactly the probe prefixes and pointwise modulus rows inspected before depth D;*
8. *H stores componentwise* hsame *transports for the fan, compact, metric, continuity, rational, depth, witness-window, provenance, and local naming rows;*
9. *C stores displayed* Cont *replay routes for bar inspection, compact-probe readback, pointwise-modulus readback, rational-tolerance comparison, and uniform-depth export;*

10. *P is* Pkg *provenance over* $\mathsf{UniformBar}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformBar}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite branch, an open cover, a selected subcover, an ambient compactness theorem, a host modulus function, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6903.2 (UniformBar NameCert obligations)**.** *For every accepted* $\mathsf{UniformBar}^{\uparrow}$ *carrier* $U = (F, K, M, A, R, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformBar}^{\uparrow}}$ *surface consists exactly of fan-bar exposure through F, compact-source exposure through K, metric comparison through M, pointwise continuity exposure through A, rational tolerance exposure through R, finite-depth exposure through D, witness-window exposure through W, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6903.1. The rows F, K, M, A, R fix the fan, compact, metric, continuity, and rational inputs before any uniform depth can be read.

The row D is the only finite-depth output, and W records the exact probe prefixes and pointwise modulus reads inspected to justify it. Thus the bar extraction is a finite ledger over displayed rows, not an appeal to an infinite branch space or an open-cover compactness principle.

Transport H and replay C preserve those rows componentwise. Provenance P and the local row N then repack the same inventory as the local $\mathsf{NameCert}_{\mathsf{UniformBar}^{\uparrow}}$ surface, so the obligation surface contains no hidden subcover selection, host modulus function, or real-completion coordinate. □

Theorem 6903.3 (UniformBar finite-depth modulus)**.** *Every* $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, *or L10 real-completion consumer that reads an accepted* $\mathsf{UniformBar}^{\uparrow}$ *carrier receives a modulus only through the finite route*

$$\mathsf{FanTheorem}^{\uparrow},\ \mathsf{Compact}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Continuous}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ D,\ W,\ H,\ C,\ P,\ N.$$

The extracted modulus is the displayed depth D together with the witness window W and its rational tolerance ledger. It cannot be replaced by open-cover compactness, Brouwer bar induction, a selected infinite branch, a host supremum of pointwise moduli, quotient real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 6903.2. Any consumer read must expose the fan-bar row, compact source row, metric comparison row, pointwise continuity row, rational tolerance row, depth row, witness-window row, and the structural rows of the packet.

The finite fan row contributes only the decidable bar and unary branch-depth ledger, as in the public finite fan route of Definition 400.7. The compact and metric rows determine which probes are inspected, and the continuity rows attach pointwise modulus data only to those probes.

Finally read the rational request through R and the extracted depth through D. The witness window W lists every pointwise row used before that depth, while H, C, P, N preserve the same finite route under transport, replay, provenance, and naming. Since the carrier exposes no open-cover, branch-selection, host-modulus, quotient-real, or real-completion coordinate, the consumer receives exactly the finite-depth modulus described above. □

Falsifiable prediction: Any accepted $\mathsf{CompactUniformContinuity}^{\uparrow}$ or $\mathsf{UniformModulus}^{\uparrow}$ consumer that obtains a uniform depth without first exposing $F, K, M, A, R, D, W, H, C, P, N$ refutes the carrier surface of Definition 6903.1.

Independence witness: fan theorem, compact source, metric source, continuity row, rational tolerance: no listed sibling is bijective to $\mathsf{UniformBar}^{\uparrow}$, because this packet jointly binds a finite

bar depth, compact probe inspection, pointwise modulus reads, rational tolerance response, componentwise transport, replay, provenance, and local NameCert rows into one extraction carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformBar}\uparrow}$.

Constructive story: A $\mathsf{UniformBar}^{\uparrow}$ packet is generated from a FanTheoremUp finite bar row, CompactUp or CompactMetricUp source probes, MetricUp comparison rows, ContinuousUp or ContinuousMapUp pointwise modulus rows, a positive RatUp tolerance request, a finite depth row, a witness-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformBar}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6903.1, Definition 6903.2, and Definition 6903.3 seed the finite-depth bar extraction surface over FanTheoremUp, CompactUp, CompactMetricUp, MetricUp, ContinuousUp, ContinuousMapUp, RatUp, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformBar}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Brouwer bar induction, open-cover compactness, selected infinite branches, host modulus extraction, quotient real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bar exposure, compact probe inspection, pointwise modulus exposure, rational tolerance response, depth-window exactness, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.UniformBarUp.

Chapter 6904

A Concrete Naming Certificate for $\mathsf{InverseFunctionModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{InverseFunctionModulus}^{\uparrow}$ packet records the local inverse data that must be visible before an inverse-function read is treated as quantitative. It sits downstream of the local inverse carrier of chapter 2055, the derivative source rows of chapter 122, the pointwise continuity route of chapter 130, the terminal real-name seal of chapter 38, the regular rational readback schedule of chapter 301, and the finite Newton-step service of chapter 223. The packet names a finite modulus boundary for local inverse construction; it does not turn local data into a global inverse theorem, host topology, or choice-selected inverse branch.

Definition 6904.1 (Inverse-function modulus carrier)**.** *An* $\mathsf{InverseFunctionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, L, B, R, C_m, N_t, H, K, P, N)$$

with the following rows:

1. *W is the source point window, naming the base point, source radius, target radius, and the finite neighbourhood on which the local inverse read is allowed.*
2. *L is the derivative lower-bound row, recording the displayed nonzero derivative or invertible-linear lower estimate used to keep the inverse step separated from collapse.*
3. *B is the* $\mathsf{Real}^{\uparrow}$ *local ball row, sealing the source and target ball endpoints as real-name data rather than as host open sets.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rate-budget row, carrying the rational modulus schedule and the finite tolerance ledger used to compare requested output precision with input-window precision.*
5. *C_m is the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row for the displayed map on the same window.*
6. *N_t is the* $\mathsf{NewtonIteration}^{\uparrow}$ *or Picard contraction row, recording the finite contraction certificate and the first accepted iteration window.*
7. *H records componentwise* hsame *transport for source windows, derivative lower bounds, Real balls, rate budgets, continuous-map modulus rows, Newton or Picard rows, provenance, and local naming.*
8. *K records displayed* Cont *replay through*

$$W, L, B, R, C_m, N_t \longmapsto \mathsf{NameCert}_{\mathsf{InverseFunctionModulus}^{\uparrow}}.$$

9. *P is the* Pkg *provenance over* InverseFunctionModulus$^{\uparrow}$, InverseFunction$^{\uparrow}$, Derivative$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, NewtonIteration$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{InverseFunctionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, L, B, R, C_m, N_t, H, K, P, N$. It has no coordinate for a global inverse function, a selected inverse branch outside the displayed window, ambient completeness, classical open mapping, or choice-based local selection.

Theorem 6904.2 (Inverse-function modulus local bijection obligation)**.** *For every accepted* InverseFunctionModulus *carrier*

$$M = (W, L, B, R, C_m, N_t, H, K, P, N),$$

the local inverse-bijection obligation is read only from the displayed source window, derivative lower-bound row, Real local ball, RegSeqRat rate budget, ContinuousMap modulus row, Newton or Picard contraction row, componentwise transport, replay, provenance, and local naming. In particular, any local inverse read exported through M must keep the same window W, lower bound L, ball B, budget R, modulus C_m, and contraction row N_t visible at the consumer boundary.

Proof. Project the carrier of Definition 6904.1. The rows W, L, B, R, C_m, N_t are the only analytic rows in the packet, and each is tied to the same local window by the classifier.

The lower-bound row L and the continuous-map modulus row C_m provide the quantitative separation and continuity data that a local inverse read may inspect. The Real ball B and the RegSeqRat budget R keep the neighbourhood and tolerance data inside displayed real names and finite regular-rational schedules.

The Newton or Picard row N_t supplies the finite contraction service on this same window. Componentwise hsame transport and displayed Cont replay repack exactly those rows into the local NameCert$_{\text{InverseFunctionModulus}^{\uparrow}}$ surface, so no global inverse function, host open mapping theorem, selected inverse branch, or ambient completeness coordinate is introduced. □

Theorem 6904.3 (Inverse-function modulus Newton-window stability)**.** *Classified* InverseFunctionModulus$^{\uparrow}$ *packets remain classified after replacing the source point window, derivative lower-bound row, Real local ball, RegSeqRat rate budget, ContinuousMap modulus row, or Newton/Picard contraction row by componentwise* hsame*-related rows, provided the replay row still displays the same route*

$$W, L, B, R, C_m, N_t \longmapsto \text{NameCert}_{\text{InverseFunctionModulus}^{\uparrow}}.$$

The resulting packet exports the same local inverse-modulus boundary and does not add a fresh window, selected inverse branch, or unbudgeted convergence claim.

Proof. Start with two accepted packets and the componentwise hsame comparisons for W, L, B, R, C_m, N_t. The classifier of Definition 6904.1 permits transport only along those displayed coordinates and the structural rows H, K, P, N.

Use the transported Real ball and RegSeqRat rate budget to keep the local metric and tolerance rows attached to the same source window. Then transport the ContinuousMap modulus row and the Newton or Picard contraction row through the same comparison data. The replay row K repacks this transported route as one displayed history.

Since the transported packet still uses the same ten rows, it has no coordinate from which to choose a new inverse branch, enlarge to a global inverse theorem, import completeness, or appeal to classical open mapping. The local inverse-modulus boundary is therefore stable under the displayed componentwise transport. □

Closure status for $\mathsf{NameCert}_{\mathsf{InverseFunctionModulus}\uparrow}$.

Constructive story: An $\mathsf{InverseFunctionModulus}^{\uparrow}$ packet is generated from a source point window, derivative lower-bound row, Real local ball, RegSeqRat rate budget, ContinuousMap modulus row, Newton or Picard contraction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InverseFunctionModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6904.1, Definition 6904.2, and Definition 6904.3 seed the finite local inverse-modulus route over Real, RegSeqRat, continuous-map, derivative, and Newton/Picard rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InverseFunctionModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global inverse-function theorem, RealUp completeness, classical open mapping, choice-based local selection, selected inverse germs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, local bijection obligation coverage, Newton-window stability, rate-budget exactness, provenance exactness, and local naming for BEDC.Derived.InverseFunctionModulusUp.

Chapter 6905

A Concrete Naming Certificate for $\mathsf{PseudoArc}^{\uparrow}$

Following Bing's pseudo-arc construction, the $\mathsf{PseudoArc}^{\uparrow}$ packet records a hereditarily indecomposable chainable compact metric continuum through finite inverse-limit rows rather than through a host continuum object. It sits over the compact-metric source of chapter 129, the finite projection discipline of chapter 2168, the complete-metric boundary of chapter 128, the stream-window surface of chapter 126, and the regular rational readback of chapter 301. The packet names only displayed finite chain covers, projection refinements, and indecomposability obstruction rows before any continuum-facing consumer may read it.

Definition 6905.1 (Pseudo-arc carrier)**.** *A* $\mathsf{PseudoArc}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (K, I, C, D, R, E, H, T, G, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing finite metric covers, compact-metric provenance, and distance readback for the current continuum window.*
2. *I is the* $\mathsf{InverseLimitMetric}^{\uparrow}$ *row, recording a finite prefix of compact metric continua, bonding-map windows, and projection-compatibility checks.*
3. *C is the chainability row: for each displayed scale it lists a finite chain cover and its adjacency ledger over the same compact metric source.*
4. *D is the hereditary-indecomposability row, recording finite obstruction tests for splitting a displayed subcontinuum window into two proper subcontinua.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the diameters, overlap tolerances, and bonding-map moduli inspected by C and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the requested tolerance budget.*
7. *H records componentwise* hsame *transport for compact-metric, inverse-limit, chainability, indecomposability, readback, seal, provenance, and naming rows.*
8. *T records displayed* Cont *replay from compact-metric cover requests through inverse-limit projections, chain covers, obstruction tests, and regular rational readback.*
9. *G is the* Pkg *provenance over* $\mathsf{PseudoArc}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{InverseLimitMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{PseudoArc}^\uparrow}$ *row.*

The classifier compares accepted packets only through $K, I, C, D, R, E, H, T, G, N$. It has no coordinate for a host pseudo-arc, quotient continuum equality, a choice-selected inverse-limit point, open-cover compactness, or an ambient completeness theorem.

Theorem 6905.2 (Pseudo-arc NameCert obligations)**.** *For every accepted* $\mathsf{PseudoArc}^\uparrow$ *carrier $P = (K, I, C, D, R, E, H, T, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{PseudoArc}^\uparrow}$ *surface consists exactly of compact-metric source admission through K, finite inverse-limit prefix admission through I, displayed chain-cover coverage through C, hereditary-indecomposability obstruction exposure through D, regular rational tolerance readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through T, provenance through G, and local naming through N.*

Every continuum-facing consumer must read these rows before it may use the packet as pseudo-arc data, and no obligation row is discharged by a host pseudo-arc theorem, quotient equality of continua, selected inverse-limit representatives, open-cover compactness, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 6905.1. The compact source K and inverse-limit prefix I are the only continuum-source rows, so every consumer begins with displayed compact-metric covers and finite projection compatibility.

The chainability and hereditary-indecomposability rows are finite. The row C lists chain covers at inspected scales, while D lists obstruction windows preventing a displayed subcontinuum split. The regular rational row R supplies the tolerance readback needed by both rows before the real seal E is consumed.

Transport and replay keep the packet local. The rows H and T preserve the same compact-metric, inverse-limit, chainability, obstruction, readback, and seal data under hsame and Cont, while G and N provide provenance and naming.

Since the carrier has no coordinate for a host pseudo-arc, quotient continuum equality, selected inverse-limit point, open-cover compactness, countable choice, or ambient real completeness, the local NameCert surface is exhausted by the displayed rows. □

Lean4 (statement) `BEDC.Derived.PseudoArcUp`

Falsifiable prediction: Every accepted $\mathsf{PseudoArc}^\uparrow$ read exposes compact-metric cover rows, finite inverse-limit prefix rows, chain-cover rows, hereditary-indecomposability obstruction rows, regular rational tolerance readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before a continuum-facing consumer can inspect the packet.

Independence witness: compactmetric, inverse-limit-metric, completemetric, streamname, regseqrat: $\mathsf{PseudoArc}^\uparrow$ is not bijective to any listed sibling because this packet binds chainability rows, hereditary-indecomposability obstruction rows, finite inverse-limit prefixes, compact-metric source rows, readback, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{PseudoArc}^\uparrow}$**.**

Constructive story: A $\mathsf{PseudoArc}^\uparrow$ packet is generated from CompactMetricUp source rows, finite InverseLimitMetricUp prefix rows, chain-cover rows, hereditary-indecomposability obstruction rows, RegSeqRatUp tolerance readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PseudoArc}^\uparrow}$, seed)

Scope closed: Definition 6905.1 and Definition 6905.2 seed the finite pseudo-arc boundary over compact-metric, inverse-limit, chainability, obstruction, readback, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PseudoArc}^\uparrow}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not claim a host pseudo-arc theorem, quotient continuum equality, selected inverse-limit representatives, open-cover compactness, countable choice, Lean-checked obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite inverse-limit prefix admission, chain-cover coverage, hereditary-indecomposability obstruction exposure, tolerance readback, transport, replay, provenance, and local naming for BEDC.Derived.PseudoArcUp.

Chapter 6906

A Concrete Naming Certificate for $\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}$ packet records the finite oscillation criterion by which a displayed regular Cauchy rational name may be handed to Real and Completion consumers without quotienting streams or selecting limits. It sits after the dyadic tolerance core of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the bounded oscillation packet of chapter 6787. The packet names only the displayed windows, dyadic budgets, oscillation rows, readback route, and seal boundary.

Definition 6906.1 (Regular Cauchy oscillation criterion carrier)**.** *A* $\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, W, D, O, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the finite inspected stream-name entries of the candidate regular Cauchy rational name.*
2. *W is the finite observation-window ledger, including the paired indices and tail windows on which oscillation is tested.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget carrying the requested radius, slack, and comparison cells.*
4. *O is the finite oscillation-bound row, recording that the displayed windows are below the carried dyadic budget.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows, dyadic tolerances, and oscillation ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after S, W, D, O, R have been displayed.*
7. *H records componentwise* hsame *transport for the source, window, dyadic, oscillation, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an oscillation-criterion request through S, W, D, O, R and then to the seal E.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BoundedOscillation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, a selected limit, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyOscillationCriterionUp.RegularCauchyOscillationCriterionTasteGate single carrier alignment`

Theorem 6906.2 (Regular Cauchy oscillation criterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}$ *carrier* $K = (S, W, D, O, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillatio}}$ *surface consists exactly of carrier admission for the finite stream-name source row, observation-window ledger, dyadic tolerance budget, finite oscillation-bound row, regular rational readback, Real seal, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6906.1. The analytic rows are S, W, D, O, R, E, and the structural rows are H, C, P, N.

The source and window obligations are finite. The row S supplies the displayed stream-name entries, while W lists the paired tail windows on which the oscillation test is read.

The dyadic and oscillation obligations are also finite. The row D supplies the tolerance budget, and O records the bounded oscillation comparison against that budget before the regular rational readback R is visible.

Finally, E seals the same route as a Real-facing name, and H, C, P, N transport, replay, source, and name the packet. Since no further coordinate exists, the listed rows exhaust the NameCert surface and exclude quotient streams, selected limits, countable choice, host equality, trichotomy, and ambient completeness. □

Theorem 6906.3 (Regular Cauchy oscillation criterion RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ W,\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{BoundedOscillation}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the consumer sees the same stream source row, observation windows, dyadic tolerance budget, finite oscillation ledger, regular rational readback, and Real seal before the completion-facing boundary is available. It receives no quotient stream equality, selected limit, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $K = (S, W, D, O, R, E, H, C, P, N)$. By Definition 6906.2, the regular rational readback R is downstream of the stream source S, observation windows W, dyadic tolerance budget D, and oscillation-bound row O.

The handoff therefore cannot expose R directly. It must first display the finite windows and dyadic comparisons, then read the bounded oscillation row as the criterion that the regular Cauchy tail has stabilized within the carried budget.

After R is visible, the seal E supplies the Real-facing endpoint along the same replay route C. Componentwise transport H, provenance P, and local naming N preserve that route and add no quotient, choice, trichotomy, host equality, selected-limit, or ambient-completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}$ packet is generated from a StreamName source row, finite observation windows, DyadicRatCore tolerance budget, finite oscillation-bound row, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6906.1, Definition 6906.2, and Definition 6906.3 seed the finite regular Cauchy oscillation criterion for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationCriterion}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyOscillationCriterionUp.RegularCauchyOscillationCriterionTasteGate\_single\`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, dyadic tolerance exactness, oscillation-bound confinement, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyOscillationCriterionUp.

Chapter 6907

A Concrete Naming Certificate for $\mathsf{BergeMaximum}^{\uparrow}$

Following Berge's maximum theorem and Aubin–Frankowska set-valued analysis, the $\mathsf{BergeMaximum}^{\uparrow}$ packet records the compact-parameter, compact-valued feasible graph, and continuous real objective data needed to read the maximum-value function through finite BEDC rows. It sits over the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the terminal real seal of chapter 38, the upper-hemicontinuity boundary of chapter 6553, and the scalar finite-net readback of chapter 1493. The packet names a maximum-value ledger, not a selected optimizer or host choice principle.

Definition 6907.1 (Berge maximum carrier)**.** *A* $\mathsf{BergeMaximum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (K_0, F, G, V, M, H, C, P, N)$$

with the following displayed rows:

1. K_0 *is the compact parameter-source row, read through the compact metric certificate;*
2. F *is the compact-valued feasible-graph row, including the finite graph windows used by the upper-hemicontinuity boundary;*
3. G *is the continuous* $\mathsf{Real}^{\uparrow}$*-valued objective row on the displayed feasible graph;*
4. V *is the finite-net value-window ledger for objective reads over each displayed feasible fibre;*
5. M *is the maximum-value comparison row, obtained by folding the finite* $\mathsf{Real}^{\uparrow}$ *value windows;*
6. H *stores componentwise* hsame *transport for* K_0, F, G, V, M *and the local naming rows;*
7. C *stores the displayed* Cont *replay from compact parameter windows, feasible graph rows, objective reads, and finite value windows to the maximum-value comparison;*
8. P *is the* Pkg *provenance over the same compact-parameter and value-window packet;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{BergeMaximum}^{\uparrow}}$ *row.*

The carrier keeps the selected-argmax socket outside the exported rows: consumers may read the value ledger M*, but no row chooses an optimizer from a feasible fibre.*

Theorem 6907.2 (Berge maximum NameCert obligations)**.** *For the carrier of Definition 6907.1, the local* $\mathsf{NameCert}_{\mathsf{BergeMaximum}^{\uparrow}}$ *surface consists of five finite obligations: carrier admission for*

K; upper-hemicontinuity and compact-value boundary for F over K_0; continuous objective $\mathsf{Real}^{\uparrow}$ *sealing for G; finite-net maximum-value readback through V and M; and refusal of selected argmax data, open-cover compactness, and choice outside the displayed packet.*

Theorem 6907.3 (Finite-net maximum-value attainment route)**.** *Every accepted* $\mathsf{BergeMaximum}^{\uparrow}$ *packet exports its maximum-value ledger by a finite* ProbeBundle *fold over compact nets and* $\mathsf{Real}^{\uparrow}$*-sealed objective values. The exported row is the value comparison M together with its* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *boundary; no exported row selects an optimizer.*

Proof. Read the compact parameter row K_0 and feasible graph row F through the compact metric and upper-hemicontinuity certificates. These rows provide finite feasible-fibre windows for the current parameter read, rather than an ambient open-cover compactness theorem.

Next replay the continuous objective row G through the $\mathsf{Real}^{\uparrow}$ seal. Each finite feasible-window read contributes a value window in V, and the comparison row M is obtained by folding those displayed real value windows.

Finally transport the folded value row through H, replay it through C, and record its provenance in P and local name in N. The fold exposes a maximum-value ledger, while the selected-argmax request remains outside $K_0, F, G, V, M, H, C, P, N$. □

Lean4 (statement) `BEDC.Derived.BergeMaximumUp`

Closure status for $\mathsf{NameCert}_{\mathsf{BergeMaximum}^{\uparrow}}$.

Constructive story: A $\mathsf{BergeMaximum}^{\uparrow}$ packet is generated from compact parameter data, a compact-valued feasible graph, a continuous real objective, finite-net value windows, a maximum-value comparison row, componentwise transport, replay, provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BergeMaximum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6907.1, Definition 6907.2, and Definition 6907.3 name the finite maximum-value carrier and selected-argmax refusal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BergeMaximum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close selected optimizer extraction, open-cover compactness, countable choice, quotient function equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-hemicontinuity compact-value boundary, continuous objective sealing, finite-net value readback, and local naming for the same packet.

Chapter 6908

A Concrete Naming Certificate for $\mathsf{CompactFunctionAlgebra}^{\uparrow}$

Following the Stone–Weierstrass and Gelfand traditions for continuous functions on compact spaces, the $\mathsf{CompactFunctionAlgebra}^{\uparrow}$ packet records a finite algebra of $\mathsf{Real}^{\uparrow}$-valued continuous functions over a compact metric source. It realizes the compact-uniform-continuity route of chapter 9237 through the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the terminal real seal of chapter 38, the uniform-modulus surface of chapter 369, the compact-open function-space carrier of chapter 2221, and the approximation interface of chapter 1919. The exported object is a finite operation and norm ledger, not an ambient function quotient.

Definition 6908.1 (Compact function algebra carrier)**.** *A* $\mathsf{CompactFunctionAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, F, +, \cdot, 1, U, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row;*
2. *F is the finite family of continuous* $\mathsf{Real}^{\uparrow}$*-valued function rows over K;*
3. *$+$ and $\cdot$ are pointwise addition and multiplication rows on displayed members of F;*
4. *1 is the constant-one row, read as a continuous* $\mathsf{Real}^{\uparrow}$*-valued function;*
5. *U records uniform-modulus data for every displayed function and every displayed operation output;*
6. *S is the sup-norm finite-net readback row, computed from compact-net value windows and* $\mathsf{Real}^{\uparrow}$ *comparison rows;*
7. *H stores componentwise* hsame *transport for $K, F, +, \cdot, 1, U, S$ and the local naming rows;*
8. *C stores the displayed* Cont *replay from compact-source reads, continuous-function rows, operation rows, uniform-modulus rows, and sup-norm windows to the algebra ledger;*
9. *P is the* Pkg *provenance over the same compact function packet;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactFunctionAlgebra}^{\uparrow}}$ *row.*

The carrier exports operation stability and uniform-norm readback only for the displayed finite packet; it does not identify functions by an ambient quotient or import a completed Banach algebra.

Theorem 6908.2 (Compact function algebra NameCert obligations)**.** *For the carrier of Definition 6908.1, the local* $\mathsf{NameCert}_{\mathsf{CompactFunctionAlgebra}^{\uparrow}}$ *surface consists of five finite obligations: carrier admission for A; stability of pointwise addition, pointwise multiplication, and the constant-one row inside the displayed family; uniform-modulus handoff for each displayed function and operation output; sup-norm readback through finite compact nets and* $\mathsf{Real}^{\uparrow}$ *value windows; and refusal of ambient function quotienting, completed Banach-algebra closure, unrestricted infinite linear combinations, and selected dense approximation data outside the packet.*

Theorem 6908.3 (Compact function algebra uniform-norm route)**.** *Every accepted* $\mathsf{CompactFunctionAlgebra}^{\uparrow}$ *packet reads its sup-norm row through compact finite nets and* $\mathsf{Real}^{\uparrow}$*-sealed value windows. The resulting ledger is transported by H, replayed by C, recorded by P, and named by N without exporting an ambient function quotient or a completed algebra.*

Proof. Read the compact metric source row K and the finite family F through the displayed continuous-map rows. The pointwise operation rows $+$, $\cdot$, and 1 stay inside the finite packet, so operation stability is checked before any norm comparison is read.

Next use the uniform-modulus row U to pass from pointwise value windows to compact finite-net windows. Each sampled value is sealed as a $\mathsf{Real}^{\uparrow}$ read, and the sup-norm row S is obtained by folding the displayed value-window comparisons over the finite net.

Finally transport the operation and sup-norm ledger through H, replay the route through C, record provenance in P, and attach the local name N. The route exposes finite algebra and norm data, while completed closure, quotient equality, and selected approximation witnesses remain outside A. □

Lean4 (statement) `BEDC.Derived.CompactFunctionAlgebraUp`

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFunctionAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactFunctionAlgebra}^{\uparrow}$ packet is generated from a compact metric source, finite continuous real-valued function rows, pointwise addition and multiplication rows, a constant-one row, uniform-modulus rows, sup-norm finite-net readback, componentwise transport, replay, provenance, and a local naming row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactFunctionAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 6908.1, Definition 6908.2, and Definition 6908.3 name the finite compact function algebra carrier and uniform-norm readback boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactFunctionAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close completed Banach-algebra structure, unrestricted Stone–Weierstrass approximation, quotient function equality, selected dense witnesses, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operation stability, uniform-modulus handoff, sup-norm finite-net readback, and local naming for the same packet.

Chapter 6909

A Concrete Naming Certificate for $\mathsf{DyadicNetTree}^{\uparrow}$

Following Christ's dyadic cubes and finite metric net-tree practice in constructive metric analysis, the $\mathsf{DyadicNetTree}^{\uparrow}$ packet records a multiscale finite-net skeleton as BEDC NameCert data. It sits over the metric source of chapter 57, the doubling control of chapter 2035, the levelwise finite-net rows of chapter 1767, the total-bounded coverage surface of chapter 127, the covering-number budget of chapter 2187, and the dyadic scale ledger of chapter 291. The packet names the finite multiscale route only; it does not import a host cover tree, quotient equality of trees, selected centers outside the displayed net rows, or ambient compactness.

Definition 6909.1 (DyadicNetTree carrier)**.** *A* $\mathsf{DyadicNetTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, S, E, T, B, L, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, recording the carrier, distance-reading route, and local metric naming surface.*
2. *S is the* $\mathsf{DoublingMetric}^{\uparrow}$ *scale-control row, recording the finite doubling budget used to compare adjacent dyadic levels.*
3. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *family row, exposing the center bundle selected at each displayed dyadic level.*
4. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *coverage row, asserting only the displayed finite coverage witnesses read from the same levelwise nets.*
5. *B is the* $\mathsf{MetricCoveringNumber}^{\uparrow}$ *budget row, storing the finite upper bound consumed by the level ledger.*
6. *L is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale ledger, storing level indices, dyadic radii, mesh comparisons, and late-radius requests.*
7. *R is the parent-child refinement row, recording for every displayed child center the parent center, scale comparison, containment witness, and nonescape certificate visible at the next coarser level.*
8. *H records componentwise* hsame *transport for the metric source, doubling row, finite-net family, total-bounded coverage, covering budget, dyadic ledger, parent-child refinement, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a multiscale net-tree request through M, S, E, T, B, L, R, H.*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicNetTree}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DoublingMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{MetricCoveringNumber}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicNetTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, E, T, B, L, R, H, C, P, N$. It has no coordinate for a selected host tree, an unbounded center oracle, minimal cover cardinality, open-cover compactness, quotient equality of trees, or ambient completion.

Theorem 6909.2 (DyadicNetTree NameCert obligations)**.** *For every accepted* $\mathsf{DyadicNetTree}^{\uparrow}$ *carrier*

$$D = (M, S, E, T, B, L, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicNetTree}^{\uparrow}}$ *surface consists exactly of carrier admission through M, scale visibility through S and L, levelwise coverage through E and T, parent-child refinement through R, budget nonescape through B, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 6909.1. The metric source row M is the only carrier admission surface, while S and L expose the doubling and dyadic scale data before any level is read.

The levelwise coverage obligations are then forced through E and T. The finite-net row displays the centers at each inspected level, and the total-bounded row supplies only the coverage witnesses attached to those displayed centers.

The budget and refinement rows are separate. The row B keeps the covering-number budget visible, and the row R records the parent of each displayed child center together with the containment and nonescape witnesses needed for the next coarser level.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no host-tree, minimal-cardinality, open-cover, quotient-tree, center-oracle, or ambient-completion coordinate, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{DyadicNetTree}^{\uparrow}$ read exposes the MetricUp source, DoublingMetricUp scale-control row, FiniteEpsilonNetUp level centers, TotallyBoundedUp coverage witnesses, MetricCoveringNumberUp budget, DyadicRatCoreUp scale ledger, parent-child refinement row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any multiscale tree consumer reads the packet.

Independence witness: metric, doublingmetric, finite-epsilon-net, totallybounded, metric-covering-number, dyadicratcore: no listed sibling is bijective with $\mathsf{DyadicNetTree}^{\uparrow}$ because this packet jointly stores levelwise centers, scale control, coverage, budget, dyadic ledger, parent-child refinement, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicNetTree}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicNetTree}^{\uparrow}}$, seed)

Scope closed: Definition 6909.1 and Definition 6909.2 seed the dyadic net-tree packet over displayed metric, doubling, finite-net, total-bounded, covering-budget, dyadic-scale, parent-child, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicNetTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host cover-tree equality, selected centers outside displayed net rows, minimal covering cardinality, open-cover compactness, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, scale visibility, levelwise coverage, parent-child refinement, budget nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicNetTreeUp.

Constructive story: A DyadicNetTree$^{\uparrow}$ packet is generated from a MetricUp source row, DoublingMetricUp scale-control row, FiniteEpsilonNetUp centers per dyadic level, TotallyBoundedUp coverage row, MetricCoveringNumberUp budget row, DyadicRatCoreUp scale ledger, parent-child refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6910

A Concrete Naming Certificate for $\mathsf{DedekindCutBoundary}^{\uparrow}$

Following Dedekind and Bishop–Bridges constructive analysis, the $\mathsf{DedekindCutBoundary}^{\uparrow}$ packet records the L10 constraint that Dedekind cuts are comparison data, not a construction of $\mathsf{Real}^{\uparrow}$. It sits between the located cut surface of chapter 404, the Dedekind real comparison surface of chapter 3629, the regular Cauchy comparison route of chapter 1424, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the finite boundary at which a cut-shaped read may be compared with regular Cauchy data without becoming an ambient real construction.

Definition 6910.1 (Dedekind cut boundary carrier)**.** *A* $\mathsf{DedekindCutBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, D, Q, R, S, Y, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *comparison row, recording only the displayed lower–upper separation witnesses used by finite consumers.*
2. *D is the* $\mathsf{DedekindReal}^{\uparrow}$ *comparison row, read as a cut-shaped interface rather than as a constructor for* $\mathsf{Real}^{\uparrow}$*.*
3. *Q is the* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *boundary row comparing L, D with regular Cauchy readback data.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed regular rational windows.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite inspected entries of the regular rational name.*
6. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the displayed rational comparison budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after the comparison route L, D, Q, R, S, Y has been displayed.*
8. *H records componentwise* hsame *transport for the located-cut, Dedekind-real, comparison, regular-readback, stream-window, dyadic, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from cut-shaped observations through the comparison row and then through the regular Cauchy readback to the seal E.*

10. *P is the* Pkg *provenance over* $\mathsf{DedekindCutBoundary}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DedekindReal}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCutBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a quotient cut, host supremum, selected representative, trichotomy branch, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.DedekindCutBoundaryUp`

Theorem 6910.2 (Dedekind cut boundary NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCutBoundary}^{\uparrow}$ *carrier* $B = (L, D, Q, R, S, Y, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DedekindCutBoundary}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the* $\mathsf{LocatedCut}^{\uparrow}$ *comparison row,* $\mathsf{DedekindReal}^{\uparrow}$ *cut-shaped comparison row,* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *boundary row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budgets, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.DedekindCutBoundaryUp.DedekindCutBoundaryNameCertObligations`

Proof. Project the carrier of Definition 6910.1. The analytic rows are L, D, Q, R, S, Y, E, and the structural rows are H, C, P, N.

The cut-shaped rows are comparison data. The located-cut row L and the Dedekind-real row D are not read directly as a real constructor; they first pass through the $\mathsf{DedekindCauchyComparison}^{\uparrow}$ row Q.

The regular readback rows are finite. The row R is inspected through the stream windows S and dyadic tolerance ledger Y before the terminal seal E can be read.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier lists no quotient cut, selected representative, trichotomy branch, countable-choice selector, host supremum, or ambient completeness row, the displayed rows exhaust the local NameCert surface. □

Theorem 6910.3 (Dedekind cut boundary Real non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{DedekindCutBoundary}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedCut}^{\uparrow},\ \mathsf{DedekindReal}^{\uparrow} \longmapsto \mathsf{DedekindCauchyComparison}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto$$

Thus the packet may compare cut-shaped observations with regular Cauchy data, but it cannot construct $\mathsf{Real}^{\uparrow}$ *from Dedekind cuts or export quotient cut equality, selected representatives, countable choice, trichotomy, host supremum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $B = (L, D, Q, R, S, Y, E, H, C, P, N)$. By Definition 6910.2, the $\mathsf{Real}^{\uparrow}$ seal E is downstream of the located-cut, Dedekind-real, comparison, regular-readback, stream-window, and dyadic rows.

The cut-shaped observations therefore cannot reach E directly. They are first compared at Q, then read through the regular rational row R, the finite stream windows S, and the tolerance row Y.

The structural rows H, C, P, N preserve this route but add no constructor coordinate. Hence a downstream consumer may use the packet as a boundary between Dedekind-cut comparison and regular Cauchy readback, not as a construction of $\mathsf{Real}^{\uparrow}$ from cuts. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCutBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCutBoundary}^{\uparrow}$ packet is generated from LocatedCut comparison rows, DedekindReal comparison rows, DedekindCauchyComparison boundary rows, RegSeqRat readback, StreamName windows, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCutBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6910.1, Definition 6910.2, and Definition 6910.3 seed the finite Dedekind-cut comparison boundary for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCutBoundary}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DedekindCutBoundaryUp.DedekindCutBoundaryNameCertObligations`

Bridge status: none

Not claimed: This chapter does not close quotient cuts, selected representatives, countable choice, trichotomy, host supremum, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, axiom purity, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, LocatedCut comparison, DedekindReal comparison, DedekindCauchyComparison factorization, RegSeqRat readback, StreamName windows, DyadicRatCore tolerance exactness, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.DedekindCutBoundaryUp.

Chapter 6911

A Concrete Naming Certificate for $\mathsf{PoincareBendixsonTrap}^{\uparrow}$

Following Poincare and Bendixson, the $\mathsf{PoincareBendixsonTrap}^{\uparrow}$ packet records the finite trapping-region certificate used by planar autonomous dynamics before any periodic-orbit conclusion is read. It sits over the displayed ODE row of chapter 193, the flow-state surface of chapter 195, the compact metric carrier of chapter 129, the continuous-map route of chapter 130, and the terminal real-name seal of chapter 38. The packet names only the trap boundary and finite flow-window obligations; it does not select a host trajectory, complete a global flow, quotient path equality, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6911.1 (Poincare–Bendixson trap carrier)**.** *A* $\mathsf{PoincareBendixsonTrap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (O, D, K, F, B, I, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *row, naming the planar vector-field equation and the finite right-hand-side reads inspected by the packet.*
2. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *row, naming the local flow-window discipline available to the trap without asserting global flow completion.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row for the displayed trapping carrier and its compact metric boundary.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row used to read the local flow map on the displayed windows.*
5. *B is the inward-boundary ledger, recording the finite boundary faces, normal-side tests, and exit-refusal checks for the trap.*
6. *I is the invariant-window row, recording that every accepted local flow read re-enters the displayed compact trap before any downstream consumer reads a recurrence claim.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for coordinates, distances, and boundary-side comparisons.*
8. *H records componentwise* hsame *transport for ODE, dynamics, compact metric, continuous-map, boundary, invariant-window, real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from ODE reads through local flow windows, compact boundary checks, inward tests, invariant-window routing, and real-coordinate sealing.*

10. *P records* Pkg *provenance over* $\mathsf{PoincareBendixsonTrap}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareBendixsonTrap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $O, D, K, F, B, I, R, H, C, P, N$. It has no coordinate for selected host trajectories, completed global flows, quotient equality of paths, countable-choice selectors, or ambient real-completeness principles.

Theorem 6911.2 (Poincare–Bendixson trap NameCert obligations)**.** *For every accepted* $\mathsf{PoincareBendixsonTrap}^{\uparrow}$ *carrier $T = (O, D, K, F, B, I, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PoincareBendixsonTrap}^{\uparrow}}$ *surface consists exactly of displayed ODE admission, local dynamical-window admission, compact metric trap exposure, continuous-map flow-window exposure, inward-boundary ledger visibility, invariant-window routing,* $\mathsf{Real}^{\uparrow}$ *seal separation, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6911.1. The rows $O, D, K, F, B, I, R, H, C, P, N$ are the only data visible to the local certificate, so displayed ODE and dynamics reads arrive before any trap conclusion can be consumed.

Read the finite trap rows next. The compact metric row K gives the displayed carrier, the continuous-map row F gives the local flow windows, and the inward-boundary ledger B records the boundary-side checks used to refuse exits.

The invariant-window row I is downstream of those reads. It can only state that the displayed local windows re-enter the compact trap through the rows already named by O, D, K, F, B, R.

Finally attach H, C, P, N. Transport, replay, provenance, and local naming preserve the same route, and no carrier coordinate supplies a selected host trajectory, global flow completion, quotient path equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 6911.3 (Poincare–Bendixson compact-flow handoff)**.** *Every compact-flow consumer of an accepted* $\mathsf{PoincareBendixsonTrap}^{\uparrow}$ *packet must first read the route*

$$\mathsf{Ode}^{\uparrow} \longmapsto \mathsf{DynSystem}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The inward-boundary and invariant-window rows may then be consumed as a trapping-region certificate for planar dynamics, but only through the displayed finite rows of Definition 6911.1. The handoff exports no selected trajectory, global flow completion, quotient path equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the ODE and dynamics rows. The row O names the displayed planar equation, while D names the local flow-window discipline; neither row carries a completed host trajectory.

Use the continuous-map and compact metric rows. The flow-window read F is interpreted only on the compact trap carrier K, so the consumer receives a finite compact-flow route rather than a global flow object.

Read the boundary and invariant-window rows after that route. The ledger B records the inward boundary tests, and I records the trap re-entry surface reached by the accepted local reads.

The terminal real-coordinate seal R and the structural rows H, C, P, N preserve this order. Since all public reads are projections of the displayed carrier, no hidden selected trajectory, quotient path equality, countable-choice selector, global completion, or ambient real-completeness theorem is available. □

Falsifiable prediction: Every accepted $\mathsf{PoincareBendixsonTrap}^{\uparrow}$ read exposes one OdeUp row, one DynSystemUp local flow-window row, one CompactMetricUp trap row, one ContinuousMapUp flow row, one inward-boundary ledger, one invariant-window row, one RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any compact-flow consumer reads the trap.

Independence witness: ode, dynsystem, compactmetric, continuousmap, real: none is bijective with $\mathsf{PoincareBendixsonTrap}^{\uparrow}$ because the packet jointly stores the displayed planar ODE, local flow windows, compact trap carrier, continuous-map reads, inward-boundary ledger, invariant-window route, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareBendixsonTrap}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareBendixsonTrap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6911.1, Definition 6911.2, and Definition 6911.3 seed the finite planar trapping-region certificate over displayed ODE, local dynamics, compact metric, continuous-map, boundary, invariant-window, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareBendixsonTrap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected host trajectories, global flow completion, quotient path equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked ODE admission, local dynamics admission, compact trap exposure, continuous flow-window exposure, inward-boundary stability, invariant-window routing, Real seal separation, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{PoincareBendixsonTrap}^{\uparrow}$ packet is generated from an OdeUp row, DynSystemUp local flow-window row, CompactMetricUp trap row, ContinuousMapUp row, inward-boundary ledger, invariant-window row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6912

A Concrete Naming Certificate for CompactContinuousImageDiameter$^{\uparrow}$

Following Heine–Cantor's compact finite-net proof in the compact-uniform-continuity vision of chapter 9237, the CompactContinuousImageDiameter$^{\uparrow}$ packet records the finite image-diameter consumer that reads compact nets, pointwise continuity rows, a uniform modulus, metric-distance comparisons, and a terminal real seal before exporting a bounded-image estimate. It sits after the compact metric source of chapter 129, the continuous-map row of chapter 130, the metric-distance carrier of chapter 57, the uniform-modulus consumer of chapter 369, and the real-name boundary of chapter 38. The packet names a finite image-diameter read only; it does not choose a host finite subcover, select a global modulus, quotient functions, invoke countable choice, or import ambient Real$^{\uparrow}$ completeness.

Definition 6912.1 (Compact continuous image-diameter carrier)**.** *A* CompactContinuousImageDiameter$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, U, M, A, D, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, including the finite net windows inspected by the packet.*
2. *F is the* ContinuousMap$^{\uparrow}$ *row, exposing the displayed function graph and pointwise continuity reads on those net windows.*
3. *U is the* UniformModulus$^{\uparrow}$ *row consumed after compact-net and pointwise-continuity data have been displayed.*
4. *M is the* Met$^{\uparrow}$ *distance row for target-space diameter comparisons.*
5. *A is the finite image-sample ledger, recording the displayed net centers, their image reads, and the pairwise distance windows inspected by the packet.*
6. *D is the image-diameter bound row, recording the rational or real-sealed upper diameter requested by downstream compact-image consumers.*
7. *R is the* Real$^{\uparrow}$ *seal boundary for the numeric diameter and distance comparisons.*
8. *H records componentwise* hsame *transport for compact source, continuous map, uniform modulus, metric distance, image samples, diameter bound, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from compact-net requests through pointwise map reads, uniform-modulus routing, metric-distance comparison, image-diameter bounding, and real sealing.*
10. *P records* Pkg *provenance over* $\mathsf{CompactContinuousImageDiameter}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactContinuousImageDiameter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, U, M, A, D, R, H, C, P, N$. It has no coordinate for a selected host subcover, a chosen global modulus outside the displayed row, quotient equality of functions, countable choice, or ambient real completeness.

Theorem 6912.2 (Compact continuous image-diameter NameCert obligations)**.** *For every accepted* $\mathsf{CompactContinuousImageDiameter}^{\uparrow}$ *carrier $G = (K, F, U, M, A, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactContinuousImageDiameter}^{\uparrow}}$ *surface consists exactly of compact finite-net exposure, continuous-map exposure, uniform-modulus visibility, metric-distance comparison, finite image-sample ledger visibility, image-diameter bound separation,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6912.1. The compact source row K and continuous-map row F expose the finite net windows and their image reads before a diameter bound is visible.

Read the modulus and metric rows next. The row U is the uniform-modulus consumer produced from the compact finite-net route, and M is the metric-distance row used to compare displayed image samples.

The rows A, D, R package the finite image ledger, the diameter upper-bound row, and the terminal real seal. They are downstream of K, F, U, M, so the packet cannot replace the finite image read by a host compactness theorem.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same rows. Since the carrier has no other coordinate, the NameCert obligations are exactly the displayed finite-net, modulus, metric, image-diameter, and real-seal obligations. □

Theorem 6912.3 (Compact continuous image-diameter uniform bound)**.** *Every bounded-image consumer of an accepted* $\mathsf{CompactContinuousImageDiameter}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Only after that route is displayed may the consumer inspect the finite image-sample ledger and the image-diameter bound row. The handoff exports a reusable compact-image diameter estimate without selected finite subcovers, hidden global moduli, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the compact metric source. The row K supplies only displayed finite net windows, so a consumer receives a finite compact source rather than an open-cover compactness oracle.

Use the continuous-map and uniform-modulus rows. The image reads in F are tied to the displayed net windows, and U gives the tolerance route consumed by the diameter comparison.

Apply the target metric and real seal. The metric row M compares the displayed image samples, while D and R record the diameter bound and its real-name boundary.

The structural rows H, C, P, N then preserve this finite route for downstream compact-image consumers. No selected subcover, host modulus, quotient function equality, countable-choice selector, or ambient real-completeness principle is introduced. □

Falsifiable prediction: Every accepted $\mathsf{CompactContinuousImageDiameter}^{\uparrow}$ read displays one CompactMetricUp finite-net source, one ContinuousMapUp image-read row, one UniformModulusUp row, one MetricUp distance row, one finite image-sample ledger, one image-diameter bound row, one RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: compactmetric, continuousmap, uniformmodulus, metric, real: none is bijective with $\mathsf{CompactContinuousImageDiameter}^{\uparrow}$ because the packet jointly stores compact finite-net windows, continuous image reads, uniform-modulus routing, metric-distance comparisons, finite image samples, a diameter bound, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactContinuousImageDiameter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactContinuousImageDiameter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6912.1, Definition 6912.2, and Definition 6912.3 seed the finite compact-image diameter packet over compact-net, continuous-map, uniform-modulus, metric-distance, image-ledger, bound, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactContinuousImageDiameter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected finite subcovers, hidden global moduli, quotient equality of functions, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source exposure, continuous-map exposure, uniform-modulus visibility, metric-distance comparison, image-sample ledger visibility, image-diameter bound separation, Real seal routing, transport, replay, provenance, and local naming.

Constructive story: A $\mathsf{CompactContinuousImageDiameter}^{\uparrow}$ packet is generated from CompactMetricUp finite-net rows, ContinuousMapUp image reads, UniformModulusUp rows, MetricUp distance rows, a finite image-sample ledger, an image-diameter bound, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6913

A Concrete Naming Certificate for $\mathsf{LocatedRationalInterval}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of located intervals and regular rational approximation, the $\mathsf{LocatedRationalInterval}^{\uparrow}$ packet records the finite interval-location object used on the L10 real-completion path. It sits between the dyadic tolerance core of chapter 291, the rational interval carrier of chapter 354, the located endpoint carrier of chapter 394, the stream-window interface of chapter 126, the regular rational readback of chapter 301, the Real seal of chapter 38, and the interval-domain consumer of chapter 1543. The chapter names only a finite location certificate for rational intervals; it is not a quotient-cut construction, endpoint selector, trichotomy principle, host real equality, or ambient completeness theorem.

Definition 6913.1 (LocatedRationalInterval carrier)**.** *A* $\mathsf{LocatedRationalInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, L, D, W, Q, E, H, C, P, N)$$

with the following visible rows:

1. *R is the* $\mathsf{RationalInterval}^{\uparrow}$ *row carrying rational endpoint order, containment, and rational width data.*
2. *L is the located-endpoint row inherited from* $\mathsf{LocatedInterval}^{\uparrow}$*, binding each endpoint read to a displayed location witness.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare rational widths and endpoint windows.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which finite endpoint requests are read.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the same endpoint windows with regular rational observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, L, D, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the rational interval, located endpoints, dyadic tolerance, stream window, regular readback, and Real seal rows.*
8. *C records displayed* Cont *replay for the same row order.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRationalInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRationalInterval}^{\uparrow}}$ *evidence row.*

The classifier compares packets only by these displayed finite rows and their transports. No carrier coordinate supplies quotient cuts, selected endpoints, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6913.2 (LocatedRationalInterval NameCert obligations)**.** *For an accepted* $\mathsf{LocatedRationalInterval}^{\uparrow}$ *carrier* $I = (R, L, D, W, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRationalInterval}^{\uparrow}}$ *surface consists exactly of carrier admission, located-endpoint stability, dyadic tolerance stability, stream-window readback, Real-seal non-escape, componentwise transport, displayed replay, provenance, and local naming. Every interval-location read must display the rational interval row, located endpoints, dyadic tolerance,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row before a completion-facing consumer can inspect the packet.*

Proof. Carrier admission is projection from Definition 6913.1. The tuple lists $R, L, D, W, Q, E, H, C, P, N$ as the complete visible surface of the packet.

Located-endpoint stability reads R, L, H, C. The rational interval row supplies endpoint order and containment, while the located endpoint row supplies the displayed location witnesses transported with the same interval read.

Dyadic tolerance stability and stream-window readback read D, W, Q. The dyadic row supplies the finite tolerance budget for endpoint windows, the stream row names the finite requests, and the regular rational row supplies the readbacks for those same requests.

The Real-seal clause follows because E is downstream of R, L, D, W, Q and the structural rows. Since the carrier has no quotient-cut, endpoint-selector, trichotomy, host-equality, or completeness coordinate, none of those principles is exported by the local NameCert obligations. □

Theorem 6913.3 (LocatedRationalInterval Real seal handoff)**.** *Let* $I = (R, L, D, W, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedRationalInterval}^{\uparrow}$ *carrier. Any* $\mathsf{IntervalDomain}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion-facing consumer of the seal row* E *must first read the finite route*

$$\mathsf{RationalInterval}^{\uparrow}, \mathsf{LocatedInterval}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameC}$$

The handoff is a displayed interval-location route over rational endpoints and regular readbacks; it exports no quotient cuts, selected endpoints, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 6913.2. They force a completion-facing read to expose $R, L, D, W, Q, E, H, C, P, N$ before the seal can be consumed.

Read R and L through the sibling rational and located interval routes. The rational interval row supplies endpoint order and width data, while the located interval row supplies the finite endpoint-location witnesses.

Read D, W, Q next. The dyadic tolerance row supports the displayed endpoint windows, the $\mathsf{StreamName}^{\uparrow}$ row names those requests, and the $\mathsf{RegSeqRat}^{\uparrow}$ row gives the regular rational readback used by the downstream completion route.

Only then can the consumer inspect E. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the handoff remains available to $\mathsf{IntervalDomain}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ without adding quotient cuts, selected endpoints, trichotomy, host real equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRationalInterval}^{\uparrow}}$ **.**

Constructive story: A LocatedRationalInterval$^{\uparrow}$ packet is generated from a RationalIntervalUp row, located endpoint rows, a DyadicRatCoreUp tolerance row, StreamNameUp windows, RegSeqRatUp readbacks, a RealUp seal, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{LocatedRationalInterval}^{\uparrow}}$, seed)

Scope closed: Definition 6913.1, Definition 6913.2, and Definition 6913.3 seed the finite located rational interval route for L10 completion-facing consumers.

Formal verification: FormalStatus(NameCert$_{\text{LocatedRationalInterval}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient cuts, selected endpoints, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-endpoint stability, dyadic tolerance stability, stream-window readback, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRationalInterv

Chapter 6914

A Concrete Naming Certificate for $\mathsf{ContractiveSequence}^{\uparrow}$

Following Bishop and Bridges on contractive iteration, the $\mathsf{ContractiveSequence}^{\uparrow}$ packet records the finite route by which contraction-stage budgets become displayed regular rational sequence data before any Real-facing seal is consumed. It sits between the interval-contraction surface of chapter 5867, the contraction and iteration sources of chapter 3529 and chapter 2359, the dyadic budget ledger of chapter 291, the finite window source of chapter 126, the regular rational readback of chapter 301, and the terminal seal boundary of chapter 38. The packet names a finite sequence certificate; it is not a selected fixed point, a quotient stream, countable choice, an endpoint existence theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6914.1 (Contractive sequence carrier)**.** *A* $\mathsf{ContractiveSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, F, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source interval or metric-domain row read from* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *and the surrounding contraction setup.*
2. *F is the contraction or Picard-step row, read through* $\mathsf{BanachContraction}^{\uparrow}$ *or* $\mathsf{PicardIteration}^{\uparrow}$ *as finite BEDC data.*
3. *L is the stage-budget ledger recording the contraction depth, retained prefix, and shrinkage request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the contraction budgets and error windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected prefixes of the sequence.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and dyadic tolerances.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after I, F, L, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval, contraction, stage-budget, dyadic, stream, regular-rational, Real-seal, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a contractive-sequence request through the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{ContractiveSequence}^{\uparrow}$, $\mathsf{BishopIntervalContraction}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ContractiveSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, L, D, W, R, E, H, C, P, N$. It has no coordinate for a selected fixed point, selected limit, quotient stream equality, countable choice, endpoint existence, host iteration equality, or ambient real completeness.

Theorem 6914.2 (Contractive sequence NameCert obligations)**.** *For every accepted* $\mathsf{ContractiveSequence}^{\uparrow}$ *carrier*

$$S = (I, F, L, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContractiveSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed interval or domain row, contraction-step row, stage-budget ledger, dyadic tolerance ledger, finite windows, regular rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming rows. Every completion-facing consumer must read contraction stability through I, F, L, D, finite prefix exposure through W, regular rational handoff through R, and the structural route E, H, C, P, N before treating the sequence as Real-facing data.*

Proof. Project the carrier of Definition 6914.1. The tuple lists the complete finite inventory available to a contractive-sequence consumer, beginning with the source interval or domain row and the displayed contraction-step row.

Read the stage budget through L, D. The contraction depth and dyadic tolerance ledger are part of the packet, so a consumer cannot replace them by a host convergence theorem or by an implicit infinite schedule.

Next use the sibling routes. The interval-contraction certificate of chapter 5867 supplies the shrinkage discipline, while chapter 126 and chapter 301 expose only finite windows and regular rational readback.

Finally the rows E, H, C, P, N seal, transport, replay, source, and name the same route. Since no row stores a selected fixed point, quotient stream, countable-choice schedule, endpoint theorem, or ambient completeness principle, the listed obligations exhaust the local certificate surface. □

Theorem 6914.3 (Contractive sequence RegSeqRat handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{ContractiveSequence}^{\uparrow}$ *packet factors through*

$$\mathsf{BishopIntervalContraction}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the displayed rows $I, F, L, D, W, R, E, H, C, P, N$. The handoff may use $\mathsf{BanachContraction}^{\uparrow}$ *or* $\mathsf{PicardIteration}^{\uparrow}$ *to read the contraction-step row F, but it cannot claim a selected limit, quotient stream equality, endpoint existence, countable choice, a completed fixed point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted packet. The contraction data is read through I, F, L, while the dyadic tolerance budget is read through D before any finite sequence window is exposed.

Use the finite-window route through W. Each inspected prefix is a displayed $\mathsf{StreamName}^{\uparrow}$ read, not an implicit infinite stream or a selected tail.

Use the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R and then the terminal $\mathsf{Real}^{\uparrow}$ seal row E. This places the regular rational handoff after the same contraction and dyadic budget rows named by the carrier.

The structural rows H, C, P, N preserve the route for downstream consumers. Thus the handoff produces a finite RegSeqRat-to-Real seal path and leaves selected limits, quotient streams, countable choice, fixed-point existence, and ambient Real completeness outside the packet. □

Falsifiable prediction: An accepted $\mathsf{ContractiveSequence}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without displaying $I, F, L, D, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: bishop-interval-contraction, banach-contraction, picard-iteration, dyadicratcore, streamname, regseqrat, real: no listed sibling by itself supplies the joint packet containing contraction-stage budgets, dyadic tolerance rows, finite prefix windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{ContractiveSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{ContractiveSequence}^{\uparrow}$ packet is generated from a source interval or domain row, a contraction-step row, a stage-budget ledger, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractiveSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6914.1, Definition 6914.2, and Definition 6914.3 seed the finite contraction-budget route from displayed iteration data to regular rational and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractiveSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, selected limits, quotient streams, countable choice, endpoint existence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-stage budget exposure, dyadic tolerance exactness, finite-window readback, RegSeqRat handoff, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.ContractiveSequenceUp.

Chapter 6915

A Concrete Naming Certificate for $\mathsf{DyadicSignedDigitStream}^{\uparrow}$

Following Bishop–Bridges signed-digit real-name practice, the $\mathsf{DyadicSignedDigitStream}^{\uparrow}$ packet records a finite stream interface in which each observed dyadic digit is signed, locally normalized, and routed toward the regular rational and Real-name layers without quotienting streams. It sits beside the dyadic tolerance core of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a signed-digit real-name carrier, not a host real, selected limit, quotient stream class, trichotomy oracle, or ambient completeness theorem.

Definition 6915.1 (Dyadic signed-digit stream carrier)**.** *A* $\mathsf{DyadicSignedDigitStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, A, B, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the signed dyadic digit stream window row, listing the inspected positions and their digits in $\{-1, 0, 1\}$.*
2. *A is the digit-admissibility row, checking that every displayed digit lies in the signed dyadic alphabet and is attached to the requested dyadic place.*
3. *B is the carry and normalization budget row, recording the finite carry radius and local overlap bounds used to compare neighbouring windows.*
4. *M is the* $\mathsf{StreamName}^{\uparrow}$ *window row that schedules the same finite observation as a stream-name request.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, reading the normalized signed-window prefix as a regular rational approximation.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after W, A, B, M, Q have been displayed.*
7. *H records componentwise* hsame *transport for W, A, B, M, Q, E and the local naming row.*
8. *C records displayed* Cont *replay from signed dyadic windows through normalization, stream-name scheduling, regular rational readback, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicSignedDigitStream}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicSignedDigitStream}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $W, A, B, M, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6915.2 (Dyadic signed-digit stream NameCert obligations)**.** *For every accepted* DyadicSignedDigitStream *carrier $S = (W, A, B, M, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicSignedDigitStream}^{\uparrow}}$ *surface consists exactly of signed-window admission, digit-admissibility checking, carry and normalization budget exposure,* $\mathsf{StreamName}^{\uparrow}$ *window scheduling,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6915.1. The signed-window row W, admissibility row A, carry budget row B, stream-name row M, regular readback row Q, and Real seal row E are the only analytic coordinates of an accepted packet.

The normalization budget is finite. It records how signed digits may carry across neighbouring displayed places before the window is read as a regular rational approximation, so the handoff cannot bypass A or B.

The structural rows H, C, P, N transport, replay, source, and name exactly the same finite route. Since the carrier contains no quotient stream, selected representative, host real equality, trichotomy, countable-choice schedule, or ambient completeness coordinate, none of those endpoints belongs to the local NameCert surface. □

Theorem 6915.3 (Dyadic signed-digit stream RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicSignedDigitStream}^{\uparrow}$ *packet must first expose the signed dyadic window W, digit-admissibility row A, carry and normalization budget row B, and* $\mathsf{StreamName}^{\uparrow}$ *window row M. The resulting handoff reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *through Q and reaches* $\mathsf{Real}^{\uparrow}$ *through E only as the finite route*

$$W, A, B, M \longmapsto Q \longmapsto E, H, C, P, N.$$

It is not a quotient-stream construction, selected host limit, host real equality, trichotomy principle, countable-choice route, or ambient Real completeness theorem.

Proof. Start with the NameCert obligations of Definition 6915.2. They force every consumer-facing read to expose the signed-window, admissibility, normalization-budget, stream-window, readback, seal, transport, replay, provenance, and naming rows.

The regular rational handoff is downstream of normalization. A displayed signed digit may contribute to neighbouring dyadic places only through the finite budget B, so the readback row Q is read from W, A, B, M together, not from a raw stream of host digits.

Finally the Real seal row E is consumed after Q. Transport and replay preserve the same route through H and C, with P and N recording provenance and local naming. The excluded endpoints require coordinates absent from the packet and cannot be exported by this handoff. □

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicSignedDigitStream}^{\uparrow}$ is not bijective to any listed sibling because it stores signed dyadic windows, digit admissibility, a carry and normalization budget, stream-window scheduling, regular rational readback, terminal Real sealing, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicSignedDigitStream}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicSignedDigitStream}^{\uparrow}$ packet is generated from signed dyadic digit windows, digit-admissibility checks, carry and normalization budgets, StreamName windows, RegSeqRat handoff rows, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicSignedDigitStream}\uparrow}$, seed)

Scope closed: Definition 6915.1, Definition 6915.2, and Definition 6915.3 seed the finite signed-digit stream route from dyadic windows to RegSeqRat and Real consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicSignedDigitStream}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed dyadic signed-digit stream route.

Chapter 6916

A Concrete Naming Certificate for $\mathsf{CofinalCauchyFilter}^{\uparrow}$

Following Kelley and Bishop–Bridges on filters and constructive Cauchy approximation, the $\mathsf{CofinalCauchyFilter}^{\uparrow}$ packet records the finite BEDC route by which a filter-style Cauchy carrier is read through cofinal finite windows rather than through a quotient filter or a selected limit. It sits after the Cauchy carrier of chapter 3413, the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, the completion boundary of chapter 95, and the terminal real-name seal of chapter 38. The packet lets Completion and Real consumers ask for cofinal Cauchy evidence without importing host filter equality, countable choice, selected limits, or ambient Real completeness.

Definition 6916.1 (Cofinal Cauchy filter carrier)**.** *A* $\mathsf{CofinalCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (C, S, R, Q, W, E, H, A, P, N)$$

with the following rows:

1. *C is the* $\mathsf{Cauchy}^{\uparrow}$ *source row exposing the Cauchy request interface.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect named stream segments.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row for tolerance comparisons.*
4. *Q is the cofinal refinement row, recording which later windows refine a requested Cauchy witness.*
5. *W is the finite-window projection row, sending a filter request to an inspected stream window and a rational tolerance.*
6. *E is the completion-facing exactness row, exposed only after C, S, R, Q, W are visible.*
7. *H records componentwise* hsame *transport for the Cauchy, stream, rational, cofinal, projection, and exactness rows.*
8. *A records displayed* Cont *replay of the same finite route.*
9. *P is the* Pkg *provenance over* $\mathsf{CofinalCauchyFilter}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalCauchyFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, countable choice, host equality of filters, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6916.2 (Cofinal Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{CofinalCauchyFilter}^{\uparrow}$ *carrier* $F = (C, S, R, Q, W, E, H, A, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalCauchyFilter}^{\uparrow}}$ *surface consists exactly of Cauchy source exposure through* C*, stream-window exposure through* S*, regular rational readback through* R*, cofinal refinement through* Q*, finite-window projection through* W*, completion-facing exactness through* E*, componentwise transport through* H*, displayed replay through* A*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The source row C supplies the Cauchy request, while S and R expose the finite stream and rational tolerance data on which the request is inspected.

The cofinal refinement row Q records how later windows answer the same request, and W projects each filter-style demand to the finite window actually read by the packet. The exactness row E is therefore reached through finite-window projection and cofinal refinement, not through a quotient filter.

The structural rows H, A, P, N transport, replay, source, and name that same route. Since no further coordinate is present, the local NameCert cannot export selected limits, countable choice, host filter equality, or ambient Real completeness. □

Theorem 6916.3 (Cofinal Cauchy filter RegSeqRat handoff)**.** *Every Completion or Real consumer of an accepted* $\mathsf{CofinalCauchyFilter}^{\uparrow}$ *carrier must read the regular rational handoff through the displayed route*

$$C, S, R, Q, W, E \longmapsto H, A, P, N.$$

Consequently a cofinal Cauchy filter request reaches $\mathsf{RegSeqRat}^{\uparrow}$ *only after the StreamName finite window and cofinal refinement rows are visible, and it reaches* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *only through the completion-facing exactness row.*

Proof. Begin with the Cauchy source row C and the stream window row S. They determine which finite segment of the name is inspected for the current request.

The regular rational row R then supplies the tolerance comparison. Cofinal refinement through Q and projection through W ensure that later filter-style requests reuse a displayed finite-window route rather than a host-level filter representative.

Only after those rows are exposed may the exactness row E hand data to Completion or Real consumers. The rows H, A, P, N preserve the same handoff under transport, replay, provenance, and local naming, so the consumer obtains no bypass around StreamName, RegSeqRat, cofinal refinement, or the Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalCauchyFilter}^{\uparrow}$ packet is generated from a Cauchy source row, StreamName finite windows, RegSeqRat readback, cofinal refinement, finite-window projection, completion-facing exactness, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CofinalCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 6916.1, Definition 6916.2, and Definition 6916.3 seed the cofinal Cauchy-filter bridge for StreamName, RegSeqRat, Completion, and Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CofinalCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal refinement, finite-window projection, RegSeqRat handoff, completion exactness, transport, replay, provenance, and local naming for BEDC.Derived.CofinalCauchyFilterUp.

Chapter 6917

A Concrete Naming Certificate for $\mathsf{MetaCICDecidableFragment}^{\uparrow}$

Following the Tait, Girard, and Coquand tradition of bounded decidability arguments around typed calculi, the $\mathsf{MetaCICDecidableFragment}^{\uparrow}$ packet records the finite fragment in which closed checking, bounded normal comparison, and endpoint refusal are displayed together before a decidability-facing consumer reads any result. It sits beside the decidability boundary of chapter 749, the closed checker seal of chapter 2182, the bounded normal-equality checker of chapter 752, and the normalization frontier of chapter 892. The packet names a finite decidable fragment, not global conversion decidability, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Definition 6917.1 (MetaCIC decidable fragment carrier)**.** *A* $\mathsf{MetaCICDecidableFragment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, S, E, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed-term input row, listing the finite typed closed terms and the bounded query being inspected.*
2. *S is the checker-seal row, read through* $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ *and recording the accepted closed checker output.*
3. *E is the bounded normal endpoint row, read through* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *and recording the finished endpoint available at the displayed bound.*
4. *Q is the comparison-result row, read through* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *and recording the bounded normal comparison output.*
5. *R is the refusal-boundary row, naming global conversion decidability, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, and kernel consistency as unavailable endpoints.*
6. *H records componentwise* hsame *transport for I, S, E, Q, R and the local naming row.*
7. *C records displayed* Cont *replay from the closed-term input through checker sealing, bounded endpoint comparison, refusal retention, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{MetaCICDecidableFragment}^{\uparrow}$, $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$, $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableFragment}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, E, Q, R, H, C, P, N$. It has no coordinate for a global closed conversion decider, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Theorem 6917.2 (MetaCIC decidable fragment NameCert obligations)**.** *For every accepted* MetaCICDecidableFrag *carrier $F = (I, S, E, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableFragment}^{\uparrow}}$ *surface consists exactly of closed-term input exposure, checker-seal exposure, bounded normal endpoint exposure, comparison-result exposure, refusal-boundary retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6917.1. The rows I, S, E, Q, R are the complete decidability-facing data, and H, C, P, N are the structural rows that transport, replay, source, and name that data.

The checker and comparison rows are bounded. The checker seal S accepts only the displayed closed input, the endpoint row E records only the finished normal data available at the bound, and the comparison row Q records only the bounded comparison result.

The refusal row R remains part of the same packet. Since no carrier coordinate contains global conversion decidability, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency, those endpoints cannot be exported by the local NameCert surface. □

Theorem 6917.3 (MetaCIC decidable fragment closed-checker handoff)**.** *Every decidability-facing consumer of an accepted* $\mathsf{MetaCICDecidableFragment}^{\uparrow}$ *packet must read the closed-term input row I, checker-seal row S, bounded normal endpoint row E, comparison-result row Q, and refusal-boundary row R before it consumes a fragment decision. The handoff is the finite route*

$$I \longmapsto S \longmapsto E, Q, R, H, C, P, N.$$

It is a bounded closed-checker handoff and not a global conversion decision procedure, subject-reduction theorem, evaluator equality, quotient syntax equality, or kernel-consistency certificate.

Proof. Start with the NameCert obligations of Definition 6917.2. They force a consumer to expose the closed input, checker seal, bounded endpoint, comparison result, refusal boundary, transport, replay, provenance, and naming rows before reading the fragment decision.

The closed checker handoff is then ordered by the carrier. The input row I is checked by S, the bounded endpoint row E supplies the normal form surface at the displayed bound, and Q records the comparison result under the retained refusal row R.

Finally H, C, P, N preserve the same finite route. A consumer that wants global conversion decidability, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency must supply a separate certificate outside this packet. □

Theorem 6917.4 (MetaCIC decidable fragment bounded-normal refusal)**.** *An accepted* MetaCICDecidableFragment *packet may consume bounded normal endpoint rows and bounded comparison rows through E and Q, after the closed input I and checker seal S have been displayed, but it exports no arbitrary-fuel normalizer, no global conversion decider, no subject-reduction theorem, no evaluator equality, no*

quotient syntax equality, and no kernel-consistency certificate. The refusal row R remains part of the public finite route

$$I, S, E, Q, R, H, C, P, N.$$

Proof. Project the carrier $F = (I, S, E, Q, R, H, C, P, N)$ of Definition 6917.1. The rows E and Q are named only as bounded normal endpoint and bounded comparison data, and the preceding rows I and S keep the read tied to the displayed closed input and checker seal.

The structural rows H, C, P, N transport, replay, source, and name this same finite route. They do not add a coordinate for arbitrary fuel, global conversion, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

The refusal row R is therefore not auxiliary prose; it is one of the displayed carrier rows. Any consumer that reads E or Q must retain R with the same package provenance, so the bounded-normal surface cannot be reinterpreted as an unrestricted conversion procedure. □

Theorem 6917.5 (MetaCIC decidable fragment gallery handoff)**.** *Gallery sanity rows attached to a* $\mathsf{MetaCICDecidableFragment}^{\uparrow}$ *packet are audit-facing examples of the finite route $I, S, E, Q, R, H, C, P, N$. They may witness that the bounded checker, endpoint, comparison, and refusal rows are populated in displayed cases, but they are not the source of general typing completeness, global conversion decidability, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.*

Proof. Read the gallery row only through the carrier of Definition 6917.1. A gallery example can expose a closed input I, a checker seal S, a bounded endpoint E, a comparison result Q, the refusal row R, and the structural rows H, C, P, N.

That exposure is example-facing rather than theorem-generating. The NameCert obligations of Definition 6917.2 already identify the complete public surface, and Definition 6917.4 keeps the bounded-normal read from escaping its refusal boundary.

Thus a gallery handoff can support audit rows for particular closed checks, but no gallery row supplies a new coordinate for general typing completeness or for any endpoint named in R. □

Independence witness: metacicdecidableboundary, closed-type-checker-seal, bounded-normal-equality-checker, metacicnormalizationfrontier: $\mathsf{MetaCICDecidableFragment}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores closed-term input, checker seal, bounded normal endpoint, comparison result, refusal boundary, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDecidableFragment}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDecidableFragment}^{\uparrow}$ packet is generated from closed-term input rows, closed checker seal rows, bounded normal endpoint rows, comparison-result rows, refusal-boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableFragment}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6917.1, Definition 6917.2, and Definition 6917.3 seed the finite bounded decidable fragment for MetaCIC decidability consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableFragment}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global conversion decidability, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed MetaCIC decidable fragment route.

Chapter 6918

A Concrete Naming Certificate for $\mathsf{RealCompletionAdjunction}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on adjunctions, the $\mathsf{RealCompletionAdjunction}^{\uparrow}$ packet records the finite unit/counit surface by which dyadic, stream, regular-rational, and real-name rows support a completion-facing universal route. It sits after the dyadic tolerance core of chapter 291, the finite stream-name discipline of chapter 126, the regular-rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet names Real completion as displayed unit and counit data rather than as quotient completion equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or open-cover compactness.

Definition 6918.1 (Real completion adjunction carrier)**.** *A* $\mathsf{RealCompletionAdjunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, S, Q, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording precision cells, refinement slack, and comparison budgets used by the completion request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger, listing the source windows inspected before any real-name seal or completion endpoint is read.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, exposing the regular rational data consumed by the completion route.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q have been displayed.*
5. *U is the unit row, routing the displayed rational or regular-rational source into the Real-completion surface without choosing a quotient representative.*
6. *E is the counit and extension row, recording the finite handoff from a completion-facing consumer back through the same* $\mathsf{Real}^{\uparrow}$ *seal and readback data.*
7. *H records componentwise* hsame *transport for the dyadic, stream, readback, Real seal, unit, counit, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$D, S, Q \longmapsto R \longmapsto U, E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RealCompletionAdjunction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionAdjunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, Q, R, U, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected limits, a host Cauchy-real quotient, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6918.2 (Real completion adjunction NameCert obligations)**.** *For every accepted* RealCompletionAdjuncti *carrier*

$$A = (D, S, Q, R, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionAdjunction}^{\uparrow}}$ *surface consists exactly of dyadic tolerance exposure through D, stream-window exposure through S, regular-rational readback through Q, terminal Real seal handoff through R, unit exposure through U, counit and extension exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The projection exposes the dyadic tolerance ledger, finite stream windows, regular-rational readback, Real seal, unit, counit, transport, replay, provenance, and naming rows.

The completion-facing obligations are read in that order. The dyadic ledger fixes the precision budget, the stream ledger fixes the inspected finite windows, and the regular-rational readback is the only route by which the terminal Real seal is reached.

The unit and counit rows then record the finite adjunction surface over the same data. Componentwise transport and displayed replay preserve the route, while provenance and the local NameCert row bind it as one packet. Since no quotient representative, selected limit, open-cover compactness row, or ambient completeness theorem occurs in the carrier, the listed rows exhaust the local obligation surface. □

Theorem 6918.3 (Real completion adjunction unit-counit scope)**.** *Every completion-facing consumer of an accepted* $\mathsf{RealCompletionAdjunction}^{\uparrow}$ *packet reads the unit and counit only after the route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

has been displayed through D, S, Q, R, H, C, P, N. The handoff supplies finite Real-completion adjunction data; it does not supply quotient completion equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, host real equality, or countable choice.*

Proof. Start with the source rows D, S, Q. They provide the finite tolerance, window, and regular-rational readback data needed before a Real-completion request is admitted.

Next read the terminal seal R. The $\mathsf{Real}^{\uparrow}$ row is downstream of those source rows, so a consumer cannot detach the unit or counit from the dyadic, stream, and readback ledgers.

Finally inspect U and E with H, C, P, N. These rows bind the unit and counit to the same displayed carrier and replay route. No excluded quotient, selected-limit, compactness, choice, host-equality, or ambient-completeness coordinate is present, so the unit-counit scope is exactly the finite NameCert surface named above. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletionAdjunction}^{\uparrow}$ consumer reads dyadic tolerance, finite stream windows, regular-rational readback, Real seal, unit, counit, hsame transport,

Cont replay, Pkg provenance, and local NameCert rows before using a Real-completion adjunction endpoint.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RealCompletionAdjunction}^{\uparrow}$ is not bijective to any listed sibling because it binds the four L10 faces to explicit unit and counit rows with transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionAdjunction}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionAdjunction}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, finite StreamName windows, RegSeqRat readback, RealUp seal, unit row, counit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionAdjunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6918.1, Definition 6918.2, and Definition 6918.3 seed the finite Real-completion adjunction packet over DyadicRatCore, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionAdjunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected limits, ambient RealUp completeness, open-cover compactness, host real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, stream-window exposure, regular-rational readback, Real seal handoff, unit and counit exactness, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionAdjunctionUp.

Chapter 6919

A Concrete Naming Certificate for $\mathsf{BishopRegularInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRegularInterval}^{\uparrow}$ packet records a regular interval by finite rational endpoint data and explicit tolerance control, not by a quotient of intervals or a choice-selected limiting endpoint. It sits on the L10 route through dyadic rational rows, stream-name windows, regular rational readback, the terminal real-name seal, and located interval containment. The packet is a constructive interval carrier for downstream completion arguments.

Definition 6919.1 (Bishop regular interval carrier)**.** *A* $\mathsf{BishopRegularInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, S, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the dyadic endpoint-and-tolerance row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, containing two rational endpoint windows and a visible tolerance budget.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that records which endpoint and tolerance windows have been inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational endpoint names and their common tolerance schedule.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the endpoint readbacks supplied by R.*
5. *L is the located interval containment row, read through chapter 6913, recording which displayed rational subinterval contains the accepted endpoint windows.*
6. *H stores componentwise* hsame *transport for D, S, R, E, L.*
7. *C is the displayed* Cont *replay of the same finite interval evidence.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{LocatedRationalInterval}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient interval equality, a selected real endpoint, trichotomy of endpoints, ambient real completeness, or countable choice.

Theorem 6919.2 (Bishop regular interval NameCert obligations)**.** *For the carrier of Definition 6919.1, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for* $I = (D, S, R, E, L, H, C, P, N)$*, dyadic endpoint-and-tolerance coverage by* D*, finite window coverage by* S*, regular rational readback by* R*, terminal real sealing by* E*, located interval containment by* L*, componentwise transport by* H*, displayed replay by* C*, package provenance by* P*, and local naming by* N*.*

Proof. Project the packet. The dyadic row D supplies the only endpoint and tolerance data, and the stream row S records which finite windows are visible to the consumer.

Read the rational endpoint names through R and then through the terminal real seal E. This is the same L10-facing route used by chapter 301, chapter 126, and chapter 38.

Use the located interval row L to bind the endpoint windows to the displayed containment surface of chapter 6913. The transport, replay, provenance, and naming rows H, C, P, N carry those same rows and do not add a second interval object.

Since the carrier has no further coordinate, all NameCert obligations are exhausted by the displayed packet. □

Theorem 6919.3 (Bishop regular interval L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{BishopRegularInterval}^{\uparrow}$ *packet must read the interval through* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint tolerances,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, located interval containment, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BishopRegularInterval}^{\uparrow}}$ *row. The handoff exports no quotient interval, choice-selected endpoint, endpoint trichotomy, host real equality, or ambient completeness theorem.*

Proof. Start with the NameCert obligations of Definition 6919.2. They identify the visible route as $D, S, R, E, L, H, C, P, N$.

The numerical part of the handoff is forced through chapter 291, chapter 126, chapter 301, and chapter 38. Thus a consumer cannot skip from a rational endpoint window to an ambient real interval.

The containment part is forced through chapter 6913. It records located containment for the displayed rational interval row and supplies no quotient equality between interval representatives.

Finally H, C, P, N transport, replay, package, and name the same finite evidence. The excluded endpoint-selection and completeness readings have no carrier coordinate, so the L10 handoff is exactly the displayed constructive route. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularInterval}^{\uparrow}$ interval read must display dyadic endpoint tolerances, finite stream windows, regular rational readback, terminal Real sealing, located containment, transport, replay, provenance, and local NameCert rows before it exports interval data to a completion consumer.

Independence witness: dyadicratcore, streamname, regseqrat, real, located-rational-interval: no listed sibling is bijective to $\mathsf{BishopRegularInterval}^{\uparrow}$ because this packet jointly carries endpoint tolerances, finite read windows, regular rational endpoint names, Real sealing, located containment, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularInterval}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{BishopRegularInterval}^{\uparrow}$ packet is generated from dyadic endpoint-and-tolerance rows, StreamName finite windows, RegSeqRat readback, Real sealing, located interval containment, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6919.1, Definition 6919.2, and Definition 6919.3 describe the finite constructive interval carrier and its L10 handoff route.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopRegularInterval}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient interval theory, real-order trichotomy, ambient completeness, or selected endpoint existence.

Upgrade path: Scoped closure requires checked carrier coverage, located containment exactness, and L10 handoff nonescape for $D, S, R, E, L, H, C, P, N$.

Chapter 6920

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$

The $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$ packet realizes the observer-expansion direction of chapter 9463 as finite NameCert data. It binds boundary-shadow, visual-boundary, phase-distance, reversible transport, refusal, provenance, and local naming rows into one concrete route. The chapter is a concrete carrier site; the vision chapter remains an expressive source, not a proof surface.

Definition 6920.1 (Hyperbolic observer phase route carrier)**.** *A* $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, V, D, T, F, H, C, P, N)$$

with the following displayed rows:

1. *B is the boundary-shadow row read through* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*.*
2. *V is the visual-boundary row read through* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$*.*
3. *D is the phase-distance row read through* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ *and the terminal real-facing distance seal used there.*
4. *T is the reversible disk or phase transport row, read through* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *and* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$*.*
5. *F is the refusal row blocking interior fixed-center readings, hidden global geometry, and unlogged expansion claims.*
6. *H stores componentwise* hsame *transport for B, V, D, T, F.*
7. *C is the displayed* Cont *replay of the observer phase route.*
8. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$*,* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*,* $\mathsf{HyperbolicVisualBou}$ $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$*,* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*,* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an ambient hyperbolic manifold, a selected ideal boundary, a global geodesic completion, an empirical cosmology claim, or a hidden observer center.

Theorem 6920.2 (Hyperbolic observer phase route NameCert obligations)**.** *For the carrier of Definition 6920.1, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for* $Q = (B, V, D, T, F, H, C, P, N)$*, boundary-shadow coverage by* B*, visual-boundary coverage by* V*, phase-distance readback by* D*, reversible transport by* T*, refusal coverage by* F*, componentwise transport by* H*, displayed replay by* C*, package provenance by* P*, and local naming by* N*.*

Proof. Project the packet. The geometric input rows are B, V, D, T, F, and each is a displayed row of the finite carrier rather than a theorem about an ambient disk or manifold.

Read B through chapter 3813 and V through chapter 4181. These rows supply the boundary-facing surface before any observer expansion is consumed.

Read D through chapter 6017, then read T through chapter 3500 and chapter 3455. The refusal row F prevents those readings from becoming an interior fixed-center claim or an unlogged global-geometry assertion.

Finally H, C, P, N transport, replay, package, and name the same rows. Since the carrier has no further coordinate, the NameCert obligations are exactly the displayed route. □

Theorem 6920.3 (Hyperbolic observer phase route finite handoff)**.** *Every downstream read of an accepted* $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$ *packet factors through* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*,* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$*,* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$*,* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*,* $\mathsf{PoincareDiskPhase}$ *the refusal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}}$ *row. It exports no hidden global hyperbolic space, no selected ideal boundary, no empirical observer-expansion law, and no private phase-distance oracle.*

Proof. Use the obligation theorem Definition 6920.2. It exposes the accepted route as $B, V, D, T, F, H, C, P, N$.

The boundary side is supplied only by the boundary-shadow and visual-boundary siblings. The phase-distance and reversible-transport sides are supplied only by their displayed concrete-instance siblings, so the route cannot bypass them through a private geometry reading.

The refusal row F blocks the strong interpretations: an interior observer center, selected ideal boundary, empirical cosmology claim, and hidden global hyperbolic space. The rows H, C, P, N preserve only the displayed carrier evidence for downstream consumers. □

Future Lean coverage for this packet should require Nontrivial and FieldFaithful TasteGate instances for the boundary-shadow, visual-boundary, phase-distance, reversible-transport, and refusal rows, so that no zero-row or collapsed-field carrier can satisfy the route.

Falsifiable prediction: Every accepted $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$ read must display boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, hsame, Cont, Pkg, and local NameCert rows before it exports an observer phase route.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-visual-boundary, phase-distance-observer-expansion, poincare-boundary-fixed-transport, poincare-disk-phase-transport: no listed sibling is bijective to $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$ because this packet jointly carries boundary shadows, visual-boundary readback, phase-distance comparison, reversible transport, refusal, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$ packet is generated from boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6920.1, Definition 6920.2, and Definition 6920.3 describe the finite observer phase route and its downstream handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{HyperbolicObserverPhaseRoute}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, global hyperbolic geometry, empirical cosmology, selected ideal boundaries, or observer-center existence.

Upgrade path: Scoped closure requires checked carrier coverage, Nontrivial and FieldFaithful TasteGate instances, refusal exactness, and downstream handoff nonescape for $B, V, D, T, F, H, C, P, N$.

Chapter 6921

A Concrete Naming Certificate for $\mathsf{FrobeniusCoin}^{\uparrow}$

Following Sylvester and standard numerical-semigroup treatments, the $\mathsf{FrobeniusCoin}^{\uparrow}$ packet records the two-generator coin problem as finite BEDC data. It consumes unary natural-number rows from chapter 28, addition rows from chapter 29, and the finite semigroup surface of chapter 79. The packet names a displayed conductor window, not an ambient theorem about all natural numbers, an external greatest-common-divisor algorithm, quotient semigroup equality, or an unbounded search over representations.

Definition 6921.1 (Frobenius coin carrier)**.** *A* $\mathsf{FrobeniusCoin}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, B, G, C, W, H, T, P, N)$$

with the following displayed rows:

1. *A and B are positive unary* $\mathsf{Nat}^{\uparrow}$ *coin rows.*
2. *G is the displayed coprime row, recording a finite witness that the carried coin rows have greatest common divisor* 1 *when that witness is supplied.*
3. *C is the finite conductor row, recording the displayed bound at which the representability window begins.*
4. *W is the* $\mathsf{Add}^{\uparrow}$*-generated representability window, listing finite coefficient pairs and their displayed sums for the conductor-facing interval.*
5. *H records componentwise* hsame *transport for the coin rows, coprime row, conductor row, window row, replay, provenance, and local naming rows.*
6. *T records displayed* Cont *replay for the same rows.*
7. *P is the* Pkg *provenance over* $\mathsf{FrobeniusCoin}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{Semigroup}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusCoin}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, G, C, W, H, T, P, N$. It has no coordinate for host natural arithmetic, quotient semigroup equality, a hidden Euclidean algorithm, or an unbounded enumeration of all sums.

Lean4 ✓ `BEDC.Derived.FrobeniusCoinUp.FrobeniusCoinTasteGate single carrier alignment`

Theorem 6921.2 (Frobenius coin NameCert obligations)**.** *For every accepted* $\mathsf{FrobeniusCoin}^{\uparrow}$ *carrier* $F = (A, B, G, C, W, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FrobeniusCoin}^{\uparrow}}$ *surface consists exactly of carrier admission for the two positive unary coin rows; the displayed coprime row; representability-window exactness for the finite* $\mathsf{Add}^{\uparrow}$ *sums; the conductor bound row; the finite nonrepresentable ledger below the conductor-facing window; componentwise transport through* H*; displayed replay through* T*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier of Definition 6921.1. The rows A, B, G, C, W are the only arithmetic rows, and each is finite: two positive unary coin rows, one coprime witness row, one conductor row, and one displayed sum window.

The representability data are read through W. Each accepted entry of W supplies a finite pair of unary coefficients and an $\mathsf{Add}^{\uparrow}$ replay of the corresponding sum, while every excluded entry below the displayed conductor is accounted for by the finite nonrepresentable ledger attached to the same window.

The structural rows H, T, P, N then transport, replay, source, and name that finite inventory. Since the packet has no host arithmetic coordinate, no quotient semigroup equality coordinate, and no unbounded-search coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6921.3 (Frobenius coin conductor-window boundary)**.** *Every conductor-facing consumer of an accepted* $\mathsf{FrobeniusCoin}^{\uparrow}$ *carrier reads only the displayed finite* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*, and* $\mathsf{Semigroup}^{\uparrow}$ *rows*

$$A, B, G, C, W \longmapsto H, T, P, N.$$

In particular, the consumer receives the two positive coin rows, the copied coprime witness when present, the finite representability window, the finite below-conductor ledger, transport, replay, provenance, and local naming; it receives no host natural-number arithmetic, no quotient semigroup equality, and no unbounded search procedure.

Proof. Start with a conductor-facing request. Carrier admission forces the request to inspect A and B as positive unary $\mathsf{Nat}^{\uparrow}$ rows, not as ambient natural numbers.

The coprime and conductor information is then exposed by G and C. If the coprime row is absent, the packet does not claim the conductor theorem; if it is present, the row is still only the displayed finite witness carried by the packet.

Representability is read through W, where every accepted sum is generated by finite $\mathsf{Add}^{\uparrow}$ replay over the two coin rows and every conductor-facing refusal is recorded in the finite ledger. The $\mathsf{Semigroup}^{\uparrow}$ dependency is consumed only as this finite addition-generated surface.

Finally H, T, P, N preserve the same route under transport, replay, provenance, and local naming. No remaining carrier field can provide host arithmetic, quotient equality, or an infinite search, so every consumer is confined to the displayed conductor window. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusCoin}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrobeniusCoin}^{\uparrow}$ packet is generated from two positive unary coin rows, a displayed coprime witness row, a conductor row, a finite AddUp representability window, a finite nonrepresentable ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrobeniusCoin}^{\uparrow}}$, seed)

Scope closed: Definition 6921.1, Definition 6921.2, and Definition 6921.3 seed the finite two-generator conductor-window packet over $A, B, G, C, W, H, T, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrobeniusCoin}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a Lean proof, a standard bridge, unrestricted numerical-semigroup closure, host natural arithmetic, quotient semigroup equality, or unbounded representability search.

Upgrade path: Obligation closure requires checked carrier admission, representability-window exactness, conductor-bound coverage, below-conductor ledger, transport, replay, provenance, and local naming rows for BEDC.Derived.FrobeniusCoinUp.

Chapter 6922

A Concrete Naming Certificate for MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$

The MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$ packet realizes the subject-reduction frontier of section 9386.2 as a finite four-row discharge matrix. It sits beside the discharge socket of chapter 719, the closed application-argument route of chapter 6177, the closed Pi-domain route of chapter 3352, the closed lambda-domain route of chapter 3381, the proof-obligation gap of chapter 3460, and the open-frontier ledger of chapter 762. The matrix is a finite audit object for the four simultaneous discharge rows; it does not assert a closed subject-reduction theorem.

Falsifiable prediction: Every accepted MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$ packet exposes all four discharge rows before any subject-reduction consumer reads it.

Independence witness: `closed-app-argument-stability`, `closed-pi-domain-subject-reduction`, `closed-lam-domain-subject-reduction`, `proof-obligation-gap`, `metacic-open-frontier-ledger`: none is bijective with MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$, because this packet binds the four subject-reduction discharge rows, the obstruction ledger, matrix coverage, transport, replay, provenance, and local naming as one finite surface.

Definition 6922.1 (MetaCIC subject-reduction discharge matrix carrier)**.** *A* MetaCICSubjectReductionDischargeM *carrier is a finite* BHist *packet*

$$M = (B, A, L, P, O, S, R, H, C, Q, N)$$

with the following displayed rows:

1. *B is the beta-substitution preservation discharge row.*
2. *A is the closed application-argument stability discharge row.*
3. *L is the closed lambda-domain subject-reduction discharge row.*
4. *P is the closed Pi-domain subject-reduction discharge row.*
5. *O is the proof-obligation gap row recording the absence of an unconditional closed theorem until the four discharge rows are supplied.*
6. *S is the* SubjectReductionDischargeSocket$^{\uparrow}$ *row through which the subject-reduction consumer reads the four rows.*
7. *R is the matrix-coverage row, recording that the accepted packet exposes B, A, L, P simultaneously and does not merge them.*

8. *H records componentwise* hsame *transport for all displayed rows.*
9. *C records displayed* Cont *replay for the same matrix route.*
10. *Q is the* Pkg *provenance over* MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$, SubjectReductionDischargeSocket$^{\uparrow}$, *the four discharge rows,* ProofObligationGap$^{\uparrow}$, MetaCICOpenFrontierLedger$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{MetaCICSubjectReductionDischargeMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, A, L, P, O, S, R, H, C, Q, N$. It has no coordinate for a hidden subject-reduction proof, a quotient syntax equality, a host typing theorem, or an omitted fifth discharge row.

Theorem 6922.2 (MetaCIC discharge matrix NameCert obligations)**.** *For every accepted* MetaCICSubjectReductio *carrier $M = (B, A, L, P, O, S, R, H, C, Q, N)$, the local* NameCert$_{\text{MetaCICSubjectReductionDischargeMatrix}^{\uparrow}}$ *surface consists exactly of carrier admission for the beta-substitution row, application-argument row, lambda-domain row, Pi-domain row, proof-obligation gap row, discharge-socket row, matrix-coverage row, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6922.1. The four discharge rows are exactly B, A, L, P, and the obstruction row O records why the matrix remains a finite interface rather than an unconditional theorem.

The socket row S fixes the consumer route. A subject-reduction consumer may enter through that socket only after the matrix-coverage row R has displayed the four rows simultaneously and kept their coordinates distinct.

The structural rows H, C, Q, N transport, replay, source, and name the same route. Since the carrier has no hidden proof coordinate and no host typing coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6922.3 (MetaCIC discharge matrix four-row coverage)**.** *Every subject-reduction-facing consumer of an accepted* MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$ *carrier must read the four-row surface*

$$B, A, L, P \longmapsto O, S, R, H, C, Q, N.$$

The beta-substitution, application-argument, lambda-domain, and Pi-domain rows are all required before the socket can be consumed, and none can be replaced by the proof-obligation gap, transport, replay, provenance, local naming, or a host closed subject-reduction theorem.

Proof. Read the consumer request through the carrier. The first four coordinates B, A, L, P are the only discharge coordinates, and the matrix-coverage row R records them as simultaneous rows.

The obstruction row O has the opposite polarity from a discharge proof. It records that the closed theorem is unavailable without the four supplied rows, so it cannot replace any one of B, A, L, P.

The socket row S then exposes the consumer route, while H, C, Q, N preserve the same displayed matrix under transport, replay, provenance, and naming. Therefore every accepted subject-reduction read receives the four rows together and cannot collapse the matrix to a smaller interface. □

Closure status for NameCert$_{\text{MetaCICSubjectReductionDischargeMatrix}^{\uparrow}}$**.**

Constructive story: A MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$ packet is generated from beta-substitution, application-argument, lambda-domain, Pi-domain, proof-obligation gap, discharge-socket, matrix-coverage, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICSubjectReductionDischargeMatrix}\uparrow}$, seed)

Scope closed: Definition 6922.1, Definition 6922.2, and Definition 6922.3 seed the finite four-row discharge matrix over $B, A, L, P, O, S, R, H, C, Q, N$.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICSubjectReductionDischargeMatrix}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove closed subject reduction, beta-substitution preservation, application-argument stability, lambda-domain preservation, Pi-domain preservation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four-row coverage, socket preservation, proof-obligation-gap polarity, transport, replay, provenance, and local naming rows for BEDC.Derived.MetaCICSubjectReductionDischargeMatrixUp.

Chapter 6923

A Concrete Naming Certificate for $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$

Following van der Corput and Bishop–Bridges constructive analysis, the $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ packet records a finite-difference estimate by reading a source sequence only through named finite windows, shifted-pair difference rows, dyadic tolerance budgets, averaged correlation rows, regular rational readback, and the terminal real seal. It sits over the finite window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the real-series packet of chapter 1581. The certificate supplies downstream oscillation, Fourier, series, and completion routes with a finite estimate surface; it does not import host sequence limits, countable choice, quotient equality, selected subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6923.1 (Van der Corput finite-difference estimate carrier)**.** *A* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (A, W, S, D, \Gamma, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source-sequence row, exposed either as a* $\mathsf{RealSeries}^{\uparrow}$ *term stream or as a named regular rational stream whose observations are read only through finite requests.*
2. *W is the family of* $\mathsf{StreamName}^{\uparrow}$ *source windows naming the finite index blocks used by the estimate.*
3. *S is the shifted-pair row listing the finite pairs $(n, n+h)$ inspected for each displayed shift h.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row, carrying the precision cells for source reads, difference reads, average comparisons, and the final estimate.*
5. *Γ is the averaged correlation row recording the finite sums of shifted products or shifted differences admitted by S, W, D.*
6. *M is the finite estimate row that binds the window length, the shift bound, the dyadic slack, and the averaged correlation rows into the displayed van der Corput bound.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from M after the same finite windows and dyadic budgets have been consumed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the estimate value after regular rational readback.*

9. *H records componentwise* hsame *transport for source windows, shifted-pair rows, dyadic budgets, averaged correlations, estimate rows, readback, seal, provenance, and local naming.*
10. *C records displayed* Cont *replay from a requested estimate through $A, W, S, D, \Gamma, M, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, S, D, \Gamma, M, R, E, H, C, P, N$. It has no coordinate for an infinite Cesaro limit, a selected subsequence, quotient stream equality, countable choice, Hilbert-space compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VanDerCorputDifferenceEstimateUp.VanDerCorputDifferenceEstimateTasteGate`
`single carrier alignment`

Theorem 6923.2 (Van der Corput finite-difference estimate NameCert obligations)**.** *For every accepted* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ *carrier $V = (A, W, S, D, \Gamma, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}}$ *surface consists exactly of source admission, finite* $\mathsf{StreamName}^{\uparrow}$ *source-window admission, shifted-pair difference admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness, averaged correlation exactness, finite estimate-row exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier of Definition 6923.1. The only source observations are the source row A, the finite window family W, and the shifted-pair row S.

The tolerance row D supplies the precision cells used by the shifted differences and by the averaged correlation row Γ. The estimate row M is downstream of these rows, so it can bind only the displayed window length, shift bound, dyadic slack, and averaged correlations already present in the carrier.

The readback row R and the seal row E are reached after M. The transport, replay, provenance, and local naming rows preserve the same finite route. Since the carrier has no coordinate for infinite limits, selected subsequences, quotient stream equality, countable choice, compactness, or ambient completeness, the displayed rows exhaust the local NameCert obligations. □

Theorem 6923.3 (Van der Corput finite-window route)**.** *Every oscillation, Fourier, series, or completion-route consumer of an accepted* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ *packet receives the estimate only through the finite route*

$$A \longmapsto W \longmapsto S \longmapsto D \longmapsto \Gamma \longmapsto M \longmapsto R \longmapsto E.$$

In particular, the estimate can be consumed by $\mathsf{RealSeries}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *routes only after the same* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *budgets, shifted-pair rows, averaged correlation rows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed.*

Proof. Start with the NameCert obligations of Definition 6923.2. They force every accepted estimate read to expose $A, W, S, D, \Gamma, M, R, E, H, C, P, N$.

The finite windows W delimit the source observations, and the shifted-pair row S names the exact pairs inspected for each shift. No downstream consumer can read a correlation row before these windows and pairs have been displayed.

The dyadic budget row D then controls both the shifted difference reads and the averaged correlation row Γ. The estimate row M is the first row that binds those correlations into a numerical estimate, and the regular readback R is downstream of that row.

Finally the terminal seal E is reached only after R. Thus any consumer that enters the packet from a real-series, Fourier, oscillation, or completion route sees the same finite window route and no hidden sequence-limit object. □

Theorem 6923.4 (Van der Corput finite-difference non-escape)**.** *An accepted* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ *packet exports no data outside its displayed carrier rows. In particular, it does not export a host convergence theorem, a Cesaro-limit value, a selected density subsequence, quotient equality of streams, countable-choice schedules, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness; every exported estimate is mediated by* $W, S, D, \Gamma, M, R, E, H, C, P, N$.

Proof. Use the carrier description in Definition 6923.1. The accepted packet stores only the source row, finite windows, shifted pairs, dyadic budgets, averaged correlations, estimate row, readback, seal, and structural certificate rows.

Apply the finite-window route of Definition 6923.3. Any exported estimate must pass through W, S, D, Γ, M, R, E before the structural rows transport and replay it.

The excluded principles have no carrier coordinate and are not introduced by hsame, Cont, Pkg, or local naming. Therefore they cannot escape through the certificate surface. □

Falsifiable prediction: Every accepted $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ read factors through source windows, shifted-pair difference rows, DyadicRatCore tolerance budgets, averaged correlation rows, a finite estimate row, RegSeqRat readback, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, realseries: $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source sequence windows, shifted-pair difference rows, dyadic tolerance budgets, averaged correlation rows, finite estimate accounting, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ packet is generated from source sequence windows, shifted-pair difference rows, dyadic tolerance budgets, averaged correlation rows, a finite estimate row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6923.1, Definition 6923.2, Definition 6923.3, and Definition 6923.4 seed the finite van der Corput difference-estimate carrier, certificate surface, finite-window route, and non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequence limits, Fourier convergence, oscillation decay, selected subsequences, quotient stream equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, shifted-pair exactness, finite window coverage, dyadic tolerance exactness, averaged correlation exactness, regular readback, Real seal non-escape, transport, replay, provenance, and local NameCert coverage for BEDC.Derived.VanDerCorputDifferenceEstimateUp.

Chapter 6924

A Concrete Naming Certificate for $\mathsf{VanDerCorputSum}^{\uparrow}$

Following van der Corput and Bishop–Bridges constructive analysis, the $\mathsf{VanDerCorputSum}^{\uparrow}$ packet records a finite exponential-sum estimate as displayed NameCert data. It reads coefficient or phase streams through the finite window surface of chapter 126, dyadic tolerance budgets through chapter 291, regular rational readback through chapter 301, terminal real seals through chapter 38, the real-series source row of chapter 1581, Fourier-facing coefficient windows through chapter 124, and finite-difference control through chapter 6923. The packet names only the finite sum route; it does not claim convergence of an infinite trigonometric series, quotient equality of functions, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6924.1 (Van der Corput finite exponential-sum carrier)**.** *A* $\mathsf{VanDerCorputSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, W, \Phi, Q, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source* $\mathsf{RealSeries}^{\uparrow}$ *or Fourier coefficient row whose finite terms are inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite index block and every coefficient or phase request used by the sum.*
3. *Φ is the finite phase row, recording the exponential phases only through the displayed window requests.*
4. *Q is the quadratic or shifted-difference control row handed off from* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ *when a finite differencing estimate is used.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row for coefficient reads, phase reads, summand products, partial sums, and the final bound.*
6. *M is the finite exponential-sum ledger, listing the displayed summands, partial sums, normalization factors, and dyadic slack.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after W, Φ, Q, D, M have been consumed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed finite bound or normalized finite sum.*
9. *H records componentwise* hsame *transport for source, window, phase, difference-control, dyadic-budget, sum-ledger, readback, seal, replay, provenance, and local-name rows.*

10. *C records displayed* Cont *replay from a requested finite exponential-sum read through* $A, W, \Phi, Q, D, M, R, E, H, P$
11. *P is the* Pkg *provenance over* $\mathsf{VanDerCorputSum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VanDerCorputSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, \Phi, Q, D, M, R, E, H, C, P, N$. It has no coordinate for host Fourier convergence, an infinite exponential series, quotient equality of functions, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6924.2 (Van der Corput finite exponential-sum NameCert obligations)**.** *For every accepted* $\mathsf{VanDerCorputSum}^{\uparrow}$ *carrier $S = (A, W, \Phi, Q, D, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VanDerCorputSum}^{\uparrow}}$ *surface consists exactly of source admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission, displayed phase admission, optional finite-difference control through* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness, finite exponential-sum ledger exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier of Definition 6924.1. The only source observations are the real-series or Fourier row A, the finite window row W, and the displayed phase row Φ.

The difference-control row Q is available only as a finite handoff from chapter 6923. The dyadic row D then supplies the precision cells for the coefficient reads, phase reads, summand products, and final estimate before the sum ledger M is read.

The readback row R and Real seal row E are downstream of M. Transport, replay, provenance, and local naming preserve that same finite route. Since the carrier omits host Fourier convergence, infinite exponential series, quotient equality, selected subsequences, countable choice, and ambient completeness, the displayed rows exhaust the local NameCert obligations. □

Theorem 6924.3 (Van der Corput finite exponential-sum route)**.** *Every Fourier, real-series, oscillation, or completion-route consumer of an accepted* $\mathsf{VanDerCorputSum}^{\uparrow}$ *packet receives the finite exponential-sum read only through*

$$A \longmapsto W \longmapsto \Phi \longmapsto Q \longmapsto D \longmapsto M \longmapsto R \longmapsto E.$$

In particular, the consumer must display the $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budgets,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{RealSeries}^{\uparrow}$ *or* $\mathsf{Fourier}^{\uparrow}$ *source row, and any* $\mathsf{VanDerCorputDifferenceEstimate}^{\uparrow}$ *handoff before it can inspect the finite bound.*

Proof. Start from the obligation surface of Definition 6924.2. It forces every accepted finite-sum read to expose $A, W, \Phi, Q, D, M, R, E, H, C, P, N$.

The finite window row W controls which source coefficients and phases can be read. The phase row Φ and optional difference-control row Q are therefore downstream of the same displayed index block.

The dyadic budget row D controls the arithmetic cells used by the sum ledger M. Only after M has been displayed can the regular readback R and terminal seal E be consumed.

Thus a Fourier, real-series, oscillation, or completion-route consumer sees the same finite route and receives no host convergence theorem, selected subsequence, quotient equality, countable-choice schedule, or ambient Real completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{VanDerCorputSum}^{\uparrow}$ read factors through a RealSeries or Fourier source row, StreamName windows, phase rows, optional VanDerCorputDifferenceEstimate

control, DyadicRatCore budgets, a finite exponential-sum ledger, RegSeqRat readback, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, dyadicratcore, regseqrat, real, realseries, fourier, van-der-corput-difference-estimate: $\mathsf{VanDerCorputSum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite coefficient or phase windows, difference-control handoff, dyadic arithmetic budgets, a finite exponential-sum ledger, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{VanDerCorputSum}^{\uparrow}}$.

Constructive story: A $\mathsf{VanDerCorputSum}^{\uparrow}$ packet is generated from a RealSeries or Fourier source row, finite StreamName windows, displayed phase rows, optional VanDerCorputDifferenceEstimate handoff, DyadicRatCore tolerance budgets, a finite exponential-sum ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VanDerCorputSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6924.1, Definition 6924.2, and Definition 6924.3 seed the finite exponential-sum carrier, certificate surface, and consumer route over displayed BEDC rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VanDerCorputSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Fourier convergence, infinite exponential-series convergence, quotient function equality, selected subsequences, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite window coverage, phase admission, finite-difference handoff, dyadic tolerance exactness, exponential-sum ledger exactness, regular readback, Real seal non-escape, transport, replay, provenance, and local NameCert coverage for BEDC.Derived.VanDerCorputSumUp.

Chapter 6925

A Concrete Naming Certificate for $\mathsf{LocatedRealModulusExtractor}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealModulusExtractor}^{\uparrow}$ packet records the finite extraction route that reads located-real enclosure data as a regular-Cauchy modulus surface rather than as quotient real equality or an ambient completeness theorem. It sits over the located-real carrier of chapter 1933, the dyadic precision ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the located modulus route of chapter 3406, and the regular Cauchy modulus handoff of chapter 292. The packet gives the Phase Real and Completion route a named bridge from located-real locator rows to finite modulus extraction without claiming $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6925.1 (LocatedRealModulusExtractor carrier)**.** *A* $\mathsf{LocatedRealModulusExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, D, S, R, M, W, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *locator row whose interval and apartness-enclosure data answer the displayed precision request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording the requested radius, endpoint slack, and comparison budget used for the extraction.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened from L at the budget recorded by D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite window and dyadic tolerance ledger.*
5. *M is the extracted* $\mathsf{CauchyModulus}^{\uparrow}$ *row, recording the threshold supplied by the located data for the regular-Cauchy consumer.*
6. *W is the terminal* $\mathsf{Real}^{\uparrow}$ *seal route reached only after L, D, S, R, M have been displayed.*
7. *H stores componentwise* hsame *transport for the locator row, dyadic ledger, finite window, regular readback, extracted modulus, real seal, replay route, provenance, and local naming.*
8. *C stores the displayed* Cont *replay from a precision request through L, D, S, R, M to the seal row W and to downstream completion consumers.*

9. *P is the* Pkg *provenance over* LocatedRealModulusExtractor$^{\uparrow}$, LocatedReal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{LocatedRealModulusExtractor}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient real equality, trichotomy, a choice-selected subsequence, a selected limiting representative, countable choice, host completeness, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6925.2 (LocatedRealModulusExtractor NameCert obligations)**.** *For an accepted* LocatedRealModulusEx *carrier $E = (L, D, S, R, M, W, H, C, P, N)$, the local* NameCert$_{\text{LocatedRealModulusExtractor}^{\uparrow}}$ *surface consists exactly of carrier admission, located-real locator exposure, dyadic precision-ledger exactness, finite stream-window coverage, regular rational readback compatibility, extracted Cauchy-modulus exposure, real-seal nonescape, componentwise transport, continuation replay, provenance, and local naming for the packet of Definition 6925.1.*

Proof. Carrier admission is projection from the displayed tuple. The analytic rows are L, D, S, R, M, W, and the structural rows are H, C, P, N.

The located-real row L supplies locator data for the precision request, while D records the dyadic budget under which that request is read. The stream row S and readback row R are opened only at the displayed budget, so the extracted modulus row M is tied to the same finite window.

The seal row W is downstream of the extraction route. Transport and replay preserve the order through H and C, while P and N add provenance and naming without introducing quotient equality, trichotomy, selected limits, choice, host completeness, or ambient Real$^{\uparrow}$ completeness. □

Theorem 6925.3 (LocatedRealModulusExtractor readback route)**.** *Every regular-Cauchy or Real and Completion consumer of an accepted* LocatedRealModulusExtractor$^{\uparrow}$ *packet must read the route*

$$L, D, S, R, M, W, H, C, P, N$$

before using the extracted modulus. The route exposes the LocatedReal$^{\uparrow}$ *locator,* DyadicRatCore$^{\uparrow}$ *precision ledger,* StreamName$^{\uparrow}$ *finite window,* RegSeqRat$^{\uparrow}$ *readback, extracted* CauchyModulus$^{\uparrow}$ *row, and terminal* Real$^{\uparrow}$ *seal as one finite packet; it exports no quotient real equality, trichotomy, selected representative, countable choice, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with the carrier inventory of Definition 6925.1. The located-real row and dyadic ledger precede the finite-window and regular-rational rows, and the modulus row M is displayed only after those rows have been read.

Use the local obligations of Definition 6925.2. They require locator exposure, dyadic exactness, window coverage, regular rational readback compatibility, and extracted-modulus exposure to be certified for the same packet.

Finally read the handoff through W, H, C, P, N. These rows seal, transport, replay, source, and name the same finite route, so a downstream consumer receives the extracted modulus only through the displayed packet and not through any refused external principle. □

Falsifiable prediction: An accepted LocatedRealModulusExtractor$^{\uparrow}$ packet cannot provide a regular-Cauchy modulus unless the same packet displays the located-real locator row, dyadic precision ledger, finite stream window, and regular rational readback that produce it.

Independence witness: located-real-modulus, cauchymodulus, regseqrat: LocatedRealModulusExtractor$^{\uparrow}$ joins locator rows to an extracted CauchyModulus row and a Real-facing seal in one packet; the sibling packets expose their own carriers but do not provide this combined extraction surface.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealModulusExtractor}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealModulusExtractor}^{\uparrow}$ packet is generated from a displayed LocatedReal locator row, a DyadicRatCore precision ledger, a StreamName finite-window row, a RegSeqRat readback row, an extracted CauchyModulus row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealModulusExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6925.1, Definition 6925.2, and Definition 6925.3 seed the finite located-real modulus-extraction route over LocatedReal, DyadicRatCore, StreamName, RegSeqRat, CauchyModulus, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealModulusExtractor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real equality, trichotomy, selected limits, countable choice, host completeness, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, locator exposure, dyadic-window coverage, regular readback compatibility, extracted-modulus exposure, RealUp seal nonescape, transport stability, continuation replay, provenance, and local naming for BEDC.Derived.LocatedRealModulusExtractorUp.

Chapter 6926

A Concrete Naming Certificate for $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$ packet records the finite observation data by which a regular rational name is refined before a Real-facing consumer may read a terminal seal. It sits over the stream-window discipline of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance core of chapter 291, the Cauchy modulus route of chapter 292, the finite envelope of chapter 365, and the real-name boundary of chapter 38. The packet is a finite-window refinement certificate; it is not a quotient of streams, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6926.1 (Finite-window RegSeqRat refinement carrier)**.** *A* $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, M, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row whose finite windows are inspected before any regular-rational refinement is read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row naming the source regular rational readback.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the coarse and refined windows.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row supplying the finite threshold that bounds the requested refinement.*
5. *W is the* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *row packaging the refined window, its source window, and the dyadic tolerance request in one envelope.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, R, D, M, W have been displayed.*
7. *H records componentwise* hsame *transport for the displayed rows.*
8. *C records displayed* Cont *replay from a refinement request through the same finite packet.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{FiniteWindowEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, R, D, M, W, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable-choice schedules, host real equality, or ambient completeness.

Lean4 (definition) `BEDC.Derived.FiniteWindowRegSeqRatRefinementUp.FiniteWindowRegSeqRatRefinementUp`

Theorem 6926.2 (Finite-window RegSeqRat refinement NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$ *carrier* $F = (S, R, D, M, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *source readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold exposure,* $\mathsf{FiniteWindowEnvelope}^{\uparrow}$ *refinement packaging, terminal* $\mathsf{Real}^{\uparrow}$ *seal discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6926.1. The rows S, R, D, M, W, E display the whole finite observation route before any structural row is read.

The numerical rows are exhausted by S, R, D, M, W. Stream windows are opened in S, regular rational readback is exposed by R, dyadic tolerance accounting is displayed in D, the modulus threshold is supplied by M, and the finite-window envelope W records the refinement boundary.

The structural rows are exhausted by H, C, P, N. They transport, replay, source, and name the same displayed packet, while the carrier provides no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient completeness. □

Theorem 6926.3 (Finite-window RegSeqRat refinement Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$ *carrier* $F = (S, R, D, M, W, E, H, C, P, N)$ *must read*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{FiniteWindowEnvelope}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows S, R, D, M, W, E before the terminal seal is consumed. The handoff exports no quotient stream, selected host limit, countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier projection. The only available source window is S, the only regular rational readback is R, and the only tolerance ledger is D.

Read the modulus and envelope rows next. The threshold row M bounds the finite refinement request, while W packages the refined window and the source window in the same finite packet.

Finally consume the seal row E through H, C, P, N. Because the packet has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness, the Real-facing consumer receives only the displayed finite-window handoff. □

Falsifiable prediction: Every accepted $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$ Real-facing read displays StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a CauchyModulus threshold, a FiniteWindowEnvelope refinement row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, cauchymodulus, finitewindowenvelope, real: $\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}$ is not bijective to any listed sibling because it packages the finite refinement envelope between regular rational readback and the terminal Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowRegSeqRatRefinement}^{\uparrow}}$.

Constructive story: A FiniteWindowRegSeqRatRefinement$^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a CauchyModulus threshold, a FiniteWindowEnvelope refinement row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteWindowRegSeqRatRefinement}^{\uparrow}}$, seed)

Scope closed: Definition 6926.1, Definition 6926.2, and Definition 6926.3 seed the finite-window RegSeqRat refinement route before any Real-facing seal consumption.

Formal verification: FormalStatus(NameCert$_{\text{FiniteWindowRegSeqRatRefinement}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.FiniteWindowRegSeqRatRefinementUp.FiniteWindowRegSeqRatRefinementUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exposure, regular readback, dyadic tolerance accounting, modulus threshold exposure, envelope exactness, seal discipline, transport, replay, provenance, and local naming.

Chapter 6927

A Concrete Naming Certificate for FiniteCoverBarModulus$^{\uparrow}$

Following Bishop and Bridges' finite-cover route to uniform continuity on compact metric spaces, the FiniteCoverBarModulus$^{\uparrow}$ packet records the boundary where a compact finite cover, local pointwise moduli, a dyadic lower-bound fold, regular-rational readback, and a terminal Real seal are packaged as L10 Real-and-Completion data. It sits after the compact finite-net carrier of chapter 129, the continuous-map rows of chapter 130, the compact-uniform route of chapter 388, and the tolerance-only modulus consumer of chapter 369. The packet names a finite bar-cover modulus without open-cover compactness, selected subcovers, host functions, quotient stream equality, or ambient Real$^{\uparrow}$ completeness.

Definition 6927.1 (Finite cover bar modulus carrier)**.** *A* FiniteCoverBarModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, L, D, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-cover or finite-net source row inspected by the bar.*
2. *F is the finite bar-cover row listing the displayed centers, cover radii, and branch-depth ledger used by the compact source.*
3. *L is the* ContinuousMap$^{\uparrow}$ *local-modulus row attached to each displayed cover member.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance and lower-bound fold row.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row produced from the displayed dyadic fold.*
6. *E is the terminal* Real$^{\uparrow}$ *seal for the modulus bound read from R.*
7. *U is the* UniformModulus$^{\uparrow}$ *consumer row available only after K, F, L, D, R, E have been displayed.*
8. *H stores componentwise* hsame *transport for the compact source, bar cover, local moduli, dyadic fold, regular readback, Real seal, uniform-modulus row, replay, provenance, and local naming.*
9. *C stores displayed* Cont *replay from a compact-uniform-continuity request through $K, F, L, D, R, E, U, H, P, N$.*
10. *P is the* Pkg *provenance over* FiniteCoverBarModulus$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{FiniteCoverBarModulus}^{\uparrow}}$ *row.*
The carrier has no coordinate for open-cover compactness, a selected finite subcover, a host modulus function, quotient equality of functions or streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6927.2 (Finite cover bar modulus NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ *carrier* $B = (K, F, L, D, R, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverBarModulus}^{\uparrow}}$ *surface consists exactly of compact finite-cover admission, finite bar-cover exposure, local-modulus visibility, dyadic lower-bound fold exactness, regular-rational readback, terminal Real sealing, uniform-modulus handoff, componentwise transport, displayed replay, provenance, and local naming for the rows of Definition 6927.1.*

Proof. Project the carrier. The analytic rows are K, F, L, D, R, E, U, and the structural rows are H, C, P, N.

The compact source and bar-cover rows K, F list the finite cover data before any local modulus is read. The row L then attaches pointwise modulus data to the displayed cover members, while D folds the resulting dyadic lower bounds inside the same finite packet.

The readback row R, terminal seal E, and uniform-modulus row U are downstream of that finite fold. Transport, replay, provenance, and local naming preserve the same inventory, so the local NameCert surface contains exactly the listed obligations and no hidden subcover selection or host modulus. □

Theorem 6927.3 (Finite cover bar modulus Real-and-Completion handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ *packet must read the route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}$$

through the displayed rows $K, F, L, D, R, E, U, H, C, P, N$. The exported modulus is the finite bar-cover lower-bound fold, not an open-cover compactness theorem, selected subcover, quotient function equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with the obligation surface of Definition 6927.2. It forces the consumer to expose the compact source, bar-cover row, local moduli, dyadic fold, regular readback, Real seal, and uniform-modulus handoff before the packet is exported.

The Real-and-Completion read therefore reaches $\mathsf{RegSeqRat}^{\uparrow}$ only after the finite dyadic fold D has been displayed. It reaches $\mathsf{Real}^{\uparrow}$ only through the readback row R, and it reaches $\mathsf{UniformModulus}^{\uparrow}$ only after the terminal seal E is visible.

Since the carrier inventory has no row for an open cover, selected subcover, host modulus function, quotient function equality, choice schedule, or ambient completeness theorem, the handoff is exhausted by $K, F, L, D, R, E, U, H, C, P, N$. □

Theorem 6927.4 (Finite cover bar modulus compact-uniform route)**.** *Every accepted* $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ *packet consumed by chapter 388 or chapter 369 exposes the same finite bar-cover row F, local-modulus row L, dyadic fold D, regular readback R, Real seal E, and uniform-modulus row U. Thus the compact-uniform-continuity route remains a finite NameCert route over displayed compact, continuous-map, dyadic, regular-rational, Real, and uniform-modulus data.*

Proof. Apply Definition 6927.2. The compact-uniform consumer may inspect only the displayed carrier rows and the structural replay rows.

Use Definition 6927.3. The downstream route orders the dyadic fold before the RegSeqRat readback, the readback before the Real seal, and the Real seal before the UniformModulus consumer row.

The sibling chapters cited in the introduction supply the compact source, continuous-map route, compact-uniform route, and uniform-modulus consumer. The present packet joins those surfaces as one finite bar-cover modulus carrier and exports no further principle. □

Theorem 6927.5 (Finite cover bar modulus nonescape)**.** *An accepted* $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ *read cannot infer open-cover compactness, a selected finite subcover, host function equality, quotient stream equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness unless one of those rows is explicitly added to the displayed carrier. The carrier of Definition 6927.1 adds none of them.*

Proof. Project the displayed tuple $B = (K, F, L, D, R, E, U, H, C, P, N)$. Each coordinate is one of the compact finite-cover, bar-cover, local-modulus, dyadic-fold, regular-readback, Real-seal, uniform-modulus, transport, replay, provenance, or local-name rows.

The three preceding theorems consume exactly those rows for the NameCert obligation surface, the Real-and-Completion handoff, and the compact-uniform route. None of the arguments introduces an external cover object, choice operation, quotient, host function equality, or completeness theorem.

Therefore the refused principles are absent by carrier inventory. Any consumer that uses one of them has left the accepted $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ packet. □

Falsifiable prediction: An accepted $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ consumer that exports a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying $K, F, L, D, R, E, U, H, C, P, N$ refutes the carrier surface.

Independence witness: compact metric source, continuous-map local modulus, uniform-modulus handoff, regular rational readback: $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ binds all four with a finite bar-cover and dyadic lower-bound fold, while each sibling supplies only its own carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverBarModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverBarModulus}^{\uparrow}$ packet is generated from CompactMetricUp finite-cover rows, a finite bar-cover ledger, ContinuousMapUp local-modulus rows, a DyadicRatCoreUp lower-bound fold, RegSeqRatUp readback, RealUp seal, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverBarModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6927.1, Definition 6927.2, Definition 6927.3, and Definition 6927.4 seed the finite bar-cover modulus route for compact-uniform-continuity and Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverBarModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, host modulus functions, quotient function or stream equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bar-cover exposure, local-modulus visibility, dyadic lower-bound fold exactness, regular readback, Real seal nonescape, uniform-modulus handoff, transport stability, replay, provenance, and local naming for BEDC.Derived.FiniteCoverBarModulusUp.

Chapter 6928

A Concrete Naming Certificate for $\mathsf{CofinalMetricCompletion}^{\uparrow}$

Following Kelley and Bourbaki on uniform and metric completions, and Bishop–Bridges on constructive completion by regular approximants, the $\mathsf{CofinalMetricCompletion}^{\uparrow}$ packet names the finite cofinal-window surface by which a metric-completion consumer reads regular rational evidence before reaching a terminal real-name seal. It sits between the metric completion carrier of chapter 1506, the functorial uniform-completion route of chapter 1892, the Cauchy-completion handoff of chapter 423, the finite StreamName route of chapter 126, the RegSeqRat readback of chapter 301, the DyadicRatCore tolerance ledger of chapter 291, and the RealUp seal of chapter 38. The packet is a completion-facing cofinal-window certificate; it is not quotient completion equality, a selected representative, a choice function, or an ambient completeness principle.

Definition 6928.1 (Cofinal metric-completion carrier)**.** *A* $\mathsf{CofinalMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, U, F, W, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row exposing the metric-completion request surface.*
2. *U is the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *route row through which completion-facing functorial reads are admitted.*
3. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row downstream of M and U.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *cofinal-window ledger naming the finite observation windows served to the completion request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read from W and R.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, U, F, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the metric source, functorial route, Cauchy handoff, cofinal windows, readback, tolerance, seal, and structural rows.*
9. *C records displayed* Cont *replay of the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{CofinalMetricCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalMetricCompletion}^{\uparrow}}$ *row.*

The classifier for accepted carriers compares only $M, U, F, W, R, D, S, H, C, P, N$. It has no coordinate for quotient completion equality, host completed-real equality, selected limits, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 6928.2 (Cofinal metric-completion NameCert obligations)**.** *For every accepted* $\mathsf{CofinalMetricCompletion}^{\uparrow}$ *carrier $K = (M, U, F, W, R, D, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalMetricCompletion}^{\uparrow}}$ *surface consists exactly of metric-completion source exposure through M, uniform functorial route exposure through U, Cauchy-completion handoff through F, cofinal StreamName windows through W, RegSeqRat readback through R, DyadicRatCore tolerance through D, terminal Real seal access through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the displayed carrier of Definition 6928.1. The metric source, uniform functorial route, Cauchy handoff, cofinal-window ledger, readback, tolerance, seal, transport, replay, provenance, and local naming rows are exactly the coordinates of one finite BHist packet.

The metric-completion request first reads M and then the functorial route U, F. This places the request on the same completion-facing path used by the sibling UniformCompletionFunctor and CauchyCompletionFunctor certificates before any Real-facing row is available.

The cofinal-window surface is then fixed by W, R, D. Each precision request is served by a displayed StreamName window, regular rational readback, and dyadic tolerance ledger, so the consumer cannot replace the route by quotient completion equality, a hidden representative, or host-level complete metric data.

Finally S, H, C, P, N seal and name the same route. Since no excluded object appears among the carrier coordinates, the local NameCert obligations are exhausted by the displayed finite packet. □

Theorem 6928.3 (Cofinal metric-completion L10 handoff)**.** *Every L10 completion-facing read exported by an accepted* $\mathsf{CofinalMetricCompletion}^{\uparrow}$ *packet factors through the finite route*

$$M, U, F, W, R, D, S, H, C, P, N.$$

In particular, a consumer reaches the $\mathsf{Real}^{\uparrow}$ *seal only after reading the* $\mathsf{MetricCompletion}^{\uparrow}$ *source, the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *route, the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff, the* $\mathsf{StreamName}^{\uparrow}$ *cofinal-window ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. The rows H, C, P, N preserve the same route and do not add quotient completions, selected limits, choice, or ambient completeness.*

Proof. Start with the NameCert obligations of Definition 6928.2. They expose the route inventory and require every accepted consumer to read the displayed metric, uniform-functorial, Cauchy-handoff, cofinal-window, readback, tolerance, seal, transport, replay, provenance, and naming rows.

The sibling metric-completion and uniform-completion-functor chapters supply the source shape for the first three rows: M is the metric-completion entry point, while U, F keep the request on the functorial completion handoff rather than on a host completion object.

The finite L10 window is the middle segment W, R, D. It records the StreamName window, the RegSeqRat readback, and the DyadicRatCore tolerance ledger used by the request before the terminal Real seal is read.

The remaining rows S, H, C, P, N only seal, transport, replay, source, and name the same finite route. Therefore the handoff exported to downstream completion consumers is exactly the displayed cofinal-window packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalMetricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalMetricCompletion}^{\uparrow}$ packet is generated from a MetricCompletion source row, a UniformCompletionFunctor route row, a CauchyCompletionFunctor handoff row, StreamName cofinal windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6928.1, Definition 6928.2, and Definition 6928.3 seed the finite cofinal-window route from MetricCompletion and UniformCompletionFunctor data to RegSeqRat, DyadicRatCore, and RealUp consumer rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host completed-real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal-window exactness, RegSeqRat readback, DyadicRatCore tolerance, RealUp seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.CofinalMetricCompletio

Chapter 6929

A Concrete Naming Certificate for $\mathsf{RegularConditionalDistribution}^{\uparrow}$

Following Kallenberg and standard regular conditional probability theory, the $\mathsf{RegularConditionalDistribution}^{\uparrow}$ packet records a source random variable, a target event family, and a state-indexed probability law as finite BEDC data. It sits over the probability-space surface of chapter 184, the measurable-preimage surface of chapter 185, the pushforward-law surface of chapter 186, the projection surface of chapter 188, the state-to-distribution interface of chapter 6735, the generated-event surface of chapter 6308, the Polish presentation surface of chapter 1490, and the regular-measure surface of chapter 2263. The chapter names regular conditional laws without importing a choice-selected disintegration, host kernel equality, quotient event algebra, or ambient measurable-space oracle.

Definition 6929.1 (Regular conditional distribution carrier)**.** *A* $\mathsf{RegularConditionalDistribution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (\Omega, S, T, X, Y, \mathcal{A}_S, \mathcal{A}_T, \kappa, D, E, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the source* $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the probability measure from which conditioning is read.*
2. S *is the conditioning-state row, read through a* $\mathsf{StandardBorelSpace}^{\uparrow}$ *presentation and the underlying* $\mathsf{PolishSpace}^{\uparrow}$ *event generator.*
3. T *is the target-state row, with target events carried by* $\mathcal{A}_T$*.*
4. X *is the conditioning* $\mathsf{RandomVar}^{\uparrow}$ *row from* Ω *into* S*.*
5. Y *is the target* $\mathsf{RandomVar}^{\uparrow}$ *row from* Ω *into* T*.*
6. $\mathcal{A}_S$ *and* $\mathcal{A}_T$ *are the displayed source and target measurable-event families.*
7. κ *is the state-indexed endpoint assignment sending each displayed conditioning state* s *and target event* $B \in \mathcal{A}_T$ *to a* $\mathsf{Real}^{\uparrow}$ *endpoint* $\kappa(s, B)$*.*
8. D *records that each fixed state* s *reads as a* $\mathsf{Distribution}^{\uparrow}$ *row over target events and as a* $\mathsf{MarkovKernel}^{\uparrow}$ *fiber from* S *to* T*.*
9. E *records conditional-expectation exactness: for each displayed target event* B*, the row* $s \mapsto \kappa(s, B)$ *is the* $\mathsf{CondExp}^{\uparrow}$ *readback of the indicator of* $Y^{-1}(B)$ *over the conditioning row* X*.*

10. *H records componentwise* hsame *transport for source states, target events, endpoints, distribution fibers, conditional-expectation rows, and regular-measure boundaries.*
11. *C records displayed* Cont *replay from $\Omega, X, Y, S, T, \mathcal{A}_S, \mathcal{A}_T$ through κ, D, E, H, P, N.*
12. *P is the* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{MarkovKernel}^{\uparrow}$, $\mathsf{StandardBorelSpace}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularConditionalDistribution}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected disintegration, host conditional probability object, quotient event equality, external sigma-algebra completion, or unledgered kernel equality.

Theorem 6929.2 (Regular conditional distribution NameCert obligations)**.** *For the carrier of Definition 6929.1, the local* $\mathsf{NameCert}_{\mathsf{RegularConditionalDistribution}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$R = (\Omega, S, T, X, Y, \mathcal{A}_S, \mathcal{A}_T, \kappa, D, E, H, C, P, N),$$

source probability exposure through Ω, conditioning and target random-variable exposure through X, Y, generated event exposure through $S, T, \mathcal{A}_S, \mathcal{A}_T$, endpoint readback through κ, distribution-fiber and Markov-kernel exposure through D, conditional-expectation exactness through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.

Consequently an accepted $\mathsf{RegularConditionalDistribution}^{\uparrow}$ *packet is a finite state-indexed law whose measurable fibers are read through the displayed* $\mathsf{StandardBorelSpace}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{MarkovKernel}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, *and* $\mathsf{RadonMeasure}^{\uparrow}$ *rows. It is not a selected disintegration theorem and not a host conditional-probability object.*

Proof. Project the carrier of Definition 6929.1. Its rows expose the probability source, conditioning and target random variables, generated measurable-event families, state-indexed endpoint assignment, distribution fiber, conditional-expectation exactness, transport, replay, provenance, and local name.

Read D at a fixed conditioning state. The endpoint assignment $B \mapsto \kappa(s, B)$ is a $\mathsf{Distribution}^{\uparrow}$ row over the target event family and a $\mathsf{MarkovKernel}^{\uparrow}$ fiber from the conditioning state to target events.

Read E at a fixed target event. It identifies the state-indexed endpoint row with the $\mathsf{CondExp}^{\uparrow}$ readback of the target-event indicator along X, using only the displayed random-variable and probability-space rows.

The rows H, C, P, N preserve and name the same packet. Since no coordinate carries selected disintegration data, quotient event equality, host kernel equality, or an ambient measurable-space oracle, the listed finite rows exhaust the NameCert obligations. □

Theorem 6929.3 (Regular conditional distribution kernel readback)**.** *Every accepted* RegularConditionalDistributio *readback factors through the displayed route*

$$\mathsf{ProbSpace}^{\uparrow}, \mathsf{RandomVar}^{\uparrow}, \mathsf{StandardBorelSpace}^{\uparrow}, \mathsf{PolishSpace}^{\uparrow} \longmapsto \mathsf{MarkovKernel}^{\uparrow} \longmapsto \mathsf{Distribution}^{\uparrow} \longmapsto \mathsf{CondExp}^{\uparrow}.$$

The target-event value $\kappa(s, B)$ is public only after the conditioning-state row s, the target event B, the distribution fiber, and the conditional-expectation exactness row are displayed on the same finite packet. The readback exports no selected disintegration, host conditional-probability equality, quotient event algebra, or ambient regularity theorem.

Proof. Start with the source rows $\Omega, X, Y, S, T, \mathcal{A}_S, \mathcal{A}_T$ of the carrier. The probability and random-variable rows give the conditioning and target events, while the standard Borel and Polish rows make the event codes available as displayed data.

Use the fiber row D. At each displayed conditioning state s, the endpoint assignment over target events is read as a $\mathsf{MarkovKernel}^{\uparrow}$ fiber and as a $\mathsf{Distribution}^{\uparrow}$ row, so the consumer receives a state-indexed law rather than a detached host object.

Finally apply the exactness row E. For every target event B, the endpoint $\kappa(s, B)$ is tied to the $\mathsf{CondExp}^{\uparrow}$ readback of the indicator of $Y^{-1}(B)$ along X. The transport and replay rows preserve that same route, so no selected disintegration or host kernel equality can enter the public readback. □

Theorem 6929.4 (Regular conditional distribution ledger nonescape)**.** *No accepted* $\mathsf{RegularConditionalDistribution}^{\uparrow}$ *packet exports a conditional law outside the displayed rows*

$$\Omega, S, T, X, Y, \mathcal{A}_S, \mathcal{A}_T, \kappa, D, E, H, C, P, N.$$

In particular, the packet does not export a choice-selected disintegration, a host conditional-probability primitive, quotient event equality, a hidden standard Borel completion, or an unledgered Radon regularity claim.

Proof. Begin with Definition 6929.2. It exhausts the local certificate by the probability source, random-variable rows, generated event rows, endpoint assignment, distribution fiber, conditional-expectation exactness, transport, replay, provenance, and local name.

Use Definition 6929.3 to keep every public endpoint on the same finite route from conditioning state and target event to kernel fiber, distribution row, and conditional-expectation readback.

The $\mathsf{StandardBorelSpace}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, and $\mathsf{RadonMeasure}^{\uparrow}$ dependencies provide displayed event generation and regular-measure boundaries, but the carrier records them through P, H, C rather than as ambient host structure. Thus the listed rows are the only public coordinates, and the stated escape routes are not exports of this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularConditionalDistribution}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularConditionalDistribution}^{\uparrow}$ packet is generated from a probability source, conditioning and target random variables, standard Borel and Polish event rows, state-indexed endpoint fibers, distribution and Markov-kernel readback, conditional-expectation exactness, regular-measure provenance, transport, replay, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularConditionalDistribution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6929.1, Definition 6929.2, Definition 6929.3, and Definition 6929.4 seed the finite regular-conditional-law packet and its kernel readback boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularConditionalDistribution}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close existence of regular conditional distributions, selected disintegration, host conditional probability, quotient event equality, Lean checking, or bridge checking for $\mathsf{RegularConditionalDistribution}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, fiber distribution readback, conditional-expectation exactness, transport, provenance, local naming, and nonescape for the same packet.

Chapter 6930

A Concrete Naming Certificate for $\mathsf{BishopCauchyLocator}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyLocator}^{\uparrow}$ packet records the finite locator surface by which a regular Cauchy rational name is read through explicit windows, dyadic tolerances, and a located tail threshold before any Real or Completion consumer may cite it. It sits beside the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance carrier of chapter 291, the located tail-modulus route of chapter 1035, and the located Cauchy real interface of chapter 1850. The packet supplies a constructive locator object for the Real and Completion corridor without quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6930.1 (Bishop Cauchy locator carrier)**.** *A* $\mathsf{BishopCauchyLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected source windows of the regular Cauchy name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those same windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested radius, endpoint slack, and comparison budget.*
4. *T is the located tail-threshold row, read through the* $\mathsf{LocatedCauchyModulus}^{\uparrow}$ *route and compatible with the located Cauchy interface of* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$*.*
5. *H stores componentwise* hsame *transport for the window, readback, dyadic tolerance, located threshold, replay, provenance, and local naming rows.*
6. *C stores the displayed* Cont *replay from a precision request through S, R, D, T to every downstream locator consumer.*
7. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyLocator}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{LocatedCauchyModulus}^{\uparrow}$*,* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyLocator}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a selected limit, a countable-choice selector, trichotomy, host real equality, or ambient completeness.

Theorem 6930.2 (Bishop Cauchy locator NameCert obligations)**.** *For an accepted* $\mathsf{BishopCauchyLocator}^{\uparrow}$ *carrier* $L = (S, R, D, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyLocator}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-window exposure, regular rational readback, dyadic tolerance exactness, located tail-threshold exposure, componentwise transport, continuation replay, provenance, and local naming for the packet of Definition 6930.1.*

Proof. Project the displayed carrier. The analytic rows are S, R, D, T, and the structural rows are H, C, P, N.

The stream row S supplies the finite inspection window, while R records the regular rational readback on that same window. The dyadic row D fixes the tolerance under which the readback is tested, and the located threshold row T records the tail boundary available to Real and Completion consumers.

The remaining rows do not add a second locator. Transport, replay, provenance, and naming preserve the same displayed packet, so the local certificate obligations are exhausted by S, R, D, T, H, C, P, N. □

Theorem 6930.3 (Bishop Cauchy locator window stability)**.** *Let* $L = (S, R, D, T, H, C, P, N)$ *and* $L' = (S', R', D', T', H', C', P', N')$ *be accepted* $\mathsf{BishopCauchyLocator}^{\uparrow}$ *carriers. If* H *and* H' *record componentwise* hsame *transport preserving the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, and located tail-threshold rows, then every located Cauchy consumer reading* L' *factors through the same ordered window route*

$$S', R', D', T', H', C', P', N'.$$

No transported read may replace the displayed window by a quotient stream, replace the threshold by a selected limit, or cite countable choice or ambient completeness.

Proof. Start from the NameCert obligations of Definition 6930.2. They require the transported packet to expose a finite window, regular readback, dyadic tolerance, and located threshold before a consumer can read the locator.

Componentwise hsame transport preserves the row positions named by H and H'. Thus the target packet still opens the window row S', then reads R' under the dyadic budget D', and only then consumes the threshold row T'.

The continuation row C' replays this route; it cannot create a hidden stream quotient or selected limit. Provenance and local naming record the same route through P' and N', so every accepted transported read remains inside the displayed packet. □

Falsifiable prediction: An accepted $\mathsf{BishopCauchyLocator}^{\uparrow}$ packet cannot supply a located tail threshold unless the same packet displays the finite StreamName window, RegSeqRat readback, and DyadicRatCore tolerance used to locate it.

Independence witness: streamname, regseqrat, dyadicratcore, locatedcauchymodulus, bishoplocatedcauchyreal: none is bijective to $\mathsf{BishopCauchyLocator}^{\uparrow}$ because the locator carrier binds source windows, regular readback, dyadic tolerance, located threshold, transport, replay, provenance, and local NameCert rows in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyLocator}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyLocator}^{\uparrow}$ packet is generated from a StreamName finite-window row, a RegSeqRat readback row, a DyadicRatCore tolerance row, a located tail-threshold row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6930.1, Definition 6930.2, and Definition 6930.3 seed the finite locator route over StreamName, RegSeqRat, DyadicRatCore, located tail threshold, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopCauchyLocator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, RealUp completeness, quotient stream equality, selected limits, countable choice, trichotomy, or host real equality.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular readback, dyadic tolerance exactness, located threshold exposure, transport stability, continuation replay, provenance, and local naming for BEDC.Derived.BishopCauchyLocatorUp.

Chapter 6931

A Concrete Naming Certificate for PipelineDiscoveryClassifier$^{\uparrow}$

The PipelineDiscoveryClassifier$^{\uparrow}$ packet realizes the classifier-shift boundary of chapter 9410 as finite NameCert data. It sits after the pipeline calculus of chapter 5914, the before-and-after classifier ledger of chapter 6765, the theorem-genome evolution packet of chapter 6358, and the theorem-DNA scoring taste gate of chapter 9460. The packet classifies a discovery claim only when a concrete before/after classifier disagreement, public weight profile, theorem-genome route, ledger row, transport, replay, provenance, and local naming are all displayed.

Definition 6931.1 (Pipeline discovery classifier carrier)**.** *A* PipelineDiscoveryClassifier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, B, A, W, G, L, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DiscoveryPipelineCalculus$^{\uparrow}$ *admission row, displaying the source theory state, automation record, theorem-genome extraction, score account, lineage, classifier-shift row, gate, and refusal boundary.*
2. *B is the before-classifier row read from the* ClassifierChannelShiftLedger$^{\uparrow}$ *surface.*
3. *A is the after-classifier row read from the same classifier-channel ledger.*
4. *W is the public weight-profile row used by the scoring taste gate when the claim is presented as positive discovery rather than merely classifier movement.*
5. *G is the* TheoremGenomeEvolution$^{\uparrow}$ *genome-route row, exposing theorem-flow, recognizer, theorem-DNA, classifier-shift, mutation, selection, and ledger data.*
6. *L is the classifier-channel shift ledger row, recording record growth separately from classifier disagreement.*
7. *T is the TasteGate boundary row, naming the Nontrivial and FieldFaithful obligations required in* `lean4/BEDC/Derived/PipelineDiscoveryClassifierUp/TasteGate.lean`.
8. *H stores componentwise* hsame *transport for the pipeline, classifier, weight, genome, ledger, TasteGate, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from the pipeline admission row through the before/after classifier comparison and the public weight profile.*

10. *P is the* Pkg *provenance over* PipelineDiscoveryClassifier$^{\uparrow}$, DiscoveryPipelineCalculus$^{\uparrow}$, ClassifierChannelShiftLedger TheoremGenomeEvolution$^{\uparrow}$, *the theorem-DNA scoring taste gate,* BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{PipelineDiscoveryClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for positive discovery by prose alone, raw record growth, hidden weights, unledgered lineage, a classifier claim with no before/after disagreement, or a TasteGate admission that drops carrier fields.

Theorem 6931.2 (Pipeline discovery classifier NameCert obligations)**.** *For an accepted* PipelineDiscoveryClassifier$^{\uparrow}$ *carrier $K = (D, B, A, W, G, L, T, H, C, P, N)$, the local* NameCert$_{\text{PipelineDiscoveryClassifier}^{\uparrow}}$ *surface consists exactly of pipeline admission, before-classifier exposure, after-classifier exposure, public weight-profile exposure, theorem-genome route exposure, classifier-channel ledger exposure, TasteGate boundary exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the displayed carrier. The pipeline row D supplies the admission calculus, while B, A, L supply the concrete classifier-channel comparison and keep record growth separate from classifier movement.

The weight row W and genome row G supply the public scoring and theorem-genome surfaces needed before a positive discovery claim can be read. The TasteGate row T records that any Lean realization must keep the carrier nontrivial and field-faithful rather than collapsing the rows into a prose classifier.

The structural rows H, C, P, N preserve and name the same packet. Since the carrier contains no hidden weight, unledgered lineage, or prose-only discovery coordinate, the local certificate obligations are exhausted by the displayed rows. □

Theorem 6931.3 (Pipeline discovery classifier positive-claim gate)**.** *Any positive discovery claim read through an accepted* PipelineDiscoveryClassifier$^{\uparrow}$ *packet must display a concrete disagreement between the before-classifier row B and after-classifier row A, together with the public weight profile W, theorem-genome route G, classifier-channel ledger L, TasteGate boundary T, and structural rows H, C, P, N. If B and A agree on the displayed source scope, the packet may record automation or record growth through D and L, but it does not classify the claim as positive discovery.*

Proof. Start with the carrier of Definition 6931.1. The only before/after classifier comparison is the pair B, A, and the only record-growth separation row is L.

Use the NameCert obligations of Definition 6931.2. A positive read must expose the classifier comparison, public weights, theorem-genome route, TasteGate boundary, transport, replay, provenance, and local naming as one packet.

If B and A agree on the displayed source scope, the classifier-channel ledger has no disagreement row to feed the positive claim. The pipeline row D may still record generated material, but record growth without classifier disagreement is routed as non-positive by the displayed carrier boundary. □

Falsifiable prediction: A positive PipelineDiscoveryClassifier$^{\uparrow}$ claim requires a concrete before/after classifier disagreement plus a public weight profile; a trace with raw automation growth and no displayed B, A, W surface refutes the positive classifier claim.

Independence witness: discovery-pipeline-calculus, classifier-channel-shift-ledger, theorem-genome-evolution, theorem-dna-scoring-taste-gate: none is bijective to PipelineDiscoveryClassifier$^{\uparrow}$ because this packet jointly carries pipeline admission, before/after classifier rows, a public weight profile,

genome evolution, classifier-channel ledger, TasteGate boundary, transport, replay, provenance, and local NameCert rows.

The Lean boundary for $\mathsf{PipelineDiscoveryClassifier}^{\uparrow}$ is the future file `lean4/BEDC/Derived/PipelineDiscoveryC` It must provide explicit $\mathsf{Nontrivial\ PipelineDiscoveryClassifier}^{\uparrow}$ and $\mathsf{FieldFaithful\ PipelineDiscoveryClassifier}^{\uparrow}$ instances preserving $D, B, A, W, G, L, T, H, C, P, N$ as separate fields before any checked classifier theorem can serve as the carrier-alignment witness.

Closure status for $\mathsf{NameCert}_{\mathsf{PipelineDiscoveryClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{PipelineDiscoveryClassifier}^{\uparrow}$ packet is generated from pipeline admission, before-classifier, after-classifier, public weight-profile, theorem-genome, classifier-channel ledger, TasteGate boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PipelineDiscoveryClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6931.1, Definition 6931.2, and Definition 6931.3 seed the finite classifier boundary for positive pipeline discovery claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PipelineDiscoveryClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global positive-discovery certification, automated theorem proving, hidden scoring, unledgered lineage, or prose-only classifier novelty.

Upgrade path: Obligation closure requires checked carrier admission, before/after classifier disagreement, public weight-profile exposure, theorem-genome route exposure, classifier-channel ledger exactness, Nontrivial PipelineDiscoveryClassifierUp, and FieldFaithful PipelineDiscoveryClassifierUp in TasteGate.lean.

Chapter 6932

A Concrete Naming Certificate for DecimalEndpointAmbiguity$^{\uparrow}$

Following Bishop and Bridges on constructive real approximation and the classical terminating-decimal convention, the DecimalEndpointAmbiguity$^{\uparrow}$ packet records the finite boundary where a terminating decimal window and a repeating-nine window present the same endpoint route. It sits after chapter 1417, chapter 1429, chapter 5150, and chapter 3952, and it hands all real-facing reads through chapter 301, chapter 291, and chapter 38. The packet names only the finite endpoint ambiguity surface for inspected decimal windows; it does not assert uniqueness of all decimal expansions, select a host real representative, or quotient arbitrary decimal streams.

Definition 6932.1 (DecimalEndpointAmbiguity carrier)**.** *A* DecimalEndpointAmbiguity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, E, S, M, Q, R, Y, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DecimalExpansion$^{\uparrow}$ *source ledger for the inspected finite decimal prefixes.*
2. *E is the* DecimalEndpointNormalization$^{\uparrow}$ *endpoint row that records the terminating side and the repeating-nine side inside the same window.*
3. *S is the* SignedDecimalExpansion$^{\uparrow}$ *sign and zero-window row, when the endpoint ambiguity is read through a signed presentation.*
4. *M is the* RealDecimalNormalForm$^{\uparrow}$ *normal-form route reached after the endpoint row has been displayed.*
5. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row attached to the same endpoint window.*
6. *R is the* RegSeqRat$^{\uparrow}$ *handoff row produced from the normalized endpoint window.*
7. *Y is the terminal* Real$^{\uparrow}$ *seal row reached only after D, E, S, M, Q, R have been exposed.*
8. *H records componentwise* hsame *transport for the decimal source, endpoint-normalization, signed-window, normal-form, dyadic, regular, real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the decimal window through endpoint normalization, normal-form readback, dyadic tolerance, regular handoff, and the real seal.*
10. *P is the* Pkg *provenance over* DecimalEndpointAmbiguity$^{\uparrow}$, DecimalExpansion$^{\uparrow}$, DecimalEndpointNormalization$^{\uparrow}$, SignedDecimalExpansion$^{\uparrow}$, RealDecimalNormalForm$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalEndpointAmbiguity}^{\uparrow}}$ *row.*
The classifier compares accepted endpoint-ambiguity packets only through $D, E, S, M, Q, R, Y, H, C, P, N$. It has no coordinate for global decimal uniqueness, quotient stream equality, selected representatives, arbitrary real-name trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DecimalEndpointAmbiguityUp.DecimalEndpointAmbiguityTasteGate single carrier alignment`

Theorem 6932.2 (DecimalEndpointAmbiguity NameCert obligations)**.** *For every accepted* DecimalEndpointAmbig *carrier*

$$A = (D, E, S, M, Q, R, Y, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DecimalEndpointAmbiguity}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, endpoint-pair exposure through E, signed-window compatibility through S, normal-form routing through M, dyadic tolerance exposure through Q, regular rational handoff through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through Y, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the terminating-versus-repeating-nine boundary must read that finite surface before treating the endpoint as real-facing data.*

Proof. Carrier admission is projection from Definition 6932.1. The visible decimal coordinates are exactly D, E, S, M, Q, R, Y, while H, C, P, N carry transport, replay, provenance, and local naming.

Endpoint-pair exposure is local to E. The terminating side and the repeating-nine side are compared only because the endpoint-normalization row lists them inside the same inspected finite window.

Signed-window compatibility uses S only as a displayed signed presentation of that same endpoint window. It cannot introduce a second magnitude stream or an endpoint selector outside the packet.

The real-facing route is ordered by M, Q, R, Y. Normal form is read first, then dyadic tolerance, then the regular rational handoff, and only then the terminal real seal. The structural rows preserve this finite route, so no global uniqueness, quotient equality, chosen representative, trichotomy, countable-choice schedule, or completeness row can be consumed. □

Theorem 6932.3 (DecimalEndpointAmbiguity real normal-form route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DecimalEndpointAmbiguity}^{\uparrow}$ *packet factors through the finite route*

$\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{DecimalEndpointNormalization}^{\uparrow}$, $\mathsf{SignedDecimalExpansion}^{\uparrow}$, $\mathsf{RealDecimalNormalForm}^{\uparrow}$, RegSeqR

The route records the terminating and repeating-nine windows as finite endpoint data before the normal-form, dyadic, regular-rational, and real-seal rows are public.

Proof. Start with an accepted packet $A = (D, E, S, M, Q, R, Y, H, C, P, N)$. The source row D supplies only finite decimal prefixes, and E supplies the endpoint normalization row for the same inspected window.

The signed row S is read before the normal-form route M. Thus positive, negative, and zero-window presentations are attached to the displayed endpoint row rather than to an independent stream representative.

Now read the arithmetic handoff rows. The dyadic tolerance row Q and the regular rational row R are reached from the normal-form route, and the terminal real seal Y is downstream of both.

Finally apply the structural rows H, C, P, N. They transport, replay, source, and name the same finite endpoint surface, so the real read is a route through the displayed packet rather than a proof of decimal uniqueness. □

Theorem 6932.4 (DecimalEndpointAmbiguity nonescape)**.** *An accepted* $\mathsf{DecimalEndpointAmbiguity}^{\uparrow}$ *packet exports no global decimal uniqueness theorem, quotient stream equality, selected endpoint representative, arbitrary real-name trichotomy, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness. Every endpoint read remains inside the displayed rows* $D, E, S, M, Q, R, Y, H, C, P, N$.

Proof. Inspect the carrier inventory. The only endpoint ambiguity coordinate is E, and it is tied to the finite decimal source D and signed-window row S.

The normal-form and real-facing rows M, Q, R, Y are downstream of that finite endpoint row. They can transport an already displayed terminating or repeating-nine window to a regular rational or real seal, but they cannot select representatives for arbitrary decimal streams.

The structural rows H, C, P, N do not add carrier data. They preserve, replay, source, and name the displayed route. Since the excluded objects are not coordinates of A, no accepted consumer can read them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalEndpointAmbiguity}^{\uparrow}}$.

Constructive story: A $\mathsf{DecimalEndpointAmbiguity}^{\uparrow}$ packet is generated from finite DecimalExpansion source rows, DecimalEndpointNormalization endpoint rows, SignedDecimalExpansion sign and zero-window rows, RealDecimalNormalForm routes, DyadicRatCore tolerance rows, RegSeqRat handoff rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DecimalEndpointAmbiguity}^{\uparrow}}$, seed)

Scope closed: Definition 6932.1, Definition 6932.2, Definition 6932.3, and Definition 6932.4 seed the finite trailing-nine and trailing-zero endpoint ambiguity surface for decimal Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DecimalEndpointAmbiguity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close uniqueness of all decimal expansions, quotient stream equality, selected representatives, arbitrary real-name trichotomy, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-pair exposure, signed-window compatibility, normal-form routing, dyadic tolerance exposure, RegSeqRat handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DecimalEndpointAmbiguityUp.

Chapter 6933

A Concrete Naming Certificate for $\mathsf{RHZeroWindow}^{\uparrow}$

Following the Riemann zeta zero tradition and the finite RH-route boundary of chapter 9336, the $\mathsf{RHZeroWindow}^{\uparrow}$ packet records bounded inspection windows for supplied zeta-zero witnesses. It sits downstream of chapter 73, chapter 72, chapter 9342, and chapter 39. The packet names a finite witness surface only: it does not prove RH, enumerate all zeros, decide all zero locations, or supply a global route-closure oracle.

Definition 6933.1 (RHZeroWindow carrier)**.** *An* $\mathsf{RHZeroWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Z, S, A, X, B, T, H, C, P, N)$$

with the following displayed rows:

1. *Z is the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *zero-witness row for the inspected complex history.*
2. *S is the* $\mathsf{CritStrip}^{\uparrow}$ *row recording the critical-strip boundary or obstruction data visible to the window.*
3. *A is the* $\mathsf{ZetaCont}^{\uparrow}$ *continuation row through which the zeta value is read.*
4. *X is the* $\mathsf{Complex}^{\uparrow}$ *point row for the inspected source history and zero-value comparison.*
5. *B is the finite bound row naming the inspected height, depth, precision, or source-prefix budget of the window.*
6. *T is the provenance row tying the zero row, strip row, continuation row, complex point, and finite bound to the same RH-route request.*
7. *H records componentwise* hsame *transport for $Z, S, A, X, B, T, C, P, N$.*
8. *C records displayed* Cont *replay for the zero, strip, continuation, complex, bound, and provenance rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RHZeroWindow}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaCont}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RHZeroWindow}^{\uparrow}}$ *row.*

The classifier compares accepted zero-window packets only through $Z, S, A, X, B, T, H, C, P, N$. It has no coordinate for a proof of RH*, a counterexample, a complete zero enumeration, host complex equality, quotient zero-set equality, or a global zero-location decider.*

Theorem 6933.2 (RHZeroWindow NameCert obligations)**.** *For every accepted* $\mathsf{RHZeroWindow}^{\uparrow}$ *carrier*

$$W = (Z, S, A, X, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RHZeroWindow}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, zeta-zero source exposure through* Z*, critical-strip exposure through* S*, continuation exposure through* A*, complex point exposure through* X*, finite-bound exposure through* B*, route-provenance exposure through* T*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 6933.1. The zero-facing rows are exactly Z, S, A, X, B, T, while H, C, P, N are the structural transport, replay, package, and naming rows.

The zeta-zero source is supplied, not searched for. The row Z records a zero witness already presented by $\mathsf{ZetaZeros}^{\uparrow}$, and the strip row S only records the finite critical-strip boundary visible to this same window.

The continuation and complex rows are also finite inputs. The row A gives the $\mathsf{ZetaCont}^{\uparrow}$ route used for the inspected zeta value, while X names the complex-history point and zero-value comparison consumed by the window.

Finally the bound and provenance rows B, T keep the read inside one finite inspection budget. Since no other carrier coordinate is present, the packet cannot export an RH proof, a counterexample, all zeros, host equality, quotient zero-set equality, or a global zero-location decider. □

Theorem 6933.3 (RHZeroWindow zeta source route)**.** *Every zero-facing read of an accepted* $\mathsf{RHZeroWindow}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ZetaZeros}^{\uparrow},\ \mathsf{CritStrip}^{\uparrow},\ \mathsf{ZetaCont}^{\uparrow},\ \mathsf{Complex}^{\uparrow}.$$

The finite bound row B *and route-provenance row* T *must be displayed before the packet can be consumed by an RH-route boundary argument.*

Proof. Start with an accepted packet $W = (Z, S, A, X, B, T, H, C, P, N)$. The zero source row Z is the first public zero-facing datum, and it is read together with the critical-strip row S rather than with an ambient zero search.

The continuation row A and complex row X identify the value route and the inspected point. They are finite rows of the same packet, so a consumer cannot replace them by host analytic continuation or host complex equality.

The bound row B and provenance row T then fix the inspection budget and the RH-route request. Only after those rows are exposed may the structural rows H, C, P, N transport, replay, source, and name the zero window. □

Theorem 6933.4 (RHZeroWindow nonescape)**.** *An accepted* $\mathsf{RHZeroWindow}^{\uparrow}$ *packet records finite inspection windows for zeta-zero witnesses and exports no proof of* RH*, no counterexample, no complete zero enumeration, no host complex equality, no quotient zero-set equality, and no decision procedure for all zeros.*

Proof. Inspect the packet coordinates. The only zero data are the supplied $\mathsf{ZetaZeros}^{\uparrow}$ row Z, the critical-strip row S, the continuation row A, the complex point row X, the finite bound row B, and the provenance row T.

The rows H, C, P, N preserve and name that displayed route. They do not add a new witness, a zero search, an equality quotient, or an RH decision datum.

Thus every accepted consumer remains inside the finite window $Z, S, A, X, B, T, H, C, P, N$, and the excluded global conclusions are outside the carrier surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RHZeroWindow}^{\uparrow}}$.

Constructive story: An $\mathsf{RHZeroWindow}^{\uparrow}$ packet is generated from a supplied ZetaZeros row, a critical-strip row, a ZetaCont continuation row, a Complex point row, a finite inspection-bound row, route provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RHZeroWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6933.1, Definition 6933.2, Definition 6933.3, and Definition 6933.4 seed the finite zero-inspection surface for RH-route boundary consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RHZeroWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RH, counterexamples to RH, complete zero enumeration, host complex equality, quotient zero-set equality, all-zero decision, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zeta-zero source exposure, critical-strip exposure, continuation exposure, complex point exposure, finite-bound exposure, route-provenance exposure, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RHZeroWindowUp.

Chapter 6934

A Concrete Naming Certificate for $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real arithmetic, the $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$ packet records the finite route by which two regular Cauchy real names remain readable after an algebraic operation. It sits over the finite observation windows of chapter 126, the dyadic tolerance budget of chapter 291, the regular rational readback of chapter 301, the product-facing operation route of chapter 464, and the terminal real-name seal of chapter 38. The packet is a completion-facing handoff for displayed algebraic reads; it is not a quotient-real operation, selected limit, host completeness theorem, or ambient field structure for $\mathsf{Real}^{\uparrow}$.

Definition 6934.1 (Regular Cauchy algebra closure carrier)**.** *A* $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, R, O, S_L, S_R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy source rows.*
2. *O is the operation selector, naming the displayed algebraic operation to be read from the two sources.*
3. *S_L and S_R are synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows for the two sources.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget, recording the requested precision, operation slack, and rational comparison allowances.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the operation output after the synchronized windows and dyadic budget have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the output read.*
7. *H records componentwise* hsame *transport for the source, operation, window, tolerance, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through the same finite algebraic route.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient real equality, host real arithmetic, selected Cauchy limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6934.2 (Regular Cauchy algebra closure NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$ *carrier* $A = (L, R, O, S_L, S_R, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAlgeb}}$ *surface consists exactly of carrier admission, two-source* $\mathsf{RegSeqRat}^{\uparrow}$ *source exposure, operation selection, synchronized* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget exposure, output* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6934.1. The only source rows are L and R, and the only algebraic choice is the operation selector O.

The finite-window induction is simultaneous over the two synchronized stream rows. At each window stage, S_L and S_R expose the source observations, D supplies the dyadic tolerance budget for the selected operation, and Q records the resulting regular rational output readback.

The terminal seal and structural rows do not add analytic data. The row E seals the displayed output read for $\mathsf{Real}^{\uparrow}$ consumers, while H, C, P, N transport, replay, source, and name the same finite packet.

Since no further row exists, quotient real equality, host arithmetic, selected limits, countable choice, and ambient completeness cannot be exported by the local NameCert surface. □

Theorem 6934.3 (Regular Cauchy algebra closure operation handoff)**.** *Every algebraic read exported by an accepted* $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$ *packet factors through the finite route*

$$L, R, O, S_L, S_R, D, Q, E, H, C, P, N.$$

Thus a $\mathsf{CauchyProduct}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer receives the output only after the two source names, operation selector, synchronized stream windows, dyadic tolerance budget, output readback, seal, transport, replay, provenance, and local naming rows have all been displayed.*

Proof. Start with an operation request. The carrier gives the request only one selector row O and two source rows L, R, so the operation cannot be read before both regular Cauchy sources are visible.

Open the synchronized windows by finite induction. The base stage reads the initial windows from S_L and S_R; the induction step extends both windows together and updates the tolerance budget D before the output readback row Q is consumed.

Now route the result to downstream consumers. The $\mathsf{CauchyProduct}^{\uparrow}$ handoff reads the displayed product-facing operation ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ readback is the row Q, and the $\mathsf{Real}^{\uparrow}$ endpoint is sealed only at E.

Finally, H, C, P, N keep the handoff inside the accepted packet. A consumer can forget unused rows for a projection, but it cannot import quotient real arithmetic, host completeness, selected limits, or countable choice because no such coordinate is present. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$ read is refuted if a Real-facing algebraic output is consumed without first displaying the two RegSeqRat source rows, operation selector, synchronized StreamName windows, DyadicRatCore tolerance budget, output RegSeqRat readback, RealUp seal, transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchyproduct: RegularCauchyAlgebraClosur is not bijective to any listed sibling because it jointly carries two source names, an operation selector, synchronized finite windows, a dyadic operation budget, output readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}$ packet is generated from two RegSeqRat source rows, an operation selector, synchronized StreamName windows, a DyadicRatCore tolerance budget, an output RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6934.1, Definition 6934.2, and Definition 6934.3 seed the finite algebraic closure route for regular Cauchy names over synchronized StreamName windows, DyadicRatCore budgets, RegSeqRat readback, CauchyProduct handoff, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyAlgebraClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real arithmetic, selected limits, countable choice, host real field structure, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-source readback, operation selection, synchronized window induction, dyadic tolerance accounting, output RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyAlgebraClosureUp.

Chapter 6935

A Concrete Naming Certificate for ErdosSzekeresMonotoneSubsequence$^{\uparrow}$

Following Erdos and Szekeres on finite monotone subsequences, the ErdosSzekeresMonotoneSubsequence$^{\uparrow}$ packet records the finite combinatorial surface that turns a long enough ordered list into either an increasing branch of prescribed length or a decreasing branch of prescribed length. The carrier sits after the finite spine discipline of chapter 36, the comparison surface of chapter 1378, and the finite coloring handoff of chapter 203. It is a displayed finite NameCert route, not an infinite subsequence selector, a countable-choice principle, or a host order-completeness theorem.

Definition 6935.1 (Erdos–Szekeres monotone subsequence carrier)**.** *An* ErdosSzekeresMonotoneSubsequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, I, D, L, O, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the source window ledger, recording the inspected finite list entries and the requested increasing and decreasing lengths.*
2. *I is the increasing-branch ledger, listing the retained positions and order comparisons for an accepted increasing branch when that side is selected.*
3. *D is the decreasing-branch ledger, listing the retained positions and order comparisons for an accepted decreasing branch when that side is selected.*
4. *L is the* List$^{\uparrow}$ *spine row that fixes the finite source order and the retained branch subspines.*
5. *O is the* Order$^{\uparrow}$ *comparison row used to classify each inspected pair of retained positions.*
6. *R is the* Ramsey$^{\uparrow}$ *coloring handoff row for the finite pair-coloring route that separates increasing-facing and decreasing-facing comparisons.*
7. *H stores componentwise* hsame *transport for windows, branch rows, list spines, order comparisons, Ramsey rows, replay rows, provenance rows, and local naming rows.*
8. *C stores displayed* Cont *replay from W to L, O, from L, O to R, and from R to the selected branch row I or D.*
9. *P is the* Pkg *provenance over* ErdosSzekeresMonotoneSubsequence$^{\uparrow}$, List$^{\uparrow}$, Order$^{\uparrow}$, Ramsey$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for countable choice, an infinite subsequence object, a host total-order oracle, order completeness, or ambient sequence compactness.

Theorem 6935.2 (Erdos–Szekeres monotone subsequence NameCert surface)**.** *For every accepted* $\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}$ *carrier*

$$E = (W, I, D, L, O, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite source window, one selected branch ledger, the* $\mathsf{List}^{\uparrow}$ *spine row, the* $\mathsf{Order}^{\uparrow}$ *comparison row, the* $\mathsf{Ramsey}^{\uparrow}$ *coloring handoff row, componentwise transport, replay, provenance, and the local name.*

Proof. Project the carrier of Definition 6935.1. The rows $W, I, D, L, O, R, H, C, P, N$ are the only coordinates available to the local classifier, so carrier admission is admission of those displayed rows.

The finite source discipline is read through chapter 36. The row L fixes the inspected list spine and the retained branch subspines, while W records the finite window and the requested branch lengths.

The comparison and coloring data are then read through chapter 1378 and chapter 203. The order row O supplies the pairwise comparison cells, and the Ramsey row R records the finite two-color handoff that selects either the increasing branch ledger I or the decreasing branch ledger D.

Finally the structural rows H, C, P, N transport, replay, source, and name that same finite route. Since no coordinate carries an infinite selector, countable-choice schedule, host order oracle, completeness principle, or compactness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 6935.3 (Erdos–Szekeres Ramsey handoff)**.** *Every* $\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}$ *consumer that reaches the selected monotone branch must first read the finite list spine through chapter 36, classify retained pairs through chapter 1378, and pass the resulting two-color finite graph row through chapter 203. The exported branch is therefore a finite route*

$$W \longmapsto L, O \longmapsto R \longmapsto I \text{ or } D$$

rather than an independent subsequence selector.

Proof. Start with the source window. The row W exposes only finitely many inspected entries, and L supplies their $\mathsf{List}^{\uparrow}$ order, so the consumer cannot begin from an infinite sequence or from an unrecorded subsequence choice.

Next classify the retained pairs. The row O records the $\mathsf{Order}^{\uparrow}$ comparison cells used to color each pair as increasing-facing or decreasing-facing, and the replay row C sends those cells to the finite Ramsey handoff row R.

The Ramsey consumer then returns one displayed side of the dichotomy. If the increasing side is selected, the branch is read from I; if the decreasing side is selected, the branch is read from D. In both cases H, C, P, N preserve and name the same finite packet, so the handoff exports only the displayed list, order, and Ramsey route. □

Lean4 (statement) `BEDC.Derived.ErdosSzekeresMonotoneSubsequenceUp`

Closure status for $\mathsf{NameCert}_{\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6935.1, Definition 6935.2, and Definition 6935.3 seed the finite carrier, local NameCert surface, and Ramsey/List/Order handoff for the monotone subsequence route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim infinite subsequence selection, countable choice, a host total-order oracle, order completeness, ambient compactness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch ledger stability, ListUp spine exactness, OrderUp comparison exactness, and RamseyUp handoff non-escape for BEDC.Derived.ErdosSzekeresMonotoneSubsequenceUp.

Constructive story: An $\mathsf{ErdosSzekeresMonotoneSubsequence}^{\uparrow}$ packet is generated from a finite source window, increasing and decreasing branch ledgers, a ListUp spine row, an OrderUp comparison row, a RamseyUp coloring handoff row, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 6936

A Concrete Naming Certificate for KolmogorovZeroOneLaw$^{\uparrow}$

Following Kolmogorov on independent coordinates and tail events, the KolmogorovZeroOneLaw$^{\uparrow}$ packet records the finite-window surface behind the zero-one law as displayed BEDC data. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the independence ledger of chapter 187, the finite repeated-hit boundary of chapter 2357, and the event-family surface of chapter 5186. The packet names tail-event inspection through finite windows and a visible zero-one verdict row; it is not a host product-measure theorem, a completed tail sigma algebra, a quotient almost-sure equality, or an ambient probability-limit principle.

Definition 6936.1 (Kolmogorov zero-one law carrier)**.** *A* KolmogorovZeroOneLaw$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (\Omega, X, W, A, I, Z, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* ProbSpace$^{\uparrow}$ *source row carrying the probability measure, total-event endpoint, and event classifier.*
2. X *is the displayed* RandomVar$^{\uparrow}$ *event-sequence row whose coordinates generate the inspected tail windows.*
3. W *is the finite tail-window row, recording the displayed initial cutoff, surviving tail coordinates, and event names inspected beyond that cutoff.*
4. A *is the* SigmaAlgebra$^{\uparrow}$ *admission row for the finite tail events exposed by* W*.*
5. I *is the* Independence$^{\uparrow}$ *ledger row, recording the finite independence witnesses used to separate initial windows from tail windows.*
6. Z *is the zero-one verdict row, recording that the inspected tail-event probability is routed to the displayed* 0_R *or* 1_R *endpoint only through the preceding finite rows.*
7. H *records componentwise* hsame *transport for the probability source, random-variable row, finite tail windows, event admission, independence ledger, verdict row, replay, provenance, and local naming row.*
8. C *records displayed* Cont *replay from a tail-event request through* Ω, X, W, A, I, Z *in that order.*
9. P *is the* Pkg *provenance over* KolmogorovZeroOneLaw$^{\uparrow}$, ProbSpace$^{\uparrow}$, RandomVar$^{\uparrow}$, Independence$^{\uparrow}$, BorelCantelli$^{\uparrow}$, SigmaAlgebra$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{KolmogorovZeroOneLaw}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a completed infinite product measure, a host tail sigma algebra, quotient almost-sure equality, countable-choice tail selectors, or an ambient proof that all external tail events have probability zero or one.

Theorem 6936.2 (Kolmogorov zero-one law NameCert obligations)**.** *For every accepted* $\mathsf{KolmogorovZeroOneLaw}^{\uparrow}$ *carrier*

$$K = (\Omega, X, W, A, I, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KolmogorovZeroOneLaw}^{\uparrow}}$ *surface consists exactly of probability-source admission through Ω; random-variable event exposure through X; finite tail-window admission through W; sigma-algebra event admission through A; independence-ledger exposure through I; zero-one verdict routing through Z; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6936.1. The tuple exposes the probability source, random-variable event sequence, finite tail windows, sigma-algebra admission, independence ledger, zero-one verdict, transport, replay, provenance, and local naming rows.

The tail-event read is finite-window data. It first displays the cutoff and surviving coordinates in W, then reads event admission through A and independence evidence through I before the verdict row Z can be inspected.

The structural rows H, C, P, N preserve and replay the same packet. Since no coordinate supplies a completed tail sigma algebra, quotient almost-sure equality, product-measure extension, or countable-choice selector, the listed rows exhaust the local NameCert obligations. □

Theorem 6936.3 (Kolmogorov zero-one law tail-event induction)**.** *Every accepted* $\mathsf{KolmogorovZeroOneLaw}^{\uparrow}$ *tail-event consumer must inspect tail events by finite-window induction over W. At the base cutoff it reads Ω, X, A to admit the displayed event; at each successor cutoff it transports the same tail request through H, replays the independence comparison through C and I, and only then reads the verdict row Z. Thus the public zero-one read is a finite NameCert route and not a host tail sigma-algebra theorem.*

Proof. The base cutoff is a carrier projection. Rows Ω and X give the probability source and coordinate event sequence, while A admits the displayed event in the sigma-algebra surface.

For the successor cutoff, use the finite tail-window row W. Componentwise transport H keeps the same source, event, admission, and independence rows attached to the shifted window.

Replay C and then read the independence ledger I. The verdict row Z is therefore consumed only after the finite cutoff, event admission, and independence comparison are visible.

Since the carrier has no row for a completed tail sigma algebra, quotient almost-sure equality, countable-choice tail selector, or ambient product-measure proof, the induction exports only the displayed finite-window route. □

Falsifiable prediction: Every accepted $\mathsf{KolmogorovZeroOneLaw}^{\uparrow}$ read displays a ProbSpace source row, RandomVar event-sequence row, finite tail-window row, SigmaAlgebra event-admission row, Independence ledger row, zero-one verdict row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: probspace, randomvar, independence, borel-cantelli, sigma-algebra: $\mathsf{KolmogorovZeroOneLaw}^{\uparrow}$ is not bijective to any listed sibling because it binds finite tail windows,

event admission, independence separation, and a zero-one verdict row into one probability tail-event packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovZeroOneLaw}\uparrow}$.

Constructive story: A $\mathsf{KolmogorovZeroOneLaw}^{\uparrow}$ packet is generated from a ProbSpace source row, RandomVar event-sequence row, finite tail-window row, SigmaAlgebra event-admission row, Independence ledger row, zero-one verdict row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovZeroOneLaw}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6936.1, Definition 6936.2, and Definition 6936.3 seed the finite probability-source, event-sequence, tail-window, event-admission, independence-ledger, zero-one-verdict, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovZeroOneLaw}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host product measures, completed tail sigma algebras, quotient almost-sure equality, countable-choice tail selectors, ambient probability limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tail-window exactness, event-admission stability, independence-ledger exposure, zero-one verdict routing, transport, replay, provenance, and local naming for BEDC.Derived.KolmogorovZeroOneLawUp.

Chapter 6937

A Concrete Naming Certificate for $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$ packet records the constructive Cauchy-real reading used at the current L10 Real and Completion boundary without forming quotient classes of streams. It binds the dyadic tolerance source of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the pointwise locator induction route of chapter 4225. The certificate is a displayed finite-row interface for Real-facing consumers; it is not a quotient construction, a selected limit operator, or an ambient completeness theorem.

Definition 6937.1 (Quotient-free Cauchy real carrier)**.** *A* $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (D, W, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying signed mantissa rows, positive-unary scale rows, denominator rows, distance rows, radius rows, and local dyadic naming data.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule that tells each consumer which finite observation windows of the Cauchy stream are public.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row obtained from the displayed windows and dyadic tolerance data.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed after the dyadic, stream, and regular-rational faces have been displayed.*
5. *L is the* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *route that records pointwise locator reads over the same displayed finite windows.*
6. *H records componentwise* hsame *transport for the dyadic, stream, readback, seal, locator, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for finite-window tolerance reads.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealLocatorPointwiseInd}$ BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}}$ *row.*

Carrier comparison is rowwise over $D, W, Q, R, L, H, C, P, N$. The carrier has no coordinate for quotient real equality, quotient streams, countable choice, selected limits, trichotomy, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6937.2 (Quotient-free Cauchy real classifier stability)**.** *Let*

$$X = (D, W, Q, R, L, H, C, P, N)$$

be an accepted $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$ *carrier. Replacing the dyadic tolerance ledger, finite stream schedule, regular-rational readback, Real seal, and pointwise locator induction rows by displayed componentwise* hsame *rows, and replaying the replacement through C, preserves the public Cauchy-real classifier read. The classifier remains the finite route*

$$D, W \longmapsto Q \longmapsto R, L \longmapsto H, C, P, N$$

and does not inspect quotient real equality, quotient stream equality, countable choice, selected limits, trichotomy, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 6937.1. The visible classifier source is exactly the dyadic tolerance ledger D together with the finite stream schedule W.

The readback row Q is downstream of those two rows, and the Real seal R is downstream of the readback. The locator induction route L reads the same displayed window and tolerance surface through chapter 4225.

The transport row H records the componentwise replacement, and C replays that replacement through the displayed route. Since P only records provenance and N only names the local packet, no additional classifier coordinate is introduced.

Thus the public classifier is stable under the displayed transport. The excluded quotient, choice, order, and completeness objects have no row in the carrier, so they cannot affect the classifier read. □

Theorem 6937.3 (Quotient-free Cauchy real finite-window tolerance readback)**.** *For every accepted* $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$ *carrier*

$$X = (D, W, Q, R, L, H, C, P, N),$$

each Real-facing tolerance request is answered by a finite window of W, the corresponding $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, and the terminal seal row R. The answer is a BEDC-visible finite row readback; it is not a representative of a quotient stream, a selected limit, a countable-choice selection, a trichotomy decision, or an appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Real-facing tolerance request at the accepted carrier. The only public schedule for inspecting the Cauchy stream is the finite $\mathsf{StreamName}^{\uparrow}$ row W, so the request first selects a displayed finite window rather than an infinite representative.

Read the dyadic bound for that window from D. This uses the signed mantissa, scale, denominator, distance, and radius rows supplied by chapter 291.

Now pass to Q. The regular-rational readback consumes the same finite window and dyadic ledger, matching the route of chapter 301. The Real-facing seal R is then read only after those rows are displayed.

The remaining rows L, H, C, P, N record pointwise locator compatibility, transport, replay, provenance, and local naming. Since none of these rows stores quotient stream equality, selected limits, countable choice, trichotomy, metric completeness, or ambient Real completeness, the tolerance answer is exactly the stated finite-window readback. □

Theorem 6937.4 (Quotient-free Cauchy real locator-induction compatibility)**.** *Let*

$$X = (D, W, Q, R, L, H, C, P, N)$$

be an accepted $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$ *carrier. Every pointwise locator induction read in* L *is compatible with the same finite-window tolerance route used by* D, W, Q, R*: the branch ledger opens a displayed* $\mathsf{StreamName}^{\uparrow}$ *window, reads the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, passes through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and reaches the same* $\mathsf{Real}^{\uparrow}$ *seal before the local* $\mathsf{NameCert}$ *row is public.*

Proof. Project the locator row L. By chapter 4225, each accepted pointwise branch is read through a displayed StreamName window, DyadicRatCore tolerance row, RegSeqRat readback, and Real seal.

Compare those rows with the carrier rows W, D, Q, R. The $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$ packet stores no second stream schedule or second dyadic ledger, so the branch ledger in L must use the same finite-window tolerance route already exposed by the classifier and readback rows.

The componentwise transport H and replay C preserve this route, while P and N source and name it locally. Therefore the locator-induction branch becomes public only through the same displayed finite rows.

The compatibility claim uses no quotient real equality, quotient streams, countable choice, selected limits, trichotomy, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, because none of those objects occurs in the accepted carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6937.1, Definition 6937.2, Definition 6937.3, and Definition 6937.4 seed the quotient-free Cauchy-real interface over DyadicRatCore, StreamName, RegSeqRat, RealUp, CauchyRealLocatorPointwiseInduction, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, quotient streams, countable choice, selected limits, trichotomy, metric completeness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, finite-window tolerance readback, locator-induction compatibility, and local NameCert registration for BEDC.Derived.CauchyRealsWithoutQuotientUp.

Constructive story: A $\mathsf{CauchyRealsWithoutQuotient}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, one StreamName finite schedule, a RegSeqRat readback row, a RealUp seal row, a CauchyRealLocatorPointwiseInduction route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6938

A Concrete Naming Certificate for $\mathsf{CauchyBishopBridge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyBishopBridge}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name can be read back as Bishop located-Cauchy data without passing through quotient real equality or an ambient completeness principle. It sits between the certified stream-name surface of chapter 126, the regular rational sequence carrier of chapter 301, the dyadic tolerance ledger of chapter 291, the located-Cauchy request surface of chapter 6930, and the terminal real-name seal of chapter 38.

Definition 6938.1 (Cauchy-Bishop bridge carrier)**.** *A* $\mathsf{CauchyBishopBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, D, L, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row supplying the inspected windows of the rational name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the positive dyadic budgets used by the readback.*
4. *L is the* $\mathsf{BishopCauchyLocator}^{\uparrow}$ *located-Cauchy request row, recording the finite witness that a requested precision has a displayed tail location.*
5. *W is the bridge-witness row matching each located request in L with a regular readback and tolerance entry in R, D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D, L, W have been displayed.*
7. *H records componentwise* hsame *transport for the stream, readback, tolerance, locator, bridge-witness, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the same finite route.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyBishopBridge}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopCauchyLocator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBishopBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, L, W, E, H, C, P, N$. It has no coordinate for quotient real equality, a selected limit, countable choice, host real completeness, or an uninspected infinite sequence.

Theorem 6938.2 (Cauchy-Bishop bridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBishopBridge}^{\uparrow}$ *carrier* $B = (S, R, D, L, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyBishopBridge}^{\uparrow}}$ *surface consists exactly of stream-window exposure, regular rational readback, dyadic tolerance accounting, located-Cauchy request coverage, bridge-witness matching, terminal Real seal routing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6938.1. The packet exposes precisely the rows $S, R, D, L, W, E, H, C, P, N$, so carrier admission cannot appeal to an external sequence, quotient class, or host completeness fact.

The regular Cauchy side is read through S, R, D. A consumer first inspects a finite stream window in S, then reads the regular rational evidence in R, and then checks the requested precision against the dyadic tolerance ledger D.

The Bishop located-Cauchy side is read through L, W. Each located request in L must be matched in W to the already displayed regular readback and tolerance rows, so the bridge does not choose a new representative or import countable choice.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since no additional coordinate exists, the local NameCert obligations are exhausted by the displayed rows. □

Theorem 6938.3 (Regular readback to Bishop located-Cauchy data)**.** *Every accepted* $\mathsf{CauchyBishopBridge}^{\uparrow}$ *packet turns a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *read over* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances into a* $\mathsf{BishopCauchyLocator}^{\uparrow}$ *read only through*

$$S, R, D, L, W, H, C, P, N.$$

Thus a located-Cauchy consumer receives finite locator data after the regular readback and dyadic tolerance rows have already been displayed.

Proof. Start with the regular readback rows S, R, D. The stream row supplies the inspected finite windows, the regular-sequence row supplies the rational readback, and the dyadic row supplies the positive tolerance budget.

Now inspect the located request row L. For each requested precision, the bridge-witness row W names the displayed window and tolerance entry that covers the requested tail location. This is a finite matching operation inside the packet, not an appeal to an infinite choice of moduli.

The structural rows H, C, P, N preserve the same matching data under transport, replay, provenance, and local naming. Therefore the located-Cauchy read is available exactly through the bridge rows and not through quotient real equality or host completion. □

Theorem 6938.4 (Cauchy-Bishop bridge Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{CauchyBishopBridge}^{\uparrow}$ *packet factors through the displayed route*

$$S, R, D, L, W, E, H, C, P, N.$$

The terminal seal row E does not export quotient equality, selected limits, countable choice, host real completeness, or an uninspected infinite sequence.

Proof. Use the NameCert obligations of Definition 6938.2. They force every accepted export to expose stream windows, regular readback, dyadic tolerance, located requests, bridge witnesses, and the terminal seal before a Real-facing consumer reads the packet.

Apply the readback theorem Definition 6938.3. The located-Cauchy data is already bound to displayed regular Cauchy rows, so the Real-facing seal cannot replace the route by a quotient representative or a selected limit.

The rows H, C, P, N keep the seal inside the same finite packet. Since the carrier has no coordinate for the excluded objects, no Real-seal read can escape the displayed bridge route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBishopBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyBishopBridge}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat regular readback, a DyadicRatCore tolerance ledger, BishopCauchyLocator requests, bridge witnesses, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyBishopBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6938.1, Definition 6938.2, Definition 6938.3, and Definition 6938.4 seed the finite bridge route from regular Cauchy readback to Bishop located-Cauchy requests and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyBishopBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, host real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular readback, located request coverage, bridge-witness matching, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyBishopBridgeUp.

Chapter 6939

A Concrete Naming Certificate for $\mathsf{ClosureCapstoneRealization}^{\uparrow}$

The $\mathsf{ClosureCapstoneRealization}^{\uparrow}$ packet realizes the closure-capstone route of chapter 9387 as finite NameCert data. It packages the refusal of unwitnessed closure, the generator-induction replacement, explicit transport, replay, provenance, and local naming into one carrier that can be inspected without importing choice, quotient soundness, propositional extensionality, or a meta-level oracle.

The generator-induction and refusal rows consume the sibling boundaries of chapter 515, chapter 566, and chapter 1012 before the capstone packet exposes its local NameCert row.

Definition 6939.1 (Closure capstone realization carrier)**.** *A* $\mathsf{ClosureCapstoneRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, G, R, T, E, P, N)$$

with the following displayed rows:

1. *A is the closure-axis row, recording the term, type, and proposition strata named by the capstone.*
2. *G is the generator-induction row, recording the finite replacement route used when a witness, representative, or equality token is demanded.*
3. *R is the refusal row, recording that unwitnessed choice, quotient representative selection, and proposition equality by extensionality are not accepted as kernel inputs.*
4. *T is the transport row, recording explicit* hsame *and* psame *transport through displayed implications and classifier-respecting routes.*
5. *E is the replay row, recording the* Cont *trace by which the replacement route is recomputed from the finite rows.*
6. *P is the* Pkg *provenance over* $\mathsf{ClosureCapstoneRealization}^{\uparrow}$*, the closure-capstone vision route,* BHist*,* hsame*,* psame*,* Cont*, and* NameCert*.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosureCapstoneRealization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through A, G, R, T, E, P, N. It has no coordinate for Classical.choice*,* Quot.sound*,* propext*, hidden representatives, erased implication directions, or unwitnessed existential closure.*

Theorem 6939.2 (Closure capstone realization NameCert obligations)**.** *For every accepted* ClosureCapstoneRealiza *carrier $K = (A, G, R, T, E, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosureCapstoneRealization}^{\uparrow}}$ *surface consists exactly*

of closure-stratum exposure, generator-induction replacement, refusal recording, explicit transport, replay, provenance, and local naming.

Proof. Project the carrier of Definition 6939.1. The row list A, G, R, T, E, P, N is the whole packet, so no accepted read can draw on a hidden representative, erased proposition equality, or external choice function.

The closure-axis row A names the three syntactic strata. The generator row G supplies the finite replacement route at each stratum, while the refusal row R records which unwitnessed closure move is not available.

Transport and replay are explicit. The row T keeps each implication or classifier-respecting route visible, and the row E records the Cont replay that recomputes the replacement route from the displayed rows.

Finally P and N source and name the same packet. Since the excluded axioms and oracle moves are not carrier coordinates, the local NameCert obligations are exactly the displayed rows. □

Theorem 6939.3 (Closure capstone vision route)**.** *The closure-capstone route of chapter 9387 is realized by an accepted* ClosureCapstoneRealization$^{\uparrow}$ *packet only through*

$$A, G, R, T, E, P, N.$$

The route exports finite closure, generator-induction replacement, refusal, transport, replay, provenance, and NameCert rows, but it exports no unwitnessed existential input to later arguments.

Proof. Start from the capstone vision route. Its three strata are recorded in A, and each requested closure move is then routed either to generator induction in G or to a refusal entry in R.

The explicit transport row T replaces proposition-level equality by displayed directions and classifier-respecting transport. The replay row E then records the same route as a finite continuation trace rather than as a meta-level oracle.

The provenance and naming rows P, N bind the realized route to the local carrier. Therefore the concrete landing of the vision is precisely the row list A, G, R, T, E, P, N. □

Falsifiable prediction: An accepted ClosureCapstoneRealization$^{\uparrow}$ packet refutes any closure-capstone read that consumes an unwitnessed choice function, quotient representative selector, or proposition-equality token before displaying the generator-induction, refusal, transport, replay, provenance, and local NameCert rows.

Independence witness: unwitnessedexistenceclosure, propexttransportboundary, effective-replacement-ledger, quotient-soundness-boundary, term-stratum-choice-closure: ClosureCapstoneRealization$^{\uparrow}$ is not bijective to any listed sibling because it combines all three closure strata with generator induction, refusal, explicit transport, replay, provenance, and local naming in one packet.

The future Lean `TasteGate.lean` for ClosureCapstoneRealization$^{\uparrow}$ must provide explicit Nontrivial ClosureCapsto and FieldFaithful ClosureCapstoneRealization$^{\uparrow}$ instances before downstream consumers may cite the packet as a field-faithful capstone carrier.

Closure status for NameCert$_{\text{ClosureCapstoneRealization}^{\uparrow}}$ **·**

Constructive story: A ClosureCapstoneRealization$^{\uparrow}$ packet is generated from closure-stratum rows, generator-induction replacement rows, refusal rows, explicit hsame and psame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ClosureCapstoneRealization}^{\uparrow}}$, seed)

Scope closed: Definition 6939.1, Definition 6939.2, and Definition 6939.3 seed the finite concrete route from the closure-capstone vision to displayed replacement, refusal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{ClosureCapstoneRealization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, axiom-purity proofs, or every downstream replacement theorem named by the capstone vision.

Upgrade path: Obligation closure requires checked carrier admission, generator-induction coverage, refusal exactness, transport preservation, replay determinacy, provenance, and local naming for BEDC.Derived.ClosureCapstoneRealizationUp.

Chapter 6940

A Concrete Naming Certificate for ClosedBoundedIntervalFiniteSubcover$^{\uparrow}$

Following Bishop and Bridges on constructive compact intervals, the ClosedBoundedIntervalFiniteSubcover$^{\uparrow}$ packet records the finite route by which a displayed closed bounded interval cover request is reduced to inspected located subinterval rows and a finite covering list. It sits after the interval-net surface of chapter 1250, the finite compact-open exhaustion route of chapter 6756, and the located endpoint discipline of chapter 394. The packet names a constructive finite-subcover handoff for closed bounded intervals; it is not a general open-cover compactness principle, not a selected cover from a host powerset, and not an ambient completeness theorem for Real$^{\uparrow}$.

Definition 6940.1 (Closed bounded interval finite-subcover carrier)**.** *A* ClosedBoundedIntervalFiniteSubcover$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, N, E, L, S, W, H, C, P, M)$$

with the following displayed rows:

1. *I is the closed bounded interval source row, including its endpoint reads and boundedness witness.*
2. *N is the* ClosedBoundedIntervalNet$^{\uparrow}$ *row supplying the finite dyadic interval-net inspection surface.*
3. *E is the* CompactOpenExhaustion$^{\uparrow}$ *row recording the finite exhaustion stage used by the cover request.*
4. *L is the* LocatedInterval$^{\uparrow}$ *row that keeps each inspected subinterval attached to displayed endpoint comparisons.*
5. *S is the finite subcover list, whose entries are selected only from rows already displayed by N, E, L.*
6. *W is the cover-witness row matching every retained net cell to an entry of S.*
7. *H records componentwise* hsame *transport for the interval, net, exhaustion, located subinterval, subcover, and witness rows.*
8. *C records displayed* Cont *replay through the same finite route.*
9. *P is the* Pkg *provenance over* ClosedBoundedIntervalFiniteSubcover$^{\uparrow}$, ClosedBoundedIntervalNet$^{\uparrow}$, CompactOpenExhaustion$^{\uparrow}$, LocatedInterval$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. M is the local $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, N, E, L, S, W, H, C, P, M$. It has no coordinate for arbitrary open covers, host compactness, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6940.2 (Closed bounded interval finite-subcover NameCert obligations)**.** *For every accepted* $\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}$ *carrier $K = (I, N, E, L, S, W, H, C, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}}$ *surface consists exactly of interval-source admission, finite interval-net exposure, compact-open exhaustion-stage exposure, located subinterval comparison, finite subcover listing, cover-witness matching, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6940.1. The rows $I, N, E, L, S, W, H, C, P, M$ are the full packet, so no accepted read can appeal to a detached open-cover object or a host compactness theorem.

The constructive cover side is finite. The interval-net row N supplies the inspected dyadic cells, the exhaustion row E fixes the displayed cover stage, and the located row L keeps the endpoint comparisons attached to those cells.

The subcover list S is then checked by the witness row W. Each entry is matched against a displayed cell before the structural rows H, C, P, M transport, replay, source, and name the same route. □

Theorem 6940.3 (Closed bounded interval finite-subcover route)**.** *Every accepted* $\mathsf{ClosedBoundedIntervalFiniteSubc}$ *packet exports a finite-subcover read only through*

$$\mathsf{ClosedBoundedIntervalNet}^{\uparrow}, \quad \mathsf{CompactOpenExhaustion}^{\uparrow}, \quad \mathsf{LocatedInterval}^{\uparrow}.$$

In carrier notation, the consumer-visible route is

$$I, N, E, L, S, W, H, C, P, M.$$

The route supplies a finite list and displayed coverage witnesses for the inspected closed bounded interval request; it exports no general open-cover compactness principle, cover selection from a host powerset, quotient $\mathsf{Real}^{\uparrow}$ *equality, countable choice schedule, or ambient completeness theorem.*

Proof. Start with the finite interval-net surface of chapter 1250. It gives the inspected cells before any cover witness is read.

Next use the compact-open exhaustion route of chapter 6756 and the located interval boundary of chapter 394. These rows attach each cover request to a displayed exhaustion stage and endpoint comparison.

Finally apply the local obligations above. The rows S, W list and verify the finite subcover, while H, C, P, M only preserve and name that displayed route. Since no other carrier coordinate exists, the excluded compactness, choice, quotient, and completeness objects cannot be exported. □

Falsifiable prediction: An accepted $\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}$ read is refuted if it consumes an arbitrary open-cover compactness theorem before displaying the interval-net, compact-open exhaustion, located interval, finite subcover, witness, transport, replay, provenance, and local NameCert rows.

Independence witness: closedboundedintervalnet, compact-open-exhaustion, locatedinterval: $\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an interval source, interval-net cells, exhaustion-stage data, located endpoint comparisons, a finite subcover list, coverage witnesses, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}$ packet is generated from closed bounded interval rows, interval-net cells, compact-open exhaustion stages, located interval comparisons, finite subcover lists, witness rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6940.1, Definition 6940.2, and Definition 6940.3 seed the finite-subcover route for inspected closed bounded interval cover requests.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalFiniteSubcover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, host cover selection, quotient Real equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-net coverage, exhaustion-stage compatibility, located interval matching, finite subcover witness coverage, transport, replay, provenance, and local naming for BEDC.Derived.ClosedBoundedIntervalFiniteSubcoverUp.

Chapter 6941

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ packet records the finite cofinal-window selector used when a diagonal-limit or real-completion consumer asks for a tail window of a regular Cauchy family. It realizes the regular-Cauchy route of section 9238.1 through the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the diagonal-limit representative packet of chapter 1205. The selector is a displayed finite tail-window row, not a hidden choice function, quotient equality of real names, or ambient completeness principle.

Definition 6941.1 (Regular Cauchy tail-window selector carrier)**.** *A* $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, S, R, A, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the requested positive tail budget.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the family of regular Cauchy names.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected window.*
4. *A is the tail-admission row, recording that the inspected window lies beyond the displayed Cauchy modulus request.*
5. *Q is the cofinal selector row, naming the finite tail window consumed by the diagonal or completion-facing read.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R, A, Q have been displayed.*
7. *H records componentwise* hsame *transport for the tolerance, window, readback, admission, selector, and seal rows.*
8. *C records displayed* Cont *replay of the same selector route.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, A, Q, E, H, C, P, N$. It has no coordinate for countable choice, a selected infinite subsequence, quotient real equality, hidden limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6941.2 (Regular Cauchy tail-window selector NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ *carrier* $T = (D, S, R, A, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyT}}$ *surface consists exactly of dyadic tolerance admission, finite stream-window exposure, regular rational readback, tail-admission evidence, cofinal selector exposure, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6941.1. The rows $D, S, R, A, Q, E, H, C, P, N$ are the full selector packet, so there is no separate coordinate for an infinite choice schedule or hidden limit.

The finite selector is read in order. The dyadic tolerance row D fixes the requested budget, S supplies the inspected stream window, R reads the regular rational data, and A records that the window is admitted as a tail row.

The cofinal selector row Q then names the window handed to diagonal and real-completion consumers. The rows E, H, C, P, N seal, transport, replay, source, and name the same displayed route. □

Theorem 6941.3 (Regular Cauchy tail-window selector route)**.** *Every accepted* $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ *packet supplies a finite tail-window selector for the diagonal-limit and real-completion route only through*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{DiagonalLimitRepresentative}^{\uparrow}.$$

In carrier notation, the consumer-visible route is

$$D, S, R, A, Q, E, H, C, P, N.$$

The selector exports a cofinal finite window and its displayed tolerance/readback evidence; it exports no countable-choice schedule, hidden subsequence selector, quotient $\mathsf{Real}^{\uparrow}$ *equality, selected limit, or ambient completeness theorem.*

Proof. Start from the regular-Cauchy vision route of section 9238.1. A diagonal-limit consumer asks for one displayed tail window at a requested dyadic tolerance, not for a completed infinite schedule.

Read the sibling rows in order. The $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the budget, the $\mathsf{StreamName}^{\uparrow}$ row supplies the inspected finite window, and the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational readback consumed before the $\mathsf{Real}^{\uparrow}$ seal.

Finally connect the selector to chapter 1205. The cofinal row Q is the finite window handed to the diagonal representative, while H, C, P, N transport, replay, source, and name the same packet. The refused choice, quotient, selected-limit, and completeness objects have no carrier coordinate. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ read is refuted if a diagonal-limit or Real-completion consumer receives a tail window before the dyadic tolerance, StreamName window, RegSeqRat readback, tail-admission, cofinal selector, Real seal, transport, replay, provenance, and local NameCert rows are displayed.

Independence witness: dyadicratcore, streamname, regseqrat, real, diagonallimitrepresentative: $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a

tolerance request, stream window, regular rational readback, tail admission, cofinal selector, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailWindowSelector}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, tail-admission rows, cofinal selector rows, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailWindowSelector}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6941.1, Definition 6941.2, and Definition 6941.3 seed the finite cofinal-window selector route for diagonal-limit and real-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailWindowSelector}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient Real equality, hidden subsequence selection, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance coverage, stream-window readback, tail-admission evidence, cofinal selector exactness, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailWindowSelectorUp.

Chapter 6942

A Concrete Naming Certificate for $\mathsf{BusemannConvexMetric}^{\uparrow}$

Following Busemann and Bridson–Haefliger on convexity in geodesic metric spaces, the $\mathsf{BusemannConvexMetric}^{\uparrow}$ packet records the finite midpoint-distance convexity surface that sits between displayed geodesic metric data and stronger CAT(0) or Hadamard consumers. It sits over the metric carrier of chapter 57, the segment-window route of chapter 2213, the convex-set rows of chapter 208, the CAT(0) comparison surface of chapter 6336, the Hadamard-space carrier of chapter 6734, and the terminal real-name seal of chapter 38. The packet names midpoint convexity for displayed geodesic windows; it is not a full CAT(0) comparison theorem, not a selected geodesic family, not quotient path equality, and not ambient completeness.

Definition 6942.1 (Busemann convex metric carrier)**.** *A* $\mathsf{BusemannConvexMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, G, X, Y, S, T, D, R, V, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing only point classifiers, distance readbacks, and the metric-law ledger used by the convexity request.*
2. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *row naming the finite geodesic segment windows inspected by the packet.*
3. *X and Y are endpoint-pair rows for two displayed geodesic windows, with every endpoint admitted through M.*
4. *S and T are the finite segment-parameter rows for the two windows, including the midpoint or equal-parameter addresses used by the convexity comparison.*
5. *D is the distance-comparison row, recording the finite Busemann convexity inequality that the distance between equal-parameter points on the two displayed windows is bounded by the corresponding convex combination of endpoint distances.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the distance values read by D, reached only after the metric, geodesic, endpoint, and parameter rows have been displayed.*
7. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *handoff row for consumers that read the same midpoint or equal-parameter windows as convex-domain data.*
8. *H records componentwise* hsame *transport for the metric, geodesic, endpoint, parameter, distance-comparison, Real-seal, convex-handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite Busemann-convexity request through*

$$M, G, X, Y, S, T, D, R, V \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{BusemannConvexMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{HadamardSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BusemannConvexMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a global CAT(0) triangle comparison, a Hadamard-space theorem, selected geodesics, quotient path equality, nearest-point projection, or ambient completeness.

Theorem 6942.2 (Busemann convex metric NameCert obligations)**.** *For every accepted* $\mathsf{BusemannConvexMetric}^{\uparrow}$ *carrier*

$$B = (M, G, X, Y, S, T, D, R, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BusemannConvexMetric}^{\uparrow}}$ *surface consists exactly of metric-source admission, geodesic segment-window admission, endpoint-pair admission, finite parameter admission, Busemann distance-convexity ledger exactness, terminal* $\mathsf{Real}^{\uparrow}$ *distance sealing, convex-window handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming over the rows of Definition 6942.1.*

Proof. Carrier admission is projection from Definition 6942.1. The accepted packet displays the metric source, geodesic row, two endpoint-pair rows, two finite parameter rows, the distance-convexity ledger, Real seal, convex handoff, transport, replay, provenance, and local name.

The convexity obligation is localized in D. That row reads only the equal-parameter or midpoint observations supplied by S and T, compares their distance through M, and seals the resulting distance data through R.

Rows V, H, C, P, N do not enlarge the geometric object. They route the same displayed convexity window to convex-domain consumers, preserve the rows componentwise, replay the same finite request, record provenance, and name the local certificate. Thus no obligation row can be read as CAT(0) comparison, Hadamard completeness, selected geodesics, quotient path equality, projection selection, or ambient completeness. □

Theorem 6942.3 (Busemann convex midpoint non-escape)**.** *Every midpoint-facing or equal-parameter consumer of an accepted* $\mathsf{BusemannConvexMetric}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{GeodesicMetric}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

It may consume the displayed Busemann convexity ledger for the named segment windows, but it cannot infer a CAT(0) comparison triangle, a Hadamard-space theorem, selected geodesics, quotient path equality, nearest-point projection, or ambient completeness.

Proof. Use Definition 6942.2. The consumer receives midpoint or equal-parameter information only after the metric source, geodesic windows, endpoint pairs, finite parameter rows, distance-convexity ledger, and Real seal have been displayed.

The convex-domain handoff then passes through V. This lets a later $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CATZeroMetric}^{\uparrow}$, or $\mathsf{HadamardSpace}^{\uparrow}$ consumer read the finite Busemann convexity row as local certificate data, without converting it into a stronger global comparison theorem.

Inspecting the carrier gives the exclusion. There is no row for a full CAT(0) triangle ledger, global Hadamard completeness, selected geodesic family, path quotient, projection selector, or ambient completeness proof, so any route requiring one of those objects lies outside the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BusemannConvexMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{BusemannConvexMetric}^{\uparrow}$ packet is generated from a MetricSpace source, GeodesicMetric segment-window rows, endpoint pairs, finite parameter rows, a Busemann distance-convexity ledger, a RealUp seal, a ConvexSet handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BusemannConvexMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6942.1, Definition 6942.2, and Definition 6942.3 seed the finite Busemann convexity route from displayed metric and geodesic data through convex, CAT(0), Hadamard, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BusemannConvexMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim CAT(0) triangle comparison, Hadamard completeness, selected geodesics, quotient path equality, nearest-point projections, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-pair exposure, parameter-row exactness, Busemann distance-convexity stability, Real sealing, convex handoff, transport, replay, provenance, and local naming for BEDC.Derived.BusemannConvexMetricUp.

Chapter 6943

A Concrete Naming Certificate for $\mathsf{KripkeSemantics}^{\uparrow}$

Following Kripke and standard intuitionistic semantics, the $\mathsf{KripkeSemantics}^{\uparrow}$ packet records a finite forcing model as a NameCert surface rather than as an ambient metatheorem about all intuitionistic consequence. It reads the preorder-world discipline of chapter 52, the formula and syntax handoff of chapter 197, and the model-facing valuation surface of chapter 198. The packet keeps monotone forcing visible as a finite BHist route before any consumer may read a semantic validity claim.

Definition 6943.1 (Kripke semantics carrier)**.** *A* $\mathsf{KripkeSemantics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, F, V, R, M, H, C, P, N)$$

with the following displayed rows:

1. *W is the preorder-world row, read through* $\mathsf{Preorder}^{\uparrow}$*, listing the finite worlds and the accessibility relation used by forcing.*
2. *F is the formula row, read through* $\mathsf{FirstOrder}^{\uparrow}$*, exposing the finite intuitionistic formulas inspected by the packet.*
3. *V is the valuation row, read through* $\mathsf{ModelTheory}^{\uparrow}$*, assigning atomic forcing data at the displayed worlds.*
4. *R is the monotone forcing row, recording that atomic valuation and compound forcing are preserved along the preorder accessibility route.*
5. *M is the* $\mathsf{ModelTheory}^{\uparrow}$ *and* $\mathsf{FirstOrder}^{\uparrow}$ *handoff row, keeping syntactic formula reads and semantic valuation reads on the same finite packet.*
6. *H records componentwise* hsame *transport for W, F, V, R, M and the local naming row.*
7. *C records displayed* Cont *replay from a forcing request through preorder access, formula inspection, valuation readback, monotone forcing, provenance, and naming.*
8. *P is the* Pkg *provenance over* $\mathsf{KripkeSemantics}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, $\mathsf{ModelTheory}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KripkeSemantics}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, F, V, R, M, H, C, P, N$. It has no coordinate for classical truth tables, Boolean completeness, global proof search, quotient syntax equality, or a standard bridge theorem.

Theorem 6943.2 (Kripke semantics NameCert obligations)**.** *For every accepted* $\mathsf{KripkeSemantics}^{\uparrow}$ *carrier* $K = (W, F, V, R, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KripkeSemantics}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *expose the preorder-world row W through the* $\mathsf{Preorder}^{\uparrow}$ *sibling surface;*
2. *expose the formula row F through the* $\mathsf{FirstOrder}^{\uparrow}$ *sibling surface;*
3. *expose the valuation row V and model handoff row M through the* $\mathsf{ModelTheory}^{\uparrow}$ *sibling surface;*
4. *preserve forcing by the monotone row R under componentwise* hsame *transport and displayed* Cont *replay;*
5. *retain* Pkg *provenance and local naming in P, N without exporting classical completeness, Boolean collapse, quotient syntax equality, or bridge checking.*

Proof. Project the carrier of Definition 6943.1. The rows W, F, V, R, M are the complete forcing-facing data, while H, C, P, N are the structural rows that transport, replay, source, and name that data.

The preorder, first-order, and model-theory rows are read from their sibling NameCert packets. Thus a forcing consumer cannot inspect worlds without the preorder row, formulas without the syntax row, or valuations without the model row.

The monotone forcing row is then local. It preserves the valuation and compound forcing reads along the displayed preorder accessibility route, and the structural rows keep that route attached to the same finite packet.

Since no carrier coordinate contains classical completeness, Boolean collapse, quotient syntax equality, or bridge data, those endpoints are not exported by the local NameCert surface. □

Theorem 6943.3 (Kripke semantics monotone forcing route)**.** *Every forcing consumer of an accepted* $\mathsf{KripkeSemantics}^{\uparrow}$ *carrier factors through the preorder-world row W, formula row F, valuation row V, monotone forcing row R, model handoff row M, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. The route is therefore*

$$\mathsf{Preorder}^{\uparrow},\ \mathsf{FirstOrder}^{\uparrow},\ \mathsf{ModelTheory}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

before any intuitionistic forcing read is accepted.

Proof. Start with the NameCert obligations of Definition 6943.2. They require the world, formula, valuation, monotonicity, handoff, transport, replay, provenance, and naming rows to be visible before a forcing consumer reads the packet.

The preorder row supplies the accessibility relation used by monotonicity. The formula row supplies the finite syntax being forced, and the model row supplies the valuation surface from which atomic forcing is read.

Now use the monotone forcing row R. Any forcing read that moves along accessibility must preserve the relevant valuation and compound forcing data through R, then pass through H and C so that the read is transported and replayed on the same BHist packet.

Finally P and N package the route as a local NameCert. A consumer omitting one of these rows has not produced a $\mathsf{KripkeSemantics}^{\uparrow}$ forcing read; it has only a detached preorder, syntax, or valuation fragment. □

Lean4 (statement) `BEDC.Derived.KripkeSemanticsUp`

Closure status for $\mathsf{NameCert}_{\mathsf{KripkeSemantics}^{\uparrow}}$.

Constructive story: A $\mathsf{KripkeSemantics}^{\uparrow}$ packet is generated from preorder-world rows, formula rows, valuation rows, monotone forcing rows, model-theory handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KripkeSemantics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6943.1, Definition 6943.2, and Definition 6943.3 seed the finite Kripke forcing route over preorder worlds, formula reads, valuation reads, monotonicity, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KripkeSemantics}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.KripkeSemanticsUp`

Bridge status: none

Not claimed: This chapter does not close classical completeness, Boolean semantics, global proof search, quotient syntax equality, Lean-checked NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, preorder-world exposure, formula exposure, valuation exposure, monotone forcing stability, transport, replay, provenance, and local naming for BEDC.Derived.KripkeSemanticsUp.

Chapter 6944

A Concrete Naming Certificate for $\mathsf{ArcLengthParameter}^{\uparrow}$

Following Bishop and Bridges constructive analysis of rectifiable curves, the $\mathsf{ArcLengthParameter}^{\uparrow}$ packet records the finite route by which a displayed curve receives arc-length parameter data from partition-length ledgers and regular rational readbacks. It sits over the metric carrier of chapter 4230, the continuous-map surface of chapter 130, the dyadic tolerance core of chapter 291, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, the Darboux partition ledger of chapter 3429, and the located integral route of chapter 5947. The packet names only finite rectifiable-curve parameter data; it is not a quotient of curves, a host length functional, a selected reparameterization, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6944.1 (Arc-length parameter carrier)**.** *An* $\mathsf{ArcLengthParameter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, M, D, V, R, L, J, S, H, C, P, N)$$

with the following displayed rows:

1. *G is the curve row, naming the displayed source interval, target points, and the curve graph through the* $\mathsf{ContinuousMap}^{\uparrow}$ *surface.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to measure adjacent curve samples.*
3. *D is the finite Darboux or tagged partition row, recording the ordered sample ledger from which polygonal lengths are read.*
4. *V is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *variation-bound row, carrying dyadic upper and lower budgets for partition-length comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the resulting length approximants.*
6. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row naming the accumulated length read.*
7. *J is the located-integral handoff row, available when the same partition ledger is consumed through* $\mathsf{LocatedRiemannIntegral}^{\uparrow}$*.*
8. *S is the local parameter-scale row, pairing initial segment requests with their displayed length readbacks.*
9. *H records componentwise* hsame *transport for curve, metric, partition, dyadic variation, regular readback, Real seal, integral handoff, parameter-scale, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from a parameter request through G, M, D, V, R, L, J, S.*
11. *P is the* Pkg *provenance over* $\mathsf{ArcLengthParameter}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ArcLengthParameter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $G, M, D, V, R, L, J, S, H, C, P, N$. It has no coordinate for host limits of partition sums, quotient curves, chosen inverse parameters, global geodesic structure, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6944.2 (Arc-length parameter NameCert obligations)**.** *For every accepted* $\mathsf{ArcLengthParameter}^{\uparrow}$ *carrier $A = (G, M, D, V, R, L, J, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ArcLengthParameter}^{\uparrow}}$ *surface consists exactly of carrier admission, curve-row admission, metric distance readback, finite partition-length ledger exposure, dyadic variation-bound accounting, regular rational readback stability, Real seal stability, located integral handoff, parameter-scale replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6944.1. The rows G, M, D, V, R, L, J, S are the whole numerical and geometric surface before any structural row is read.

The curve and length data are exhausted by G, M, D, V. The curve row gives the displayed continuous map, the metric row gives adjacent-sample distances, the partition row records the finite ledger of samples, and the dyadic variation row stores the comparison budgets for polygonal length reads.

The readback and parameter data are exhausted by R, L, J, S. Regular rational readback turns the partition ledger into a finite Cauchy-style name, the Real seal records the terminal length read, the located-integral handoff supplies the sibling integral route, and the parameter-scale row pairs initial segment requests with those displayed length reads.

Finally H, C, P, N transport, replay, source, and name exactly the same displayed rows. Since the carrier contains no coordinate for host partition limits, quotient curves, selected inverse parameters, global geodesic structure, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows are precisely the NameCert obligation surface. □

Theorem 6944.3 (Arc-length parameter Real metric handoff)**.** *Every metric or rectifiable-curve consumer of an accepted* $\mathsf{ArcLengthParameter}^{\uparrow}$ *carrier must read*

$$\mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the finite Darboux partition ledger and the $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ *handoff before it consumes the parameter-scale row S. The handoff exports no host length functional, quotient curve equality, selected reparameterization, countable-choice schedule, global geodesic object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier $A = (G, M, D, V, R, L, J, S, H, C, P, N)$. The curve row G is read through the displayed $\mathsf{ContinuousMap}^{\uparrow}$ surface, and the distance row M is read through the $\mathsf{Met}^{\uparrow}$ carrier before any length comparison is available.

Next read the finite length ledger. The partition row D supplies the Darboux-style ordered sample data, while V supplies dyadic variation bounds through $\mathsf{DyadicRatCore}^{\uparrow}$. Thus every polygonal length comparison remains a finite ledger comparison.

The Real-facing handoff then passes through R, L, J. The $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular rational readback, the $\mathsf{Real}^{\uparrow}$ seal records the terminal length name, and the $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ row records the sibling integral route using the same finite partition data.

Only after those rows have been displayed may the consumer read S. The structural rows H, C, P, N preserve the same route, so the packet cannot introduce a host length functional, quotient curve equality, selected reparameterization, countable-choice schedule, global geodesic object, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{ArcLengthParameter}^{\uparrow}$ consumer that reaches the parameter-scale row displays a ContinuousMap curve row, MetricSpace distance row, finite partition-length ledger, DyadicRatCore variation bounds, RegSeqRat readback, RealUp seal, LocatedRiemannIntegral handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: continuousmap, metric-space, dyadicratcore, regseqrat, real, located-riemann-integral, closed-bounded-interval-darboux-partition: $\mathsf{ArcLengthParameter}^{\uparrow}$ is not bijective to any listed sibling because it jointly records curve samples, metric distances, partition-length ledgers, dyadic variation bounds, regular rational readback, Real sealing, integral handoff, and parameter-scale replay.

Closure status for $\mathsf{NameCert}_{\mathsf{ArcLengthParameter}^{\uparrow}}$.

Constructive story: An $\mathsf{ArcLengthParameter}^{\uparrow}$ packet is generated from a ContinuousMap curve row, MetricSpace distance row, finite partition-length ledger, DyadicRatCore variation-bound row, RegSeqRat readback, RealUp seal, LocatedRiemannIntegral handoff, local parameter-scale row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArcLengthParameter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6944.1, Definition 6944.2, and Definition 6944.3 seed the finite arc-length parameter route for rectifiable curve data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArcLengthParameter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host length functionals, quotient curve equality, selected inverse parameters, global geodesic structure, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, curve-row admission, metric distance readback, partition-length ledger exposure, dyadic variation accounting, regular rational readback, Real seal stability, located integral handoff, parameter-scale replay, transport, replay, provenance, and local naming for BEDC.Derived.ArcLengthParameterUp.

Chapter 6945

A Concrete Naming Certificate for $\mathsf{TestFunction}^{\uparrow}$

Following Schwartz and Treves, the $\mathsf{TestFunction}^{\uparrow}$ packet records compactly supported smooth test probes as finite BEDC NameCert data. It sits next to the rapidly decreasing smooth carrier of chapter 3399, the Schwartz-space packet of chapter 5877, the weak-derivative route of chapter 2210, and the distribution-facing scalar boundary of chapter 2310. The packet exposes the finite support window, finite derivative ledger, local scalar readback, and replay route required by distribution, Fourier, Sobolev, and viscosity-solution consumers without importing a global LF-space topology, quotient germ equality, countable choice, or ambient smooth-completeness theorem.

Definition 6945.1 (Test-function carrier)**.** *A* $\mathsf{TestFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, D, L, Q, S, V, H, C, P, N)$$

with the following displayed rows:

1. *W is the compact support window row. It displays the bounded local chart window on which the probe may be nonzero and records that all public reads outside the window are the zero read.*
2. *D is the finite derivative-order ledger. It lists the derivative orders inspected by the packet and the finite smoothness obligations replayed for those orders.*
3. *L is the localization domain row. It records the coordinate chart, bump-support inclusion, and domain restriction through which the test probe is consumed.*
4. *Q is the rational observation row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*, for coefficient windows, derivative tolerances, and support-bound comparisons.*
5. *S is the scalar seal row, read through* $\mathsf{Real}^{\uparrow}$*, that turns the rational observations in Q into Real-facing scalar names for probe values and derivative bounds.*
6. *V is the weak-derivative compatibility row. It records the sign, derivative-order, and integration-by-parts bookkeeping consumed by* $\mathsf{WeakDerivative}^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for $W, D, L, Q, S, V, C, P, N$.*
8. *C records displayed* Cont *replay from a test-probe request through support localization, derivative inspection, rational readback, Real scalar sealing, weak-derivative compatibility, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{TestFunction}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{SchwartzSpace}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{FourierTransform}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TestFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, D, L, Q, S, V, H, C, P, N$. It has no coordinate for a global smooth-function topology, quotient germ equality, nonconstructive partitions of unity, countable support selection, or an ambient distribution theorem.

Theorem 6945.2 (Test-function NameCert obligations)**.** *For every accepted* $\mathsf{TestFunction}^{\uparrow}$ *carrier $T = (W, D, L, Q, S, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TestFunction}^{\uparrow}}$ *surface consists exactly of compact support-window exposure, finite derivative-ledger exposure, localization-domain exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rational readback,* $\mathsf{Real}^{\uparrow}$ *scalar sealing,* $\mathsf{WeakDerivative}^{\uparrow}$ *compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6945.1. The rows W, D, L are the complete geometric and smoothness data visible to a test-probe consumer: support, derivative orders, and localization.

Read the scalar data next. The row Q supplies the finite rational observations for coefficients, derivative tolerances, and support bounds, while S seals those observations as $\mathsf{Real}^{\uparrow}$ scalar names.

The compatibility row V is the only weak-derivative-facing row. It records the sign and derivative-order bookkeeping used by $\mathsf{WeakDerivative}^{\uparrow}$ without adding a distribution value or Sobolev norm as a carrier coordinate.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no global smooth-function topology, quotient germ equality, nonconstructive partition row, countable support-selection row, or ambient distribution theorem, the listed obligations exhaust the local NameCert surface. □

Theorem 6945.3 (Test-function tempered-distribution handoff)**.** *Every* $\mathsf{TemperedDistribution}^{\uparrow}$ *or* $\mathsf{FourierTransform}^{\uparrow}$ *consumer that reads a test probe from an accepted* $\mathsf{TestFunction}^{\uparrow}$ *packet factors through*

$$W, D, L, Q, S, V, H, C, P, N.$$

Consequently the handoff exposes a compact support window, finite derivative ledger, localization domain, rational and Real scalar readback, weak-derivative compatibility, transport, replay, provenance, and local naming before any distribution pairing, Fourier pairing, Sobolev test, or viscosity-solution probe is public.

Proof. Begin with the support and localization rows. The compact window W and localization domain L determine where the probe may be read, and the derivative ledger D determines which smoothness obligations are available to downstream chapters.

Use the scalar readback route Q, S. The regular rational and dyadic observations in Q provide the finite numerical budgets, and the $\mathsf{Real}^{\uparrow}$ seal in S makes those budgets available to distribution and Fourier pairings.

Now pass through the weak-derivative compatibility row V. This is the row consumed by $\mathsf{WeakDerivative}^{\uparrow}$ when an integration-by-parts sign or derivative order is needed, and it is the row that keeps Sobolev and viscosity-solution test probes tied to the same finite carrier.

Finally replay the route through H, C, P, N. The sibling rows from $\mathsf{SchwartzFunction}^{\uparrow}$ and $\mathsf{SchwartzSpace}^{\uparrow}$ provide smooth decay and space-level comparison surfaces when a consumer needs them, while the $\mathsf{TestFunction}^{\uparrow}$ handoff itself remains compact-support data. No distribution pairing can bypass these rows to obtain quotient germ equality, a selected partition of unity, a global LF-space topology, or an ambient smooth-completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{TestFunction}^{\uparrow}$ read must expose compact support windows, finite derivative ledgers, localization domains, RegSeqRat and DyadicRatCore rational observations, RealUp scalar seals, WeakDerivative compatibility, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any distribution, Fourier, Sobolev, or viscosity-solution consumer may use the test probe.

Independence witness: schwartzfunction, schwartzspace, weakderivative, tempereddistribution, fouriertransform, real: $\mathsf{TestFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact support windows, finite derivative ledgers, localization domains, rational and Real scalar readback, weak-derivative compatibility, transport, replay, provenance, and local naming while refusing global smooth-function topology, quotient germ equality, selected partitions of unity, and ambient distribution theorems.

Closure status for $\mathsf{NameCert}_{\mathsf{TestFunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TestFunction}^{\uparrow}$ packet is generated from compact support windows, finite derivative-order ledgers, localization domains, RegSeqRat and DyadicRatCore rational readbacks, Real scalar seals, WeakDerivative compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TestFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6945.1, Definition 6945.2, and Definition 6945.3 seed the compact-support smooth test-probe certificate used by distribution, Fourier, Sobolev, and viscosity-solution consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TestFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a global LF-space topology, quotient germ equality, nonconstructive partitions of unity, countable support selection, Lean verification, or bridge checking for $\mathsf{TestFunction}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, compact support-window exactness, finite derivative-ledger stability, localization replay, scalar readback, weak-derivative compatibility, transport, replay, provenance, and local naming for BEDC.Derived.TestFunctionUp.

Chapter 6946

A Concrete Naming Certificate for $\mathsf{CompactIntervalFanBridge}^{\uparrow}$

Following Bishop–Bridges compact-interval analysis and Brouwer fan-theorem grounding, the CompactIntervalFanBr packet records the finite route by which compact interval data may be consumed through fan and bar finite-modulus rows before a Real-and-Completion reader reaches a terminal seal. It sits between the Bishop compact-interval source of chapter 3986, the finite fan route of chapter 5863, the stream-window interface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the real-name boundary of chapter 38. The packet names a finite compact-interval fan bridge; it is not open-cover compactness, sequential compactness, a selected cover, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6946.1 (Compact interval fan bridge carrier)**.** *A* $\mathsf{CompactIntervalFanBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *source row, recording the displayed endpoints, interval order data, and compact-interval admission surface.*
2. *F is the fan and bar finite-modulus row, recording a finite prefix ledger, bar boundary, branch-depth ledger, and modulus output for the displayed interval request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the dyadic precision request and every dyadic comparison used by the finite-modulus row.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing exactly the stream windows inspected before readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from S and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after K, F, D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the compact source, finite-modulus row, dyadic ledger, stream windows, regular readback, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a compact-interval request through $K, F, D, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalFanBridge}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{FiniteFanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactIntervalFanBridge}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $K, F, D, S, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, sequential compactness, choice-selected covers, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6946.2 (Compact interval fan bridge NameCert obligations)**.** *For every accepted* CompactIntervalFanBrid *carrier $G = (K, F, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalFanBridge}^{\uparrow}}$ *surface consists exactly of compact-interval source exposure, fan and bar finite-modulus exposure, dyadic tolerance accounting, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6946.1. The analytic route is exhausted by K, F, D, S, R, E, and the structural route is exhausted by H, C, P, N.

The compact source row K displays the interval before any fan data is read. The finite-modulus row F records only a finite prefix and bar ledger, while the dyadic ledger D records the tolerance comparisons used by that finite row.

The windows S, readback R, and seal E are downstream of the displayed finite data. Transport, replay, provenance, and local naming preserve exactly that inventory, so the NameCert surface contains the listed obligations and no hidden open-cover, sequential, choice, quotient, trichotomy, or completeness endpoint. □

Theorem 6946.3 (Compact interval fan bridge finite route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{CompactIntervalFanBridge}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{BishopCompactInterval}^{\uparrow} \longmapsto \mathsf{FiniteFanTheorem}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $K, F, D, S, R, E, H, C, P, N$. The exported bridge is the finite fan and bar modulus route from compact interval data to regular-rational readback, not an open-cover compactness theorem, sequential compactness theorem, choice-selected cover, quotient real equality, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with Definition 6946.2. A consumer must expose the compact source, finite-modulus ledger, dyadic tolerance ledger, stream windows, regular readback, terminal seal, transport, replay, provenance, and local naming before reading the bridge.

The route reaches $\mathsf{StreamName}^{\uparrow}$ only after the dyadic tolerance ledger and finite bar boundary have been displayed. It reaches $\mathsf{RegSeqRat}^{\uparrow}$ only through those finite windows, and it reaches $\mathsf{Real}^{\uparrow}$ only through the terminal seal row.

Since the carrier has no row for open covers, sequential compactness, selected covers, quotient real equality, trichotomy, or ambient completeness, the finite route is exhausted by $K, F, D, S, R, E, H, C, P, N$. □

Falsifiable prediction: An accepted $\mathsf{CompactIntervalFanBridge}^{\uparrow}$ consumer that exports a $\mathsf{Real}^{\uparrow}$ seal without displaying $K, F, D, S, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: bishop compact interval, finite fan theorem, streamname, dyadicratcore, regseqrat, real: $\mathsf{CompactIntervalFanBridge}^{\uparrow}$ is not bijective to any listed sibling because it packages compact-interval source data, finite fan and bar modulus data, dyadic tolerance accounting, finite stream windows, regular rational readback, Real seal, transport, replay, provenance, and local NameCert rows in one bridge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalFanBridge}^{\uparrow}}$.

Constructive story: A CompactIntervalFanBridge$^{\uparrow}$ packet is generated from BishopCompactIntervalUp source rows, fan and bar finite-modulus rows, DyadicRatCoreUp tolerance ledgers, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompactIntervalFanBridge}^{\uparrow}}$, seed)

Scope closed: Definition 6946.1, Definition 6946.2, and Definition 6946.3 seed the finite compact-interval fan bridge for Real-and-Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactIntervalFanBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, sequential compactness, selected covers, quotient real equality, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for the displayed compact interval fan bridge route.

Chapter 6947

A Concrete Naming Certificate for $\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}$

The $\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}$ packet realizes the normal-equality boundary of section 9379.3 as finite MetaCIC audit data. It sits beside the bounded normal-equality checker of chapter 752, the decidable conversion frontier of chapter 4097, the bounded decidable fragment of chapter 6917, and the decidable neutral-spine packet of chapter 3909. The packet names the frontier where normalizer fuel, closedness rows, finished normal forms, equality checking, transport, replay, provenance, and local naming remain visible together; it does not claim unrestricted beta-conversion decidability, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Definition 6947.1 (Bounded normal-equality frontier carrier)**.** *A* $\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, F, L, N, E, R, H, C, P, A)$$

with the following displayed rows:

1. *I is the closed MetaCIC input row, listing the two closed terms, their type context, and the bounded equality query.*
2. *F is the finite normalizer-fuel row, recording the shared fuel value and the bounded evaluation trace admitted for each side.*
3. *L is the closedness ledger, recording the closed-term and closed-normal-form checks consumed by the frontier.*
4. *N is the finished-normal-form row, displaying the two bounded normal forms and the witnesses that the displayed fuel has reached finished endpoints.*
5. *E is the equality-checker row, recording the structural comparison of the finished normal forms.*
6. *R is the refusal row, naming unrestricted beta conversion, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, and kernel consistency as unavailable endpoints.*
7. *H records componentwise* hsame *transport for the input, fuel, closedness, finished-normal, equality-checker, refusal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the audit-map query through $I, F, L, N, E, R, H, P, A$.*

9. *P is the* Pkg *provenance over* BoundedNormalEqualityFrontier$^{\uparrow}$, BoundedNormalEqualityChecker$^{\uparrow}$, MetaCICDecidableConversionFrontier$^{\uparrow}$, MetaCICDecidableFragment$^{\uparrow}$, MetaCICDecidableNeutralSpine$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *A is the local* NameCert$_{\text{BoundedNormalEqualityFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, F, L, N, E, R, H, C, P, A$. It has no coordinate for an unrestricted conversion decider, arbitrary-fuel normalization completeness, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Lean4 (definition) `BEDC.Derived.BoundedNormalEqualityFrontierUp.BoundedNormalEqualityFrontierUp`

Theorem 6947.2 (Bounded normal-equality frontier NameCert obligations)**.** *For every accepted* BoundedNormalEqualityFrontier$^{\uparrow}$ *carrier $Q = (I, F, L, N, E, R, H, C, P, A)$, the local* NameCert$_{\text{BoundedNormalEqualityFron}}$ *surface consists exactly of closed input exposure, finite normalizer-fuel exposure, closedness ledger exposure, finished-normal-form exposure, equality-checker exposure, refusal-boundary retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6947.1. The rows I, F, L, N, E, R are the complete normal-equality audit data, and H, C, P, A are the structural rows that transport, replay, source, and name that data.

The fuel row F bounds the normalizer traces. The closedness row L records that the query and the finished endpoints are closed, while the finished-normal row N exposes the two normal forms before any equality result is read.

The equality-checker row E is therefore consumed only under the retained refusal row R. Since no carrier coordinate contains unrestricted beta conversion, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency, those endpoints cannot be exported by the local NameCert surface. □

Theorem 6947.3 (Bounded normal-equality frontier finished soundness route)**.** *Every MetaCIC decidability consumer of an accepted* BoundedNormalEqualityFrontier$^{\uparrow}$ *carrier must read*

$$I \longmapsto F \longmapsto L \longmapsto N \longmapsto E \longmapsto R, H, C, P, A$$

before treating a positive equality-checker row as a finished bounded normal-equality result. The route is conditional on displayed fuel, closedness, finished endpoints, and structural equality of the displayed normal forms; it is not unrestricted beta-conversion decidability, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Proof. Start with Definition 6947.2. A consumer must expose the input, bounded fuel, closedness ledger, finished normal forms, equality checker, refusal boundary, transport, replay, provenance, and local naming before reading the frontier.

The normal-equality result reaches the checker row E only after the finite fuel row F, closedness row L, and finished-normal row N have been displayed. Thus any positive checker read is a finished bounded-normal-form readback rather than a global conversion decision.

The refusal row R remains in the exported route. A consumer that wants arbitrary fuel, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency must supply a separate certificate outside this packet. □

Falsifiable prediction: An accepted BoundedNormalEqualityFrontier$^{\uparrow}$ consumer that exports a normal-equality result without displaying $I, F, L, N, E, R, H, C, P, A$ refutes the frontier surface.

Independence witness: metacic-decidable-conversion-frontier, metacic-decidable-fragment, metacic-decidable-typing-frontier, metacic-decidable-neutral-spine: $\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores normalizer fuel, closedness, finished-normal-form, equality-checker, refusal, transport, replay, provenance, and local NameCert rows. Later Lean instances should expose nontriviality by producing two distinct accepted frontier packets and field faithfulness by showing that equality of frontier fields is exactly equality of $I, F, L, N, E, R, H, C, P, A$.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}$ packet is generated from closed MetaCIC input rows, finite normalizer-fuel rows, closedness ledgers, finished-normal-form rows, equality-checker rows, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6947.1, Definition 6947.2, and Definition 6947.3 seed the finite bounded normal-equality frontier for MetaCIC decidability consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted beta-conversion decidability, arbitrary-fuel completeness, subject reduction, evaluator equality, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier, Nontrivial and FieldFaithful instances, and checked NameCert obligations for the displayed bounded normal-equality frontier route.

Chapter 6948

A Concrete Naming Certificate for $\mathsf{MerayCauchyReal}^{\uparrow}$

Following Méray and Bishop–Bridges on Cauchy presentations of the real line, the $\mathsf{MerayCauchyReal}^{\uparrow}$ packet records the historical construction as finite displayed name data rather than as a quotient of Cauchy sequences. It sits after the Cauchy-real presentation of chapter 1511, the quotient-free boundary of chapter 6937, the stream-window carrier of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives the Real and Completion phase a traditional source row whose public reads remain finite all the way to the $\mathsf{Real}^{\uparrow}$ seal.

Definition 6948.1 (Méray Cauchy-real carrier)**.** *A* $\mathsf{MerayCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the displayed Cauchy source row. It records the rational Cauchy presentation used by the historical construction, with its modulus and tolerance requests shown as finite data.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window service row. It exposes exactly the inspected prefixes of the source and no infinite stream equality.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It converts the displayed windows into the regular rational sequence data consumed by downstream real-name readers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the Cauchy source, window reads, regular readback, and terminal seal.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after A, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the Cauchy source, windows, readback, tolerance ledger, seal, replay, provenance, and local name rows.*
7. *C records displayed* Cont *replay along the finite route*

$$A, W, R, D \longmapsto E, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{MerayCauchyReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{MerayCauchyReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the nine displayed rows. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 6948.2 (Méray Cauchy-real NameCert obligations)**.** *For every accepted* $\mathsf{MerayCauchyReal}^{\uparrow}$ *carrier* $M = (A, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MerayCauchyReal}^{\uparrow}}$ *surface consists exactly of the finite carrier row, displayed Cauchy-source admission, StreamName window locality, RegSeqRat readback, DyadicRatCore tolerance accounting, RealUp seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside those rows.*

Proof. Project the carrier of Definition 6948.1. The tuple lists the Cauchy source, finite window service, regular rational readback, dyadic ledger, terminal seal, transport, replay, provenance, and local name.

The analytic rows are then read in order. The source row A supplies only displayed rational Cauchy data, W exposes the finite windows inspected from it, R records the regular readback of those windows, and D accounts for every tolerance used before the seal.

The structural rows add no extra primitive. The hsame row transports the displayed coordinates, the Cont row replays the same route, and P, N source and name the packet. Since quotient classes, selected representatives, host equality, choice, trichotomy, and ambient completeness are not coordinates of M, the listed rows exhaust the local certificate surface. □

Theorem 6948.3 (Méray Cauchy-real RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MerayCauchyReal}^{\uparrow}$ *packet must first read the displayed Cauchy source row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the componentwise* hsame *transport, the displayed* Cont *replay, the* Pkg *provenance, and the local* NameCert *row. The handoff exports no quotient stream equality, selected Cauchy representative, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 6948.2. They force every accepted read to stay inside $A, W, R, D, E, H, C, P, N$.

The pre-seal route is explicit. A RegSeqRat consumer receives R only as the readback of the displayed windows W over the Cauchy source A, with every tolerance charged to D.

The Real-facing route is downstream of the same readback. The seal row E is available only after A, W, R, D have been displayed and replayed through H, C, P, N. Thus the historical Cauchy-real presentation hands off to regular rational and real-name consumers without adding any quotient, selector, host equality, choice, trichotomy, or completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{MerayCauchyReal}^{\uparrow}}$.

Constructive story: A $\mathsf{MerayCauchyReal}^{\uparrow}$ packet is generated from a displayed rational Cauchy source, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MerayCauchyReal}^{\uparrow}}$, seed)

Scope closed: Definition 6948.1, Definition 6948.2, and Definition 6948.3 seed the historical quotient-free Cauchy-real presentation boundary over StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MerayCauchyReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real construction, selected Cauchy representatives, host real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-source display, StreamName locality, RegSeqRat handoff, DyadicRatCore tolerance accounting, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.MerayCauchyRealUp.

Chapter 6949

A Concrete Naming Certificate for $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$

The $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$ packet realizes the finite-budget route named by the Real completeness vision of chapter 9238. It separates observation budget, selector budget, stream-window access, regular rational readback, dyadic tolerance accounting, and terminal real-seal admission before any completion-facing consumer can treat the route as a real-name handoff. The packet sits over chapter 126, chapter 301, chapter 291, chapter 38, and the CauchyLimitSeal consumer boundary already used by the Real-completion siblings.

Definition 6949.1 (Real completion budget-router carrier)**.** *A* $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (o, s, W, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *o is the observation-budget row. It bounds which StreamName windows may be inspected.*
2. *s is the selector-budget row. It records the finite selector requests allowed before a completion-facing route is admitted.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row available under o.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the request, windows, readback, limit-seal handoff, and terminal seal.*
6. *L is the CauchyLimitSeal-compatible handoff row consuming only o, s, W, R, D.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after the budgeted window and readback route has passed through L.*
8. *H records componentwise* hsame *transport for the budget, window, readback, tolerance, seal, replay, provenance, and local name rows.*
9. *C records displayed* Cont *replay along the finite route from o, s, W, R, D through L to E, H, P, N.*
10. *P is the* Pkg *provenance over* $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionBudgetRouter}^{\uparrow}}$ *row.*

The classifier accepts only packets whose completion-facing reads are routed through these rows. It has no coordinate for unbounded observation, an external selector, quotient stream equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6949.2 (Real completion budget-router NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$ *carrier* $B = (o, s, W, R, D, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionBudgetRout}}$ *surface consists exactly of budget admission, selector admission, StreamName window locality, RegSeqRat readback, DyadicRatCore tolerance accounting, CauchyLimitSeal-compatible handoff, RealUp seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6949.1. Its coordinates expose the two budget rows, the window and readback rows, the dyadic ledger, the seal handoff, the terminal seal, and the structural transport, replay, provenance, and naming rows.

The route order is forced by the carrier shape. A StreamName read is admitted only under o, a selector read only under s, a RegSeqRat row only as readback from W, and a tolerance comparison only through D.

The handoff and endpoint rows add no second source. The row L consumes the same budgeted W, R, D route, and E is exposed only after that route has been replayed through H, C, P, N. Hence the listed rows exhaust the local NameCert surface. □

Theorem 6949.3 (Real completion budget-router non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or CauchyLimitSeal-facing consumer of an accepted* $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$ *packet reads only the observation budget, selector budget,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, CauchyLimitSeal-compatible handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. It cannot bypass the budget rows or import an unbounded observation service, external selector, quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use Definition 6949.2 to identify the only rows available to any accepted consumer. The window row W is behind o, the readback row R is behind W, and all tolerance comparisons are behind D.

Now read the completion-facing rows. The CauchyLimitSeal-compatible handoff L and terminal seal E consume the same displayed budgeted route; neither row carries a detached selector or completed real object.

Finally replay through H, C, P, N. These structural rows preserve the displayed route and name its provenance, so a consumer has no remaining coordinate from which an unbudgeted observation, quotient, chosen limit, host equality, choice principle, or ambient completeness theorem could be read. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$ consumer can be audited by checking that its first reads are the observation-budget and selector-budget rows before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, CauchyLimitSeal, or $\mathsf{Real}^{\uparrow}$ rows are consumed.

Independence witness: Nearest siblings: streamname, regseqrat, dyadicratcore, real, and cauchy-limit-seal routes. The router is not bijective to any one sibling because it carries the two budget gates together with the downstream window, readback, tolerance, handoff, and seal rows; deleting either budget row changes the admitted consumer route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionBudgetRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionBudgetRouter}^{\uparrow}$ packet is generated from observation-budget and selector-budget rows, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyLimitSeal-compatible handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionBudgetRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6949.1, Definition 6949.2, and Definition 6949.3 seed the finite budget-router route for Real completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionBudgetRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient stream equality, host real equality, countable choice, unbounded observation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked budget admission, selector admission, StreamName locality, RegSeqRat readback, DyadicRatCore tolerance accounting, CauchyLimitSeal-compatible handoff, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionBudgetRouterUp.

Chapter 6950

A Concrete Naming Certificate for $\mathsf{DirichletUniformTest}^{\uparrow}$

Following Hardy's treatment of Dirichlet's test for uniform convergence, the $\mathsf{DirichletUniformTest}^{\uparrow}$ packet records a finite certificate for a source function-series window whose bounded partial sums and controlled coefficient variation produce a uniform Cauchy handoff. It sits beside the real-series carrier of chapter 1581, the uniform Cauchy criterion of chapter 435, the uniform-limit boundary of chapter 463, the finite StreamName schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only displayed finite rows; it does not import host uniform convergence, selected limits, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6950.1 (Dirichlet uniform test carrier)**.** *A* $\mathsf{DirichletUniformTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, B, A, V, W, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing only finite function-series windows and their inspected partial sums.*
2. *B is the bounded-partial-sum ledger, giving a displayed bound for every inspected source window.*
3. *A is the coefficient monotonicity ledger, recording the finite order comparisons used by the coefficient row on the inspected tail.*
4. *V is the coefficient variation ledger, recording the finite total-variation budget that replaces any appeal to host monotone convergence.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule naming the source indices and parameter windows visible to the test.*
6. *U is the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *handoff row, storing the uniform tail-window request produced by B, A, V, W.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational estimates exported by the tail-window ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic and regular readbacks have been displayed.*
9. *H records componentwise* hsame *transport for the source, boundedness, coefficient, variation, window, handoff, readback, seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from S, W into B, A, V, from those ledgers into U, and from U through R into E.*
11. *P is the* Pkg *provenance over* $\mathsf{DirichletUniformTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletUniformTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, B, A, V, W, U, R, E, H, C, P, N$. It has no coordinate for a selected infinite sum, host uniform convergence, quotient equality of functions, countable choice, or ambient completeness.

Theorem 6950.2 (Dirichlet uniform test NameCert obligations)**.** *For every accepted* $\mathsf{DirichletUniformTest}^{\uparrow}$ *carrier $K = (S, B, A, V, W, U, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirichletUniformTest}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded-partial-sum exposure, coefficient monotonicity exposure, coefficient-variation exposure, StreamName window admission, UniformCauchyCriterion handoff readiness, RegSeqRat readback, Real seal non-escape, componentwise transport, displayed replay, provenance, and local naming. A downstream consumer may read a uniform Cauchy tail certificate only through those rows.*

Proof. Project the carrier rows of Definition 6950.1. The source row S gives only finite function-series windows, while B, A, V give the bounded partial-sum, monotonicity, and variation ledgers visible on those windows.

The window schedule W fixes which tails may be inspected before the handoff row U is read. Thus a consumer cannot reach a uniform tail claim until the same finite source, boundedness, coefficient, and variation rows have already been displayed.

Finally read R, E, H, C, P, N. The regular readback and Real seal are downstream of U, and the structural rows preserve exactly the same displayed route. No selected infinite sum, quotient function equality, host uniform convergence theorem, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness is introduced. □

Theorem 6950.3 (Dirichlet uniform test uniform Cauchy handoff)**.** *Every* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *or* $\mathsf{UniformLimit}^{\uparrow}$ *consumer of an accepted* $\mathsf{DirichletUniformTest}^{\uparrow}$ *carrier factors through the finite tail-window route*

$$\mathsf{DirichletUniformTest}^{\uparrow} \longmapsto \mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{UniformCauchyCr}$$

The handoff row U receives only the displayed bounded-partial-sum ledger B, coefficient monotonicity ledger A, variation ledger V, and window schedule W before it exports a uniform Cauchy request.

Proof. Start with the rows S and W. They determine the inspected source windows and the tail windows visible to the packet, so every later estimate is tied to a finite $\mathsf{StreamName}^{\uparrow}$ route.

Next use B, A, V to form the Dirichlet tail estimate on the displayed window. The bounded partial sums provide the uniform bound, the monotonicity ledger orders the coefficient row, and the variation ledger supplies the finite loss budget needed to route the estimate into U.

The readback row R and seal row E are then consumed after the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ handoff. Therefore a $\mathsf{UniformLimit}^{\uparrow}$ consumer receives only the finite uniform Cauchy surface supplied by U, R, E, H, C, P, N, not a selected host limit, quotient equality of functions, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.DirichletUniformTestUp.DirichletUniformTestCarrier uniform cauchy handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletUniformTest}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletUniformTest}^{\uparrow}$ packet is generated from RealSeries source windows, bounded partial-sum rows, coefficient monotonicity and variation ledgers, StreamName windows, a UniformCauchyCriterion handoff, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletUniformTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6950.1, Definition 6950.2, and Definition 6950.3 seed the finite uniform Dirichlet-test route over source windows, bounded partial sums, coefficient variation, uniform tail windows, regular readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletUniformTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host uniform convergence, selected sums, quotient function equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-partial-sum exposure, coefficient monotonicity and variation exposure, uniform tail-window routing, readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.DirichletUniformTestUp.

Chapter 6951

A Concrete Naming Certificate for $\mathsf{HermiteHadamard}^{\uparrow}$

Following Hermite and Hadamard, the $\mathsf{HermiteHadamard}^{\uparrow}$ packet records the interval convexity route by which a convex-function source, closed interval endpoints, the midpoint comparison, and the interval-average comparison produce the two-sided Hermite–Hadamard inequality surface. It consumes the Jensen route of chapter 2235, the finite convex comparison discipline of chapter 6313, the convex-carrier surface of chapter 208, the real-name boundary of chapter 38, the rational subdivision source of chapter 37, the vector carrier of chapter 47, and the endpoint comparison discipline of chapter 1674. The packet names the Real-facing finite interval readback for the classical convex-analysis inequality; it does not import a host integral, quotient equality of real names or functions, selected extrema, trichotomy, countable choice, or ambient real completeness.

Definition 6951.1 (Hermite–Hadamard carrier)**.** *A* $\mathsf{HermiteHadamard}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (F, I, M, A, J, K, R, Q, T, C, P, N)$$

with the following displayed rows:

1. *F is the convex-function source row, recording the displayed domain, codomain, convexity ledger, and function-read route.*
2. *I is the closed-interval endpoint row, recording endpoints $a \leq b$, their* $\mathsf{Real}^{\uparrow}$ *reads, and the* $\mathsf{RealMinMax}^{\uparrow}$ *boundary comparison.*
3. *M is the midpoint row, recording the displayed midpoint $(a+b)/2$ and its* $\mathsf{Rat}^{\uparrow}$ *coefficient read inside the interval.*
4. *A is the interval-average row, recording the finite rational subdivision windows, normalized averaging weights, and the displayed average comparison surface.*
5. *J is the* $\mathsf{JensenInequality}^{\uparrow}$ *handoff row, recording the finite midpoint and subdivision Jensen calls used on the interval carrier.*
6. *K is the* $\mathsf{KaramataInequality}^{\uparrow}$ *handoff row, recording the finite convex-order comparison between symmetric endpoint windows and interior subdivision windows.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row for the displayed two-sided inequality*

$$f((a+b)/2) \leq A_{\mathrm{int}}(f, a, b) \leq (f(a) + f(b))/2.$$

8. *Q is the endpoint row, recording the real comparison data used when a consumer reads the lower midpoint bound and upper endpoint bound together.*
9. *T records componentwise* hsame *transport for F, I, M, A, J, K, R, Q and the local naming row.*
10. *C records displayed* Cont *replay from the endpoint and subdivision rows through the Jensen and Karamata handoffs, real comparison, endpoint row, provenance, and local name.*
11. *P is the* Pkg *provenance over* $\mathsf{HermiteHadamard}^{\uparrow}$, $\mathsf{JensenInequality}^{\uparrow}$, $\mathsf{KaramataInequality}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{RealMinMax}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HermiteHadamard}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, I, M, A, J, K, R, Q, T, C, P, N$. It has no coordinate for a host integral, quotient equality of functions or real names, a selected supremum, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.HermiteHadamardUp`

Theorem 6951.2 (Hermite–Hadamard NameCert obligations)**.** *For every accepted* $\mathsf{HermiteHadamard}^{\uparrow}$ *carrier $H = (F, I, M, A, J, K, R, Q, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HermiteHadamard}^{\uparrow}}$ *surface consists exactly of carrier admission for the convex-function source row, closed-interval endpoint row, midpoint row, interval-average row, Jensen handoff row, Karamata handoff row, real comparison row, endpoint row, structural rows T, C, P, and local naming row N; endpoint accountability through I, Q; midpoint and average accountability through M, A; Jensen and Karamata comparison accountability through J, K, R; and componentwise transport, replay, provenance, and naming for the same finite interval route.*

Proof. Project the accepted packet $H = (F, I, M, A, J, K, R, Q, T, C, P, N)$. The carrier definition exposes exactly the convex-function source, closed interval, midpoint, averaging, Jensen handoff, Karamata handoff, real comparison, endpoint comparison, transport, replay, provenance, and naming rows.

The endpoint and midpoint rows are read before any inequality row. Thus I supplies the two endpoint real names and boundary comparison, while M supplies the displayed midpoint and its rational coefficient read.

The average row A then supplies the finite subdivision windows and normalized rational weights. The handoff rows J, K record the Jensen and Karamata routes that turn those finite rows into the lower midpoint comparison and upper endpoint comparison.

Finally R, Q, T, C, P, N expose the two-sided real comparison, endpoint comparison, transport, replay, provenance, and local naming. Since no host integral, quotient-equality object, selected supremum, or ambient completeness coordinate is present, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.HermiteHadamardUp.HermiteHadamardTasteGate single carrier alignment`

Theorem 6951.3 (Hermite–Hadamard Jensen interval route)**.** *Every accepted* $\mathsf{HermiteHadamard}^{\uparrow}$ *carrier routes its public two-sided inequality through*

$$I, M, A \longmapsto J, K \longmapsto R, Q \longmapsto T, C, P, N.$$

Consequently a consumer must read the closed interval endpoints, midpoint row, finite rational subdivision averages, $\mathsf{JensenInequality}^{\uparrow}$ *handoff row,* $\mathsf{KaramataInequality}^{\uparrow}$ *handoff row,* $\mathsf{Real}^{\uparrow}$ *comparison row,* $\mathsf{RealMinMax}^{\uparrow}$ *endpoint row, componentwise transport, replay, provenance, and local naming before it can cite the Hermite–Hadamard inequality surface.*

Proof. Start with a consumer read of the two-sided comparison. By Definition 6951.1, the only interval data are the endpoint row I, midpoint row M, and finite average row A.

The Jensen handoff row J is downstream of those interval rows. It supplies the midpoint and subdivision convexity comparisons only after the finite rational weights and interval membership data have been displayed.

The Karamata handoff row K is read on the same finite interval windows. It records the convex-order route from symmetric endpoint windows to the interior average comparison, so the upper endpoint inequality cannot be cited independently of the displayed subdivision ledger.

Finally R, Q, T, C, P, N expose the real comparison, endpoint comparison, transport, replay, provenance, and local naming. Thus no consumer can bypass the finite interval route by invoking a host integration theorem or an ambient real-completeness principle. □

Falsifiable prediction: Every $\mathsf{HermiteHadamard}^{\uparrow}$ consumer reads a convex-function source row, closed interval endpoint row, midpoint row, finite rational subdivision-average row, JensenInequality handoff row, KaramataInequality handoff row, Real comparison rows, RealMinMax endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the Hermite–Hadamard inequality surface is public.

Independence witness: jenseninequality, karamatainequality, convexset, real, rat, vecspace, realminmax: $\mathsf{HermiteHadamard}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries interval endpoints, midpoint data, finite subdivision averages, Jensen handoffs, Karamata handoffs, real comparison, endpoint comparison, transport, replay, provenance, and local NameCert data as one finite interval inequality packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HermiteHadamard}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HermiteHadamard}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6951.1, Definition 6951.2, and Definition 6951.3 seed the finite Hermite–Hadamard interval route over convex-function, endpoint, midpoint, finite-average, Jensen, Karamata, ConvexSet, Real, Rat, VecSpace, and RealMinMax rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HermiteHadamard}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.HermiteHadamardUp`

Bridge status: none

Not claimed: This chapter does not close host integrals, quotient equality of real names or functions, selected extrema, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint accountability, midpoint and subdivision-average exactness, Jensen and Karamata handoff exactness, Real comparison nonescape, endpoint comparison handoff, and public export scope for BEDC.Derived.HermiteHadamardUp.

Constructive story: A $\mathsf{HermiteHadamard}^{\uparrow}$ packet is generated from a convex-function source row, closed interval endpoint row, midpoint row, finite rational subdivision-average row, JensenInequality and KaramataInequality handoff rows, Real comparison rows, RealMinMax endpoint rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6952

A Concrete Naming Certificate for $\mathsf{FiniteRankOperator}^{\uparrow}$

Following finite-dimensional linear algebra and bounded-operator theory, the $\mathsf{FiniteRankOperator}^{\uparrow}$ packet records the displayed finite-rank route by which a linear operator factors through a finite-dimensional image row before compactness, spectral, Hilbert, or functional-analysis consumers may read it. It sits after the vector-space carrier of chapter 47, the linear-map surface of chapter 48, the finite matrix readback of chapter 49, the bounded-linear-operator boundary of chapter 1644, and the compact-operator sibling of chapter 1952. The packet names the finite image ledger and its operator handoff; it does not assert compact approximation, spectral decomposition, a selected basis for every image, quotient function equality, or an ambient functional-analysis theorem.

Definition 6952.1 (Finite-rank operator carrier)**.** *A* $\mathsf{FiniteRankOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, Y, T, I, B, M, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the source and target* $\mathsf{VecSpace}^{\uparrow}$ *rows.*
2. *T is the* $\mathsf{LinMap}^{\uparrow}$ *row from X to Y; when norm control is requested, the same row is also read through* $\mathsf{BoundedLinearOperator}^{\uparrow}$*.*
3. *I is the finite image-window row, listing displayed target vectors that span the image of T for the requested source window.*
4. *B is the finite-dimensional basis or spanning ledger for I, read only as BEDC rows and not as a host basis selector.*
5. *M is the optional* $\mathsf{Mat}^{\uparrow}$ *presentation row tying the displayed coefficients of T to the finite image ledger.*
6. *E is the exactness row saying that every displayed operator value in the request lands in the span recorded by I and B.*
7. *H records componentwise* hsame *transport for the vector-space endpoints, operator row, image ledger, basis ledger, matrix presentation, exactness row, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from an operator read through the finite image rows and back to bounded, compact, spectral, Hilbert, or functional-analysis consumers.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteRankOperator}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRankOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient operator algebra, an infinite basis, a quotient representative of the image, a compactness theorem, or a spectral theorem.

Theorem 6952.2 (Finite-rank operator NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRankOperator}^{\uparrow}$ *carrier* $R = (X, Y, T, I, B, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteRankOperator}^{\uparrow}}$ *surface consists exactly of carrier admission, source and target vector-space exposure, linear-map action exposure, finite image-window exactness, optional matrix readback compatibility, bounded-operator handoff when norm control is displayed, compact-operator handoff through the finite image rows, componentwise transport, continuation replay, provenance, and local naming.*

Any $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, *or* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer that reads finite-rank data from R must first pass through $X, Y, T, I, B, M, E, H, C, P, N$. The read exports no ambient compactness theorem, no selected infinite approximation scheme, no spectral decomposition, no quotient image equality, and no host operator-space object.*

Proof. Project the carrier of Definition 6952.1. The vector-space endpoints X, Y, the operator row T, the finite image rows I, B, and the exactness row E are displayed before any consumer-facing row is available.

Matrix compatibility is only a readback route. If M is present, its coefficients are tied to the same T, I, B rows; if it is absent, the carrier still exposes finite image exactness directly through E.

Bounded and compact consumers receive only the finite route recorded by C and P. The bounded handoff reads the norm-controlled operator row when it is displayed, while the compact handoff reads finite-rankness through the finite image ledger rather than through an ambient compactness theorem.

Transport is componentwise through H, and naming is local through N. Since no carrier coordinate stores an infinite basis, a selected approximation sequence, quotient image equality, spectral decomposition, or host operator space, the obligations listed above exhaust the $\mathsf{FiniteRankOperator}^{\uparrow}$ naming surface. □

Falsifiable prediction: Every accepted $\mathsf{FiniteRankOperator}^{\uparrow}$ consumer must display $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, finite image-window, spanning-ledger, exactness, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before finite-rank operator data is available.

Independence witness: vecspace, linearmap, matrix, boundedlinearoperator, compactoperator: $\mathsf{FiniteRankOperator}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source and target vector rows, a linear action row, finite image-window rows, spanning or basis ledger rows, optional matrix readback, exactness, transport, replay, provenance, and local naming in one operator-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRankOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteRankOperator}^{\uparrow}$ packet is generated from source and target VecSpaceUp rows, a LinearMapUp action row, a finite image-window row, a spanning or basis ledger, optional MatrixUp readback, finite image exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteRankOperator}^{\uparrow}}$, seed)

Scope closed: Definition 6952.1, Definition 6952.2, the falsifiable prediction, and the independence witness seed the finite-rank operator interface over displayed vector-space, linear-map, matrix, bounded-operator, compact-operator, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteRankOperator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim compact approximation, spectral decomposition, selected infinite bases, quotient image equality, an ambient operator-space object, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite image exactness, optional matrix compatibility, bounded and compact handoff, classifier transport, and consumer non-escape for BEDC.Derived.FiniteRankOperatorUp.

Chapter 6953

A Concrete Naming Certificate for $\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley-style net convergence, the CauchyNetConvergenceCriterio packet records the finite criterion by which a displayed Cauchy net is read as a convergence candidate only through named windows, regular rational tolerances, and the terminal real seal. It sits after the Cauchy-net carrier of chapter 589, the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the Real seal of chapter 38. The criterion is a finite BEDC NameCert surface; it does not construct quotient filters, select a limit, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6953.1 (Cauchy net convergence criterion carrier)**.** *A* $\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, S, R, D, W, T, E, H, A, P, N)$$

with the following rows:

1. *C is the* $\mathsf{CauchyNet}^{\uparrow}$ *source row exposing the directed Cauchy-net request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect named tails of the net.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance comparisons.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row, recording precision cells and refinement slack for each request.*
5. *W is the window-eventuality row, sending a requested tolerance to a displayed finite tail window.*
6. *T is the tail-coherence row, recording that later displayed windows preserve the same rational tolerance decision.*
7. *E is the Real-seal eligibility row, exposed only after C, S, R, D, W, T are visible.*
8. *H records componentwise* hsame *transport for the source, window, readback, dyadic, eventuality, coherence, and seal-eligibility rows.*
9. *A records displayed* Cont *replay of the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient filters, selected limits, countable choice, host equality of nets, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyNetConvergenceCriterionUp.CauchyNetConvergenceCriterionUp`
Lean4 ✓ `BEDC.Derived.CauchyNetConvergenceCriterionUp.CauchyNetConvergenceCriterionTasteGate`
`single carrier alignment`

Theorem 6953.2 (Cauchy net convergence criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}$ *carrier*

$$K = (C, S, R, D, W, T, E, H, A, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}}$ *surface consists exactly of Cauchy-net source exposure through C, stream-window inspection through S, regular rational readback through R, dyadic budget exposure through D, eventual tail-window selection through W, tail coherence through T, Real-seal eligibility through E, componentwise transport through H, displayed continuation replay through A, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The source row C supplies the directed Cauchy-net request, while S and R expose the finite stream window and rational readback used to inspect that request.

The dyadic budget row D fixes the tolerance cell. The eventuality row W then records which displayed tail window answers the request, and the coherence row T records that later displayed windows keep the same tolerance decision.

Only after those rows are visible may the eligibility row E reach the Real seal. The structural rows H, A, P, N transport, replay, source, and name the same finite route, so the local NameCert cannot export a quotient filter, a selected limit, countable choice, host net equality, or ambient Real completeness. □

Theorem 6953.3 (Cauchy net convergence criterion Real seal handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}$ *packet must read the handoff through the displayed route*

$$C, S, R, D, W, T, E \longmapsto H, A, P, N.$$

Consequently a Cauchy-net convergence request reaches $\mathsf{Real}^{\uparrow}$ *only after the StreamName window, RegSeqRat readback, DyadicRatCore budget, eventuality row, and tail-coherence row are all visible.*

Proof. Begin with the Cauchy-net source row C and the finite window row S. They determine which displayed tail of the net is inspected for the current tolerance request.

The regular rational row R and dyadic row D provide the comparison budget. The eventuality row W and coherence row T bind that budget to a finite tail route rather than to an unrecorded filter representative or a chosen limit.

The Real-seal row E is therefore downstream of the displayed Cauchy-net, window, readback, and budget data. Transport, replay, provenance, and local naming through H, A, P, N preserve the same route, so a Real-facing consumer obtains no bypass around StreamName, RegSeqRat, DyadicRatCore, or the terminal Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{CauchyNetConvergenceCriterion}^{\uparrow}$ packet is generated from a CauchyNet source row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore budget row, eventual tail-window evidence, tail coherence, Real-seal eligibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyNetConvergenceCriterion}\uparrow}$, seed)

Scope closed: Definition 6953.1, Definition 6953.2, and Definition 6953.3 seed the finite Cauchy-net convergence criterion for StreamName, RegSeqRat, DyadicRatCore, and Real consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchyNetConvergenceCriterion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host net equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular rational read-back, dyadic budget exposure, eventuality, tail coherence, Real-seal eligibility, transport, replay, provenance, and local naming for BEDC.Derived.CauchyNetConvergenceCriterionUp.

Chapter 6954

A Concrete Naming Certificate for $\mathsf{CauchyCompletionPullback}^{\uparrow}$

Following Bishop and Bridges on constructive completion and finite comparison of Cauchy data, the $\mathsf{CauchyCompletionPullback}^{\uparrow}$ packet records the compatibility surface where two displayed completion routes meet over one target seal. It sits beside the completion functor route of chapter 423, the metric-completion boundary of chapter 1506, the product-strength packet of chapter 6130, the terminal exact-boundary route of chapter 1120, and the regular-rational and stream-window sources of chapter 301 and chapter 126. The packet is a finite L10 compatibility object: it does not import host pullbacks, quotient completions, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6954.1 (Cauchy completion pullback carrier)**.** *A* $\mathsf{CauchyCompletionPullback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (A, B, T, f, g, W_A, W_B, R_A, R_B, H, C, P_0, N)$$

with the following displayed rows:

1. *A is the left* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *source row, exposing only its displayed completion request and local naming surface.*
2. *B is the right* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, exposing only its displayed metric-completion request and local naming surface.*
3. *T is the shared terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by both completion routes.*
4. *f is the left leg, a finite route from A through the relevant* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows to T.*
5. *g is the right leg, a finite route from B through the relevant* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows to T.*
6. *W_A and W_B are the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window rows inspected by the two legs.*
7. *R_A and R_B are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
8. *H records componentwise* hsame *transport for the two sources, two legs, two windows, two readbacks, shared seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the two routes into the same terminal seal.*

10. *P_0 is the* Pkg *provenance over* $\mathsf{CauchyCompletionPullback}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionPullback}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, B, T, f, g, W_A, W_B, R_A, R_B, H, C, P_0, N$. It has no coordinate for a host pullback object, quotient completion, selected representative, countable-choice schedule, detached limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6954.2 (Cauchy completion pullback NameCert obligations)**.** *For every accepted* CauchyCompletionPullb *carrier*

$$P = (A, B, T, f, g, W_A, W_B, R_A, R_B, H, C, P_0, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionPullback}^{\uparrow}}$ *surface consists exactly of carrier admission, leg compatibility, shared target sealing, synchronized finite windows, transport, replay, provenance, and non-escape. In particular, every public compatibility read must display the left* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row, the right* $\mathsf{MetricCompletion}^{\uparrow}$ *row, both legs, both* $\mathsf{StreamName}^{\uparrow}$ *windows, both* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the common* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows H, C, P_0, N before it may treat the two completion routes as meeting.*

Proof. Project the carrier of Definition 6954.1. Carrier admission exposes exactly the two source rows, the two leg rows, the two finite windows, the two regular-rational readbacks, the shared seal, and the four structural rows.

Leg compatibility is read from f and g together with W_A, W_B, R_A, R_B. The left leg must pass from the $\mathsf{CauchyCompletionMonad}^{\uparrow}$ row through its displayed window and readback; the right leg must pass from the $\mathsf{MetricCompletion}^{\uparrow}$ row through its displayed window and readback.

The shared target seal is the single row T. Since both legs name the same terminal $\mathsf{Real}^{\uparrow}$ coordinate only after the windows and readbacks have been displayed, the packet supplies a finite compatibility surface rather than a host pullback or quotient-completion equality.

Finally H, C, P_0, N provide componentwise transport, replay, provenance, and local naming for that same finite route. No remaining coordinate can export selected limits, countable choice, detached representatives, or ambient completeness, so the listed rows exhaust the local NameCert obligations. □

Theorem 6954.3 (Cauchy completion pullback synchronized windows)**.** *Every accepted* CauchyCompletionPullback *read factors through the synchronized finite-window route*

$$\mathsf{CauchyCompletionMonad}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

by reading $A, B, W_A, W_B, R_A, R_B, T, H, C, P_0, N$. The two completion legs may meet only at the displayed seal T over those windows and readbacks.

Proof. Start with the two source rows A and B. A completion-facing consumer receives no direct comparison between them; it receives only the leg rows f, g and the displayed windows W_A, W_B.

The windows determine the regular-rational readbacks R_A, R_B. These readbacks are the only data that can be replayed toward the shared seal, so the consumer cannot replace them with quotient Cauchy classes or selected completed representatives.

After the readbacks have been displayed, the terminal row T supplies the shared $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming keep both legs on the same finite route, and no other row remains available. □

Theorem 6954.4 (Cauchy completion pullback Hausdorff separation route)**.** *Any consumer treating a* $\mathsf{CauchyCompletionPullback}^{\uparrow}$ *comparison as separated must display the two Hausdorff separation witnesses from* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *or* $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ *after the synchronized window row and before exporting pullback equality. The consumer cannot replace those witnesses with quotient-completion equality, selected representatives, host equality, countable choice, or ambient Real completeness.*

Proof. Project the carrier of Definition 6954.1. The two source rows, two leg rows, synchronized windows, readbacks, and shared seal are the only data available to the Cauchy pullback comparison.

Apply Definition 6954.3. It fixes the common finite source windows W_A, W_B and the readback rows R_A, R_B before either completion leg may meet the terminal $\mathsf{Real}^{\uparrow}$ seal.

To read the comparison as separated, the consumer must then route through the Hausdorff completion siblings. The relevant rows are the two explicit separation witnesses supplied by $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ or $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$, not a quotient-completion equality or a chosen completed representative.

Only after those witnesses are displayed may a pullback equality be exported as public BEDC data. Transport, replay, provenance, and local naming keep the export inside the finite carrier, so countable choice, host equality, and ambient Real completeness remain unavailable. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionPullback}^{\uparrow}$ read that claims two completion routes meet must display a CauchyCompletionMonad source, a MetricCompletion source, two finite StreamName windows, two RegSeqRat readbacks, two leg rows, a shared RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: cauchycompletionfunctor, metriccompletion, cauchy-completion-strength, real-completion-exact-boundary, regseqrat, streamname: $\mathsf{CauchyCompletionPullback}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds two distinct completion sources, two leg rows, synchronized windows, paired readbacks, one terminal seal, transport, replay, provenance, and local naming in a single compatibility packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionPullback}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionPullback}^{\uparrow}$ packet is generated from a CauchyCompletionMonad row, a MetricCompletion row, a shared RealUp seal, two leg rows, two StreamName windows, two RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionPullback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6954.1, Definition 6954.2, and Definition 6954.3 seed the finite compatibility surface for two completion routes over one terminal seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionPullback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host pullbacks, quotient completions, selected limits, countable choice, detached completed representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, leg compatibility, shared target sealing, synchronized finite windows, transport, replay, provenance, and non-escape for BEDC.Derived.CauchyCompletionPullbackUp.

Chapter 6955

A Concrete Naming Certificate for ResidualSubstitutionCompatibilityWindow$^{\uparrow}$

Following the standard residual-substitution compatibility boundary from rewriting theory, the ResidualSubstitutionCompatibilityWindow$^{\uparrow}$ packet records the finite MetaCIC window on which a residual substitution claim may be checked before any confluence consumer reads it. It realizes the confluence question of chapter 9386 as concrete NameCert data and sits beside the critical-path route of chapter 765, the closed substitution boundary of chapter 538, and the bounded checker surface of chapter 3827. The packet is a bounded residual frontier; it does not assert full residual-substitution compatibility, subject reduction, arbitrary closed Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Definition 6955.1 (Residual-substitution compatibility window carrier)**.** *A* ResidualSubstitutionCompatibilityWind *carrier is a finite* BHist *packet*

$$W = (T, R, S, J, B, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed MetaCIC observation window whose source, reduct, and residual positions are all finite.*
2. *R is the residual-frontier row, recording only the residual redexes and branch-local substitution positions visible inside T.*
3. *S is the closed substitution boundary row read through chapter 538.*
4. *J is the local join row, naming the candidate join data admitted by the displayed residual frontier.*
5. *B is the bounded checker-status row inherited from chapter 3827.*
6. *O is the obstruction-retention row, recording that the bounded window has not supplied an unrestricted substitution-compatibility theorem.*
7. *H records componentwise* hsame *transport for the typed window, residual frontier, substitution boundary, local join, checker status, obstruction, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for the same bounded residual route.*
9. *P is the* Pkg *provenance over* ResidualSubstitutionCompatibilityWindow$^{\uparrow}$*,* MetaCICCriticalPath$^{\uparrow}$*,* ClosedSubstitutionBoundary$^{\uparrow}$*,* MetaCICConfluenceResidualChecker$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{ResidualSubstitutionCompatibilityWindow}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $T, R, S, J, B, O, H, C, P, N$. It has no coordinate for an unbounded residual-substitution theorem, global subject reduction, arbitrary closed confluence, host evaluator equality, quotient conversion equality, or kernel consistency.

Theorem 6955.2 (Residual-substitution compatibility window NameCert obligations)**.** *For every accepted* $\mathsf{ResidualSubstitutionCompatibilityWindow}^{\uparrow}$ *carrier $W = (T, R, S, J, B, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ResidualSubstitutionCompatibilityWindow}^{\uparrow}}$ *surface consists exactly of typed-window exposure, residual-frontier exposure, closed-substitution-boundary exposure, local-join exposure, bounded-checker status, obstruction retention, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6955.1. The displayed rows are exactly the typed window, residual frontier, closed substitution boundary, local join, bounded checker status, obstruction, transport, replay, provenance, and naming rows.

Read the compatibility boundary in order. The typed window T fixes the finite MetaCIC source window, the residual row R exposes the branch-local residual positions, and the substitution row S keeps the closed substitution boundary visible before any local join is consumed.

The local join row J and checker row B therefore operate only inside the displayed window. The obstruction row O remains part of the same carrier, so the packet cannot be read as a premise-free confluence theorem or as a discharged subject-reduction theorem.

Rows H, C, P, N preserve and name the same finite route. Since no carrier coordinate supplies unbounded compatibility, evaluator equality, quotient conversion equality, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 6955.3 (Residual-substitution compatibility window critical-path handoff)**.** *Every critical-path or confluence consumer of an accepted* $\mathsf{ResidualSubstitutionCompatibilityWindow}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{MetaCICCriticalPath}^{\uparrow},\ \mathsf{ClosedSubstitutionBoundary}^{\uparrow},\ \mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$$

through $T, R, S, J, B, O, H, C, P, N$ before it may use the window as residual-substitution evidence. The handoff preserves the bounded obstruction and exports no full confluence theorem.

Proof. Start with a consumer from the critical-path route of chapter 765. That route may inspect residual pressure only after the finite typed window and residual frontier are displayed.

The closed substitution boundary row S is then read as a sibling boundary, not as a subject-reduction theorem. It keeps source closedness, value closedness, shift, substitution, ledger, audit, and local naming data visible before the join row J can be trusted.

Finally the residual checker row B records bounded checker status for that same route, while O keeps the obstruction attached. Transport, replay, provenance, and local naming preserve the window, so the consumer receives bounded residual-substitution evidence and not full closed confluence, evaluator equality, quotient term equality, or kernel consistency. □

Falsifiable prediction: Every accepted $\mathsf{ResidualSubstitutionCompatibilityWindow}^{\uparrow}$ read that is consumed as residual-substitution evidence must display a typed MetaCIC window, residual-frontier row, closed substitution boundary row, local-join row, bounded checker-status row, obstruction row, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: metaciccriticalpath, closed-substitution-boundary, metacic-confluence-residual-checker, metacic-residual-substitution-boundary: no listed sibling is bijective to ResidualSubstitutionCompa

because this packet jointly binds a typed observation window, residual frontier, closed substitution boundary, local join, bounded checker status, obstruction retention, transport, replay, provenance, and local naming as one bounded compatibility surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ResidualSubstitutionCompatibilityWindow}\uparrow}$.

Constructive story: A $\mathsf{ResidualSubstitutionCompatibilityWindow}^{\uparrow}$ packet is generated from a typed MetaCIC observation window, residual-frontier row, closed substitution boundary row, local-join row, bounded checker-status row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ResidualSubstitutionCompatibilityWindow}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6955.1, Definition 6955.2, and Definition 6955.3 seed the bounded residual-substitution compatibility window consumed by MetaCIC confluence routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ResidualSubstitutionCompatibilityWindow}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full residual-substitution compatibility, global subject reduction, arbitrary closed Church–Rosser, evaluator equality, quotient conversion equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-frontier exposure, substitution-boundary retention, local-join exposure, bounded-checker status, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.ResidualSubstitutionCompatibilityWindowUp.

Chapter 6956

A Concrete Naming Certificate for $\mathsf{BourbakiCauchyFilter}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on Cauchy filters and constructive completion, the $\mathsf{BourbakiCauchyFilter}^{\uparrow}$ packet records the traditional Cauchy-filter presentation as finite BEDC certificate data rather than as a quotient of filters or a selected completion point. It sits after the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion-facing Cauchy-filter surface of chapter 1569. The packet gives Real and Completion consumers a human-origin source row whose public reads stay inside finite BHist, transport, replay, provenance, and local naming rows.

Definition 6956.1 (Bourbaki Cauchy-filter carrier)**.** *A* $\mathsf{BourbakiCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (F_0, B, E, W, R, D, S, H, C, P, N)$$

with the following rows:

1. F_0 *is the filter source row, exposing the displayed Cauchy-filter request that a completion consumer may inspect.*
2. B *is the finite base row, recording the named base elements used for the current filter read.*
3. E *is the entourage and tolerance row, keeping the requested closeness data explicit before any completion handoff.*
4. W *is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite observations made from the source.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *accounting row for tolerance cells, slack, and comparison budget.*
7. S *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after* F_0, B, E, W, R, D *have been displayed.*
8. H *records componentwise* hsame *transport of the source, base, tolerance, window, readback, dyadic, and seal rows.*
9. C *records displayed* Cont *replay of the same ordered route.*
10. P *is the* Pkg *provenance over* $\mathsf{BourbakiCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. N *is the local* $\mathsf{NameCert}_{\mathsf{BourbakiCauchyFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filter equality, ultrafilter extension, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6956.2 (Bourbaki Cauchy-filter NameCert obligations)**.** *For every accepted* $\mathsf{BourbakiCauchyFilter}^{\uparrow}$ *carrier*

$$F = (F_0, B, E, W, R, D, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BourbakiCauchyFilter}^{\uparrow}}$ *surface consists exactly of filter-source exposure through* F_0*, finite-base exposure through* B*, entourage and tolerance exposure through* E*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows through* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *accounting through* D*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* S*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 6956.1. The first three rows expose the Cauchy-filter source, the finite base, and the entourage or tolerance request as displayed data rather than as an ambient filter quotient.

The next four rows order the completion read through finite windows, regular rational readback, dyadic accounting, and the terminal Real seal. Thus a consumer cannot reach S before the rows F_0, B, E, W, R, D have been read.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. No row introduces quotient filter equality, ultrafilters, selected limits, countable choice, trichotomy, or ambient Real completeness. □

Theorem 6956.3 (Bourbaki Cauchy-filter RegSeqRat handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BourbakiCauchyFilter}^{\uparrow}$ *packet must factor its read through the ordered route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto B \longmapsto E \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Consequently the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff is read only after the filter source, finite base, tolerance row, and finite window service are visible, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read only after the dyadic accounting row has been displayed.*

Proof. Begin with the NameCert obligations of Definition 6956.2. They list F_0, B, E, W, R, D, S as the only analytic rows available before the structural certificate rows.

The ordered route first exposes the Cauchy-filter source and finite base. The tolerance row then fixes which finite windows are relevant, so the $\mathsf{StreamName}^{\uparrow}$ service can be read without choosing a representative sequence or a limit point.

The $\mathsf{RegSeqRat}^{\uparrow}$ row reads those windows as regular rational data, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row accounts for the displayed tolerance budget before the $\mathsf{Real}^{\uparrow}$ seal is reached. Transport, replay, provenance, and local naming preserve this order, so the handoff exports no quotient filter equality, ultrafilter argument, selected limit, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{BourbakiCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{BourbakiCauchyFilter}^{\uparrow}$ packet is generated from a Cauchy-filter source row, finite base row, entourage and tolerance row, StreamName windows, RegSeqRat readback, DyadicRatCore accounting, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BourbakiCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6956.1, Definition 6956.2, and Definition 6956.3 seed the finite Bourbaki Cauchy-filter presentation consumed by Real and Completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BourbakiCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, ultrafilters, selected limits, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-source exposure, finite-base exposure, tolerance routing, StreamName windows, RegSeqRat readback, DyadicRatCore accounting, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BourbakiCauchyFilterUp.

Chapter 6957

A Concrete Naming Certificate for AzumaHoeffdingFiniteMartingale$^{\uparrow}$

Following Azuma and Hoeffding, the AzumaHoeffdingFiniteMartingale$^{\uparrow}$ packet records the finite bounded-difference martingale route by which a displayed martingale window receives a Hoeffding-style exponential tail bound. It sits after the finite martingale carrier of chapter 190, the bounded independent-sum surface of chapter 5726, the predictable-variance concentration boundary of chapter 6408, the random-variable readback of chapter 185, and the terminal value rows of chapter 38. The chapter names the finite concentration packet; it does not import almost-sure limits, measure completion, quotient event equality, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 6957.1 (Azuma–Hoeffding finite martingale carrier)**.** *An* AzumaHoeffdingFiniteMartingale$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (\Omega, X, M, B, S, H, F, R, T, C, P, N)$$

with the following displayed rows:

1. Ω *is the probability-space row supplying the finite event and probability surface used by the concentration read.*
2. X *is the* RandomVar$^{\uparrow}$ *endpoint-family row for the displayed martingale differences and terminal martingale value.*
3. M *is the* Martingale$^{\uparrow}$ *finite-window row carrying adaptedness and conditional-expectation reads.*
4. B *is the bounded-difference row, recording the finite bound schedule for each inspected martingale difference.*
5. S *is the finite stopping-free window row, naming the displayed horizon and the prefix over which the tail estimate is read.*
6. H *is the* HoeffdingFiniteSum$^{\uparrow}$ *comparison row, used only for the finite bounded-difference exponential estimate inside the displayed window.*
7. F *is the* FreedmanInequality$^{\uparrow}$ *sibling boundary row, recording that variance-budget concentration is adjacent but not collapsed into the bounded-difference route.*
8. R *is the* Real$^{\uparrow}$ *tail-threshold row recording the displayed deviation threshold and exponential upper bound as terminal real-name reads.*

9. *T records componentwise* hsame *transport for $\Omega, X, M, B, S, H, F, R$ and the local naming row.*
10. *C records displayed* Cont *replay from a tail-event consumer through the probability, random-variable, martingale, bounded-difference, finite-window, Hoeffding, Freedman-boundary, and Real rows.*
11. *P is the* Pkg *provenance over* $\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{HoeffdingFiniteSum}^{\uparrow}$, $\mathsf{FreedmanInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $\Omega, X, M, B, S, H, F, R, T, C, P, N$. It has no coordinate for an almost-sure limiting event, completed measure algebra, quotient event equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6957.2 (Azuma–Hoeffding finite martingale NameCert obligations)**.** *For every accepted* $\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}$ *carrier $A = (\Omega, X, M, B, S, H, F, R, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}}$ *surface consists exactly of carrier admission for the probability-space, random-variable, martingale, bounded-difference, finite-window, Hoeffding finite-sum, Freedman boundary, Real tail-threshold, transport, replay, provenance, and local naming rows; bounded-difference exposure through B; finite-window accountability through S; martingale exposure through X, M; finite exponential comparison through H, R; sibling separation through F; and structural preservation through T, C, P, N.*

Proof. Project the accepted packet $A = (\Omega, X, M, B, S, H, F, R, T, C, P, N)$. The carrier displays exactly the probability, random-variable, martingale, bounded-difference, finite-window, Hoeffding, Freedman-boundary, Real, transport, replay, provenance, and local naming rows.

The martingale-facing part is X, M, B, S. The random-variable row supplies the endpoint reads, the martingale row supplies adaptedness and conditional-expectation faces, the bounded-difference row supplies the finite difference bounds, and the window row fixes the inspected horizon.

The concentration-facing part is H, F, R. The Hoeffding finite-sum row is read as the bounded-difference exponential comparison inside the same finite window, while the Freedman row remains a sibling boundary rather than a variance-budget replacement for this route.

Finally T, C, P, N transport, replay, source, and name the same rows. Since the carrier contains no limiting event, completed measure algebra, quotient event equality, choice schedule, or ambient completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6957.3 (Azuma–Hoeffding finite-window tail handoff)**.** *Every downstream tail-probability consumer of an accepted* $\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}$ *packet receives the deviation bound only after the route*

$$\mathsf{ProbSpace}^{\uparrow}, \mathsf{RandomVar}^{\uparrow}, \mathsf{Martingale}^{\uparrow} \longmapsto B, S \longmapsto \mathsf{HoeffdingFiniteSum}^{\uparrow}, \mathsf{FreedmanInequality}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P$$

has been displayed. The exported tail row is a finite bounded-difference martingale concentration handoff. It is not an almost-sure limit theorem, a measure-completion theorem, a quotient event equality, a countable-choice construction, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness consequence.*

Proof. Start with the carrier rows of Definition 6957.1. A tail-event consumer can inspect the probability-space, random-variable, and martingale rows only through the same finite packet.

Use the bounded-difference and finite-window rows. They record the horizon and the per-step bound schedule before the concentration comparison row is available, so the consumer cannot ask for an unbounded stopping route or a limiting martingale event.

Read the concentration comparison through $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ and the sibling boundary through $\mathsf{FreedmanInequality}^{\uparrow}$. The Hoeffding row supplies the bounded-difference exponential estimate, while the Freedman row keeps predictable-variance concentration adjacent but distinct.

Finally the Real tail-threshold row and the structural rows T, C, P, N export the displayed bound. The absent limiting, measure-completion, quotient-event, choice, and completeness coordinates cannot be projected from this finite route. □

Falsifiable prediction: Every accepted $\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}$ tail read exposes probability-space, RandomVar, Martingale, bounded-difference, finite-window, Hoeffding finite-sum, Freedman boundary, Real threshold, transport, replay, provenance, and local NameCert rows before the tail bound is public.

Independence witness: martingale, hoeffding-finite-sum, freedman-inequality, randomvar, real: no listed sibling supplies the joint bounded-difference martingale concentration packet containing finite martingale, random-variable, bounded-window, Hoeffding comparison, Freedman boundary, Real threshold, transport, replay, provenance, and local NameCert rows while refusing almost-sure limits, measure completion, quotient event equality, countable choice, and ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6957.1, Definition 6957.2, and Definition 6957.3 seed the finite bounded-difference martingale concentration route over MartingaleUp, HoeffdingFiniteSumUp, FreedmanInequalityUp, RandomVarUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure limits, measure completion, quotient event equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-difference exposure, finite-window accountability, martingale exposure, finite exponential comparison, sibling separation, Real tail-threshold nonescape, and structural preservation for BEDC.Derived.AzumaHoeffdingFiniteMartingaleUp.

Constructive story: An $\mathsf{AzumaHoeffdingFiniteMartingale}^{\uparrow}$ packet is generated from probability-space, random-variable, martingale, bounded-difference, finite-window, Hoeffding finite-sum, Freedman boundary, Real tail-threshold, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6958

A Concrete Naming Certificate for $\mathsf{BishopIntervalNesting}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalNesting}^{\uparrow}$ packet records a constructive nested-interval argument as finite interval-window data rather than as an ambient completeness theorem. It sits between the dyadic endpoint rows of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet gives Real and Completion consumers a named interval-nesting boundary without importing quotient streams or a host-selected limit.

Definition 6958.1 (Bishop interval nesting carrier)**.** *A* $\mathsf{BishopIntervalNesting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, R, S, Q, W, H, C, P, N)$$

with the following displayed rows:

1. *L and R are paired* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows for the left and right interval endpoints in each displayed stage.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window listing the inspected interval stages and endpoint observations.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that repacks the endpoint windows as regular rational data before any Real-facing seal is read.*
4. *W is the finite nesting ledger, recording endpoint order, containment of each displayed successor interval in its predecessor, and the local diameter budget.*
5. *H stores componentwise* hsame *transport for the endpoint rows, stream windows, regular readback row, nesting ledger, replay row, provenance row, and local name.*
6. *C stores displayed* Cont *replay from the endpoint observations through the nesting ledger and regular readback boundary.*
7. *P records* Pkg *provenance over* $\mathsf{BishopIntervalNesting}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNesting}^{\uparrow}}$ *row.*

The packet contains no coordinate for quotient stream equality, host real equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6958.2 (Bishop interval nesting NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalNesting}^{\uparrow}$ *carrier* $I = (L, R, S, Q, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNesting}^{\uparrow}}$ *surface consists exactly of carrier admission, endpoint order and containment, finite-window nesting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, structural transport, displayed replay, provenance, and local naming. Every obligation is read through* $L, R, S, Q, W, H, C, P, N$ *and through the sibling rows named in chapter 291, chapter 126, chapter 301, and chapter 38.*

The certificate exports only the finite nested-interval route. It does not export quotient streams, host real equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6958.1. The accepted packet displays the dyadic endpoint rows L, R, the stream window S, the regular rational readback Q, the nesting ledger W, and the structural rows H, C, P, N.

Endpoint order and containment are read from W after the dyadic endpoint rows have been exposed. Thus every displayed successor interval is compared inside the same finite $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, before any terminal real seal can be consumed.

The finite-window nesting clause uses S to restrict the argument to the inspected stages. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q repacks only those displayed windows, and the $\mathsf{Real}^{\uparrow}$ handoff can read the resulting regular data only through Q and the replay row C.

Finally, H, P, and N certify that transport, provenance, and local naming preserve the same packet. Since no row stores quotient stream equality, host real equality, selected limits, countable choice, trichotomy, or ambient completeness, none of those principles is a local obligation. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalNesting}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopIntervalNesting}^{\uparrow}}$, seed)

Scope closed: Definition 6958.1 and Definition 6958.2 seed the finite dyadic endpoint, stream-window, regular-readback, and Real-seal route for constructive interval nesting.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopIntervalNesting}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, host real equality, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked endpoint order, containment, finite-window nesting, regular readback, Real seal handoff, transport, replay, provenance, and local naming for the same carrier.

Constructive story: A $\mathsf{BishopIntervalNesting}^{\uparrow}$ packet is generated from dyadic left and right endpoint rows, finite StreamName windows, RegSeqRat readback rows, a nested containment ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6959

A Concrete Naming Certificate for $\mathsf{CompactFiniteLowerBound}^{\uparrow}$

Following Bishop and Bridges on the finite-cover proof of uniform continuity on compact metric spaces, the $\mathsf{CompactFiniteLowerBound}^{\uparrow}$ packet records the lower-bound fold that turns a compact finite-net radius family into one classifier-stable radius row. It sits over the compact carrier of chapter 60, the metric distance surface of chapter 57, the pointwise continuity rows of chapter 59, the rational order readback of chapter 37, and the $\mathsf{ProbeBundle}$ fold used by Definition 9237.5. The packet specializes the lower-bound handoff of chapter 4096 to compact-uniform-continuity consumers.

Definition 6959.1 (Compact finite lower-bound carrier)**.** *A* $\mathsf{CompactFiniteLowerBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, M, F, \mathcal{P}, R, O, A, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row whose displayed cover supplies the centers and coverage witnesses.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source-distance row used by the compact cover and later uniform-modulus consumer.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row attached to the same source metric.*
4. *$\mathcal{P}$ is the nonempty* $\mathsf{ProbeBundle}$ *spine indexing the finite net.*
5. *R is the finite family of positive* $\mathsf{Rat}^{\uparrow}$ *radius rows carried by the bundled probes.*
6. *O is the total-order finite-minimum readback row comparing the current accumulator with the next displayed radius.*
7. *A is the accumulator history produced by primitive recursion over $\mathcal{P}$.*
8. *L is the exported lower-bound row, classifier-stably below every displayed radius in R.*
9. *H stores componentwise* hsame *transport for the compact, metric, continuous, bundle, rational, order, accumulator, lower-bound, replay, provenance, and local-name rows.*
10. *C stores displayed* Cont *replay from compact finite-net data and pointwise-modulus rows through the rational fold to the lower-bound export.*

11. *P records* Pkg *provenance over* $\mathsf{CompactFiniteLowerBound}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactFiniteLowerBound}^{\uparrow}}$ *row.*

The packet has no row for an external selector, host minimum, completed cover, countable choice, quotient metric equality, or ambient compactness theorem.

Theorem 6959.2 (Compact finite lower-bound NameCert obligations)**.** *For every accepted* CompactFiniteLowerBou *carrier $B = (K, M, F, \mathcal{P}, R, O, A, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactFiniteLowerBound}^{\uparrow}}$ *surface consists exactly of bundle admission, nonempty seed, successor comparison, lower-bound export, classifier stability, structural transport, displayed replay, provenance, and local naming. The successor comparison consumes the* $\mathsf{Rat}^{\uparrow}$ *total-order readback row O at each displayed probe, and the export row L is available only after the finite* ProbeBundle *recursion has consumed the compact finite-net row K, metric source row M, continuous pointwise-modulus row F, and radius family R.*

Thus compact uniform-continuity consumers may read the exported lower bound as finite BEDC data, but they may not import an external selector, host minimum, completed cover, countable choice, quotient metric equality, or ambient compactness theorem.

Proof. Bundle admission projects K and $\mathcal{P}$ from Definition 6959.1. The nonempty seed is part of the displayed compact finite-net row, so the fold starts from a named radius history rather than from a host default.

At a successor probe, the row O compares the current accumulator with the next $\mathsf{Rat}^{\uparrow}$ radius in R. The accumulator A is updated by primitive recursion over the displayed ProbeBundle spine, so no outside enumeration or choice functional is used.

The lower-bound export L is then read from the completed finite recursion. Componentwise transport in H and replay in C preserve the compact, metric, continuous, rational, order, accumulator, and lower-bound rows along one packet, while P and N record the same source and local name.

Classifier stability follows because every comparison in O and every accumulator update in A is attached to the same finite bundle and radius family. Since the carrier contains no row for an external selector, host minimum, completed cover, countable choice, quotient metric equality, or ambient compactness theorem, none can appear as a local obligation. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFiniteLowerBound}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactFiniteLowerBound}^{\uparrow}}$, seed)

Scope closed: Definition 6959.1 and Definition 6959.2 seed the finite compact-net lower-bound fold over Compact, Metric, Continuous, Rat, and ProbeBundle rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactFiniteLowerBound}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim an external selector, host minimum, completed cover, countable choice, quotient metric equality, ambient compactness theorem, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked bundle admission, nonempty seed, successor comparison, lower-bound export, classifier stability, transport, replay, provenance, and local naming for the same finite fold packet.

Constructive story: A $\mathsf{CompactFiniteLowerBound}^{\uparrow}$ packet is generated from compact finite-net data, a Metric source row, Continuous pointwise-modulus rows, positive Rat radius rows, a ProbeBundle spine, total-order finite-minimum readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6960

A Concrete Naming Certificate for $\mathsf{RegularCauchyReindexing}^{\uparrow}$

Following Bishop and Bridges on cofinal subsequences of regular Cauchy names, the $\mathsf{RegularCauchyReindexing}^{\uparrow}$ packet records the finite route by which a regular Cauchy name may be read along a displayed monotone cofinal index map while preserving the regular rational and Real-facing rows. It sits beside the general reindexing surface of chapter 1568, the finite source and target schedules of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a textbook cofinal-reindexing certificate for regular Cauchy data; it is not quotient stream equality, not a selected subsequence limit, not countable choice, not host real equality, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6960.1 (Regular Cauchy reindexing carrier)**.** *A* $\mathsf{RegularCauchyReindexing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, I, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row naming the original regular Cauchy observation schedule.*
2. *T is the target* $\mathsf{StreamName}^{\uparrow}$ *row naming the reindexed observation schedule presented to downstream consumers.*
3. *I is the monotone-cofinal index route, recording the finite unary map from target requests into source requests and the cofinal witness needed for tail coverage.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the displayed precision cells, slack conversions, and comparison budgets used while the target schedule reads the source.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row reached only after the source schedule, target schedule, index route, and dyadic ledger have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after R has been read through the reindexed schedule.*
7. *H records componentwise* hsame *transport for $S, T, I, D, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from a target precision request through I, the source schedule S, the dyadic ledger D, the regular rational readback R, and the Real seal E.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReindexing}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected subsequence limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6960.2 (Regular Cauchy reindexing NameCert obligations)**.** *For every accepted* RegularCauchyReindexing *carrier* $K = (S, T, I, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexing}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{StreamName}^{\uparrow}$ *row, target* $\mathsf{StreamName}^{\uparrow}$ *row, monotone-cofinal index route,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The obligations require the target schedule to reach the source schedule through I before any dyadic tolerance, regular readback, or Real seal is consumed.*

Proof. Project the carrier of Definition 6960.1. The displayed rows S, T, I, D, R, E are the only analytic coordinates, and the structural rows H, C, P, N only preserve and name that route.

The target schedule T cannot read a source observation directly. It first consumes the monotone-cofinal route I, which supplies the target-to-source request map and the finite tail-coverage witness needed for cofinal regular Cauchy reads.

After I has fixed the source request, the dyadic ledger D records the tolerance budget for the selected source window. The regular readback R and the Real seal E are downstream of that same ledger, so they cannot supply quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness. □

Theorem 6960.3 (Regular Cauchy reindexing Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyReindexing}^{\uparrow}$ *carrier factors through the finite route*

$$T \longmapsto I \longmapsto S \longmapsto D \longmapsto R \longmapsto E.$$

The route is the regular-Cauchy specialization of the general $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff: it keeps both* $\mathsf{StreamName}^{\uparrow}$ *schedules visible, checks the cofinal target request by the dyadic tolerance ledger, reads the regular rational row, and only then exposes the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It exports no quotient stream equality, no selected subsequence limit, no countable-choice schedule, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of the seal row E. The carrier places E after the regular readback row R, and R is available only after the target request has been routed through I to the source schedule S.

The tolerance ledger D is read on the same route. It supplies the finite precision and slack data needed for the selected source observation, so the target schedule cannot bypass the displayed source window or invent a separate regular Cauchy name.

The provenance row P records the relationship with the general $\mathsf{CauchyReindexing}^{\uparrow}$ surface, while H, C, N preserve and name the same route. Therefore every Real-facing read factors through the displayed finite packet and receives none of the excluded host or quotient objects. □

Theorem 6960.4 (Regular Cauchy cofinal stream factorization)**.** *Every accepted* $\mathsf{RegularCauchyReindexing}^{\uparrow}$ *carrier* $K = (S, T, I, D, R, E, H, C, P, N)$ *exposes its target schedule first as a* $\mathsf{StreamReindexing}^{\uparrow}$ *finite-window read through chapter 7081 and then as a* $\mathsf{CofinalReindexing}^{\uparrow}$ *tail-window read through chapter 7209. Only after those sibling surfaces are displayed may the consumer read the* $\mathsf{RegSeqRat}^{\uparrow}$ *row of chapter 301 and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38.*

Proof. Project K along the carrier rows in Definition 6960.1. The target schedule T is the finite window surface presented to downstream consumers, and the index route I identifies how each target request is routed back to the source schedule S.

Read I as the cofinal target-to-source route. Its monotone tail coverage is exactly the sibling surface needed by the $\mathsf{CofinalReindexing}^{\uparrow}$ packet, while the finite target-window request is the sibling surface read by $\mathsf{StreamReindexing}^{\uparrow}$.

The rows D, R, E are downstream of this schedule. The dyadic ledger D audits the selected source window, the regular rational row R reads it as $\mathsf{RegSeqRat}^{\uparrow}$ data, and the seal row E is exposed only after that readback. Thus no accepted carrier can bypass the StreamReindexing and CofinalReindexing sibling route on its way to the regular readback and Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexing}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyReindexing}^{\uparrow}$ packet is generated from source and target StreamName rows, a monotone-cofinal index route, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReindexing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6960.1, Definition 6960.2, and Definition 6960.3 seed the finite regular Cauchy cofinal-reindexing route from displayed source and target schedules to the downstream $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyReindexing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected subsequence limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-cofinal route exposure, dyadic tolerance exactness, regular readback, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyReindexi

Chapter 6961

A Concrete Naming Certificate for $\mathsf{BanachInverseMapping}^{\uparrow}$

Following Banach and the Bishop–Bridges treatment of constructive functional analysis, the $\mathsf{BanachInverseMapping}^{\uparrow}$ packet records the finite route by which a displayed bounded linear bijection between Banach rows is read as a bounded inverse with explicit inverse-modulus data. It sits beside the complete source and target surfaces of chapter 90 and chapter 128, the bounded-operator route of chapter 1644, the graph and open-image routes of chapter 1537 and chapter 1538, and the nearby inverse theorem packet of chapter 2291. Its sibling routes include the locally convex and Frechet carriers of chapter 3386 and chapter 3495, the fixed-point endpoint discipline of chapter 396, and the continuous-map graph surface of chapter 130. The chapter names only displayed Banach endpoint rows, a bounded linear bijection graph, inverse-modulus ledgers, transport, replay, provenance, and local naming; it does not import a host inverse function, quotient operator equality, choice-selected preimages, Hahn–Banach separation, or ambient completeness outside the carried rows.

Definition 6961.1 (Banach inverse-mapping carrier)**.** *A* $\mathsf{BanachInverseMapping}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, F, I, M, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Banach}^{\uparrow}$ *row, including the displayed norm, metric, regular-Cauchy, complete-metric, and source-window ledgers used before an inverse request is admitted.*
2. *Y is the target* $\mathsf{Banach}^{\uparrow}$ *row, including the displayed norm, metric, regular-Cauchy, complete-metric, and target-window ledgers used by output-side consumers.*
3. *F is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *graph row from X to Y, carrying endpoint action, linearity, graph compatibility, norm-bound data, and bounded-operator provenance over the same endpoints.*
4. *I is the bijection and inverse-graph row: its injective side routes equal target observations through the source classifier of X, and its surjective side records target windows with displayed source preimage windows.*
5. *M is the inverse-modulus ledger. For each target tolerance and target-window row, it exposes a finite source tolerance, an operator-bound comparison, and the open-image or graph route needed before the inverse row is public.*

6. *H records componentwise* hsame *transport for X, Y, F, I, M and for the structural rows that carry inverse-modulus requests.*
7. *C records* Cont *replay from an inverse request through the source and target Banach rows, the bounded-linear graph, the bijection row, the inverse-modulus ledger, and the sibling graph and complete-metric routes.*
8. *P is the* Pkg *provenance over* $\mathsf{BanachInverseMapping}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{InverseMappingTheorem}^{\uparrow}$, $\mathsf{FrechetSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachInverseMapping}^{\uparrow}}$ *row.*

The carrier has no coordinate for an external inverse function, unrestricted operator quotient, selected source representative, nonconstructive open-map principle, or completeness datum not already displayed by X and Y.

Theorem 6961.2 (Banach inverse-mapping NameCert obligations)**.** *For an accepted* $\mathsf{BanachInverseMapping}^{\uparrow}$ *carrier $Q = (X, Y, F, I, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachInverseMapping}^{\uparrow}}$ *surface consists exactly of carrier admission for the complete source and target rows, bounded linear bijection graph exposure through F and I, inverse-modulus exposure through M, componentwise* hsame *transport through H,* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every inverse-facing consumer must read the same displayed X, Y, F, I, M rows before a bounded inverse row is public.*

Proof. Project the carrier. The source and target rows are X and Y, the bounded graph row is F, the bijection and inverse-graph row is I, and the inverse-modulus ledger is M.

The NameCert obligations are rowwise. Endpoint agreement requires F, I, and M to read the same Banach source and target rows. Transport by H preserves those endpoint rows, while replay by C exposes them in the order used by inverse-facing consumers.

The sibling routes do not add hidden coordinates. The Frechet and locally convex chapters provide neighbouring complete linear-topology reads, the fixed-point and continuous-map chapters provide endpoint and graph disciplines, and the complete-metric chapter supplies only the displayed completeness surface already present in X and Y.

Thus the local NameCert surface is exactly the finite route carried by Q. □

Theorem 6961.3 (Banach inverse-mapping complete source route)**.** *Every public read of a* $\mathsf{BanachInverseMapping}^{\uparrow}$ *inverse-modulus row must pass through the complete source row X and complete target row Y before it can inspect F, I, or M. In particular, a consumer cannot replace the Banach source route by a merely locally convex, Frechet, continuous-map, or fixed-point sibling route.*

Proof. The carrier definition places X and Y before the bounded graph, bijection, and inverse-modulus rows. Any replay of the inverse request through C therefore starts from the displayed Banach endpoints.

The sibling references are dependency routes rather than substitutes. $\mathsf{FrechetSpace}^{\uparrow}$ and $\mathsf{LocallyConvexSpace}^{\uparrow}$ can supply neighbouring linear-topology data, $\mathsf{ContinuousMap}^{\uparrow}$ can inspect graph continuity, and $\mathsf{BanachFixedPoint}^{\uparrow}$ can inspect fixed-point endpoints, but none of those rows contains both Banach endpoint completeness ledgers for this operator.

Hence an accepted inverse-modulus read must expose the complete source and target rows before it reaches F, I, or M. □

Theorem 6961.4 (Banach inverse-modulus non-escape)**.** *For an accepted* $\mathsf{BanachInverseMapping}^{\uparrow}$ *carrier, the inverse-modulus ledger* M *cannot be read as a host inverse or as a selected preimage function. It is public only as a finite route from target tolerance rows through* Y, I, F, X, H, C, P, N *to displayed source-window and operator-bound data.*

Proof. Start with the inverse-modulus row M. Its entries are tolerance requests, source windows, norm-bound comparisons, and graph or open-image handoffs; no entry is a host inverse function or an unrestricted selector.

Surjective information is carried by I and boundedness information by F. The ledger M can combine those rows only after the source and target Banach rows have been displayed, and transport and replay preserve that same finite order through H and C.

Finally P and N record provenance and local naming for the displayed route. Since the carrier has no coordinate for selected representatives or quotient operator equality, the inverse-modulus data cannot escape into a host inverse object. □

Falsifiable prediction: A consumer that reads a bounded inverse for a Banach bijection without passing through the displayed inverse-modulus row M is not reading an accepted $\mathsf{BanachInverseMapping}^{\uparrow}$ packet.

Independence witness: $\mathsf{FrechetSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, and $\mathsf{ContinuousMap}^{\uparrow}$ are non-bijective siblings for this packet: none alone carries the complete finite combination of Banach endpoints, bounded linear bijection graph, inverse-modulus ledger, transport, replay, provenance, and local NameCert data exposed by $\mathsf{BanachInverseMapping}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachInverseMapping}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BanachInverseMapping}^{\uparrow}$ packet is generated from complete Banach source and target rows, a bounded-linear graph, bijection and inverse-graph data, an inverse-modulus ledger, componentwise hsame transport, Cont replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachInverseMapping}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6961.1, Definition 6961.2, Definition 6961.3, and Definition 6961.4 seed the finite inverse-modulus route for displayed Banach bounded bijections.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachInverseMapping}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host inverse functions, quotient operator equality, selected preimages, Hahn–Banach separation, or inverse mapping for non-Banach carriers.

Upgrade path: Obligation closure requires checked carrier admission, endpoint agreement, bounded bijection graph exposure, inverse-modulus replay, transport stability, provenance, and non-escape for BEDC.Derived.BanachInverseMappingUp.

Chapter 6962

A Concrete Naming Certificate for $\mathsf{LocatedIntervalOrder}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedIntervalOrder}^{\uparrow}$ packet records comparison of located intervals by displayed endpoint windows and finite tolerance budgets, not by a host trichotomy principle for completed real endpoints. It sits beside the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located bisection route of chapter 1711. The packet gives Real and Completion consumers a Bishop-style interval comparison surface without importing classical order trichotomy, open-cover compactness, quotient equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6962.1 (LocatedIntervalOrder carrier)**.** *A* $\mathsf{LocatedIntervalOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, R, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *L is the left located-interval endpoint row, containing the displayed lower and upper endpoint windows for the first interval.*
2. *R is the right located-interval endpoint row, containing the displayed lower and upper endpoint windows for the second interval.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison-budget row, recording the finite dyadic tolerance at which the endpoint windows are compared.*
4. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *window schedule through which the two endpoint rows are inspected.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows, followed by the terminal* $\mathsf{Real}^{\uparrow}$ *seal used by Real-facing consumers.*
6. *H records componentwise* hsame *transport for L, R, D, S, Q and the structural rows.*
7. *C records displayed* Cont *replay of the comparison route through the same finite rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalOrder}^{\uparrow}}$ *row.*

The carrier has no coordinate for an exhaustive real-order decision, open-cover compactness, quotient equality of endpoint names, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6962.2 (LocatedIntervalOrder obligation surface)**.** *For an accepted* $\mathsf{LocatedIntervalOrder}^{\uparrow}$ *carrier* $O = (L, R, D, S, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the two endpoint rows, dyadic comparison-budget coverage, shared finite-window inspection, regular rational readback with terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every interval-order read must consume those rows before any downstream Real or Completion consumer may inspect the comparison.*

Proof. Project the carrier of Definition 6962.1. The only interval data available to the consumer are the two displayed endpoint rows L and R.

The comparison step is forced through D and S. The dyadic row supplies the finite tolerance budget, while the shared stream row records exactly which endpoint windows are inspected on both sides.

The readback and sealing step is forced through Q. Componentwise transport, replay, provenance, and local naming are then carried by H, C, P, N, and none of these structural rows adds a second order principle. Thus the local NameCert surface is exhausted by the displayed packet. □

Theorem 6962.3 (LocatedIntervalOrder bisection compatibility)**.** *Let* $O = (L, R, D, S, Q, H, C, P, N)$ *be an accepted* $\mathsf{LocatedIntervalOrder}^{\uparrow}$ *packet. If a* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *consumer refines either displayed interval endpoint row by a retained finite child interval, then the interval-order read remains valid exactly when the refined endpoint windows are replayed through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row* D*, shared* $\mathsf{StreamName}^{\uparrow}$ *window row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and structural rows* H, C, P, N*. The bisection handoff exports no selected infinite branch and no classical trichotomy of real endpoints.*

Proof. Begin with the accepted order packet and the displayed bisection refinement. The bisection route supplies only a finite retained-child row, so it can replace an endpoint window only by exhibiting the corresponding finite endpoint data.

Apply the obligation surface of Definition 6962.2. The order read still has to pass through D, S, Q after the refinement, because those rows are the only comparison budget, observation window, and readback route in the carrier.

Finally transport the refined endpoint row through H and replay the same route through C. Provenance and local naming remain P, N, so the bisection consumer receives a compatible finite comparison packet, not a hidden branch selector or a trichotomy witness. □

Theorem 6962.4 (LocatedIntervalOrder ledger exhaustion)**.** *The complete ledger of an accepted* $\mathsf{LocatedIntervalOrder}^{\uparrow}$ *packet is the finite route*

$$L, R, D, S, Q, H, C, P, N.$$

Every order-facing, bisection-facing, Real-facing, or Completion-facing consumer of the packet is exhausted by the displayed endpoint rows, dyadic comparison budget, shared stream window, regular rational readback, terminal seal, transport, replay, provenance, and local naming. No consumer may read trichotomy, open-cover compactness, quotient equality, selected limits, or $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Use the obligation surface to account for carrier admission, finite comparison budget, shared window inspection, readback, seal, transport, replay, provenance, and naming. These are exactly the rows listed in the carrier.

Use bisection compatibility for interval-refinement consumers. Any retained child interval must still replay through the same comparison-budget, window, readback, and structural rows.

The carrier contains no further coordinate. Therefore the ledger is exhausted by $L, R, D, S, Q, H, C, P, N$, and the excluded order, compactness, quotient, selected-limit, and completeness principles have no route into an accepted consumer read. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalOrder}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalOrder}^{\uparrow}$ packet is generated from two located endpoint rows, a DyadicRatCore comparison budget, a shared StreamName window, RegSeqRat readback with Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6962.1, Definition 6962.2, Definition 6962.3, and Definition 6962.4 seed the finite located interval comparison surface for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close trichotomy, open-cover compactness, quotient equality, selected limits, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic comparison-budget coverage, shared window inspection, readback and seal non-escape, bisection compatibility, transport, replay, provenance, and ledger exhaustion for BEDC.Derived.LocatedIntervalOrderUp.

Chapter 6963

A Concrete Naming Certificate for $\mathsf{ChoquetCapacity}^{\uparrow}$

Following Choquet and classical capacity theory, the $\mathsf{ChoquetCapacity}^{\uparrow}$ packet records finite capacity data over a compact measurable source without promoting the host outer-measure construction to a primitive. It sits beside the compact carrier of chapter 60, the measure interface of chapter 92, the Radon-measure route of chapter 2263, the Choquet-simplex boundary of chapter 6611, and the Choquet-integral consumer of chapter 6680. The packet names only displayed monotonicity, continuity-window, compact-exhaustion, polar-set, transport, replay, provenance, and local naming rows; it does not assert a host capacitability theorem, completed outer measure, quotient set algebra, countable-choice selector, or ambient measure completion.

Definition 6963.1 (Choquet capacity carrier)**.** *A* $\mathsf{ChoquetCapacity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, M, R, S, I, O, W, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *support row, exposing the compact source on which finite compact windows and exhaustion witnesses are read.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *measurable-event row, recording only the event family and finite value reads used by the capacity ledger.*
3. *R is the* $\mathsf{RadonMeasure}^{\uparrow}$ *regularity row, available when the capacity read is induced by a regular measure route.*
4. *S is the* $\mathsf{ChoquetSimplex}^{\uparrow}$ *sibling boundary row, recording that probability-boundary barycentric data are adjacent but not collapsed into capacity equality.*
5. *I is the* $\mathsf{ChoquetIntegral}^{\uparrow}$ *consumer row, recording that integral reads may consume the capacity only after the capacity rows are displayed.*
6. *O is the outer-approximation ledger, giving finite open-window majorants and compact-window minorants without introducing an outer-measure primitive.*
7. *W is the continuity-window ledger, recording finite monotonicity, continuity-from-below, and continuity-from-above checks on the displayed windows.*
8. *H records componentwise* hsame *transport for K, M, R, S, I, O, W and the local naming row.*

9. *C records displayed* Cont *replay from compact and measurable source rows into regularity, outer-approximation, continuity-window, integral-consumer, and local naming reads.*
10. *P is the* Pkg *provenance over* $\mathsf{ChoquetCapacity}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{ChoquetSimplex}^{\uparrow}$, $\mathsf{ChoquetIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoquetCapacity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, M, R, S, I, O, W, H, C, P, N$. It has no coordinate for a completed outer-measure algebra, a host capacitability theorem, selected analytic exhaustion, quotient equality of measurable sets, countable choice, or ambient measure completion.

Theorem 6963.2 (Choquet capacity obligation surface)**.** *For every accepted* $\mathsf{ChoquetCapacity}^{\uparrow}$ *carrier $Q = (K, M, R, S, I, O, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChoquetCapacity}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact, measure, Radon, Choquet-simplex boundary, Choquet-integral consumer, outer-approximation, continuity-window, transport, replay, provenance, and local naming rows; monotonicity exposure through W; compact-window accountability through K, O; measure and Radon regularity exposure through M, R; sibling separation through S, I; and structural preservation through H, C, P, N.*

Proof. Project the accepted packet $Q = (K, M, R, S, I, O, W, H, C, P, N)$. The compact source row K and measurable-event row M give the finite source surface on which a capacity can be read.

Use R, O, W for the capacity-specific obligations. The Radon row supplies the regular-measure route when present, the outer-approximation ledger gives displayed majorants and minorants, and the continuity-window ledger records monotonicity and finite continuity checks.

The rows S and I keep the adjacent Choquet simplex and Choquet integral routes visible without identifying either one with the capacity carrier. Thus barycentric probability data and integral readback remain sibling or consumer surfaces rather than hidden components of the classifier.

Finally H, C, P, N transport, replay, source, and name the same displayed rows. Since the carrier has no completed outer-measure algebra, host capacitability theorem, quotient set equality, selected exhaustion, choice schedule, or ambient measure-completion coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6963.3 (Choquet capacity consumer handoff)**.** *Every* $\mathsf{ChoquetIntegral}^{\uparrow}$ *or* $\mathsf{ChoquetSimplex}^{\uparrow}$ *consumer of an accepted* $\mathsf{ChoquetCapacity}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{Compact}^{\uparrow}, \mathsf{Measure}^{\uparrow} \longmapsto \mathsf{RadonMeasure}^{\uparrow} \longmapsto O, W \longmapsto \mathsf{ChoquetCapacity}^{\uparrow} \longmapsto \mathsf{ChoquetIntegral}^{\uparrow}, \mathsf{ChoquetSimplex}^{\uparrow}.$$

The exported row is a displayed capacity handoff over compact and measurable windows. It is not an outer-measure primitive, a host capacitability theorem, a quotient event algebra, a selected representing measure, or an ambient completion principle.

Proof. Start with K and M. They expose the compact source and measurable-event surface before any capacity value or consumer route is available.

Next read R, O, W. The regularity row, outer-approximation ledger, and continuity-window ledger provide the finite capacity evidence; none of these rows selects an external exhaustion or invokes a completed outer measure.

Only then may a consumer reach I or compare with the sibling boundary S. The structural rows H, C, P, N preserve exactly that route, so the public handoff cannot bypass the compact, measure, Radon, approximation, and continuity rows. □

Falsifiable prediction: Every accepted $\mathsf{ChoquetCapacity}^{\uparrow}$ public read exposes Compact, Measure, RadonMeasure, outer-approximation, continuity-window, ChoquetIntegral, ChoquetSimplex, transport, replay, provenance, and local NameCert rows before any capacity consumer is public.

Independence witness: compact, measure, radon-measure, choquet-simplex, choquet-integral: no listed sibling supplies the joint finite capacity packet containing compact source, measurable-event, Radon regularity, outer-approximation, continuity-window, integral-consumer, simplex-boundary, transport, replay, provenance, and local NameCert rows while refusing outer-measure primitives, host capacitability, quotient set equality, selected exhaustion, countable choice, and ambient measure completion.

Closure status for $\mathsf{NameCert}_{\mathsf{ChoquetCapacity}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoquetCapacity}^{\uparrow}$ packet is generated from Compact, Measure, RadonMeasure, ChoquetSimplex, ChoquetIntegral, outer-approximation, continuity-window, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoquetCapacity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6963.1, Definition 6963.2, and Definition 6963.3 seed the finite capacity route over compact source rows, measurable-event rows, Radon regularity, outer approximations, continuity windows, Choquet integral consumers, Choquet simplex boundaries, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoquetCapacity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host capacitability theorem, outer-measure completion, quotient event equality, selected analytic exhaustion, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window accountability, measure and Radon exposure, outer-approximation and continuity-window routing, sibling separation, transport, replay, provenance, and local naming for BEDC.Derived.ChoquetCapacityUp.

Chapter 6964

A Concrete Naming Certificate for $\mathsf{RegularCauchyConstant}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyConstant}^{\uparrow}$ packet records the constant regular Cauchy name generated from one $\mathsf{DyadicRatCore}^{\uparrow}$ row through $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and a $\mathsf{Real}^{\uparrow}$ seal. It sits beside the dyadic row of chapter 291, the finite windows of chapter 126, the regular rational handoff of chapter 301, the terminal real seal of chapter 38, and the algebraic sum route of chapter 417.

Definition 6964.1 (Regular Cauchy constant carrier)**.** *A* $\mathsf{RegularCauchyConstant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, E, R, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the source* $\mathsf{DyadicRatCore}^{\uparrow}$ *row that supplies the single dyadic value, scale, and comparison ledger.*
2. *W is the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule that repeats the same dyadic source through every displayed finite window.*
3. *E is the repeated dyadic observation ledger, recording that each visible window reads the source row D rather than a moving sequence of host rationals.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the constant stream windows and the repeated dyadic ledger.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, W, E, R have been displayed.*
6. *H stores componentwise* hsame *transport for the dyadic source, constant window schedule, observation ledger, regular readback, Real seal, continuation row, provenance, and local naming.*
7. *C stores displayed* Cont *replay from the dyadic source to each constant window, from the windows to the regular readback, and from the readback to the Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyConstant}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyConstant}^{\uparrow}}$ *row.*

The classifier compares accepted constant-name carriers only through these nine rows. It contains no coordinate for quotient streams, selected host limits, host equality, countable choice, or ambient completeness.

Theorem 6964.2 (Regular Cauchy constant NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyConstant}^{\uparrow}$ *carrier* $K = (D, W, E, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyConstant}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed nine-row packet;*
2. *constant-window exactness, stating that every displayed* $\mathsf{StreamName}^{\uparrow}$ *window in* W *reads the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row* D*;*
3. *repeated-observation exactness, stating that* E *records no observation outside the dyadic source and its visible windows;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *regularity handoff, stating that* R *is read from* D, W, E *before any Real-facing seal is available;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, stating that* S *exports no quotient stream, selected limit, host equality, countable-choice row, or ambient completeness witness;*
6. *componentwise transport, replay, provenance, and local naming for* H, C, P, N*.*

Proof. Project the carrier of Definition 6964.1. The dyadic source, constant window schedule, repeated observation ledger, regular readback, Real seal, transport, continuation, provenance, and local naming rows are exactly the classifier-visible coordinates.

The constant-window obligation follows by reading W only through the source row D. The observation ledger E then records repeated readings of the same dyadic value, so no moving host sequence or off-carrier rational stream is introduced.

The regular handoff is the next displayed row. Since R is available only after D, W, E have been read, any Real-facing consumer must pass through the regular rational readback before reaching S.

The transport, replay, provenance, and naming rows preserve this same nine-row packet. Because the carrier has no quotient, selected-limit, host-equality, choice, or completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 6964.3 (Regular Cauchy constant Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyConstant}^{\uparrow}$ *carrier* $K = (D, W, E, R, S, H, C, P, N)$ *reads the dyadic source* D*, constant window schedule* W*, repeated dyadic observation ledger* E*, regular readback* R*, Real seal* S*, componentwise transport* H*, replay row* C*, provenance* P*, and local naming row* N*. The consumer receives no quotient stream, selected limit, host equality, or ambient completeness.*

Proof. Begin with a Real-facing consumer and project the accepted carrier. The only source value available is the dyadic row D, and the only sequence-facing schedule is the constant $\mathsf{StreamName}^{\uparrow}$ row W.

The repeated observation ledger E records the finite window reads of D, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is read back from those displayed observations. The continuation row C replays this route without inserting an additional stream or limit selector.

The seal row S is reached only after D, W, E, R have been displayed. Transport through H and provenance through P preserve the same packet, while N records the local naming boundary.

Thus every Real-facing read factors through $D, W, E, R, S, H, C, P, N$. Since the carrier has no quotient stream, selected limit, host equality, or ambient completeness row, none is exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyConstant}^{\uparrow}}$**.**

Constructive story: A RegularCauchyConstant$^{\uparrow}$ packet is generated from one DyadicRatCore source row, a constant StreamName schedule, repeated dyadic observations, RegSeqRat readback, RealUp seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyConstant}^{\uparrow}}$, seed)

Scope closed: Definition 6964.1, Definition 6964.2, and Definition 6964.3 declare the finite carrier, its local NameCert obligations, and the Real seal handoff boundary for constant regular Cauchy names.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyConstant}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, host real equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Formal closure requires a Lean carrier and checked NameCert obligations for the same constant regular Cauchy packet.

Chapter 6965

Bishop Real Window NameCert Construction

Following Bishop–Bridges constructive real analysis, the $\mathsf{BishopRealWindow}^{\uparrow}$ packet records the finite rational windows through which a regular real name is inspected before a Real or Completion consumer reaches a terminal seal. It sits over the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite readback interface for one displayed real-name route; it is not quotient equality of real names, a selected limit, a choice schedule, or an ambient completeness principle.

Definition 6965.1 (Bishop real window carrier)**.** *A* $\mathsf{BishopRealWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected prefix and request schedule.*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from the displayed window.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the rational cells, endpoint budgets, and comparison slack used by the window.*
4. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after* S, R, D *have been replayed.*
5. H *records componentwise* hsame *transport for the window, readback, tolerance, seal, provenance, and local naming rows.*
6. C *records displayed* Cont *replay from the finite window through regular rational readback and dyadic comparison into the Real seal.*
7. P *is the* Pkg *provenance over* $\mathsf{BishopRealWindow}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. N *is the local* $\mathsf{NameCert}_{\mathsf{BishopRealWindow}^{\uparrow}}$ *row naming exactly this finite rational-window packet.*

The classifier compares accepted packets only through S, R, D, E, H, C, P, N*. It has no coordinate for quotient stream equality, selected real representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6965.2 (Bishop real window finite readback)**.** *For every accepted* $\mathsf{BishopRealWindow}^{\uparrow}$ *carrier* $W = (S, R, D, E, H, C, P, N)$*, every Real or Completion-facing finite rational-window read factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Equivalently, the consumer-visible rows are exactly S, R, D, E, H, C, P, N*: the inspected StreamName window is read as a regular rational sequence, checked against the dyadic tolerance ledger, transported and replayed through the local structural rows, and only then exposed as a Real seal.*

Proof. Project the carrier of Definition 6965.1. The only source window is S, the only regular rational readback is R, and the only tolerance ledger is D.

Read the route in order. A finite request first inspects the $\mathsf{StreamName}^{\uparrow}$ row S; the same displayed entries are then read through R as regular rational data; the dyadic comparisons required by the requested rational window are accounted for in D.

The rows H and C transport and replay that same finite route before the provenance and naming rows P, N admit the packet. The terminal row E is therefore exposed only after the window, readback, and dyadic ledger have all been displayed.

Since the carrier has no coordinate for quotient equality, selected limits, choice, host real equality, or ambient completeness, no consumer can obtain a second Real-facing read outside the displayed finite-window projection and regular-rational readback. □

Theorem 6965.3 (Bishop real window NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealWindow}^{\uparrow}$ *carrier* $W = (S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRealWindow}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the finite packet* W*;*
2. $\mathsf{StreamName}^{\uparrow}$ *window locality through* S*;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback through* R*;*
4. $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and rational-cell exactness through* D*;*
5. $\mathsf{Real}^{\uparrow}$ *seal ordering through* E*, together with componentwise transport, displayed replay, provenance, and local naming through* H, C, P, N*.*

No additional NameCert obligation is exported for quotient real equality, selected representatives, choice schedules, host real equality, or ambient completeness.

Proof. Carrier admission is the finite packet displayed in Definition 6965.1. Each listed row is one of its coordinates, so the local name can inspect it directly.

The obligation order follows the readback theorem Definition 6965.2. The window row supplies the inspected finite data, the regular rational row supplies the readback, the dyadic row supplies the tolerance evidence, and the Real row is exposed only at the end of that route.

The structural rows H, C, P, N preserve and name the same displayed packet. Because the forbidden objects are not carrier coordinates, they cannot create extra NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{BishopRealWindow}^{\uparrow}$ consumer can be audited by checking that its Real-facing read first displays a $\mathsf{StreamName}^{\uparrow}$ finite window, then a $\mathsf{RegSeqRat}^{\uparrow}$ readback, then a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopRealWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite window, regular rational readback,

dyadic tolerance ledger, Real seal, componentwise transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealWindow}^{\uparrow}$ packet is generated from a StreamName finite-window row, a RegSeqRat regular rational readback row, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6965.1, Definition 6965.2, and Definition 6965.3 seed the finite rational-window readback route from L10 StreamName and RegSeqRat data to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of real names, selected limits, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName locality, RegSeqRat readback, DyadicRatCore tolerance exactness, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealWindowU

Chapter 6966

A Concrete Naming Certificate for $\mathsf{FractionalIdeal}^{\uparrow}$

Following Atiyah–Macdonald and Bourbaki on fractional ideals in number fields and Dedekind domains, the $\mathsf{FractionalIdeal}^{\uparrow}$ packet records the standard carrier that sits between the ordinary ideal surface and the ideal-class quotient surface. It reads the ambient ring from chapter 43, the ideal rows from chapter 81, the Dedekind-domain source from chapter 172, the number-field carrier from chapter 168, and the ring-of-integers boundary from chapter 169. It supplies the carried endpoints consumed by chapter 170.

Definition 6966.1 (Fractional ideal carrier)**.** *A* $\mathsf{FractionalIdeal}^{\uparrow}$ *carrier over a displayed Dedekind source is a finite* BHist *packet*

$$F = (R, I, D, K, O, P_0, Q, H, C, P, N)$$

with the following rows:

1. *R is the ambient* $\mathsf{Ring}^{\uparrow}$ *row and its multiplicative compatibility data.*
2. *I is the ordinary* $\mathsf{Ideal}^{\uparrow}$ *row that records additive closure and absorption over R.*
3. *D is the* $\mathsf{Dedekind}^{\uparrow}$ *source row, including the Noetherian, integrally closed, and nonzero-prime boundary used by the packet.*
4. *K is the* $\mathsf{NumField}^{\uparrow}$ *fraction-field row through which denominators are read.*
5. *O is the* $\mathsf{RingOfIntegers}^{\uparrow}$ *row that ties the integral carrier back to the number-field source.*
6. *P_0 is the principal fractional-ideal row, recording principal generators and the principal-equivalence boundary later consumed by* $\mathsf{IdealClass}^{\uparrow}$*.*
7. *Q is the denominator-clearance ledger, naming a nonzero denominator row whose multiplication carries the fractional endpoint back into the displayed* $\mathsf{Ideal}^{\uparrow}$ *surface.*
8. *H stores componentwise* hsame *transport for all rows above.*
9. *C stores displayed* Cont *replay for denominator clearance, principal-row reads, and ordinary ideal reads.*
10. *P is the* Pkg *provenance over* $\mathsf{FractionalIdeal}^{\uparrow}$*,* $\mathsf{Ring}^{\uparrow}$*,* $\mathsf{Ideal}^{\uparrow}$*,* $\mathsf{Dedekind}^{\uparrow}$*,* $\mathsf{NumField}^{\uparrow}$*,* $\mathsf{RingOfIntegers}^{\uparrow}$*, principal fractional ideals, denominator-clearance rows,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{FractionalIdeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, I, D, K, O, P_0, Q, H, C, P, N$. It has no coordinate for a detached fraction-field subset, a host localization object, quotient equality of fractional ideals, selected generators for arbitrary ideals, or an ambient algebraic-number-theory oracle.

Theorem 6966.2 (Fractional ideal NameCert obligations)**.** *For every accepted* $\mathsf{FractionalIdeal}^{\uparrow}$ *carrier $F = (R, I, D, K, O, P_0, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FractionalIdeal}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed ring, ideal, Dedekind, number-field, ring-of-integers, principal-row, denominator-clearance, transport, replay, provenance, and local naming rows; denominator-clearance exactness through Q; principal-row visibility through P_0; componentwise* hsame *transport through H; displayed* Cont *replay through C; and* Pkg *provenance through P.*

Proof. Project the carrier of Definition 6966.1. The algebraic source rows R, I, D, K, O display the ambient ring, ordinary ideal, Dedekind, number-field, and ring-of-integers data before any fractional endpoint can be read.

The principal row P_0 and the denominator-clearance ledger Q provide the two fractional-ideal specific fields. The first records the principal endpoints used by the later quotient classifier, and the second records the finite denominator operation that returns the endpoint to the ordinary ideal surface.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no detached fraction-field subset, host localization object, quotient equality, or generator-choice coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 6966.3 (Fractional ideal Dedekind handoff)**.** *Every* $\mathsf{IdealClass}^{\uparrow}$ *read of a fractional endpoint factors first through the* $\mathsf{FractionalIdeal}^{\uparrow}$ *carrier of Definition 6966.1: the* $\mathsf{Ring}^{\uparrow}$ *source of chapter 43, the* $\mathsf{Ideal}^{\uparrow}$ *surface of chapter 81, the* $\mathsf{Dedekind}^{\uparrow}$ *source of chapter 172, the* $\mathsf{NumField}^{\uparrow}$ *carrier of chapter 168, the* $\mathsf{RingOfIntegers}^{\uparrow}$ *boundary of chapter 169, principal fractional-ideal rows, denominator-clearance rows, and the structural* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. Thus chapter 170 receives carried fractional endpoints and principal-boundary evidence, not a host quotient of detached representatives.*

Proof. Begin with the NameCert obligations of Definition 6966.2. They force every accepted fractional endpoint to expose the Dedekind, number-field, ring-of-integers, ordinary ideal, principal, and denominator-clearance rows before the endpoint can be named.

The IdealClass consumer then reads only the principal-boundary row and the carried endpoint row. Multiplication, inverse, identity, and principal equivalence can be routed through those displayed rows, while the structural rows preserve the same provenance under transport and replay.

Therefore an ideal-class packet cannot bypass $\mathsf{FractionalIdeal}^{\uparrow}$ by reading a detached fraction-field subset, a host localization, quotient equality of representatives, or selected generators. The handoff is exactly the finite Dedekind fractional-ideal route named above. □

Falsifiable prediction: Every $\mathsf{IdealClass}^{\uparrow}$ endpoint read factors through a $\mathsf{FractionalIdeal}^{\uparrow}$ carrier with displayed Ring, Ideal, Dedekind, NumField, RingOfIntegers, principal fractional-ideal, denominator-clearance, hsame, Cont, Pkg, and NameCert rows.

Independence witness: ring, ideal, dedekind, numfield, ring-of-integers, idealclass: $\mathsf{FractionalIdeal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries ordinary ideal data, fraction-field denominator clearance, principal fractional-ideal rows, and the structural handoff consumed by IdealClass.

Closure status for $\mathsf{NameCert}_{\mathsf{FractionalIdeal}^{\uparrow}}$.

Constructive story: A $\mathsf{FractionalIdeal}^{\uparrow}$ packet is generated from displayed Ring, Ideal, Dedekind, NumField, RingOfIntegers, principal fractional-ideal, denominator-clearance, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FractionalIdeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6966.1, Definition 6966.2, and Definition 6966.3 bind the finite fractional-ideal carrier consumed by IdealClass.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FractionalIdeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a public standard bridge, Lean verification, quotient equality of fractional ideals, a host localization object, or selected generators for arbitrary ideals.

Upgrade path: Obligation closure requires checked carrier admission, denominator-clearance exactness, principal-row visibility, and the Dedekind-to-IdealClass handoff for BEDC.Derived.FractionalIdealUp.

Chapter 6967

A Concrete Naming Certificate for $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$

Following Brunn and Minkowski on convex-body volume comparison, the $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$ packet records the finite dyadic-grid surface on which a Brunn–Minkowski style read can be inspected before any host measure theory or arbitrary compact-convex-body theorem is invoked. It sits beside the real-name boundary of chapter 38, the compact source of chapter 60, the convex-set row of chapter 208, the polytope carrier of chapter 209, and the metric-distance interface of chapter 57. The packet names a finite grid certificate for displayed convexity and volume-proxy comparison; it is not general measure theory, not Lebesgue volume, not arbitrary compact convex bodies, and not a quotient equality of subsets.

Definition 6967.1 (Finite Brunn–Minkowski grid carrier)**.** *A* $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, A, B, S, L, V, W, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite dyadic grid row. It lists the inspected dyadic coordinate cells, their metric adjacency data, and the endpoint comparisons read through* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*.*
2. *A and B are the two displayed convex-grid subsets. Each row records membership decisions only for cells in K, with the convexity checks routed through* $\mathsf{ConvexSet}^{\uparrow}$ *and the finite polytope faces routed through* $\mathsf{Polytope}^{\uparrow}$*.*
3. *S is the grid Minkowski-sum classifier. For each displayed cell of K, it records whether that cell is admitted by a visible pair of cells from A and B under the finite addition table of the grid.*
4. *L is the compact bounding row, naming the finite bounding window supplied by* $\mathsf{Compact}^{\uparrow}$ *before any grid count is consumed.*
5. *V is the finite cardinal and volume-proxy ledger. It stores the displayed cell counts for A, B, and S, the common cell-volume scale, and the dyadic comparison rows used by the requested Brunn–Minkowski read.*
6. *W is the public comparison row. It exposes only the finite grid inequality request generated from K, A, B, S, L, V.*
7. *H records componentwise* hsame *transport for the grid, subset rows, sum classifier, compact bound, volume-proxy ledger, comparison row, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay from a requested finite-grid comparison through K, A, B, S, L, V, W.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, A, B, S, L, V, W, H, C, P, N$. It has no coordinate for Lebesgue measure, arbitrary compact convex bodies, host subset equality, quotient completion, selected limits, countable choice, or ambient completeness.

Theorem 6967.2 (Finite Brunn–Minkowski grid NameCert obligations)**.** *For every accepted* $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$ *carrier*

$$G = (K, A, B, S, L, V, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}}$ *surface consists exactly of finite dyadic-grid admission, displayed convex-subset admission for A and B, grid Minkowski-sum classification through S, compact bounding through L, finite cardinal and volume-proxy accounting through V, public comparison exposure through W, componentwise transport, displayed replay, package provenance, local naming, and non-escape from the displayed rows.*

Proof. Project the carrier of Definition 6967.1. The geometric rows are exactly the grid row K, the displayed subset rows A, B, the grid sum classifier S, the compact bounding row L, and the finite ledger rows V, W.

The certificate first fixes the finite grid. Metric adjacency and real endpoint comparisons are read through K, while A and B expose only those convex and polytope checks whose cells occur in that displayed grid.

The sum classifier is then determined inside the same finite table. The row S stores the visible pair witnesses for admitted sum cells, and L keeps the comparison inside the displayed compact bounding window.

Finally the ledger V records cardinal counts and the common dyadic cell-volume scale before W exposes the public comparison row. The structural rows H, C, P, N transport, replay, source, and name the same finite surface, so no measure-theoretic, quotient, choice, selected-limit, or ambient-completeness datum is exported. □

Theorem 6967.3 (Finite Brunn–Minkowski grid comparison route)**.** *Every public comparison read exported by an accepted* $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$ *packet factors through the finite route*

$$K, A, B \longmapsto S \longmapsto L, V \longmapsto W \longmapsto H, C, P, N.$$

Thus the consumer receives a dyadic grid, two displayed convex-grid subsets, a finite Minkowski-sum classifier, a compact bounding window, a finite cardinal and volume-proxy ledger, and structural transport/replay rows before it reads the comparison boundary. It receives no general measure theory, no arbitrary compact-convex-body volume, no host subset equality, and no bridge-checked standard theorem.

Proof. Begin with an accepted packet $G = (K, A, B, S, L, V, W, H, C, P, N)$. The carrier lists no comparison row before the grid, subset, and finite sum-classifier rows have been displayed.

The compact and volume-proxy rows are also forced. The bounding row L supplies the finite compact window, while V supplies the only cardinal counts, cell-volume scale, and dyadic comparison rows available to the packet.

The public row W is therefore downstream of K, A, B, S, L, V. Componentwise hsame transport and displayed Cont replay carry exactly those rows through H and C, and P, N only source and name the same packet.

Since no carrier coordinate stores Lebesgue measure, arbitrary convex-body volume, quotient subset equality, selected limits, choice, or ambient completeness, the exported comparison cannot use such data. □

Falsifiable prediction: Every accepted $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$ comparison read displays a finite dyadic grid, two convex-grid subset rows, a grid Minkowski-sum classifier, a compact bounding row, a finite cardinal and volume-proxy ledger, a public comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before it is consumed.

Independence witness: real, compact, convexset, polytope, metric: $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite dyadic grid, two convex-grid subset rows, a Minkowski-sum classifier, compact bounding data, cardinal and volume-proxy ledgers, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}$ packet is generated from a finite dyadic grid, two displayed convex-grid subset rows, a finite Minkowski-sum classifier, compact bounding data, finite cardinal and volume-proxy ledgers, a public comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6967.1, Definition 6967.2, and Definition 6967.3 seed the finite dyadic-grid convexity and volume-proxy certificate over $\mathsf{Real}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteBrunnMinkowskiGrid}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general measure theory, Lebesgue volume, arbitrary compact convex bodies, host subset equality, quotient completion, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, grid exactness, convex-grid membership routing, Minkowski-sum classifier soundness, compact-bound routing, finite ledger non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteBrunnMinkowskiGridUp.

Chapter 6968

A Concrete Naming Certificate for $\mathsf{CauchyProductSeries}^{\uparrow}$

Following Hardy on products of convergent series and Bishop–Bridges on constructive Cauchy reals, the $\mathsf{CauchyProductSeries}^{\uparrow}$ packet records the finite BEDC route by which two displayed regular Cauchy series expose a product-series window. It sits over the dyadic arithmetic core of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite product route of chapter 2009. The packet names only finite convolution windows, tolerance budgets, transport, replay, provenance, and local certificate rows; it does not import a host theorem about infinite products of series.

Definition 6968.1 (Cauchy product series carrier)**.** *A* $\mathsf{CauchyProductSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, W, C, D, F, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *L and R are the two source series packets, each exposing only inspected* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *coefficient windows.*
2. *W is the finite window row naming the visible output indices and the paired source prefixes required for those indices.*
3. *C is the convolution ledger. For each displayed output index it records the finite diagonal sum of products of visible source coefficients.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row, carrying the requested precision, product slack, diagonal-sum slack, and comparison allowances.*
5. *F is the* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *row used for each displayed coefficient product before the finite diagonal sum is read.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the product-series window after the convolution and dyadic budget rows have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available to a downstream real or completion consumer only after Q has been read.*
8. *H records componentwise* hsame *transport for the source, window, convolution, budget, finite-product, readback, seal, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from source windows into coefficient products, from coefficient products into convolution rows, and from convolution rows through budgeted readback into the seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyProductSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, RegularCauchyFiniteProd BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductSeries}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the rows $L, R, W, C, D, F, Q, E, H, T, P, N$. It has no coordinate for an unconditional rearrangement theorem, absolute convergence, analytic continuation, quotient stream equality, host multiplication of completed series, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductSeriesUp.CauchyProductSeriesTasteGate single carrier alignment`

Theorem 6968.2 (Cauchy product regular convolution closure)**.** *For every accepted* $\mathsf{CauchyProductSeries}^{\uparrow}$ *carrier $K = (L, R, W, C, D, F, Q, E, H, T, P, N)$, each displayed output window is a regular convolution window over the two source series packets. More precisely, reading Q for an output index visible in W factors through the finite diagonal entries listed in C, the coefficient-product rows listed in F, and the tolerance budget D before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback can be exported.*

Proof. Project the carrier of Definition 6968.1. The only source rows are L and R, and the only output indices visible to the packet are the indices named by W.

Proceed by induction over the finite window row W. The empty window exports no readback. For a successor window, the next output index exposes a finite diagonal list in C; each diagonal entry first reads the corresponding two source coefficients from L and R, then routes their product through the matching $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ cell in F.

The dyadic row D supplies the slack used to add the finitely many product reads in the displayed diagonal. The result is recorded in Q, and the seal E is downstream of that readback.

Rows H, T, P, N transport, replay, source, and name the same route. Since the route has no further coordinate, no host convolution theorem, quotient-series equality, selected limit, or rearrangement principle can be exported by this closure claim. □

Theorem 6968.3 (Cauchy product series NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductSeries}^{\uparrow}$ *carrier $K = (L, R, W, C, D, F, Q, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductSeries}^{\uparrow}}$ *surface consists exactly of carrier admission, two-source series exposure, finite output-window admission, convolution-ledger exposure, dyadic tolerance-budget exposure, finite coefficient-product routing, regular rational readback, terminal real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Read the rows of Definition 6968.1. Carrier admission exposes the tuple K, while L, R, W, C, D, F, Q, E give the data rows available to a consumer.

The certificate surface is exhausted by projection. A read of a source coefficient must pass through L or R; a read of a product coefficient must pass through F; a read of a diagonal convolution must pass through C and D; and a read of the resulting regular sequence must pass through Q before the terminal seal E is available.

The remaining rows are structural. The row H gives componentwise transport, T gives displayed replay, P records provenance, and N names the packet. No other row is present, so the local certificate cannot certify unconditional rearrangement, absolute convergence, analytic continuation, quotient stream equality, host completed-series multiplication, or ambient completeness. □

Theorem 6968.4 (Cauchy product dyadic budget stability)**.** *Let $K = (L, R, W, C, D, F, Q, E, H, T, P, N)$ be an accepted* $\mathsf{CauchyProductSeries}^{\uparrow}$ *carrier. Any refinement of the displayed output window that preserves the source windows, coefficient-product rows, convolution ledger, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget preserves the exported* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route and the downstream* $\mathsf{Real}^{\uparrow}$ *seal route.*

Proof. Start with the accepted packet and a refined finite window. The preservation hypothesis keeps the source rows L, R, coefficient-product row F, convolution ledger C, and dyadic budget row D componentwise aligned through the transport row H.

Induct over the refined window. The base window reads the same empty or initial convolution prefix. In the successor step, the new output index uses the same finite diagonal source reads, the same finite-product cells, and the same dyadic slack ledger as the original route.

The replay row T then gives the same displayed continuation from the refined convolution data into Q. Once Q is preserved, the seal row E remains downstream of the same readback route.

Thus refinement can add inspected finite data, but it cannot replace the budgeted convolution route by a host equality, selected limit, quotient representative, absolute-convergence argument, or analytic continuation step. □

Falsifiable prediction: An accepted $\mathsf{CauchyProductSeries}^{\uparrow}$ read is refuted if a product-series output window is consumed without first displaying the two source series packets, the finite output window, the convolution ledger, the DyadicRatCore tolerance budget, the RegularCauchyFiniteProduct coefficient-product rows, the RegSeqRat readback, the RealUp seal, transport, replay, provenance, and local NameCert rows.

Independence witness: dyadicratcore, regseqrat, real, regular-cauchy-finite-product: $\mathsf{CauchyProductSeries}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two source series packets, finite convolution windows, dyadic tolerance budgets, finite coefficient-product rows, regular readback, RealUp sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductSeries}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyProductSeries}^{\uparrow}$ packet is generated from two source series packets, finite output windows, convolution ledgers, DyadicRatCore tolerance budgets, RegularCauchyFiniteProduct coefficient-product rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6968.1, Definition 6968.2, Definition 6968.3, and Definition 6968.4 seed the finite Cauchy product-series route over source series windows, convolution ledgers, dyadic budgets, finite-product coefficient rows, regular readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductSeries}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchyProductSeriesUp`

Bridge status: none

Not claimed: This chapter does not close unconditional rearrangement, absolute convergence, analytic continuation, host quotient series equality, selected infinite sums, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-source series exposure, finite convolution-window induction, dyadic tolerance-budget stability, RegularCauchyFiniteProduct coefficient-product routing, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductSeriesUp.

Chapter 6969

A Concrete Naming Certificate for $\mathsf{MoserIteration}^{\uparrow}$

Following Moser's iteration method in elliptic and parabolic regularity theory, the $\mathsf{MoserIteration}^{\uparrow}$ packet records the finite ladder by which Sobolev control, Poincare control, cutoff schedules, and exponent-step estimates are replayed before any Harnack-style consumer reads a regularity bound. It sits beside the Sobolev source of chapter 440, the Poincare control row of chapter 2329, the Morrey endpoint comparison of chapter 4005, and the terminal scalar seal of chapter 38. The packet names only displayed finite rows; it is not a host PDE theorem, not a selected weak solution, not an ambient compactness argument, and not a quotient equality of function spaces.

Definition 6969.1 (Moser iteration carrier)**.** *A* $\mathsf{MoserIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, P, J, E, R, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, including the finite energy and embedding data used by the ladder.*
2. *P is the* $\mathsf{PoincareInequality}^{\uparrow}$ *control row, recording the local oscillation and average-control estimates consumed at each step.*
3. *J is the cutoff schedule row, listing the displayed nested regions, cutoff names, and support restrictions before any estimate is read.*
4. *E is the exponent-step ledger, recording the finite sequence of exponent raises, constants, and admissible handoffs from one step to the next.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *bound readback row, sealing the scalar constants and endpoint bounds only after S, P, J, E have been displayed.*
6. *H records componentwise* hsame *transport for the Sobolev, Poincare, cutoff, exponent, Real-bound, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the same ladder for regularity and Harnack-style consumers.*
8. *Q is the* Pkg *provenance over* $\mathsf{MoserIteration}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{PoincareInequality}^{\uparrow}$, $\mathsf{MorreyInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MoserIteration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, P, J, E, R, H, C, Q, N$. It has no coordinate for a host solution space, a selected PDE solution, global elliptic regularity, parabolic compactness, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.MoserIterationUp`

Theorem 6969.2 (Moser iteration NameCert obligations)**.** *For every accepted* $\mathsf{MoserIteration}^{\uparrow}$ *carrier $M = (S, P, J, E, R, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MoserIteration}^{\uparrow}}$ *surface consists exactly of Sobolev source exposure through S; Poincare control through P; cutoff schedule exposure through J; exponent-step ledger exposure through E; Real-bound readback through R; componentwise transport through H; displayed replay through C; provenance through Q; and local naming through N.*

Proof. Project the carrier of Definition 6969.1. The rows $S, P, J, E, R, H, C, Q, N$ are exactly the Sobolev, Poincare, cutoff, exponent, Real-bound, transport, replay, provenance, and naming coordinates.

The analytic estimates are read in order. Sobolev and Poincare rows provide the source inequalities, the cutoff schedule restricts each local read, and the exponent-step ledger records the finite ladder before the Real-bound row seals constants or endpoints.

Finally H, C, Q, N preserve, replay, source, and name the same displayed packet. Since the carrier has no coordinate for a selected PDE solution, host regularity theorem, function-space quotient, choice schedule, or ambient completeness principle, the listed rows exhaust the local NameCert surface. □

Theorem 6969.3 (Moser iteration Harnack handoff)**.** *Every Harnack-style consumer of an accepted* $\mathsf{MoserIteration}^{\uparrow}$ *packet must first read the Sobolev source row S, the Poincare control row P, the cutoff schedule J, the exponent-step ledger E, the* $\mathsf{Real}^{\uparrow}$ *bound readback R, and the structural rows H, C, Q, N. The handoff supplies a finite regularity ladder for downstream Harnack inequality packets; it exports no host Harnack theorem, selected solution, quotient function equality, countable choice, open-cover compactness proof, or ambient real completeness theorem.*

Proof. Begin with Definition 6969.2. It fixes the accepted packet to the finite rows $S, P, J, E, R, H, C, Q, N$ and leaves no coordinate for a detached PDE theorem or selected solution.

The Harnack-facing read then consumes the ladder in the displayed order. The Sobolev and Poincare rows provide the source estimates, the cutoff schedule localizes the read, and the exponent-step ledger records the finite climb before any endpoint bound is sealed in R.

The structural rows complete the handoff. Componentwise transport, replay, provenance, and local naming preserve the same finite packet for downstream consumers. Therefore a Harnack-style packet receives only the displayed regularity ledger and cannot import the refused host, quotient, choice, compactness, or completeness endpoints. □

Falsifiable prediction: Every accepted Harnack-style read of $\mathsf{MoserIteration}^{\uparrow}$ must expose the Sobolev source, Poincare control, cutoff schedule, exponent-step ledger, Real-bound readback, transport, replay, provenance, and local NameCert rows before consuming a regularity bound.

Independence witness: sobolev, poincare-inequality, morrey-inequality, real: none is bijective with $\mathsf{MoserIteration}^{\uparrow}$ because this carrier alone binds cutoff schedules and exponent-step ledgers to the Sobolev, Poincare, Morrey-facing, Real-bound, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MoserIteration}^{\uparrow}}$**.**

Constructive story: A MoserIteration$^{\uparrow}$ packet is generated from Sobolev source rows, Poincare control rows, cutoff schedules, exponent-step ledgers, Real-bound readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MoserIteration}\uparrow}$, seed)

Scope closed: Definition 6969.1, Definition 6969.2, and Definition 6969.3 seed the finite PDE regularity ladder consumed by Harnack-style packets.

Formal verification: FormalStatus(NameCert$_{\text{MoserIteration}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host Harnack theorem, selected PDE solution, global regularity theorem, quotient equality of function spaces, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Sobolev and Poincare source exactness, cutoff schedule exactness, exponent-step ledger exactness, Real-bound readback, transport, replay, provenance, and local naming for BEDC.Derived.MoserIterationUp.

Chapter 6970

A Concrete Naming Certificate for $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$

Following Bishop and Bridges on completion of separated metric spaces, the $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ packet records the finite BEDC surface by which an already separated completion is recognized as fixed by the completion classifier. It sits between the completion interface of chapter 95, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the metric-completion route of chapter 1506, and the functorial completion handoff of chapter 423. The packet names the idempotence boundary for separated completions; it is not a quotient-completion equality, a selected representative, countable choice, host real equality, or ambient completeness theorem.

Definition 6970.1 (Separated completion idempotence carrier)**.** *A* $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (C, S, M, F, R, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Completion}^{\uparrow}$ *source row naming the completion-facing request.*
2. *S is the separated-classifier row, recording that zero-distance comparisons are already identified by the displayed separated completion surface.*
3. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row through which the same request reaches a metric-completion consumer.*
4. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *functorial handoff row.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row attached to the inspected completion windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the separated classifier, metric completion route, functorial handoff, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for $C, S, M, F, R, E, T, P, N$.*
8. *T records displayed* Cont *replay from a second completion request back through the same separated classifier route.*
9. *P is the* Pkg *provenance over* $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionIdempotence}^{\uparrow}}$ *row.*

The classifier for accepted packets compares only the displayed rows $C, S, M, F, R, E, H, T, P, N$. It has no coordinate for quotient completion equality, selected representatives, host equality of completed points, countable choice, or an ambient completeness principle.

Theorem 6970.2 (Separated completion idempotence NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ *carrier* $I = (C, S, M, F, R, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionIdem}}$ *surface consists exactly of carrier admission for the completion source row, separated-classifier row, metric-completion route, Cauchy-completion functorial handoff, RegSeqRat readback, Real seal, componentwise transport, displayed replay, package provenance, and local naming. The second completion read must return to the same separated classifier* S *before any* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer can be served.*

Proof. Project the carrier of Definition 6970.1. The rows $C, S, M, F, R, E, H, T, P, N$ are the complete accepted inventory.

The separated classifier is the lock. A second completion-facing request first reads C and S; only after the zero-distance classifier has been exposed may it continue to the metric route M and functorial handoff F.

The readback and terminal seal remain downstream of that route. Rows R and E record regular rational windows and the Real seal after the separated completion boundary has been displayed, while H, T, P, N transport, replay, source, and name the same packet.

Since no other coordinate is present, the local certificate cannot export quotient completion equality, a selected representative, countable choice, host equality of completed points, or ambient completeness. □

Theorem 6970.3 (Separated completion RegSeqRat route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{RegSeqRat}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ *carrier factors through the finite route*

$$C, S, M, F \longmapsto R \longmapsto E.$$

Thus applying completion again to an already separated completion exposes the same separated classifier before the regular rational readback and terminal Real seal are available. The packet supplies idempotence as a finite NameCert route, not as quotient equality of completion objects or a selected completed representative.

Proof. Start with a consumer of R or E. By Definition 6970.2, the consumer first opens the completion source row C and the separated classifier row S.

The metric and functorial rows M and F keep the request on the sibling completion route. They show that the second completion read is served by the displayed metric-completion and Cauchy-completion handoff, not by an ambient equality of completion objects.

Only then can R and E be read. The regular rational row records the inspected windows, and the Real seal remains terminal to those windows. Transport, replay, provenance, and local naming preserve this route without adding a selected representative or choice principle. □

Lean4 (statement) `BEDC.Derived.SeparatedCompletionIdempotenceUp`

Falsifiable prediction: An accepted $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ read is refuted if a second completion-facing request reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without first exposing the $\mathsf{Completion}^{\uparrow}$ source row, separated classifier row, $\mathsf{MetricCompletion}^{\uparrow}$ route, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ handoff, transport, replay, provenance, and local naming rows.

Independence witness: completion, regseqrat, real, metriccompletion, cauchycompletionfunctor: $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ is not bijective with any listed sibling because it jointly

carries the completion source, separated classifier, metric-completion route, functorial handoff, regular readback, Real seal, transport, replay, provenance, and local naming rows that witness idempotence of the separated completion classifier.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCompletionIdempotence}\uparrow}$.

Constructive story: A $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ packet is generated from a Completion row, separated-classifier row, MetricCompletion route, CauchyCompletionFunctor handoff, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionIdempotence}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6970.1, Definition 6970.2, and Definition 6970.3 seed the separated completion idempotence route over CompletionUp, RegSeqRatUp, RealUp, MetricCompletionUp, and CauchyCompletionFunctorUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionIdempotence}\uparrow}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.SeparatedCompletionIdempotenceUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completed points, ambient completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-classifier idempotence, metric-completion route exposure, functorial handoff, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCompletionIdempotenceUp.

Chapter 6971

A Concrete Naming Certificate for $\mathsf{RoundedCut}^{\uparrow}$

Following Bishop and Bridges, rounded cuts are the constructive boundary object that records rational approximation by finite open improvement data rather than by a completed quotient of predicates. The $\mathsf{RoundedCut}^{\uparrow}$ packet sits between the located-cut carrier of chapter 404, the one-sided lower-real surface of chapter 1446, the located-real interfaces of **??** and chapter 1933, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It names a finite rounded-cut certificate used by L10 Real and Completion consumers; it does not construct $\mathsf{Real}^{\uparrow}$ by Dedekind cuts.

Definition 6971.1 (Rounded cut carrier)**.** *A* $\mathsf{RoundedCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, O, Q, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *source row, carrying the lower and upper rational-observation boundary.*
2. *O is the rounded-open improvement row: every accepted rational observation is witnessed by a strictly better displayed observation on the same side.*
3. *Q is the* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row consumed by one-sided lower reads and located real reads.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the finite rational gaps used by roundedness and located comparison.*
5. *W is the finite window ledger for the rational observations inspected by downstream consumers.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after L, O, Q, D, W have been replayed.*
7. *H records componentwise* hsame *transport for the located-cut source, rounded improvement, comparison, dyadic ledger, window, real seal, continuation, provenance, and local name rows.*
8. *C records displayed* Cont *replay from a rational or dyadic request through L, O, Q, D, W before the seal row E is read.*
9. *P is the* Pkg *provenance over* $\mathsf{RoundedCut}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RoundedCut}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a quotient cut, selected representative, host real equality, ambient completeness theorem, or construction of $\mathsf{Real}^{\uparrow}$ *by Dedekind cuts.*

Theorem 6971.2 (Rounded cut NameCert obligations)**.** *For every accepted* $\mathsf{RoundedCut}^{\uparrow}$ *carrier* $R = (L, O, Q, D, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RoundedCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed located-cut source, rounded-open improvement row, lower and located real comparison row, dyadic tolerance ledger, finite observation window, terminal real seal, componentwise transport, displayed replay, provenance, and local naming rows. No obligation is stored in a quotient predicate, a selected cut representative, host real equality, ambient completeness, or a Dedekind-cut construction of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier of Definition 6971.1. The rows $L, O, Q, D, W, E, H, C, P, N$ are the complete inventory of the packet.

The rounded-open row O and the dyadic ledger D witness improvement by finite rational data, while Q records how lower-real and located-real consumers read the same finite boundary. The structural rows H, C, P, N only transport, replay, source, and name that displayed packet.

Since no further coordinate is present, the NameCert obligations are exhausted by the listed rows. In particular the packet is a finite rounded-cut certificate and does not construct $\mathsf{Real}^{\uparrow}$ by Dedekind cuts. □

Theorem 6971.3 (Rounded cut located-real handoff)**.** *Every* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{LowerReal}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RoundedCut}^{\uparrow}$ *carrier must first read the route*

$$L, O, Q, D, W, E, H, C, P, N.$$

The handoff exports rounded located rational observations, dyadic gap data, finite windows, and the terminal real seal only as displayed BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *data.*

Proof. Begin with a located-real or lower-real consumer. Carrier admission exposes the located-cut row L, the rounded-open improvement row O, and the comparison row Q before any real-facing seal can be inspected.

Next read the dyadic ledger D and window row W. These rows provide the finite gap and observation data used by roundedness and located comparison.

Finally replay through C and attach H, P, N before reading E. The consumer therefore receives only the finite route named above, not a quotient cut, selected representative, host equality, or ambient completeness principle. □

Theorem 6971.4 (Rounded cut non-Dedekind completion boundary)**.** *The* $\mathsf{RoundedCut}^{\uparrow}$ *packet is a finite rounded-cut certificate for dependency routing between located cuts, lower reals, located reals, dyadic witnesses, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It is not a construction of* $\mathsf{Real}^{\uparrow}$ *by Dedekind cuts, not a quotient completion, not a selected-limit principle, and not an ambient real-completeness theorem.*

Proof. Read the carrier inventory of Definition 6971.1. Its analytic rows are the displayed located-cut source, rounded-open improvement, lower and located real comparison, dyadic tolerance ledger, finite window, and terminal seal.

Apply Definition 6971.2 and Definition 6971.3. They force every consumer to remain inside the finite rounded-cut certificate before reaching any $\mathsf{Real}^{\uparrow}$ seal.

Thus the chapter records a boundary and handoff surface only. It does not supply Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, quotient equality of cuts, selected representatives, selected limits, or ambient completeness. □

Falsifiable prediction: A $\mathsf{RoundedCut}^{\uparrow}$ consumer that reaches a $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without first reading the displayed located-cut source, rounded-open improvement, dyadic tolerance ledger, finite observation window, replay, provenance, and local NameCert rows refutes this carrier surface.

Independence witness: locatedcut, lowerreal, locatedreal, dyadicratcore, real: no listed sibling jointly binds rounded-open improvement, dyadic gap data, lower and located real handoff, terminal Real seal, and local NameCert routing in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RoundedCut}^{\uparrow}}$.

Constructive story: A $\mathsf{RoundedCut}^{\uparrow}$ packet is generated from a displayed located-cut source, rounded-open improvement row, lower and located real comparison row, dyadic tolerance ledger, finite observation window, terminal Real seal, componentwise transport, replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoundedCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6971.1, Definition 6971.2, Definition 6971.3, and Definition 6971.4 bind the finite rounded-cut certificate over $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoundedCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient cuts, selected representatives, selected limits, ambient completeness, or a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, rounded-open improvement replay, located-real handoff, and non-Dedekind completion boundary for BEDC.Derived.RoundedCutUp.

Chapter 6972

A Concrete Naming Certificate for $\mathsf{DyadicCompletionEmbedding}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicCompletionEmbedding}^{\uparrow}$ packet names the finite route by which a displayed dyadic rational source enters the regular Cauchy completion surface and reaches the $\mathsf{Real}^{\uparrow}$ seal. It sits after the dyadic source packet of chapter 291, the finite schedule of chapter 126, the regular rational readback of chapter 301, the admission criterion of chapter 1476, and the terminal Real packet of chapter 38. The certificate is an explicit embedding handoff, not a quotient stream, selected limit, host real equality, or ambient completeness principle.

Definition 6972.1 (Dyadic completion embedding carrier)**.** *A* $\mathsf{DyadicCompletionEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, R, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, including the dyadic numerator, scale, comparison ledger, and tolerance budget used by the embedding request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window through which the dyadic source is scheduled for completion-facing reads.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance ledger.*
4. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R and the criterion row have been displayed.*
5. *Q is the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *admission row, recording that the StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal handoff are mutually compatible.*
6. *H stores componentwise* hsame *transport for the source, window, readback, seal, criterion, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from the dyadic source through the stream window, regular readback, completion criterion, and Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicCompletionEmbedding}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCompletionEmbedding}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only by these nine rows. It has no coordinate for quotient streams, selected limits, host real equality, countable choice, or ambient completeness of the Real completion.

Lean4 (definition) `BEDC.Derived.DyadicCompletionEmbeddingUp`

Theorem 6972.2 (Dyadic completion embedding NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCompletionEmbedding}^{\uparrow}$ *carrier* $E = (D, S, R, L, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicCompletionEmbedding}^{\uparrow}}$ *surface consists exactly of dyadic source exposure through* D*, finite StreamName scheduling through* S*, RegSeqRat readback through* R*, CauchyCompletionCriterion admission through* Q*, Real seal handoff through* L*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.DyadicCompletionEmbeddingUp.DyadicCompletionEmbeddingNameCertObligations`

Proof. Project the carrier of Definition 6972.1. The dyadic source, stream window, regular readback, Real seal, completion criterion, transport, replay, provenance, and local naming rows are the only classifier-visible coordinates.

The source and readback obligations are forced by the route. The dyadic row D supplies the displayed rational source and tolerance budget, the stream row S supplies the finite observation schedule, and the regular readback row R is read only after those two rows are visible.

The completion-facing obligations are then local. The criterion row Q admits the handoff to the Real seal row L, while H, C, P, N transport, replay, package, and name the same finite packet.

Since the carrier has no coordinate for quotient streams, selected limits, host real equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 6972.3 (Dyadic completion embedding Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{DyadicCompletionEmbedding}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyCompletionCriterion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer receives the dyadic source row, finite window, regular readback, criterion admission, Real seal, transport, replay, provenance, and local naming rows, and receives no quotient stream, selected limit, host real equality, countable-choice schedule, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.DyadicCompletionEmbeddingUp.DyadicCompletionEmbeddingRealSealHandoff`

Proof. Start with an accepted carrier $E = (D, S, R, L, Q, H, C, P, N)$. The only source row is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ row D, so a Real-facing read cannot begin from an unstated rational representative or a host real.

Next read the finite observation route. The $\mathsf{StreamName}^{\uparrow}$ row S schedules the dyadic source, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is the readback obtained from that schedule together with the displayed tolerance ledger.

Apply the admission row Q. It is the sole local $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ row that licenses the move from the regular rational readback to the seal row L.

The structural rows H, C, P, N preserve the same finite packet during transport, replay, provenance, and naming. Therefore the terminal $\mathsf{Real}^{\uparrow}$ consumer receives exactly the displayed handoff route and cannot read quotient streams, selected limits, host real equality, countable choice, or ambient completeness from the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCompletionEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCompletionEmbedding}^{\uparrow}$ packet is generated from a DyadicRatCore source row, StreamName observation window, RegSeqRat readback, RealUp seal, CauchyCompletionCriterion admission row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCompletionEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6972.1, Definition 6972.2, and Definition 6972.3 seed the finite dyadic-to-regular-Cauchy embedding route through StreamName, RegSeqRat, CauchyCompletionCriterion, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCompletionEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DyadicCompletionEmbeddingUp`

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName scheduling, RegSeqRat readback, completion-criterion admission, and Real seal handoff for the same dyadic source packet.

Chapter 6973

A Concrete Naming Certificate for $\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}$ packet records the criterion-level route from absolute domination to Cauchy control rather than a new summability carrier. It sits over the absolute-domination packet of chapter 1700, the finite majorant schedule of chapter 1774, the shared-tail series route of chapter 1736, the regular rational readback of chapter 301, and the endpoint seal of chapter 38. The packet gives later Real and Completion consumers one finite criterion certificate that displays the absolute-value envelope, the majorant comparison, the uniform Cauchy tail handoff, and the $\mathsf{Real}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ boundary before any endpoint-facing read is public.

Definition 6973.1 (Absolute convergence criterion carrier)**.** *An* $\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, M, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *row, including the term stream, absolute-domination ledger, and finite absolute-value envelope opened by the criterion.*
2. *M is the* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *row, including the nonnegative majorant schedule, partial-sum ledger, and displayed tail budget.*
3. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *row reached only after A and M have exposed the domination and majorant data.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite term, majorant, and partial-sum windows opened along the criterion route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, public only after A, M, U, R have been displayed.*
6. *H stores componentwise* hsame *transport for the absolute-domination, majorant, uniform-tail, readback, Real-seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from the absolute-value envelope to the majorant comparison, from the majorant comparison to the uniform Cauchy threshold, from the threshold to regular readback, and from readback to the Real seal.*

8. *P is the* Pkg *provenance over* AbsoluteConvergenceCriterion$^{\uparrow}$, AbsoluteConvergence$^{\uparrow}$, CauchyMajorantSeries$^{\uparrow}$, UniformCauchySeries$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{AbsoluteConvergenceCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, U, R, E, H, C, P, N$. It has no coordinate for a selected infinite sum, quotient stream equality, countable choice, trichotomy, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 6973.2 (Absolute convergence criterion NameCert obligations)**.** *For every accepted* AbsoluteConvergenceCriterion$^{\uparrow}$ *carrier*

$$K = (A, M, U, R, E, H, C, P, N),$$

the local NameCert$_{\text{AbsoluteConvergenceCriterion}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the absolute-domination, majorant-series, uniform Cauchy, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *absolute-value envelope exactness, requiring A to expose the selected absolute comparisons before any majorant row is read;*
3. *majorant comparison, requiring M to supply the displayed nonnegative schedule and tail budget consumed by the criterion;*
4. *uniform Cauchy tail handoff, requiring U to be read only after the absolute-value envelope and majorant comparison are both visible;*
5. Real$^{\uparrow}$/RegSeqRat$^{\uparrow}$ *nonescape, requiring R and E to expose only the finite regular readback and terminal Real seal reached by the displayed route.*

No criterion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6973.1. The accepted packet displays exactly the rows $A, M, U, R, E, H, C, P, N$, so the certificate surface has no detached coordinate for a completed sum or a host convergence theorem.

The absolute-value envelope is local to A. A criterion read begins by opening the selected term observations and their displayed absolute comparisons, and these are the only comparisons that can feed the majorant row.

The row M supplies the majorant comparison and tail schedule. Since U is downstream of A and M, the uniform Cauchy threshold cannot be read before the domination ledger and majorant budget have both been displayed.

Finally, R and E are terminal with respect to that finite route. The structural rows H, C, P, N transport, replay, source, and name the same rows, and the excluded endpoint principles never appear among the carrier coordinates. □

Theorem 6973.3 (Absolute convergence criterion majorant handoff)**.** *Every Real or Completion consumer that reads an accepted* AbsoluteConvergenceCriterion$^{\uparrow}$ *carrier factors through the finite route*

$$A \longmapsto M \longmapsto U \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer must display an AbsoluteConvergence$^{\uparrow}$ *absolute-value envelope, a* CauchyMajorantSeries$^{\uparrow}$ *comparison schedule, a* UniformCauchySeries$^{\uparrow}$ *shared tail threshold, a* RegSeqRat$^{\uparrow}$ *readback, and a terminal* Real$^{\uparrow}$ *seal before any endpoint-facing result is public.*

Proof. Project the accepted carrier $K = (A, M, U, R, E, H, C, P, N)$. The first public data are the absolute-domination rows in A, including the selected absolute-value envelope for the term stream.

The next public data are the majorant rows in M. They supply the displayed nonnegative comparison schedule and the tail budget that the criterion uses to control partial-sum differences.

The uniform Cauchy handoff occurs only after those two rows are visible. The row U records the shared threshold for the series tail, and R reads back the selected finite windows as regular rational data.

The endpoint row E is therefore a $\mathsf{Real}^{\uparrow}$ seal for the already displayed finite route. The rows H, C, P, N preserve and replay the same dependency order, so no consumer can bypass the majorant schedule or export a selected infinite sum, quotient equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Falsifiable prediction: Every $\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}$ endpoint-facing read factors through an AbsoluteConvergence absolute-value envelope, a CauchyMajorantSeries comparison schedule, a UniformCauchySeries shared tail threshold, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: absolute-convergence, cauchy-majorant-series, uniform-cauchy-series, regseqrat, real: $\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the criterion-level route from absolute domination through majorant comparison, uniform Cauchy tail control, regular readback, Real sealing, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6973.1, Definition 6973.2, and Definition 6973.3 seed the finite criterion route from absolute domination through majorant comparison, uniform Cauchy tail handoff, regular readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, absolute-value envelope exactness, majorant comparison, uniform Cauchy tail handoff, Real/RegSeqRat nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AbsoluteConvergenceCriterionUp.

Constructive story: An $\mathsf{AbsoluteConvergenceCriterion}^{\uparrow}$ packet is generated from an AbsoluteConvergence row, a CauchyMajorantSeries row, a UniformCauchySeries row, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6974

A Concrete Naming Certificate for $\mathsf{HarnackInequality}^{\uparrow}$

Following Moser's iteration method and the elliptic regularity presentation of Gilbarg–Trudinger, the $\mathsf{HarnackInequality}^{\uparrow}$ packet records the finite route by which a positive PDE solution read consumes Sobolev control, Poincare control, cutoff schedules, exponent-step ledgers, and terminal real bounds before a Harnack comparison is named. It sits after the Moser ladder of chapter 6969, the PDE relation surface of chapter 194, the Sobolev source of chapter 440, the Poincare control row of chapter 2329, and the scalar seal of chapter 38. The packet names only the displayed local comparison certificate; it is not a host regularity theorem, not a selected weak solution, not an open-cover compactness argument, and not an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 6974.1 (Harnack inequality carrier)**.** *A* $\mathsf{HarnackInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, S, P, J, E, R, B, T, C, Q, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MoserIteration}^{\uparrow}$ *handoff row, exposing the finite ladder consumed before any Harnack read.*
2. *D is the* $\mathsf{Pde}^{\uparrow}$ *relation row, naming the displayed equation and boundary classifier over the same local domain.*
3. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row whose weak-derivative and energy data feed the ladder.*
4. *P is the* $\mathsf{PoincareInequality}^{\uparrow}$ *control row for local oscillation and average comparison.*
5. *J is the cutoff and nested-region row inherited from the Moser ladder.*
6. *E is the exponent-step row that records the finite climb from local energy bounds to the comparison window.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *bound readback row for constants, radii, and positive lower-bound data.*
8. *B is the positive-solution boundary row, requiring the displayed solution window to remain inside the admitted PDE and Real-bound rows.*
9. *T records componentwise* hsame *transport for the Moser, PDE, Sobolev, Poincare, cutoff, exponent, Real-bound, positive-boundary, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same route for downstream PDE regularity consumers.*

11. *Q is the* Pkg *provenance over* $\mathsf{HarnackInequality}^{\uparrow}$, $\mathsf{MoserIteration}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{PoincareInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HarnackInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, S, P, J, E, R, B, T, C, Q, N$. It has no coordinate for an arbitrary host solution, global elliptic regularity, quotient equality of functions, selected representatives, countable choice, open-cover compactness, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.HarnackInequalityUp`

Theorem 6974.2 (Harnack inequality NameCert obligations)**.** *For every accepted* $\mathsf{HarnackInequality}^{\uparrow}$ *carrier $H = (M, D, S, P, J, E, R, B, T, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HarnackInequality}^{\uparrow}}$ *surface consists exactly of Moser-ladder exposure through M; PDE relation exposure through D; Sobolev source exposure through S; Poincare control exposure through P; cutoff schedule exposure through J; exponent-step exposure through E; Real-bound readback through R; positive-solution boundary exposure through B; componentwise transport through T; displayed replay through C; provenance through Q; and local naming through N.*

Proof. Project the carrier of Definition 6974.1. The rows $M, D, S, P, J, E, R, B, T, C, Q, N$ are exactly the Moser, PDE, Sobolev, Poincare, cutoff, exponent, Real-bound, positive-boundary, transport, replay, provenance, and naming coordinates.

The analytic rows are read in dependency order. The PDE row fixes the displayed relation, the Sobolev and Poincare rows supply the source estimates, and the Moser row brings the cutoff and exponent ladder into the same finite packet.

The endpoint rows then seal the comparison. The Real-bound row records constants and positive lower-bound data, while the positive-solution boundary row prevents the comparison from being read outside the admitted PDE window. Transport, replay, provenance, and local naming preserve only this finite route, so the listed rows exhaust the local NameCert surface. □

Theorem 6974.3 (Harnack inequality Moser handoff)**.** *Every accepted* $\mathsf{HarnackInequality}^{\uparrow}$ *read must first consume the* $\mathsf{MoserIteration}^{\uparrow}$ *handoff row together with the displayed* $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{PoincareInequality}^{\uparrow}$, *cutoff, exponent, and* $\mathsf{Real}^{\uparrow}$ *rows. The Harnack comparison is therefore a downstream read of the finite Moser ladder, not a separate host regularity theorem or selected-solution principle.*

Proof. Start with the Moser handoff of Definition 6969.3. It requires every Harnack-facing consumer to expose the Sobolev source, Poincare control, cutoff schedule, exponent ledger, Real-bound readback, and structural rows before a regularity bound is consumed.

The carrier of Definition 6974.1 imports exactly that handoff as M and keeps the source rows visible as S, P, J, E, R. Thus a Harnack read cannot bypass the Moser ladder.

Finally attach the PDE and positive-boundary rows. They restrict the comparison to the displayed relation and positive solution window, while T, C, Q, N only transport, replay, source, and name the same packet. Hence the handoff is finite and does not export a detached host theorem. □

Theorem 6974.4 (Harnack inequality positive-solution boundary)**.** *Every positive-solution comparison exported by an accepted* $\mathsf{HarnackInequality}^{\uparrow}$ *packet factors through the PDE relation row D, the positive-boundary row B, and the Real-bound readback row R after the Moser ladder rows M, S, P, J, E have been displayed. It exports no comparison for an unnamed solution, no quotient equality of representatives, and no ambient maximum principle outside*

$$M, D, S, P, J, E, R, B, T, C, Q, N.$$

Proof. Read the PDE-facing rows first. The row D fixes the displayed PDE relation and boundary classifier, while B states that the positive solution window being compared is part of that same admitted route.

Next consume the ladder and scalar seal. The rows M, S, P, J, E supply the finite Moser ladder, and R supplies the scalar constants and positive lower-bound data used by the comparison.

The structural rows finish the route. Transport, replay, provenance, and local naming through T, C, Q, N preserve the same finite packet and introduce no selected solution, quotient representative, host maximum principle, or ambient completeness theorem. Therefore every positive-solution comparison remains inside the displayed carrier rows. □

Falsifiable prediction: Every accepted $\mathsf{HarnackInequality}^{\uparrow}$ read must expose the Moser ladder, PDE relation, Sobolev source, Poincare control, cutoff schedule, exponent ledger, Real-bound readback, positive-solution boundary, transport, replay, provenance, and local NameCert rows before any Harnack comparison is consumed.

Independence witness: moser-iteration, pde, sobolev, poincare-inequality, real: no listed sibling is bijective with $\mathsf{HarnackInequality}^{\uparrow}$ because this packet alone binds the finite Moser ladder to a displayed positive PDE solution comparison and terminal Real-bound seal.

Closure status for $\mathsf{NameCert}_{\mathsf{HarnackInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{HarnackInequality}^{\uparrow}$ packet is generated from a MoserIteration handoff row, a PDE relation row, Sobolev source data, Poincare control data, cutoff schedules, exponent-step ledgers, Real-bound readback, a positive-solution boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HarnackInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6974.1, Definition 6974.2, Definition 6974.3, and Definition 6974.4 seed the finite Harnack comparison packet consumed downstream from $\mathsf{MoserIteration}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HarnackInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Harnack theorem, selected PDE solution, global regularity theorem, quotient equality of functions, countable choice, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Moser handoff exactness, PDE relation exactness, Sobolev and Poincare source exactness, cutoff and exponent ledger exactness, Real-bound readback, positive-boundary preservation, transport, replay, provenance, and local naming for BEDC.Derived.HarnackInequalityUp.

Chapter 6975

Tucker Lemma NameCert Construction

Following Tucker and the standard combinatorial proof of Borsuk–Ulam, the $\mathsf{TuckerLemma}^{\uparrow}$ packet records the finite antipodal labeling obstruction as NameCert data. It sits between the finite face inventory of chapter 238, the adjacent-color argument of chapter 2003, and the antipodal conclusion route of chapter 5828. The packet is a finite combinatorial certificate: it exposes triangulation rows, boundary antipodality rows, complementary-edge witnesses, structural transport, replay, provenance, and local naming, but it does not import compactness, quotient spheres, choice of subdivisions, or a host topological Borsuk–Ulam theorem.

Definition 6975.1 (Tucker lemma carrier)**.** *A* $\mathsf{TuckerLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, B, L, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite antipodal triangulation row, read as a* $\mathsf{SimplicialComplex}^{\uparrow}$ *face inventory with a displayed vertex-pair involution.*
2. *B is the boundary labeling row, recording the antipodal sign rule on boundary vertex pairs.*
3. *L is the interior labeling row, assigning each displayed vertex one signed label from a finite symmetric label alphabet.*
4. *E is the complementary-edge witness row, naming an inspected edge whose two endpoint labels are opposite signs with the same absolute label.*
5. *H records componentwise* hsame *transport for the triangulation, boundary rule, labeling, edge witness, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from the finite triangulation and labeling data to the complementary-edge witness.*
7. *P is the* Pkg *provenance over* $\mathsf{TuckerLemma}^{\uparrow}$*,* $\mathsf{SimplicialComplex}^{\uparrow}$*,* $\mathsf{SpernerLemma}^{\uparrow}$*,* $\mathsf{BorsukUlam}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TuckerLemma}^{\uparrow}}$ *row naming exactly this finite antipodal labeling packet.*

The classifier compares accepted packets only through K, B, L, E, H, C, P, N. It has no coordinate for an ambient sphere quotient, a selected subdivision sequence, real compactness, or a host topological fixed-point theorem.

Theorem 6975.2 (Tucker lemma finite complementary edge route)**.** *For every accepted* $\mathsf{TuckerLemma}^{\uparrow}$ *carrier* $T = (K, B, L, E, H, C, P, N)$*, every complementary-edge read factors through the displayed finite route*

$$\mathsf{SimplicialComplex}^{\uparrow} \longmapsto \textit{antipodal boundary labels} \longmapsto \textit{signed interior labels} \longmapsto \textit{complementary edge.}$$

Equivalently, the consumer-visible surface is exactly K, B, L, E, H, C, P, N*: the finite antipodal triangulation is inspected first, the boundary and interior label rows are replayed on that triangulation, and the edge witness is then exposed through the structural transport and naming rows.*

Proof. Project the carrier of Definition 6975.1. The row K is the only triangulation source, B is the only boundary antipodality source, and L is the only signed-label source.

Read the route in order. A consumer first receives a finite face inventory through $\mathsf{SimplicialComplex}^{\uparrow}$. The boundary rule B then fixes the antipodal sign comparison on displayed boundary pairs, and the labeling row L supplies the signed labels on all inspected vertices.

The witness row E is exposed only after those rows have been transported by H and replayed by C. The provenance and naming rows P, N name the same finite packet, so the complementary edge cannot be replaced by a host sphere argument or a hidden subdivision choice.

Since no coordinate records quotient spheres, compactness, selected subdivision sequences, or ambient fixed-point data, every accepted complementary-edge read remains inside the finite K, B, L, E, H, C, P, N surface. □

Theorem 6975.3 (Tucker lemma NameCert obligations)**.** *For every accepted* $\mathsf{TuckerLemma}^{\uparrow}$ *carrier* $T = (K, B, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TuckerLemma}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the finite packet* T*;*
2. *finite antipodal* $\mathsf{SimplicialComplex}^{\uparrow}$ *triangulation exposure through* K*;*
3. *boundary antipodality of the labeling row through* B*;*
4. *signed interior label exposure through* L*;*
5. *complementary-edge witness exposure through* E*;*
6. *componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming through* H, C, P, N*.*

No additional NameCert obligation is exported for compactness, quotient-sphere equality, selected subdivisions, real vector topology, or a host Borsuk–Ulam theorem.

Proof. Carrier admission is the finite tuple displayed in Definition 6975.1. Each listed obligation is one of its coordinates, so a local name can inspect it without leaving the packet.

The finite complementary-edge route of Definition 6975.2 orders the obligations. The triangulation row supplies the finite complex, the boundary and interior label rows supply the signed data, and the edge row supplies the complementary witness.

The structural rows H, C, P, N preserve and name that same packet. Because the excluded objects are not carrier coordinates, they cannot create extra NameCert obligations or a second route to the witness. □

Lean4 (statement) `BEDC.Derived.TuckerLemmaUp`

Falsifiable prediction: Every accepted $\mathsf{TuckerLemma}^{\uparrow}$ consumer can be audited by checking that its complementary-edge witness first displays a finite $\mathsf{SimplicialComplex}^{\uparrow}$ antipodal triangulation, then boundary and interior signed-label rows, before E, H, C, P, N are consumed.

Independence witness: simplicialcomplex, spernerlemma, borsukulam: $\mathsf{TuckerLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the antipodal triangulation row, boundary labeling row, interior signed-label row, complementary-edge witness, componentwise transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{TuckerLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{TuckerLemma}^{\uparrow}$ packet is generated from a finite antipodal SimplicialComplex row, boundary antipodality rows, signed interior label rows, a complementary-edge witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TuckerLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6975.1, Definition 6975.2, and Definition 6975.3 seed the finite antipodal-labeling certificate route from SimplicialComplex data to a complementary-edge witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TuckerLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim compactness, quotient-sphere equality, selected subdivisions, real vector topology, Lean proof coverage for the combinatorial theorem, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal triangulation exposure, boundary labeling, signed interior labeling, complementary-edge witness exposure, transport, replay, provenance, and local naming for BEDC.Derived.TuckerLemmaUp.

Chapter 6976

Regular Cauchy Located Limit Seal NameCert Construction

Following Bishop–Bridges constructive real analysis, the $\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}$ packet records the finite route by which a located regular Cauchy name reaches a Real seal. It sits beside the regular rational readback of chapter 301, the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the located-real surface of **??**, and the terminal Real seal of chapter 38. The packet records a displayed limit-seal handoff; it is not quotient equality of real names, a selected host limit, countable choice, or ambient completeness.

Definition 6976.1 (Regular Cauchy located limit-seal carrier)**.** *A* $\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, R, D, A, S, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that exposes the requested prefix of the regular Cauchy name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the regularity budget and located comparison cells.*
4. *A is the* $\mathsf{LocatedReal}^{\uparrow}$ *row recording the located cut information visible through the same W, R, D route.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after the window, readback, dyadic ledger, and located row have been replayed.*
6. *H records componentwise* hsame *transport for the window, readback, dyadic, located, seal, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from W, R, D, A to the Real seal S.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these nine rows. It has no coordinate for quotient stream equality, selected host limits, host real equality, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 6976.2 (Regular Cauchy located limit-seal obligations)**.** *For every accepted* $\mathsf{RegularCauchyLocatedLimitS}$ *carrier* $L = (W, R, D, A, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed nine-row packet;*
2. $\mathsf{StreamName}^{\uparrow}$ *window locality through* W*;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback through* R*;*
4. $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and located-cell exactness through* D*;*
5. $\mathsf{LocatedReal}^{\uparrow}$ *located-route compatibility through* A*, together with* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise transport, displayed replay, provenance, and local naming through* S, H, C, P, N*.*

No additional NameCert obligation is exported for quotient equality, selected limits, host real equality, countable choice, or ambient completeness.

Proof. Project the carrier of Definition 6976.1. Its classifier-visible coordinates are precisely the finite window, regular readback, dyadic tolerance ledger, located row, terminal seal, transport, replay, provenance, and local naming rows.

The window-locality and readback obligations are forced by the order of W and R. A consumer first sees the finite $\mathsf{StreamName}^{\uparrow}$ window and then reads it as a regular rational packet through $\mathsf{RegSeqRat}^{\uparrow}$.

The dyadic and located obligations are the next displayed rows. The row D supplies the tolerance and located-cell comparisons, and the row A records the located-real surface read only from the same W, R, D route.

Finally, the seal and structural rows add no second source. The row S is exposed only after W, R, D, A have been replayed through H, C, P, N, and the carrier contains no quotient, selected-limit, host-equality, choice, or completeness coordinate. Hence the five listed rows exhaust the local NameCert surface. □

Theorem 6976.3 (Regular Cauchy located Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}$ *carrier* $L = (W, R, D, A, S, H, C, P, N)$ *reads exactly the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The handoff exports no quotient stream, selected host limit, host real equality, countable-choice row, or ambient completeness principle.*

Proof. Begin with a Real-facing or completion-facing consumer and project the accepted carrier. The only source window is W, and the only regular rational readback is R.

The dyadic ledger D records the tolerance and located comparison cells used by that readback. The located row A then reads the same displayed cells; it does not supply a detached host real or a selected limit.

The Real seal S is reached only after the W, R, D, A route has been replayed through H, C, P, N. These structural rows preserve the same finite packet and provide no extra coordinate from which a quotient, selected limit, host equality, choice principle, or ambient completeness theorem could be recovered.

Thus every accepted handoff factors through the displayed StreamName, RegSeqRat, DyadicRatCore, LocatedReal, and Real rows, followed by the structural certificate rows. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}$ consumer can be audited by checking that its Real-facing read first displays a $\mathsf{StreamName}^{\uparrow}$ window, then a $\mathsf{RegSeqRat}^{\uparrow}$ readback, then a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, then a $\mathsf{LocatedReal}^{\uparrow}$ located row, before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Independence witness: Nearest siblings: streamname, regseqrat, dyadicratcore, locatedreal, and real. The packet is not bijective to any one sibling because it jointly carries the finite window, regular rational readback, dyadic tolerance ledger, located-real row, Real seal, componentwise transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}$ packet is generated from a StreamName finite-window row, a RegSeqRat regular rational readback row, a DyadicRatCore tolerance ledger, a LocatedReal row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6976.1, Definition 6976.2, and Definition 6976.3 seed the finite located regular Cauchy route from L10 StreamName, RegSeqRat, DyadicRatCore, and LocatedReal data to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedLimitSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of real names, selected host limits, host real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName locality, RegSeqRat readback, DyadicRatCore tolerance exactness, LocatedReal compatibility, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedLimitSealUp.

Chapter 6977

A Concrete Naming Certificate for $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$ packet records a nested rational interval argument as finite endpoint windows with a displayed dyadic width descent. It sits over the dyadic tolerance arithmetic of chapter 291, the finite observation schedules of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers one Bishop-style nested rational interval route without importing open-cover compactness, quotient real equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6977.1 (Constructive nested real interval carrier)**.** *A* $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are rational endpoint rows for the inspected left and right interval endpoints, each read through the dyadic tolerance discipline of chapter 291.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window listing the inspected stages and the endpoint observations available at each stage.*
3. *D is the dyadic width-descent ledger, recording $L_n \leq L_{n+1} \leq R_{n+1} \leq R_n$ and a displayed dyadic budget forcing the inspected widths below the requested tolerance.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *selector row that chooses, from each inspected interval, a midpoint or endpoint rational compatible with the displayed width budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, R, S, D, Q have been displayed.*
6. *H stores componentwise* hsame *transport for endpoint rows, stream windows, width descent, selector readback, Real seal, replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay from finite endpoint observations through width descent, selector readback, and the terminal Real seal.*
8. *P records* Pkg *provenance over* $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{ConstructiveNestedRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, S, D, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, quotient real equality, choice-selected limits, Heine–Borel, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6977.2 (Constructive nested real interval NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$ *carrier*

$$K = (L, R, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveNestedRealInterval}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for endpoint rows, finite stage windows, dyadic width descent, selector readback, terminal Real sealing, transport, replay, provenance, and local naming;*
2. *classifier visibility, requiring packet comparison to inspect only $L, R, S, D, Q, E, H, C, P, N$;*
3. *stability, requiring* hsame *transport to preserve endpoint order, successor containment, dyadic width budgets, selector reads, and the terminal seal;*
4. *exactness, requiring every selector read in Q to lie inside the displayed interval stage from which it is drawn and to use no uninspected endpoint;*
5. *ledger closure, requiring* Cont *replay and* Pkg *provenance to record the full route from finite endpoint windows through the* $\mathsf{RegSeqRat}^{\uparrow}$ *selector to the* $\mathsf{Real}^{\uparrow}$ *seal.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6977.1. The accepted packet displays exactly the endpoint, stage-window, width-descent, selector, seal, transport, replay, provenance, and local naming rows.

Classifier visibility follows because the packet has no further coordinate. A comparison of accepted packets can inspect the listed rows, but it cannot ask for open-cover compactness, quotient real equality, a selected host limit, Heine–Borel, trichotomy, or ambient completeness.

The stability and exactness clauses are read from the same displayed rows. The transport row H preserves the endpoint order, containment, width budget, selector readback, and Real seal, while D and Q record that each rational selector read is taken from an inspected interval stage and satisfies the displayed dyadic tolerance request.

Finally, C and P close the ledger. They replay and source the route from finite interval windows through the regular rational selector to the terminal seal, so no detached obligation remains available outside $L, R, S, D, Q, E, H, C, P, N$. □

Theorem 6977.3 (Constructive nested interval Cauchy selector)**.** *Every accepted* $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$ *carrier determines a* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible Cauchy selector whose terminal* $\mathsf{Real}^{\uparrow}$ *seal remains inside the displayed nested interval packet. More precisely, the selector reads only the finite endpoint windows in S, the dyadic width-descent ledger D, and the rational row Q; for each requested dyadic tolerance, a displayed stage supplies a rational selector value inside the corresponding interval, and the terminal seal E is reached only through that selector route.*

Proof. Project the accepted carrier $K = (L, R, S, D, Q, E, H, C, P, N)$. The finite stream window S tells which stages may be inspected, and the endpoint rows L, R give the rational bounds available at those stages.

The ledger D supplies successor containment and a dyadic width budget. Given a displayed tolerance request, the budget exposes an inspected stage whose interval width is below that tolerance, and containment ensures later inspected stages remain inside the earlier interval.

The selector row Q reads a rational from the displayed interval stage, for instance a midpoint or an endpoint named by the packet. Since both selected values for sufficiently narrow inspected stages lie inside a common displayed interval whose width is below the tolerance, the selected rational reads satisfy the $\mathsf{RegSeqRat}^{\uparrow}$ Cauchy condition.

The terminal row E is therefore reached only after the selector has passed through Q. The replay row C, transport row H, provenance row P, and local name N preserve that dependency, so the Real seal cannot escape the finite nested interval packet or appeal to a choice-selected limit, quotient equality, open-cover compactness, Heine–Borel, trichotomy, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$ Real-facing read factors through finite rational endpoint windows, a dyadic width-descent ledger, a RegSeqRat-compatible selector row, terminal Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries nested rational endpoints, inspected stage windows, dyadic width descent, selector readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveNestedRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveNestedRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6977.1, Definition 6977.2, and Definition 6977.3 seed the finite nested rational interval route from endpoint windows through dyadic width descent, regular rational selection, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveNestedRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient real equality, choice-selected limits, Heine–Borel, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier visibility, stability, exactness, ledger closure, selector Cauchy control, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveNestedRealI

Constructive story: A $\mathsf{ConstructiveNestedRealInterval}^{\uparrow}$ packet is generated from rational endpoint rows, finite StreamName windows, a dyadic width-descent ledger, RegSeqRat selector readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6978

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionOperator}^{\uparrow}$

Following Bishop and Bridges on Cauchy completion, the $\mathsf{RegularCauchyCompletionOperator}^{\uparrow}$ packet names the finite operator route that turns displayed regular rational Cauchy data into a Real-facing completion seal. It sits after the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the neighboring Cauchy completion operator of chapter 3379. The packet records the regular-operator handoff only; it does not quotient Cauchy names, select representatives, use countable choice, assert ambient completeness of $\mathsf{Real}^{\uparrow}$, or replace the broader Bishop completion operator of chapter 6456.

Definition 6978.1 (RegularCauchyCompletionOperator carrier)**.** *A* $\mathsf{RegularCauchyCompletionOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for every precision request and every regularity comparison.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observed windows of the Cauchy name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and readback row attached to those windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the tolerance, window, and readback rows have been exposed.*
5. *H records componentwise* hsame *transport for the dyadic tolerance, stream window, regular readback, Real seal, replay row, provenance row, and local naming row.*
6. *C records displayed* Cont *replay from a precision request through D, S, R, then through the Real seal E.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionOperator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionOperator}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient Cauchy equality, a selected representative, a chosen limit point, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6978.2 (RegularCauchyCompletionOperator NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionOperator}^{\uparrow}$ *carrier* $O = (D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComple}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure through* D*, finite-window exposure through* S*, regular rational readback and regularity exposure through* R*, ordered* $\mathsf{Real}^{\uparrow}$ *seal access through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. A completion-facing operator read must pass through those rows before it may cite the Real-facing seal.*

Proof. Project the accepted finite BHist packet. The visible carrier rows are precisely D, S, R, E, H, C, P, N, so carrier admission exposes tolerance, window, readback, terminal seal, transport, replay, provenance, and naming data.

The operator read is ordered. A precision request first reaches the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, then the $\mathsf{StreamName}^{\uparrow}$ finite windows, then the $\mathsf{RegSeqRat}^{\uparrow}$ readback and regularity row, and only afterward the terminal $\mathsf{Real}^{\uparrow}$ seal.

Transport and replay are structural. The row H moves the listed coordinates componentwise by hsame, while C replays the displayed continuation route and P, N source and name the same packet. Since no quotient Cauchy equality, selected representative, chosen limit, countable-choice schedule, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness coordinate appears in the tuple, the listed rows exhaust the local NameCert obligations. □

Theorem 6978.3 (RegularCauchyCompletionOperator seal route)**.** *Every* $\mathsf{RegularCauchyCompletionOperator}^{\uparrow}$ *consumer that reads the Real-facing output of an accepted carrier* $O = (D, S, R, E, H, C, P, N)$ *factors through the finite route*

$$D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the operator output reaches $\mathsf{Real}^{\uparrow}$ *only through DyadicRatCore tolerances, finite StreamName windows, RegSeqRat readback, the displayed seal row, componentwise transport, continuation replay, package provenance, and local NameCert data. It does not export quotient Cauchy equality, selected representatives, selected completion points, countable choice, host real equality, or any claim that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Start with a consumer request for the regular completion output. The carrier definition gives the request access to the dyadic tolerance row D and the finite window row S, so the request begins with displayed Cauchy-name observations rather than an external quotient.

Next read the regular row. The readback row R supplies the regular rational data attached to the same windows and tolerance ledger, so the terminal seal E is reached only after the regularity evidence has been displayed.

Finally replay the structural rows H, C, P, N. The route is therefore the displayed finite chain from dyadic tolerances and stream windows to the regular readback and Real seal. Because the packet contains no additional coordinate, the factorization cannot produce quotient Cauchy equality, selected representatives, selected completion points, countable choice, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionOperator}^{\uparrow}$ packet is generated from DyadicRatCore tolerances, StreamName windows, RegSeqRat regular readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6978.1, Definition 6978.2, and Definition 6978.3 seed the finite regular Cauchy completion-operator route from dyadic tolerances and finite windows to the Real-facing seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionOperator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected representatives, selected completion points, countable choice, host real equality, Lean verification, bridge checking, or any assertion that Real$^{\uparrow}$ is complete.

Upgrade path: Obligation closure requires checked carrier admission, regular readback ordering, Real-seal factorization, transport stability, and non-escape for BEDC.Derived.RegularCauchyCompletionOperatorUp.

Chapter 6979

A Concrete Naming Certificate for $\mathsf{CauchyRepletion}^{\uparrow}$

Following Bishop and Bridges on constructive completions by regular Cauchy data, the $\mathsf{CauchyRepletion}^{\uparrow}$ packet names the finite repletion corridor between displayed stream observations and the $\mathsf{Real}^{\uparrow}$ seal. It sits beside the finite windows of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, the completion-admission surface of chapter 1476, and the real-name seal of chapter 38. The packet is a non-quotient repletion object for L10 completion consumers; it does not import selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Repeated repletion reads consume the $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ route of chapter 5119 before the $\mathsf{Real}^{\uparrow}$ seal, so the repletion corridor does not create a second completed object.

Definition 6979.1 (Cauchy repletion carrier)**.** *A* $\mathsf{CauchyRepletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, R_0, D, Q, U, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule through which the repletion request reads stream data.*
2. *R_0 is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording tolerance scales, comparison bounds, and dyadic threshold data.*
4. *Q is the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *admission row, read only after S, R_0, D have been displayed.*
5. *U is the separated comparison row, recording the finite apartness and equality-refusal data used before any seal-facing comparison is exported.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the criterion and separated comparison rows.*
7. *H stores componentwise* hsame *transport for the stream schedule, readback, dyadic ledger, criterion row, separated comparison, seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from finite windows to regular readback, from readback through the dyadic and criterion rows, and from the separated comparison row to the seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRepletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRepletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, R_0, D, Q, U, E, H, C, P, N$. It has no coordinate for quotient streams, selected host limits, countable-choice schedules, host real equality, or ambient completeness.

Theorem 6979.2 (Cauchy repletion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRepletion}^{\uparrow}$ *carrier $R = (S, R_0, D, Q, U, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRepletion}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-window readback, dyadic tolerance routing, completion-criterion admission, separated comparison, Real seal exposure, componentwise transport, displayed replay, provenance, and local naming. Every repletion consumer must display the* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *row R_0,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D,* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *row Q, separated comparison row U,* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C, P, N before it reads the packet as a completion neighbour.*

Proof. Project the carrier of Definition 6979.1. The ten displayed rows are the only classifier-visible coordinates, so carrier admission and local naming are immediate row projections.

The analytic obligations are also row projections. The stream schedule S precedes the regular readback R_0, the dyadic ledger D records the tolerance data used by that readback, and the criterion row Q is the only completion-admission coordinate available before a seal-facing read.

The separated comparison row U and seal row E complete the finite route. Transport H, replay C, and provenance P preserve the same packet, while the absence of quotient, selected-limit, countable-choice, host-equality, and ambient-completeness coordinates gives the non-escape clause. □

Falsifiable prediction: Every accepted $\mathsf{CauchyRepletion}^{\uparrow}$ packet exposes StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, CauchyCompletionCriterion admission, separated comparison, Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any repletion consumer reads it.

Independence witness: streamname, regseqrat, dyadicratcore, cauchycompletioncriterion, real: $\mathsf{CauchyRepletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the window schedule, regular readback, dyadic tolerance ledger, completion criterion, separated comparison row, terminal seal, transport, replay, provenance, and local naming as one finite repletion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRepletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRepletion}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyCompletionCriterion admission row, separated comparison data, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRepletion}^{\uparrow}}$, seed)

Scope closed: Definition 6979.1 and Definition 6979.2 seed the finite non-quotient repletion surface for completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRepletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window readback, dyadic tolerance routing, completion-criterion admission, separated comparison, Real seal exposure, transport, replay, provenance, and non-escape for BEDC.Derived.CauchyRepletionUp.

Chapter 6980

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$

The $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ packet realizes the observer-expansion branch of chapter 9463 as finite boundary-tangent phase transport. It sits beside the horocycle packet of chapter 3534, the phase-ledger horocycle of chapter 3591, the boundary-fixed transport surface of chapter 3500, the observer-expansion route of chapter 4167, and the metric readback of chapter 3474. The packet records a finite phase-horocycle carrier; it does not assert an ambient hyperbolic manifold, a selected boundary limit, a global geodesic flow, or host equality of boundary points.

Definition 6980.1 (Hyperbolic phase horocycle carrier)**.** *A* $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, T, M, O, F, H_0, C, P, N)$$

with the following displayed rows:

1. *B is the boundary-tangent row read through the displayed Poincare boundary data.*
2. *T is the phase-transport row carrying the local phase ledger along the horocycle.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *readback row used to compare the transported phase position.*
4. *O is the observer-expansion row recording the focused expansion ledger consumed by the packet.*
5. *F is the refusal row excluding selected boundary limits, ambient geodesic flow, host point equality, and global hyperbolic manifold structure.*
6. *H_0 stores componentwise* hsame *transport for the boundary-tangent, phase-transport, metric, observer-expansion, refusal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from boundary-tangent data through phase transport and metric readback to the observer-expansion row.*
8. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$, *with sibling pointers to the horocycle, phase-ledger, boundary-fixed transport, and observer-expansion packets.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, M, O, F, H_0, C, P, N$. It has no coordinate for an ambient manifold, selected far-end limit, global flow, quotient boundary equality, or unlogged observer expansion.

Theorem 6980.2 (Hyperbolic phase horocycle NameCert obligations)**.** *For every accepted* HyperbolicPhaseHorocyc *carrier* $H = (B, T, M, O, F, H_0, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}}$ *surface consists exactly of carrier admission, boundary-tangent exposure, phase-transport replay, hyperbolic-metric readback, observer-expansion routing, refusal coverage, componentwise transport, provenance, and local naming. Any phase-horocycle consumer must display* $B, T, M, O, F, H_0, C, P, N$ *before it reads the packet.*

Proof. Project the carrier of Definition 6980.1. The displayed rows are the only classifier-visible coordinates, so carrier admission and local naming are immediate row projections.

The boundary and phase obligations are read from B and T. The metric row M supplies the hyperbolic readback for the same transported phase surface, and the observer-expansion row O records the focused ledger consumed by that readback.

The refusal row F excludes the ambient objects not carried by the packet. Transport H_0, replay C, and provenance P preserve the same finite route, so the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ packet exposes boundary-tangent, phase-transport, hyperbolic-metric, observer-expansion, refusal, transport, replay, provenance, and NameCert rows before any phase-horocycle consumer reads it.

Independence witness: hyperbolic-horocycle, phase-ledger-horocycle, poincare-boundary-fixed-transport, hyperbolic-observer-expansion, hyperbolic-metric: $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds boundary-tangent phase transport, metric readback, observer-expansion routing, refusal, transport, replay, provenance, and local naming in one packet.

Lean follow-up requires Nontrivial $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ witnesses in the corresponding TasteGate surface.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ packet is generated from boundary-tangent data, phase transport, hyperbolic metric readback, observer-expansion routing, refusal coverage, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}}$, seed)

Scope closed: Definition 6980.1 and Definition 6980.2 seed the finite boundary-tangent phase-horocycle surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient hyperbolic manifolds, selected boundary limits, global geodesic flows, host boundary equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-tangent exposure, phase-transport replay, hyperbolic-metric readback, observer-expansion routing, refusal coverage, transport, provenance, and non-escape for BEDC.Derived.HyperbolicPhaseHorocycleUp.

Chapter 6981

A Concrete Naming Certificate for $\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed Cauchy modulus can be replaced by a dominating displayed modulus along the same Real and Completion route. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the base modulus schedule of chapter 292, the completion-admission surface of chapter 1476, and the terminal Real seal of chapter 38. The packet is a finite dominance criterion for Real and Completion consumers; it is not a quotient stream equality, selected limit, countable-choice schedule, host real equality, trichotomy split, or ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 6981.1 (Cauchy modulus dominance criterion carrier)**.** *A* $\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, D, M_0, M_1, B, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the observations consumed by the base Cauchy read.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the dyadic precision requests shown to the consumer.*
4. *M_0 is the base* $\mathsf{CauchyModulus}^{\uparrow}$ *row assigning a finite tail threshold to each displayed dyadic request.*
5. *M_1 is the dominating* $\mathsf{CauchyModulus}^{\uparrow}$ *row for the same displayed requests, with each shown threshold at least as far out as the corresponding threshold in M_0.*
6. *B is the local dominance-criterion row, recording that M_1 dominates M_0 on exactly the dyadic requests displayed by D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the same Real and Completion route after S, Q, D, M_0, M_1, B have been displayed.*
8. *H records componentwise* hsame *transport for the windows, readback, dyadic requests, both modulus rows, dominance row, seal row, replay, provenance, and local naming row.*

9. *C records displayed* Cont *replay from each finite dyadic request through*

$$D, M_0, M_1, B, S, Q \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* CauchyModulusDominanceCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyModulus$^{\uparrow}$, CauchyCompletionCriterion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyModulusDominanceCriterion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected tail functions, selected limits, countable choice, host sequence equality, host real equality, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 6981.2 (Cauchy modulus dominance criterion NameCert obligations)**.** *For every accepted* CauchyModulusDominanceCriterion$^{\uparrow}$ *carrier*

$$K = (S, Q, D, M_0, M_1, B, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyModulusDominanceCriterion}^{\uparrow}}$ *surface consists exactly of carrier exposure for the displayed packet, finite-window exposure through S, regular rational readback through Q, dyadic tolerance exposure through D, base-modulus exposure through M_0, dominating-modulus exposure through M_1, dominance exposure through B, terminal* Real$^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier in Definition 6981.1. Each obligation names one coordinate of the same finite BHist packet, and the local naming row N records that these coordinates form the certificate surface.

The analytic part is read in the displayed order. A dyadic request first enters the ledger D, then reads the base threshold M_0 and the dominating threshold M_1, and then checks the dominance row B for that displayed request. The stream windows S and regular readback Q are therefore attached to the same finite request route.

The structural rows H, C, P, N only transport, replay, source, and name this route. Since the carrier has no coordinate for quotient stream equality, selected tails, selected limits, countable choice, host equality, trichotomy, or ambient completeness, none of those objects can be exported by the local NameCert obligations. □

Theorem 6981.3 (Cauchy modulus dominance criterion Real-seal route)**.** *Every* Real$^{\uparrow}$*-facing or completion-facing consumer of an accepted* CauchyModulusDominanceCriterion$^{\uparrow}$ *carrier*

$$K = (S, Q, D, M_0, M_1, B, E, H, C, P, N)$$

may replace the displayed base modulus row M_0 by the displayed dominating row M_1 only through the same finite route

$$\text{StreamName}^{\uparrow} \longmapsto \text{RegSeqRat}^{\uparrow} \longmapsto \text{DyadicRatCore}^{\uparrow} \longmapsto \text{CauchyModulus}^{\uparrow} \longmapsto \text{CauchyCompletionCriterion}^{\uparrow} \longmapsto \text{Real}^{\uparrow}$$

The replacement preserves the terminal seal row E and exports no quotient stream row, selected limit row, countable-choice row, host equality row, trichotomy row, or ambient Real$^{\uparrow}$ *completeness row.*

Proof. Start with the NameCert obligations of Definition 6981.2. They expose the base modulus, dominating modulus, and dominance row only after the same dyadic request ledger and before the same terminal seal row.

The dominance condition is local to displayed requests: M_1 dominates M_0 only on the requests present in D. Thus replacing M_0 by M_1 cannot introduce a hidden schedule, selected tail, or quotient stream comparison; it merely moves the finite threshold farther along the already displayed route.

Finally read the provenance and replay rows. They attach the dominance route to the completion-admission surface and the terminal Real seal without adding another carrier coordinate. Hence the Real seal route remains the one displayed in the theorem statement, and all excluded host or ambient principles remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}$ Real-facing read factors through displayed StreamName windows, RegSeqRat readback, DyadicRatCore tolerance requests, a base CauchyModulus row, a dominating CauchyModulus row, a dominance-criterion row, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, cauchymodulus, cauchycompletioncriterion, real: $\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries one base modulus row, one dominating modulus row, the displayed requestwise dominance criterion, the shared Real and Completion route, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a base CauchyModulus row, a dominating CauchyModulus row, a requestwise dominance row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6981.1, Definition 6981.2, and Definition 6981.3 seed the finite criterion by which a displayed Real and Completion route may replace a base CauchyModulus row by a dominating CauchyModulus row on displayed dyadic requests.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusDominanceCriterion}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, requestwise dominance, NameCert exposure, and Real-seal nonescape for BEDC.Derived.CauchyModulusDominanceCriterionUp.

Chapter 6982

A Concrete Naming Certificate for $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$

Following Birkhoff and von Neumann, the $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$ packet records the finite orbit-average surface that precedes any pointwise or mean ergodic convergence theorem. It sits between the measure-preserving source of chapter 196, the displayed transition rows of chapter 195, the probability-space ledger of chapter 184, and the terminal real-name seal of chapter 38. The packet gives later mean-ergodic and recurrence-facing chapters a finite average row without importing measure-theoretic choice principles.

Definition 6982.1 (Birkhoff ergodic finite-average carrier)**.** *A* $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (E, D, P, W, O, S, R, A, H, C, Q, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Ergodic}^{\uparrow}$ *source row, exposing the measure-preserving transformation, invariant-row ledger, and finite measure endpoint data consumed by the average.*
2. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *step row for the same transformation, recording the displayed source point, successor route, and finite iterate endpoints.*
3. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *averaging provenance row, recording the unit-mass probability source and the event or observable window through which the average is read.*
4. *W is the finite orbit-window row, storing the inspected segment $x, Tx, \ldots, T^{n-1}x$ together with the visible window length n.*
5. *O is the finite observation row, recording the observable values attached to the window entries and read only through* $\mathsf{StreamName}^{\uparrow}$ *finite observations.*
6. *S is the finite sum and denominator row used to form the displayed average of O over W.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the rational regular-name route for the average value before the terminal real seal is read.*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *averaged endpoint seal, downstream of E, D, P, W, O, S, R and never a selected almost-everywhere limit.*

9. *H records componentwise* hsame *transport for the ergodic source, dynamic steps, probability provenance, orbit window, observations, finite sum, rational readback, real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a finite averaging request through $E, D, P, W, O, S, R, A, H, Q, N$.*
11. *Q is the* Pkg *provenance over* $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$, $\mathsf{Ergodic}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, D, P, W, O, S, R, A, H, C, Q, N$. It has no coordinate for the full almost-everywhere Birkhoff theorem, invariant sigma-algebra projection, countable choice, quotient a.e. equality, selected orbit limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6982.2 (Birkhoff finite-average NameCert obligations)**.** *For every accepted* $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$ *carrier $F = (E, D, P, W, O, S, R, A, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}}$ *surface consists exactly of carrier admission, measure-preserving source exposure, dynamic-step window exactness, probability-provenance visibility, finite StreamName observation routing, finite sum and denominator exactness, RegSeqRat readback, Real seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the finite carrier of Definition 6982.1.*

Proof. Carrier admission is projection from Definition 6982.1. The accepted packet exposes exactly the ergodic source, dynamic step row, probability provenance row, finite orbit window, observation row, finite sum row, rational readback row, Real seal, transport, replay, provenance, and local name.

Window exactness is read from D, W, O. The dynamic row supplies the inspected iterates, the window row fixes the finite prefix, and the observation row records only the StreamName-visible values attached to that prefix.

The averaging obligation is read from P, S, R, A. The probability-space provenance fixes the averaging source, the finite sum and denominator row computes the displayed average, the RegSeqRat row exposes the rational regular-name readback, and the Real seal is visible only after those rows have been displayed.

The structural obligations are exhausted by H, C, Q, N. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming preserve the same finite route and add no convergence theorem, invariant sigma-algebra projection, quotient a.e. equality, countable-choice schedule, selected limit, or ambient Real completeness coordinate. □

Theorem 6982.3 (Birkhoff finite-average readback route)**.** *Every average exported by an accepted* $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Ergodic}^{\uparrow},\ \mathsf{DynSystem}^{\uparrow},\ \mathsf{ProbSpace}^{\uparrow} \longmapsto W, O, S \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a downstream mean-ergodic or recurrence-facing consumer receives a displayed orbit window, finite observation ledger, finite average row, regular rational readback, and terminal real-name seal before it can consume the average.

Proof. Start with an averaging request. The request first opens the $\mathsf{Ergodic}^{\uparrow}$ and $\mathsf{DynSystem}^{\uparrow}$ rows, so the transformation and its finite iterates are read from displayed BEDC rows rather than from a host measurable dynamical system.

Next read the $\mathsf{ProbSpace}^{\uparrow}$ provenance and the window rows W, O, S. These rows fix the probability source, the inspected orbit segment, the observed values, and the finite sum with its denominator.

The average then passes through R before A is visible. This forces the regular rational readback to appear before any $\mathsf{Real}^{\uparrow}$ seal is consumed, so the exported endpoint is a finite NameCert route rather than a hidden limit.

Finally transport and replay through H, C, Q, N. Since the carrier has no coordinate for the full almost-everywhere Birkhoff theorem, invariant sigma-algebra projection, countable choice, quotient a.e. equality, selected orbit limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every exported average follows the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$ average read factors through one ErgodicUp source row, one DynSystemUp finite orbit-window row, one ProbSpaceUp averaging provenance row, finite StreamNameUp observations, a finite sum and denominator row, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: ergodic, dynsystem, probspace, streamname, regseqrat, real: BirkhoffErgodicFiniteAverag is not bijective to any listed sibling because it jointly carries a measure-preserving source, dynamic orbit windows, probability provenance, finite observations, finite average rows, rational readback, Real sealing, transport, replay, provenance, and local naming while excluding convergence, quotient, choice, and completeness coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}}$.

Constructive story: A $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$ packet is generated from ErgodicUp measure-preserving source rows, DynSystemUp finite orbit-window rows, ProbSpaceUp averaging provenance rows, StreamNameUp finite observation rows, RegSeqRatUp readback rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6982.1, Definition 6982.2, and Definition 6982.3 seed the finite orbit-average carrier, its local NameCert obligation surface, and its readback route through ErgodicUp, DynSystemUp, ProbSpaceUp, StreamNameUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the full almost-everywhere Birkhoff theorem, invariant sigma-algebra projection, countable choice, quotient a.e. equality, selected orbit limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dynamic-window exactness, probability-provenance visibility, finite observation routing, finite average exactness, RegSeqRat readback, Real seal ordering, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.BirkhoffErgodicFiniteAverageUp.

Chapter 6983

A Concrete Naming Certificate for $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$ packet records the finite selector route by which a displayed nested closed interval argument is read as regular Cauchy data before a terminal real-name seal is opened. It sits after the nested closed-interval surface of chapter 4012, the dyadic endpoint ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the Cauchy naming surface of chapter 3413, and the terminal real-name seal of chapter 38. The packet names only the finite selector and handoff rows; it does not assert quotient real equality, a selected limit, countable choice, trichotomy, Heine–Borel compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6983.1 (Nested closed interval selector carrier)**.** *A* $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested closed-interval row, read through* $\mathsf{ClosedIntervalNesting}^{\uparrow}$*, carrying the inspected closed interval stages and successor-containment evidence.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *shrink ledger, recording endpoint arithmetic, displayed width budgets, and the finite stage bound at which the inspected closed interval is narrower than the requested tolerance.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the interval stages, endpoints, midpoint or endpoint selector values, and shrink witnesses inspected by the selector.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selector values in W after the shrink ledger D has fixed the tolerance request.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the nested interval row, shrink ledger, finite windows, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for the nested interval row, shrink ledger, finite windows, readback, seal, replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay from a Cauchy-facing tolerance request through*

$$I, D, W, R \longmapsto E, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$, $\mathsf{ClosedIntervalNesting}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedClosedIntervalSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, W, R, E, H, C, P, N$. It has no coordinate for quotient real equality, a selected completed real, countable choice, trichotomy, Heine–Borel compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6983.2 (Nested closed interval selector NameCert obligations)**.** *For every accepted* $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$ *carrier*

$$K = (I, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedClosedIntervalSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, nested closed-interval exposure through I, dyadic shrink-ledger exactness through D, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal non-escape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6983.1. The nested interval source, shrink ledger, finite windows, regular readback, terminal seal, and structural rows are exactly $I, D, W, R, E, H, C, P, N$.

The interval obligations are read first. The row I exposes only inspected closed interval stages and successor containment, while D attaches the dyadic endpoint arithmetic and width budget to those same stages.

The finite-window obligations are then forced by W. A selector value is visible only when its interval stage, endpoints, and shrink witness are all present in the displayed window, and the readback row R is downstream of that window.

Finally, E, H, C, P, N seal, transport, replay, source, and name the same route. Since no carrier coordinate stores quotient real equality, a selected completed real, countable choice, trichotomy, compactness, or ambient completeness, those principles cannot appear among the local NameCert obligations. □

Theorem 6983.3 (Nested closed interval selector Cauchy handoff)**.** *Every Cauchy-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$ *carrier*

$$K = (I, D, W, R, E, H, C, P, N)$$

reaches a regular rational Cauchy read only through the finite route

$$\mathsf{ClosedIntervalNesting}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

For each displayed tolerance request, the shrink ledger supplies an inspected stage whose closed interval is narrower than that tolerance, the window row exposes the selector value at that stage, and the readback row packages those values as the regular Cauchy handoff before the terminal seal is consumed.

Proof. Start with a displayed tolerance request. The shrink ledger D gives a finite stage bound and a dyadic width inequality for the closed interval stage exposed by I.

Induct on the finite window prefix in W. The empty prefix exposes no selector value. In the successor step, the newly inspected stage carries its endpoints, containment witness, shrink

witness, and selector value; successor containment keeps later inspected selector values inside the earlier displayed closed interval.

When two inspected stages are beyond the displayed bound for a tolerance, both selector values lie in a common closed interval whose dyadic width is below that tolerance. The row R therefore reads the selector stream as regular rational Cauchy data without appealing to an unlisted limit object.

The terminal row E is opened only after R. The transport, replay, provenance, and local naming rows preserve this order, so the handoff cannot export quotient equality, countable choice, trichotomy, Heine–Borel compactness, a selected completed real, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$ Cauchy-facing read factors through a ClosedIntervalNesting row, DyadicRatCore shrink ledger, StreamName finite windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: closed-interval-nesting, dyadicratcore, streamname, regseqrat, cauchy, real: $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the nested closed-interval row, dyadic shrink ledger, finite selector windows, regular Cauchy readback, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedClosedIntervalSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedClosedIntervalSelector}^{\uparrow}$ packet is generated from a ClosedIntervalNesting row, DyadicRatCore shrink ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedClosedIntervalSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6983.1, Definition 6983.2, and Definition 6983.3 seed the finite selector route from nested closed interval rows through shrink-ledger Cauchy readback and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedClosedIntervalSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, trichotomy, Heine–Borel compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested closed-interval exposure, shrink-ledger exactness, finite-window induction, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NestedClosedIntervalSelectorUp.

Chapter 6984

A Concrete Naming Certificate for $\mathsf{SlaterCondition}^{\uparrow}$

Following Slater's constraint qualification as presented in standard convex optimization texts, the $\mathsf{SlaterCondition}^{\uparrow}$ packet records strict feasibility as a finite NameCert surface for convex programs. It sits beside the stationarity and complementary-slackness rows of chapter 300, the separation boundary of chapter 6185, and the cone carrier of chapter 310. The chapter names the strict-feasibility interface only; it does not assert strong duality, existence of an optimizer, differentiability, or any host-level constraint qualification beyond the displayed rows.

Definition 6984.1 (Slater condition carrier)**.** *A* $\mathsf{SlaterCondition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, M, B, K, H, C, P, N)$$

with the following visible rows:

1. *F is the convex feasible source, read through the* $\mathsf{ConvexSet}^{\uparrow}$ *carrier and the displayed constraint rows of the surrounding optimization packet.*
2. *W is a strict interior witness row, giving one carried feasible point together with the finite strict-inequality comparisons used by the classifier.*
3. *M is the finite margin ledger recording the positive slack, cone-interior, or barrier-side comparisons that make W strict.*
4. *B is the* $\mathsf{FarkasLemma}^{\uparrow}$ *separation-boundary row that records which finite alternative is blocked by the displayed strict margins.*
5. *K is the* $\mathsf{KKT}^{\uparrow}$ *multiplier handoff row, exposing only the multiplier, residual, stationarity, feasibility, and complementary-slackness slots that are allowed to consume strict feasibility.*
6. *H stores componentwise* hsame *transport for the feasible source, strict witness, margin ledger, separation boundary, multiplier handoff, continuation, provenance, and local naming rows.*
7. *C records the finite* Cont *replay that routes strict feasibility through F, W, M, B, K without adding a solver or analytic duality theorem.*
8. *P is the* Pkg *provenance over* $\mathsf{SlaterCondition}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{FarkasLemma}^{\uparrow}$, $\mathsf{KKT}^{\uparrow}$, $\mathsf{SemidefiniteCone}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SlaterCondition}^{\uparrow}}$ *row.*

The carrier has no coordinate for strong duality, selected primal or dual optimizers, differentiability, closedness of a host cone, or a host real-valued minimization semantics.

Theorem 6984.2 (Slater condition NameCert obligations)**.** *For every accepted* $\mathsf{SlaterCondition}^{\uparrow}$ *packet* $S = (F, W, M, B, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SlaterCondition}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, strict interior exposure through* W*, finite margin accounting through* M*, separation-boundary compatibility through* B*, KKT multiplier handoff through* K*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Every obligation is read through the visible dependencies $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{FarkasLemma}^{\uparrow}$*,* $\mathsf{KKT}^{\uparrow}$*, and* $\mathsf{SemidefiniteCone}^{\uparrow}$*. No obligation asserts strong duality beyond the strict-feasibility handoff described by the packet.*

Proof. Project the carrier of Definition 6984.1. The feasible source, strict witness, margin ledger, separation boundary, KKT handoff, transport, replay, provenance, and local name are exactly the displayed rows.

The strict witness row W is usable only with the finite margin ledger M. Thus the classifier sees strict feasibility as carried slack data, not as an ambient interior predicate. The $\mathsf{SemidefiniteCone}^{\uparrow}$ dependency contributes only the cone-facing row when the surrounding program is semidefinite; it does not add spectral closure or host interior semantics.

The separation row B is read through chapter 6185. It records the finite alternative boundary blocked by the displayed margins. The handoff row K is read through chapter 300; it exposes only the multiplier and stationarity-facing slots that consume strict feasibility.

Finally, H, C, P, N transport, replay, package, and name the same route. Since none of the carrier rows stores strong duality, a selected optimizer, differentiability, or host minimization semantics, the listed obligations exhaust the NameCert surface. □

Theorem 6984.3 (Slater condition KKT handoff)**.** *Let* $S = (F, W, M, B, K, H, C, P, N)$ *be an accepted* $\mathsf{SlaterCondition}^{\uparrow}$ *carrier. Any downstream* $\mathsf{KKT}^{\uparrow}$ *consumer that uses the strict-feasibility row of* S *receives only the finite handoff*

$$F \longmapsto W \longmapsto M \longmapsto B \longmapsto K.$$

The row B *keeps the* $\mathsf{FarkasLemma}^{\uparrow}$ *separation boundary explicit, and the provenance row may cite* $\mathsf{SemidefiniteCone}^{\uparrow}$ *when the feasible source is cone-valued. The handoff supplies no strong-duality theorem, no selected optimizer, no differentiability oracle, and no host constraint qualification beyond the displayed strict-feasibility packet.*

Proof. Begin with the accepted carrier in Definition 6984.1. The only strict-feasibility data available to a consumer are the convex feasible source F, the strict witness W, and the margin ledger M.

Next read the separation boundary. By the placement of B, any Farkas-style obstruction is compared against the same displayed margins, so the downstream route remains a finite alternative boundary rather than a topological separation theorem.

Now read the KKT handoff row K. The $\mathsf{KKT}^{\uparrow}$ consumer receives the multiplier-facing and stationarity-facing slots named by K, with no additional primal-dual conclusion. Componentwise hsame transport, Cont replay, Pkg provenance, and the local NameCert row preserve that route and do not add any coordinate outside F, W, M, B, K. □

Closure status for $\mathsf{NameCert}_{\mathsf{SlaterCondition}^{\uparrow}}$.

Constructive story: A $\mathsf{SlaterCondition}^{\uparrow}$ packet is generated from a convex feasible source, a strict interior witness, a finite margin ledger, a Farkas separation boundary, a KKT multiplier handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SlaterCondition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6984.1, Definition 6984.2, and Definition 6984.3 seed the strict-feasibility interface consumed by KKT and convex-duality packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SlaterCondition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim strong duality, selected primal or dual optimizers, differentiability, closedness of a host cone, or bridge checking.

Upgrade path: A formal route can encode the nine-row carrier and prove the strict-feasibility handoff to the KKT multiplier surface.

Chapter 6985

A Concrete Naming Certificate for $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$

The $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ packet realizes the before-and-after disagreement surface of section 9462.2 as finite NameCert data. It sits beside the world-model classifier of chapter 6124, the black-box decomposition certificate of chapter 6100, the positive interpretability classifier of chapter 6202, and the audit membrane of chapter 524. The packet names a classifier-shift residue ledger; it is not record growth under an unchanged classifier and not a positive-discovery verdict by itself.

Definition 6985.1 (Classifier shift ledger residue carrier)**.** *A* $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, A, S, D, L, G, U, H, C, P, N)$$

with the following displayed rows:

1. *B is the before-classifier row, naming the source scope, classifier relation, certificate state, and ledger policy before the inspected passage.*
2. *A is the after-classifier row, naming the corresponding source scope, classifier relation, certificate state, and ledger policy after the passage.*
3. *S is the source-overlap row, proving that B and A are compared over a displayed common source rather than over unrelated records.*
4. *D is the classifier-disagreement row, exposing a finite before-and-after classifier judgment that differs on the shared source.*
5. *L is the residue ledger, recording which rows are newly classified, which rows remain outside the after classifier, and which rows witness the disagreement.*
6. *G is the gap-detection row, separating record-only growth, unchanged classifier presentation, hidden source switch, and genuine classifier disagreement.*
7. *U is the discovery-status row, recording whether downstream consumers may treat the passage as candidate structural discovery, rejected record growth, or ledger-incomplete classifier shift.*
8. *H stores componentwise* hsame *transport for the before row, after row, source overlap, disagreement, residue ledger, gap detection, discovery status, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from source overlap through disagreement, residue accounting, gap detection, discovery status, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$, $\mathsf{WorldModelClassifier}^{\uparrow}$, BlackBoxDecompositionCertific PositiveInterpretabilityClassifier$^{\uparrow}$, $\mathsf{AuditMembrane}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}}$ *row.*

The carrier has no coordinate for record length alone, unchanged-classifier presentation, hidden source switching, unledgered discovery status, positive-discovery certification, or a host semantic novelty score.

Theorem 6985.2 (Classifier shift ledger residue NameCert obligations)**.** *For every accepted* ClassifierShiftLedgerRes *packet $R = (B, A, S, D, L, G, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}}$ *surface consists exactly of before-classifier admission, after-classifier admission, source-overlap admission, classifier-disagreement exposure, residue-ledger exposure, gap-detection exposure, discovery-status exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6985.1. The before and after classifier rows are B, A, the comparison rows are S, D, the ledger and verdict rows are L, G, U, and the structural rows are H, C, P, N.

The source-overlap row must be read before disagreement. This prevents a hidden source switch from masquerading as classifier shift, because the disagreement row D is licensed only on the shared source S.

The residue ledger L then records the rows that changed classifier status and the rows that remain outside the after classifier. The gap row G separates this finite residue from record-only growth or unchanged-classifier presentation, and U records the downstream discovery status permitted by that evidence.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since record length alone, hidden source switching, unledgered discovery status, positive-discovery certification, and host novelty scores have no carrier coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 6985.3 (Classifier shift ledger residue gap detection)**.** *An accepted* $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ *packet rejects any record-only passage whose classifier row is unchanged on the displayed source overlap. If B and A agree as classifier relations over S, then no row of D, L, G, U, H, C, P, N can supply the missing classifier disagreement required by the carrier.*

Proof. Read S first. It fixes the common source on which the before and after classifier rows are compared.

If the classifier relations in B and A agree over S, the disagreement row D has no displayed pair on which to witness a changed classifier judgment. The residue ledger L may still record more material, but without D that material is record growth under the same classifier.

The gap-detection row G therefore classifies the passage as unchanged-classifier presentation or record-only growth, and U cannot promote it to classifier-shift discovery status. The structural rows preserve the same failed route and do not create a disagreement coordinate. □

Falsifiable prediction: A record-only passage with unchanged classifier relation over the displayed source overlap cannot satisfy the $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ carrier of Definition 6985.1.

Independence witness: world_model_classifier, black_box_decomposition_certificate, positive_interpretability_classifier, auditmembrane: none is bijective to $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$

because the packet jointly carries before and after classifier rows, source overlap, classifier disagreement, residue ledger, gap detection, discovery status, transport, replay, provenance, and local naming rows.

The Lean `TasteGate.lean` file for $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ will provide explicit Nontrivial ClassifierShiftLedge and FieldFaithful $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ instances for the displayed eleven-row carrier before any checked TasteGate target can serve as a closure witness.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ packet is generated from before and after classifier rows, a source-overlap row, a classifier-disagreement row, a residue ledger, gap detection, discovery status, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6985.1, Definition 6985.2, and Definition 6985.3 seed the finite before and after classifier-disagreement ledger for the classifier-shift information principle.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim positive-discovery certification, global interpretability quality, host semantic novelty scoring, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-overlap comparison, classifier-disagreement exposure, residue-ledger accounting, gap detection, discovery-status routing, transport, replay, provenance, local naming, Nontrivial, and FieldFaithful rows for BEDC.Derived.ClassifierShiftLedgerResidueUp.

Chapter 6986

A Concrete Naming Certificate for $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$ packet records the finite interval-refinement tree used when compact interval work branches a cover or modulus request over nested dyadic subintervals. It sits after the compact interval modulus route of chapter 3868, the dyadic interval arithmetic of chapter 1645, and the linear interval-chain boundary of chapter 6443. The packet names a finite tree carrier for refinement reasoning; it is not open-cover compactness, a selected subcover, a fan theorem, countable choice, quotient endpoint equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6986.1 (Bishop interval-refinement tree carrier)**.** *A* $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, E, D, B, L, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the root compact-interval request read through* $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$.
2. *E stores the dyadic endpoint enclosure and containment data supplied by* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$.
3. *D is the finite descendant ledger, listing each split interval, its parent, and its endpoint refinement witnesses.*
4. *B is the branch-frontier row naming the currently inspected leaves and their cover or modulus obligations.*
5. *L is the sibling* $\mathsf{BishopFiniteIntervalChain}^{\uparrow}$ *row obtained by reading any chosen level of leaves as a finite adjacent chain.*
6. *A records acceptance of each refinement step by local interval containment and leaf-frontier coverage.*
7. *H stores componentwise* hsame *transport for R, E, D, B, L, A and the structural rows.*
8. *C stores displayed* Cont *replay from the compact request through dyadic splits, branch frontiers, and level-chain reads.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$, $\mathsf{CompactIntervalModulusBridge}^{\uparrow}$, $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$, $\mathsf{BishopFiniteIntervalChain}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalRefinementTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an infinite refinement tree, selected branch, open-cover subcover, fan principle, quotient endpoint equality, countable choice, or host compactness theorem.

Theorem 6986.2 (Bishop interval-refinement tree NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$ *carrier* $T = (R, E, D, B, L, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalRefinementTree}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-root exposure, dyadic endpoint-refinement exactness, finite descendant-ledger stability, leaf-frontier coverage, level-chain readback through* $\mathsf{BishopFiniteIntervalChain}^{\uparrow}$*, refinement-step acceptance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The root row R is the only compact-interval request, the endpoint row E is the only dyadic arithmetic source, and the descendant ledger D stores every split relation inspected by the packet.

The branch-frontier and chain rows give the consumer-facing tree shape. The row B names the visible leaves, while L reads any displayed level as the adjacent finite-chain surface already provided by chapter 6443.

The acceptance and structural rows then exhaust the certificate. The row A records local containment and coverage for each refinement step, and H, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate is present, the listed obligations are exactly the local NameCert surface. □

Theorem 6986.3 (Bishop interval-refinement tree refinement non-escape)**.** *Every accepted* $\mathsf{BishopIntervalRefinemen}$ *refinement read factors through*

$$\mathsf{CompactIntervalModulusBridge}^{\uparrow}, \mathsf{DyadicIntervalArithmetic}^{\uparrow}, \mathsf{BishopFiniteIntervalChain}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{Name}$$

For a carrier $T = (R, E, D, B, L, A, H, C, P, N)$*, a consumer may inspect only the compact root request, dyadic endpoint refinements, finite descendant ledger, visible leaf frontier, level-chain readback, refinement-step acceptance, transport, replay, provenance, and local name. No consumer receives an infinite tree, selected branch, open-cover subcover, fan theorem, countable-choice schedule, quotient endpoint equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the carrier inventory of Definition 6986.1. The rows R, E, D, B, L, A are the complete finite refinement data, and the rows H, C, P, N are the complete structural data.

Apply the obligation surface of Definition 6986.2. It forces every refinement read through the compact root row, dyadic endpoint refinements, finite descendant ledger, leaf frontier, level-chain readback, and local acceptance row before the packet can be consumed.

The three cited sibling chapters supply only the displayed services: compact modulus bridging, dyadic interval arithmetic, and finite interval chains. None supplies an infinite branch selector, an open-cover subcover, or a host compactness object.

Thus the accepted refinement read remains inside $R, E, D, B, L, A, H, C, P, N$. Transport and replay preserve this finite route, provenance records it, and the local name does not add any unrecorded source. □

Falsifiable prediction: Every accepted $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$ read factors through a compact interval modulus root, dyadic endpoint-refinement rows, a finite descendant ledger, a leaf-frontier row, a finite interval-chain readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compact-interval-modulus-bridge, dyadic-interval-arithmetic, bishop-finite-interval-chain: none is bijective because $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$ binds the compact request, dyadic endpoint refinements, finite descendant tree ledger, leaf-frontier coverage, level-chain readback, refinement acceptance, transport, replay, provenance, and local NameCert rows in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalRefinementTree}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalRefinementTree}^{\uparrow}$ packet is generated from a compact interval modulus root, dyadic endpoint-refinement rows, a finite descendant ledger, leaf-frontier rows, finite interval-chain readback, refinement-step acceptance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalRefinementTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6986.1, Definition 6986.2, and Definition 6986.3 seed the finite interval-refinement tree carrier and its non-escape route through compact modulus, dyadic interval arithmetic, finite interval chains, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalRefinementTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not assert open-cover compactness, a selected subcover, a fan theorem, countable choice, quotient endpoint equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint-refinement exactness, descendant-ledger stability, leaf-frontier coverage, level-chain readback, refinement-step acceptance, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalRefinementTreeUp.

Chapter 6987

A Concrete Naming Certificate for $\mathsf{LocatedCauchyProductGuard}^{\uparrow}$

Following Bishop and Bridges on located constructive real names and product stability of regular Cauchy data, the $\mathsf{LocatedCauchyProductGuard}^{\uparrow}$ packet records the finite guard that lets a product read proceed only after both factor names expose located dyadic tolerance windows. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the product packet of chapter 464, and the regular product route of chapter 461. The packet gives later Real algebra and completion consumers a non-quotient product-stability guard over displayed rows only.

Definition 6987.1 (Located Cauchy product guard carrier)**.** *A* $\mathsf{LocatedCauchyProductGuard}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (L, R, W_L, W_R, D_L, D_R, Q, M, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two accepted regular Cauchy source rows whose product is being guarded.*
2. *W_L and W_R are* $\mathsf{StreamName}^{\uparrow}$ *finite windows exposing the factor observations read for the current product request.*
3. *D_L and D_R are located* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-window rows. Each row names a dyadic radius, a finite inspection bound, and the located apartness or enclosure evidence needed before multiplication is read.*
4. *Q is the* $\mathsf{CauchyProduct}^{\uparrow}$ *product-source row assembled from the two windows and tolerance rows.*
5. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *handoff row, available only after Q, D_L, D_R, W_L, W_R are displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached through the regular rational readback, not by a selected product limit.*
7. *H records componentwise* hsame *transport for the source rows, windows, dyadic tolerance rows, product row, regular handoff, seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from each product-stability request through*

$$L, R, W_L, W_R, D_L, D_R, Q, M \longmapsto E, H, P, N.$$

9. *P is the* Pkg *provenance over* LocatedCauchyProductGuard$^\uparrow$, CauchyProduct$^\uparrow$, RegularCauchyProduct$^\uparrow$, DyadicRatCore$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{LocatedCauchyProductGuard}^\uparrow}$ *row.*

The classifier compares accepted packets only through $L, R, W_L, W_R, D_L, D_R, Q, M, E, H, C, P, N$. It has no coordinate for Real completeness, quotient equality of names, a selected product limit, trichotomy, countable choice, or host multiplication.

Theorem 6987.2 (Located Cauchy product guard NameCert obligations)**.** *For every accepted* LocatedCauchyProductGuard$^\uparrow$ *carrier*

$$G = (L, R, W_L, W_R, D_L, D_R, Q, M, E, H, C, P, N),$$

the local NameCert$_{\text{LocatedCauchyProductGuard}^\uparrow}$ *surface consists exactly of carrier admission for the two regular Cauchy source rows, finite* StreamName$^\uparrow$ *window admission for both factors, located* DyadicRatCore$^\uparrow$ *tolerance-window exactness,* CauchyProduct$^\uparrow$ *source assembly,* RegularCauchyProduct$^\uparrow$ *handoff, terminal* Real$^\uparrow$ *sealing through regular readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6987.1. The only rows available to a certificate checker are the two source rows, the two finite windows, the two located dyadic tolerance rows, the product row, the regular handoff, the terminal seal, and the structural rows.

The located tolerance rows are read before the product row. Thus Q cannot be consumed until D_L, D_R, W_L, W_R have fixed the finite dyadic windows for the current request.

The regular product handoff M is downstream of Q. The rows H, C, P, N transport, replay, source, and name that same finite route, so the listed rows exhaust the local certificate surface without adding completion, quotient, selected-limit, choice, trichotomy, or host multiplication data. □

Theorem 6987.3 (Located Cauchy product guard regular product handoff)**.** *Every* RegularCauchyProduct$^\uparrow$ *or* Real$^\uparrow$ *consumer of an accepted* LocatedCauchyProductGuard$^\uparrow$ *packet must first expose the finite route*

$$\text{StreamName}^\uparrow,\quad \text{DyadicRatCore}^\uparrow,\quad \text{CauchyProduct}^\uparrow,\quad \text{RegSeqRat}^\uparrow,\quad \text{RegularCauchyProduct}^\uparrow,\quad \text{Real}^\uparrow.$$

For each displayed product request, the guard reads both factor windows, matches them with located dyadic tolerance windows, assembles the CauchyProduct$^\uparrow$ *row, and only then releases the regular product handoff and terminal seal.*

Proof. Start with a product-facing read. Carrier admission exposes the factor rows and finite windows, but neither M nor E is available before the located tolerance rows have been displayed.

Read the dyadic guard. The rows D_L and D_R bind the requested product tolerance to concrete dyadic windows on the two factor names. This is a finite BHist read, so no selected limit or ambient completeness principle enters the route.

Now consume Q and M. The product row is assembled from the displayed factor windows, and the regular handoff is downstream of that assembly. Componentwise hsame transport and displayed Cont replay preserve the same row order for every accepted packet.

The terminal Real$^\uparrow$ seal is therefore a downstream read of the regular product handoff. Since the packet never stores quotient equality of names, host multiplication, countable choice, trichotomy, or Real completeness, none of those objects can be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCauchyProductGuard}^{\uparrow}$ product-stability read factors through two regular Cauchy source rows, paired StreamName windows, located DyadicRatCore tolerance windows, a CauchyProduct row, RegSeqRat readback, a RegularCauchyProduct handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: cauchyproduct, regularcauchyproduct, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedCauchyProductGuard}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two located factor windows, dyadic tolerance guards, product-source assembly, regular product handoff, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyProductGuard}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchyProductGuard}^{\uparrow}$ packet is generated from two regular Cauchy source rows, paired StreamName windows, located DyadicRatCore tolerance windows, a CauchyProduct row, RegSeqRat readback, a RegularCauchyProduct handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyProductGuard}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6987.1, Definition 6987.2, and Definition 6987.3 seed the finite located-tolerance guard for product stability of regular Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyProductGuard}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient equality of names, selected product limits, countable choice, trichotomy, host multiplication, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located dyadic tolerance-window exactness, finite-window product assembly, regular product handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchyProductGuardUp.

Chapter 6988

A Concrete Naming Certificate for $\mathsf{PrincipalCauchyEmbedding}^{\uparrow}$

Following Bishop and Bridges' regular Cauchy presentation of the real line, the $\mathsf{PrincipalCauchyEmbedding}^{\uparrow}$ packet names the finite BEDC unit that sends a displayed dyadic rational point into regular Cauchy completion data by the constant stream route. It sits between the dyadic endpoint core of chapter 291, the finite observation interface of chapter 126, the regular sequence route of chapter 301, the displayed real-name seal of chapter 38, and the completion boundary of chapter 1639. The packet records the point-to-completion embedding row; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, or host real equality.

Definition 6988.1 (Principal Cauchy embedding carrier)**.** *A* $\mathsf{PrincipalCauchyEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, S, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source point row, exposing one displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *point together with its dyadic endpoint ledger.*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *window row, recording that every finite observation requested by the completion route reads the same source point row Q.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row for the constant sequence generated by S.*
4. *D is the dyadic tolerance row, recording that every requested tail budget is discharged by the equality of the repeated dyadic readback.*
5. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after Q, S, R, D have been read.*
6. *H records componentwise* hsame *transport for the source point, constant window, regularity, tolerance, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through Q, S, R, D and then into the terminal Real seal row A.*
8. *P is the* Pkg *provenance over* $\mathsf{PrincipalCauchyEmbedding}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *chapter 1639,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PrincipalCauchyEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, S, R, D, A, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, or detached equality of Real names.*

Theorem 6988.2 (Principal Cauchy embedding finite route)**.** *Every accepted* $\mathsf{PrincipalCauchyEmbedding}^{\uparrow}$ *carrier*

$$E = (Q, S, R, D, A, H, C, P, N)$$

exports a completion-facing read only after the source $\mathsf{DyadicRatCore}^{\uparrow}$ *point row, constant* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, dyadic tolerance row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row have been displayed in that order. The exported route may be consumed by the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *packet as point-generated regular Cauchy data, but it exports no* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limit, countable-choice schedule, host real equality, or hidden equality of Real names.*

Proof. Project the carrier of Definition 6988.1. The only source data available to a completion-facing consumer is the dyadic point row Q together with the constant finite observation row S.

Read the regularity and tolerance rows next. Since S repeats the same dyadic point through each finite window, the regular sequence row R and dyadic tolerance row D are both downstream of the displayed point ledger, not of a selected stream representative.

The Real seal row A is reached only after Q, S, R, D are visible. Componentwise transport and replay through H and C preserve that order, while P and N attach provenance and the local NameCert boundary.

The carrier inventory contains no quotient stream equality, selected limit, countable-choice schedule, host real equality, ambient Real completeness, or detached Real-name equality coordinate. Therefore the point-generated completion route is exactly the displayed finite route consumed by chapter 1639. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrincipalCauchyEmbedding}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrincipalCauchyEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6988.1 and Definition 6988.2 seed the finite point-to-completion embedding route over displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrincipalCauchyEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, constant-window regularity, dyadic tolerance routing, Real-seal handoff, classifier transport, non-escape, package provenance, and local naming for BEDC.Derived.PrincipalCauchyEmbeddin

Constructive story: A $\mathsf{PrincipalCauchyEmbedding}^{\uparrow}$ packet is generated from one displayed dyadic source point, a constant StreamName window, a RegSeqRat regularity row, a dyadic tolerance row, a terminal Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6989

A Concrete Naming Certificate for $\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}$

Following Bishop and Bridges on constructive completions by regular Cauchy data, the RegularCauchyRepletionBoun packet records the finite boundary where $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, the existing $\mathsf{CauchyRepletion}^{\uparrow}$ corridor, and the terminal $\mathsf{Real}^{\uparrow}$ seal are all displayed before any completion-facing consumer reads a repleted name. It sits beside the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational handoff of chapter 301, the repletion corridor of chapter 6979, and the real-name seal of chapter 38. The packet is a boundary object, not a second construction of completed reals.

Definition 6989.1 (Regular Cauchy repletion boundary carrier)**.** *A* $\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule read by the boundary.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording precision scales, comparison bounds, and displayed dyadic thresholds.*
4. *Q is the* $\mathsf{CauchyRepletion}^{\uparrow}$ *corridor row through which the boundary receives completion-facing repletion data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after S, R, D, Q have been displayed.*
6. *H stores componentwise* hsame *transport for the stream schedule, regular readback, dyadic ledger, repletion corridor, seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from finite windows to regular readback, from readback through the dyadic ledger, from the dyadic ledger into the repletion corridor, and from the corridor to the terminal seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyRepletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, R, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected host limits, countable-choice schedules, trichotomy, host real equality, or ambient completeness.

Theorem 6989.2 (Regular Cauchy repletion boundary NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}$ *carrier* $B = (S, R, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRepletionBoun}}$ *surface consists exactly of carrier admission, finite-window exposure, regular rational readback, dyadic tolerance routing, Cauchy repletion corridor admission, terminal Real seal exposure, componentwise transport, displayed replay, provenance, and local naming. Every boundary consumer must display the* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*,* $\mathsf{CauchyRepletion}^{\uparrow}$ *row* Q*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and structural rows* H, C, P, N *before it reads the packet as repleted regular Cauchy data.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRepletionBoundaryUp.RegularCauchyRepletionBoundaryNamecertObligations`

Proof. Project the carrier of Definition 6989.1. The nine displayed rows are the only classifier-visible coordinates, so carrier admission and local naming are row projections.

The analytic obligations are the four displayed source steps. The stream schedule S supplies finite observations, R reads those observations as regular rational data, D records the dyadic tolerances used by the readback, and Q is the only repletion-corridor coordinate available before the seal-facing row can be read.

The structural rows preserve the same packet. The transport row H moves each displayed coordinate by hsame, the replay row C records the Cont route through the window, readback, dyadic, repletion, and seal rows, and P records the Pkg provenance for the local $\mathsf{NameCert}$ row N. Since no other classifier coordinate exists, the listed obligations exhaust the local surface. □

Theorem 6989.3 (Window repletion boundary)**.** *Let* $B = (S, R, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}$ *carrier. Any completion-facing read of the terminal row* E *factors through the finite window row* S*, the regular readback row* R*, the dyadic tolerance row* D*, and the* $\mathsf{CauchyRepletion}^{\uparrow}$ *corridor row* Q*; no consumer can read* E *from* S *or* R *alone.*

Proof. Use the displayed replay row C. Its route is ordered from S to R, from R through D, from D into Q, and from Q to E, so the seal-facing read is a replay of the whole boundary rather than a direct projection from a stream or readback row.

Transport does not change the dependency order. The row H only supplies componentwise hsame transport of the same displayed packet, and P, N only record provenance and naming. Thus a consumer reading E through the local $\mathsf{NameCert}$ must pass through the repletion row Q after the finite window, readback, and dyadic rows have been displayed. □

Theorem 6989.4 (Regular Cauchy repletion boundary non-escape)**.** *Every accepted* $\mathsf{RegularCauchyRepletionBound}$ *carrier is insensitive to quotient equality of streams, selected limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness. The only seal-facing information exported to a consumer is the displayed route through* BHist*,* hsame*,* Cont*,* Pkg*, and the local* $\mathsf{NameCert}$ *rows named in Definition 6989.1.*

Proof. Inspect the carrier coordinates. The tuple contains $S, R, D, Q, E, H, C, P, N$ and no row for quotient stream equality, a chosen host limit, a countable-choice schedule, trichotomy, or an ambient completeness principle.

It remains to check that the structural rows cannot add a hidden source. The hsame row H transports only displayed coordinates, the Cont row C replays only the boundary route already

present in the carrier, and the Pkg row P records provenance for the local NameCert row N. Therefore any exported seal-facing fact is confined to the finite boundary rows. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}$ packet exposes StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a CauchyRepletion corridor row, a Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any completion-facing consumer reads a repleted name.

Independence witness: dyadicratcore, streamname, regseqrat, cauchy-repletion, real: RegularCauchyRepletionBo is not bijective to any listed sibling because it jointly carries the window schedule, regular readback, dyadic tolerance ledger, repletion corridor, terminal seal, transport, replay, provenance, and local naming as one finite boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat regular rational readback, a DyadicRatCore tolerance ledger, a CauchyRepletion corridor row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6989.1, Definition 6989.2, Definition 6989.3, and Definition 6989.4 seed the finite non-quotient boundary between regular Cauchy repletion data and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRepletionBoundary}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyRepletionBoundaryUp.RegularCauchyRepletionBoundaryNamecertObligations`

Bridge status: none

Not claimed: This chapter does not close quotient equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window readback, dyadic tolerance routing, repletion corridor admission, Real seal exposure, transport, replay, provenance, and non-escape for BEDC.Derived.RegularCauchyRepletionBound

Chapter 6990

A Concrete Naming Certificate for MetaCICSubstitutionSpineRealizer$^{\uparrow}$

Following the standard de Bruijn account of shifting and substitution under binders, the MetaCICSubstitutionSpineR packet realizes the audit map of chapter 9380 as finite BEDC spine data. It sits after the closed substitution spine of chapter 6103, the substitution audit packet of **??**, the closed substitution boundary of chapter 538, and the subject-reduction obstruction map of chapter 9377. The packet records closed shift, closed substitution, closed composition, and binder-seal audit rows; it does not claim unrestricted substitution commutation, beta-substitution preservation, closed subject reduction, quotient syntax equality, host evaluator soundness, or kernel consistency.

Definition 6990.1 (MetaCIC substitution spine realizer carrier)**.** *A* MetaCICSubstitutionSpineRealizer$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, I, B, Z, S, U, K, L, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed MetaCIC term row, exposing the source term, payload term, and binder depth used by the audit map.*
2. *I is the de Bruijn index row, recording cutoff, depth, and successor arithmetic needed by the closed shift and substitution clauses.*
3. *B is the binder-seal row, recording the* ClosedAt *boundary that advances under lambda and Pi constructors.*
4. *Z is the closed shift row, read through the displayed term, index, and binder-seal rows.*
5. *S is the closed substitution row, read through the same closed boundary and payload visibility.*
6. *U is the closed composition row, restricted to the checked closed-fragment composition and swap laws named by the audit map.*
7. *K is the subject-reduction handoff row, retaining the beta-substitution preservation boundary as an obligation surface rather than a discharged theorem.*
8. *L is the local audit ledger row, recording that the consumer may inspect Z, S, U before reaching K.*
9. *H records componentwise* hsame *transport for term, index, binder-seal, shift, substitution, composition, handoff, ledger, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a substitution-audit request through T, I, B, Z, S, U, K, L.*
11. *P is the* Pkg *provenance over* MetaCICSubstitutionSpineRealizer$^{\uparrow}$*, chapter 9380, chapter 6103, chapter 538, chapter 9377,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionSpineRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, I, B, Z, S, U, K, L, H, C, P, N$. It has no coordinate for unrestricted substitution calculus, beta-substitution preservation, closed subject reduction, quotient syntax equality, host evaluator soundness, erased derivation semantics, or kernel consistency.

Lean4 ✓ `BEDC.Derived.MetaCICSubstitutionSpineRealizerUp.MetaCICSubstitutionSpineRealizerTasteGate`
`single carrier alignment`

Theorem 6990.2 (MetaCIC substitution spine realizer boundary)**.** *For every accepted* MetaCICSubstitutionSpineRe *carrier*

$$R = (T, I, B, Z, S, U, K, L, H, C, P, N),$$

the closed shift row Z, closed substitution row S, and closed composition row U are readable only after the term row T, de Bruijn index row I, and binder-seal row B have been displayed. A consumer that reaches the subject-reduction handoff K receives only the syntax-side audit ledger L and the structural rows H, C, P, N; it receives no beta-substitution preservation theorem, no closed subject-reduction theorem, no quotient syntax equality, and no host evaluator soundness row.

Proof. Project the carrier of Definition 6990.1. The rows preceding the operation surface are exactly the term data T, index data I, and binder-seal data B.

Read the operation rows in that order. The closed shift row Z and closed substitution row S both depend on the displayed ClosedAt boundary, while the composition row U is limited to the checked closed-fragment laws cited by the audit map.

The subject-reduction handoff K is a boundary row. The local ledger L records that the syntax-side rows Z, S, U may be inspected before this boundary, but it does not fill the beta-substitution preservation obligation.

Transport and replay through H and C preserve the same row order, while P and N attach provenance and local naming. Since no carrier coordinate stores unrestricted substitution commutation, beta preservation, closed subject reduction, quotient syntax equality, host evaluator soundness, erased derivation semantics, or kernel consistency, the consumer cannot export any of those endpoints from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionSpineRealizer}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionSpineRealizer}^{\uparrow}}$, seed)

Scope closed: Definition 6990.1 and Definition 6990.2 seed the finite substitution-audit realizer over displayed MetaCIC term, de Bruijn index, binder-seal, closed shift, closed substitution, closed composition, handoff, ledger, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionSpineRealizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted substitution commutation, beta-substitution preservation, closed subject reduction, quotient syntax equality, host evaluator soundness, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, binder-seal gating, closed shift routing, closed substitution routing, closed composition routing, subject-reduction handoff non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICSubstitutionSpineRealizerUp.

Constructive story: A MetaCICSubstitutionSpineRealizer$^{\uparrow}$ packet is generated from closed MetaCIC term data, de Bruijn index data, a ClosedAt binder seal, closed shift rows, closed substitution rows, closed composition rows, a subject-reduction handoff row, an audit ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6991

A Concrete Naming Certificate for $\mathsf{TaitReducibility}^{\uparrow}$

Following Tait and Girard on reducibility candidates, the $\mathsf{TaitReducibility}^{\uparrow}$ packet records the traditional candidate method as finite BEDC NameCert data for the MetaCIC strong-normalization route. It sits beside the critical-path packet of chapter 765, the normalization-budget packet of chapter 755, the bounded candidate frontier of chapter 4196, the logical-relation surface $\mathsf{LogicalRelation}^{\uparrow}$, and the normalization-by-evaluation surface $\mathsf{NormalizationByEvaluation}^{\uparrow}$. The packet names the closed typed term row, reducibility-candidate row, beta, application, and Pi closure rows, finite replay and provenance rows, and a local naming row before any MetaCIC consumer may read a candidate-mediated strong-normalization handoff.

Definition 6991.1 (Tait reducibility carrier)**.** *A* $\mathsf{TaitReducibility}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, E, B, A, \Pi, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term row, recording the term, its type, its context boundary, and the closedness evidence consumed by the MetaCIC route.*
2. *E is the reducibility-candidate row, recording the candidate predicate, candidate membership evidence, and the closed-candidate or candidate-family witness used for the inspected type.*
3. *B is the beta-closure row, recording that the candidate read is stable under the displayed beta step window admitted by the route.*
4. *A is the application-closure row, recording the function-side candidate evidence, argument candidate evidence, and the application handoff row.*
5. *Π is the Pi-closure row, recording binder-side candidate data, dependent-family routing, and the displayed adequacy boundary for Pi-shaped terms.*
6. *S is the candidate-mediated strong-normalization handoff row, downstream of E, B, A, Π and still attached to the closed typed term row T.*
7. *Q records the refusal boundary for evidence-free closed-term normalization, unrestricted subject reduction, full Church–Rosser, global beta-conversion decidability, and completed consistency.*
8. *H records componentwise* hsame *transport for $T, E, B, A, \Pi, S, Q, C, P, N$.*

9. *C records finite* Cont *replay from the MetaCIC critical-path and normalization-budget consumers through the displayed candidate route.*
10. *P is the* Pkg *provenance over* $\mathsf{TaitReducibility}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationBudget}^{\uparrow}$, $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$, $\mathsf{LogicalRelation}^{\uparrow}$, $\mathsf{NormalizationByEvaluation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TaitReducibility}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, E, B, A, \Pi, S, Q, H, C, P, N$. It has no coordinate for unconditional strong normalization, full subject reduction, full Church–Rosser, beta-conversion decidability, or consistency.

Theorem 6991.2 (Tait reducibility NameCert obligations)**.** *For an accepted* $\mathsf{TaitReducibility}^{\uparrow}$ *carrier*

$$R = (T, E, B, A, \Pi, S, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TaitReducibility}^{\uparrow}}$ *surface consists exactly of closed typed term exposure through T, reducibility-candidate exposure through E, beta-closure exposure through B, application closure through A, Pi closure through Π, candidate-mediated strong-normalization handoff through S, refusal exactness through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6991.1. The closed typed term row T supplies the inspected endpoint, while E is the only positive candidate row.

Read the closure rows B, A, Π as stability data for the same candidate. Beta stability, application closure, and Pi closure do not introduce independent normalization theorems; they keep the candidate route well formed for the displayed term and type rows.

The handoff row S is downstream of E, B, A, Π. Requests for evidence-free normalization, full subject reduction, full Church–Rosser, beta-conversion decidability, or consistency are sent to the refusal row Q.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed rows. Hence the NameCert surface is the finite Tait-candidate route, not a global metatheorem about every MetaCIC term. □

Theorem 6991.3 (Tait reducibility candidate-SN handoff)**.** *Every strong-normalization read exported from an accepted* $\mathsf{TaitReducibility}^{\uparrow}$ *carrier must first display the route*

$$T \longmapsto E \longmapsto (B, A, \Pi) \longmapsto S$$

and must keep the refusal row Q visible when it is consumed by $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationBudget}^{\uparrow}$ *or* $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$ *routes. The handoff may be compared with* $\mathsf{LogicalRelation}^{\uparrow}$ *and* $\mathsf{NormalizationByEvaluation}^{\uparrow}$ *as neighboring method surfaces, but it does not claim full subject reduction, Church–Rosser, beta-conversion decidability, arbitrary strong normalization, or consistency.*

Proof. Start with the accepted carrier. The closed term row T and reducibility-candidate row E are both visible before any normalization handoff appears.

Apply Definition 6991.2. Its beta, application, and Pi closure clauses place B, A, Π between candidate evidence and the strong-normalization handoff S.

Now read the downstream MetaCIC consumers. The critical-path, normalization-budget, and bounded-candidate chapters may inspect the displayed candidate route as dependency data, while the refusal row Q keeps the open metatheoretic principles outside the packet.

The neighboring logical-relation and normalization-by-evaluation surfaces can compare methods only through displayed provenance and replay rows. They cannot replace E, B, A, Π, S, Q by a hidden global theorem, so the exported handoff remains candidate-mediated. □

Closure status for $\mathsf{NameCert}_{\mathsf{TaitReducibility}^{\uparrow}}$.

Constructive story: A $\mathsf{TaitReducibility}^{\uparrow}$ packet is generated from a closed typed MetaCIC term row, reducibility-candidate row, beta-closure row, application-closure row, Pi-closure row, candidate-mediated strong-normalization handoff, refusal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaitReducibility}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6991.1, Definition 6991.2, and Definition 6991.3 seed the finite Tait-candidate method surface for MetaCIC normalization consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TaitReducibility}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full strong normalization, Church–Rosser, subject reduction, consistency, beta-conversion decidability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate exposure, beta, application, and Pi closure routing, candidate-mediated strong-normalization handoff, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.TaitReducibilityUp.

Chapter 6992

A Concrete Naming Certificate for $\mathsf{DirectedCofinalSubset}^{\uparrow}$

Following Moore–Smith and Kelley directed subsets, the $\mathsf{DirectedCofinalSubset}^{\uparrow}$ packet records a cofinal retained index surface inside an already named directed-index carrier. It refines the finite upper-window data of chapter 1607 for downstream net and completion arguments that need to restrict an index substrate without quotienting indices, selecting a cofinal sequence, or importing a choice-indexed thinning function.

The packet is a sibling handoff for the net routes of $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyNetLimit}^{\uparrow}$, $\mathsf{MooreSmithConvergence}^{\uparrow}$, and the completion-facing Cauchy chapters. It keeps the ambient directed packet and the retained cofinal packet visible at the same time, so a consumer can prove that every ambient finite request is met inside the retained surface by displayed rows rather than by an external cofinality theorem.

Definition 6992.1 (Directed cofinal subset carrier)**.** *A* $\mathsf{DirectedCofinalSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, J, \preceq, W_I, W_J, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the ambient directed-index row read from a* $\mathsf{DirectedSet}^{\uparrow}$ *packet.*
2. *J is the retained index row naming the finite cofinal subset surface.*
3. *$\preceq$ is the displayed comparison row inherited from the ambient directed packet and restricted to the retained rows when both endpoints lie in J.*
4. *W_I is the ambient finite-window row for downstream net or completion requests.*
5. *W_J is the retained finite-window row whose entries lie in J.*
6. *U is the cofinal-witness row, assigning to every displayed ambient request in W_I a retained address in J above that request by $\preceq$.*
7. *H records componentwise* hsame *transport for the ambient row, retained row, comparison row, ambient and retained windows, cofinal witnesses, continuation replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an ambient finite-window request through the retained cofinal witness route.*
9. *P is the* Pkg *provenance over* $\mathsf{DirectedCofinalSubset}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, *the downstream net and completion consumers,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{DirectedCofinalSubset}^{\uparrow}}$ *row.*
The carrier has no quotient of directed indices, no selected cofinal sequence, no countable choice schedule, no total-order refinement, and no host-level completeness principle.

Lean4 (statement) `BEDC.Derived.DirectedCofinalSubsetUp`

Theorem 6992.2 (Directed cofinal subset NameCert obligations)**.** *For an accepted* $\mathsf{DirectedCofinalSubset}^{\uparrow}$ *carrier* $S = (I, J, \preceq, W_I, W_J, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DirectedCofinalSubset}^{\uparrow}}$ *surface consists of carrier admission for the displayed rows, ambient directed-index readability through* $\mathsf{DirectedSet}^{\uparrow}$*, retained-row stability for* J *and* W_J*, cofinal-window coverage through* U*, componentwise transport and replay through* H *and* C*, provenance through* P*, and local naming through* N*. Every obligation is discharged by the finite rows of* S*.*

Proof. Carrier admission is projection from Definition 6992.1. The ambient index row, retained index row, comparison row, window rows, cofinal-witness row, transport row, replay row, provenance row, and local naming row are the complete visible packet.

Ambient directed-index readability is inherited from chapter 1607: comparisons and upper-window requests are read through the displayed $\mathsf{DirectedSet}^{\uparrow}$ rows before the retained subset is consulted.

For retained-row stability and cofinal-window coverage, inspect J, W_J, U. The retained window row names only addresses in J, and the cofinal-witness row supplies, for each ambient request in W_I, a retained address certified above the request by the displayed comparison row.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since no coordinate stores quotient indices, a cofinal sequence, countable choice, a total-order refinement, or ambient completeness, the NameCert surface is exhausted by the rows of S. □

Theorem 6992.3 (Directed cofinal subset net handoff)**.** *Every* $\mathsf{CauchyNet}^{\uparrow}$*,* $\mathsf{CauchyNetLimit}^{\uparrow}$*,* $\mathsf{MooreSmithConvergence}^{\uparrow}$*, or completion-facing consumer that reads a directed index through an accepted* $\mathsf{DirectedCofinalSubset}^{\uparrow}$ *packet receives only the ambient directed row* I*, retained row* J*, comparison row* $\preceq$*, ambient and retained finite windows* W_I, W_J*, cofinal-witness row* U*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* N*. The handoff may restrict a net read to the retained cofinal surface, but it does not provide a quotient net, selected subnet sequence, countable-choice selector, host directed set, or Real completeness datum.*

Proof. Begin with a downstream finite-window request. The request is first read as an ambient directed-window row in W_I over the $\mathsf{DirectedSet}^{\uparrow}$ substrate of chapter 1607.

The cofinal witness row U then names a retained address in J above the requested ambient window, and W_J records the retained window through which the downstream net or completion consumer continues.

Transport and replay through H and C keep the same ambient row, retained row, comparison row, window rows, and cofinal witness. The provenance and naming rows package exactly that route, so the consumer cannot replace it by a quotient net, selected subnet sequence, countable-choice selector, host directed set, or Real completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirectedCofinalSubset}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DirectedCofinalSubset}^{\uparrow}$ packet is generated from an ambient directed-index row, a retained index row, a displayed comparison row, ambient and retained finite-window rows, a cofinal-witness row, componentwise transport, continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirectedCofinalSubset}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6992.1, Definition 6992.2, and Definition 6992.3 seed the finite cofinal-subset carrier and its net-facing handoff over a displayed $\mathsf{DirectedSet}^{\uparrow}$ substrate.

Formal verification: FormalStatus(NameCert$_{\mathsf{DirectedCofinalSubset}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient nets, selected subnet sequences, countable choice, host directed sets, Real completeness, Lean verification of the obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, retained-row stability, cofinal-window coverage, net handoff, non-escape, and package provenance for the same finite packet.

Chapter 6993

A Concrete Naming Certificate for $\mathsf{BezoutIdentity}^{\uparrow}$

Following Bezout and Euclid, the $\mathsf{BezoutIdentity}^{\uparrow}$ packet records the finite arithmetic surface in which a displayed common divisor is reached by backtracking through a Euclidean trace. It sits over the natural-number rows of chapter 28, the signed coefficient rows of chapter 31, and the multiplication-witness divisibility ledger of chapter 331. The packet names only the displayed trace, coefficient ledger, divisor boundary, history transport, continuation replay, package provenance, and local certificate row; it does not select a unique gcd normalization, host integer equality, quotient ideals, classical Euclidean-domain generality, or an algorithm outside the finite trace shown by the carrier.

Definition 6993.1 (Bezout identity carrier)**.** *A* $\mathsf{BezoutIdentity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (g, a, b, x, y, e, d, h, c, p, n)$$

with the following displayed rows:

1. g, a, b *are accepted arithmetic rows naming the displayed common divisor and the two input rows, with* a *and* b *read through* $\mathsf{Nat}^{\uparrow}$ *or through the signed readback supplied by* $\mathsf{Int}^{\uparrow}$ *when coefficients are consumed.*
2. x *and* y *are accepted* $\mathsf{Int}^{\uparrow}$ *coefficient rows.*
3. e *is the finite Euclidean backtracking trace, listing the displayed remainder steps and the coefficient substitutions used by the trace.*
4. d *is the divisibility boundary row, recording displayed witnesses that* g *divides* a *and* g *divides* b *through the* $\mathsf{Divisibility}^{\uparrow}$ *multiplication-witness surface.*
5. h *records componentwise* hsame *transport for the input rows, coefficient rows, trace row, divisibility boundary, continuation, provenance, and local naming rows.*
6. c *stores the* Cont *replay route that reads the trace as the displayed identity surface* $x \cdot a + y \cdot b = g$ *together with the divisor boundary.*
7. p *is the* Pkg *provenance over* $\mathsf{BezoutIdentity}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Divisibility}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. n *is the local* $\mathsf{NameCert}_{\mathsf{BezoutIdentity}^{\uparrow}}$ *row.*

The carrier exports no row for unique gcd normalization, host integer equality, quotient ideals, an ambient Euclidean domain, or a selected algorithm beyond the finite Euclidean trace e.

Theorem 6993.2 (BezoutIdentity NameCert obligations)**.** *For every accepted* $\mathsf{BezoutIdentity}^{\uparrow}$ *carrier*

$$B = (g, a, b, x, y, e, d, h, c, p, n),$$

the local $\mathsf{NameCert}_{\mathsf{BezoutIdentity}^{\uparrow}}$ *surface consists exactly of carrier admission for B, input admission for g, a, b, integer-coefficient admission for x, y, Euclidean-trace exposure through e, divisibility-boundary exposure through d, componentwise* hsame *stability through h,* Cont *replay through c,* Pkg *provenance through p, and local naming through n.*

Proof. Project the accepted carrier of Definition 6993.1. The rows g, a, b name the divisor and inputs, while x, y name the signed coefficient rows supplied by the integer certificate.

The trace row e is the only place where Euclidean backtracking is stored. Its displayed substitutions are replayed by c as the identity surface $x \cdot a + y \cdot b = g$.

The divisor boundary row d is read through chapter 331. It supplies multiplication-witness divisibility of a and b by g, not a quotient ideal or a host gcd predicate.

Finally, the rows h, p, n transport, source, and name the same finite packet. Since the carrier has no coordinate for unique normalization, host integer equality, classical Euclidean-domain generality, or an algorithm selector outside e, none of those objects belongs to the local NameCert surface. □

Theorem 6993.3 (Bezout Euclidean backtracking)**.** *Every downstream consumer of an accepted* $\mathsf{BezoutIdentity}^{\uparrow}$ *carrier that reads a displayed identity $x \cdot a + y \cdot b = g$ must factor through the finite route*

$$e, d \longmapsto h, c, p, n.$$

The Euclidean trace e supplies the only backtracking substitutions, and the continuation row c is the only route by which those substitutions are read as a signed $\mathsf{Int}^{\uparrow}$ *coefficient identity over the input rows.*

Proof. Begin with an accepted packet $B = (g, a, b, x, y, e, d, h, c, p, n)$. The rows x and y are integer coefficient rows, while a and b are the input rows cited by the trace.

The Euclidean trace e lists the finite remainder and substitution steps. Reading the displayed identity requires replaying those steps through c, so the consumer cannot replace the trace by a host-level algorithm or by an untracked extended-gcd routine.

The rows h, p, n then preserve, source, and name the same trace route. Any selected algorithm outside e would require an additional coordinate, and Definition 6993.1 has none. □

Theorem 6993.4 (Bezout gcd-divisibility boundary)**.** *For every accepted* $\mathsf{BezoutIdentity}^{\uparrow}$ *carrier $B = (g, a, b, x, y, e, d, h, c, p, n)$, the common-divisor information exported by the packet is exactly the displayed* $\mathsf{Divisibility}^{\uparrow}$ *boundary row d together with the Euclidean trace e. The packet may be consumed as a Bezout witness for the named divisor row g, but it does not identify g with a uniquely normalized gcd, does not quotient integer rows by host equality, does not build a quotient ideal, and does not assert Euclidean-domain generality beyond the displayed finite trace.*

Proof. Read d through the divisibility carrier of chapter 331. It exposes multiplication witnesses for the two divisor claims involving g, a, b.

Read e through the backtracking theorem Definition 6993.3. This supplies the displayed coefficient identity over the same input rows and coefficient rows.

Together these two rows give the Bezout witness surface: a named divisor row, displayed divisibility of both inputs, and a finite signed coefficient identity. The carrier contains no row for least positive representative, associate-class normalization, quotient ideals, or ambient Euclidean-domain law, so the gcd boundary remains exactly the displayed divisibility boundary. □

Falsifiable prediction: A consumer that claims a $\mathsf{BezoutIdentity}^{\uparrow}$ certificate while omitting the Euclidean trace row, the divisibility boundary row, integer coefficient rows, hsame, Cont, Pkg, or the local NameCert row refutes the carrier of Definition 6993.1.

Independence witness: nat, int, divisibility: $\mathsf{BezoutIdentity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a Euclidean backtracking trace, signed coefficient rows, and a divisibility boundary. NatUp supplies unsigned arithmetic rows; IntUp supplies signed coefficient rows without a Euclidean trace; DivisibilityUp supplies multiplication-witness divisor rows without the coefficient identity route.

Closure status for $\mathsf{NameCert}_{\mathsf{BezoutIdentity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BezoutIdentity}^{\uparrow}$ packet is generated from displayed input rows, signed coefficient rows, a finite Euclidean backtracking trace, a divisibility boundary, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BezoutIdentity}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6993.1, Definition 6993.2, Definition 6993.3, and Definition 6993.4 form the obligation surface for finite Bezout backtracking over NatUp, IntUp, and DivisibilityUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BezoutIdentity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unique gcd normalization, host integer equality, quotient ideals, classical Euclidean-domain generality, Lean verification, bridge checking, or a selected algorithm outside the displayed finite trace.

Upgrade path: Scoped closure requires a consumer certificate showing that later dyadic, rational, modular, and divisibility readers factor through the displayed Euclidean trace and divisor boundary.

Chapter 6994

A Concrete Naming Certificate for $\mathsf{SchurComplement}^{\uparrow}$

Following Schur and standard finite block-matrix linear algebra, the $\mathsf{SchurComplement}^{\uparrow}$ packet records the finite displayed route by which a block matrix with an invertible pivot block exposes its complement row. It consumes the matrix carrier of chapter 49, the linear-map surface of chapter 48, the determinant rows of chapter 84, the field scalar source of chapter 45, and the vector-space rows of chapter 47. The packet names only displayed block rows, pivot invertibility evidence, finite multiplication rows, transport, replay, provenance, and local naming; it does not assert a host matrix inverse theorem, quotient matrix equality, Gaussian elimination over arbitrary ambient objects, or a selected global decomposition.

Definition 6994.1 (Schur complement carrier)**.** *A* $\mathsf{SchurComplement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, V, M, A, B, C, D, I, Q, E, H, R, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Field}^{\uparrow}$ *scalar row and V is the finite* $\mathsf{VecSpace}^{\uparrow}$ *row used by the block coordinates.*
2. *M is the ambient* $\mathsf{Mat}^{\uparrow}$ *row, read as the displayed block matrix with rows A, B, C, D.*
3. *I is the pivot-invertibility row for D, recording the finite right and left inverse checks available inside the matrix packet.*
4. *Q is the displayed product row for $BD^{-1}C$ and the complement row $A - BD^{-1}C$.*
5. *E is the exactness row tying the complement to the block multiplication and determinant handoff.*
6. *H records componentwise* hsame *transport for the field, vector, block, inverse, product, exactness, replay, provenance, and naming rows.*
7. *R records displayed* Cont *replay from the block matrix through the complement row to determinant, inverse, and factorization consumers.*
8. *P is the* Pkg *provenance over* $\mathsf{SchurComplement}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SchurComplement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host matrix equality, an unbounded inverse operator, a selected Gaussian-elimination trace outside the displayed block ledger, or choice of bases beyond the finite vector-space rows already named.

Theorem 6994.2 (Schur complement NameCert obligations)**.** *For every accepted* $\mathsf{SchurComplement}^{\uparrow}$ *carrier* $S = (F, V, M, A, B, C, D, I, Q, E, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SchurComplement}^{\uparrow}}$ *surface consists exactly of carrier admission, field and vector-space exposure, block-matrix exposure, pivot-invertibility display, finite product display, complement exactness, determinant-facing handoff, componentwise transport, replay, provenance, and local naming.*

The five-row obligation sketch is:

1. *block admission exposes* F, V, M, A, B, C, D *as displayed* $\mathsf{Field}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*, and* $\mathsf{LinMap}^{\uparrow}$ *rows;*
2. *pivot admission exposes* I *only as finite inverse checks for the chosen pivot block;*
3. *complement formation exposes* Q *only as the displayed multiplication and subtraction row for* $A - BD^{-1}C$*;*
4. *determinant handoff exposes* E *only through the determinant-facing route, with no host determinant lemma imported as theorem content;*
5. *structural replay exposes* H, R, P, N *as transport, continuation, provenance, and naming rows, and exports no hidden matrix equality principle.*

Proof. Project the carrier of Definition 6994.1. The field, vector-space, block-matrix, pivot, product, and exactness rows are displayed before any consumer-facing route is available.

The pivot row I supplies only finite inverse checks for the displayed block D. The product row Q then records the multiplication path through B, the inverse witness, and C, and the exactness row E binds the result to the complement read.

The determinant-facing handoff is routed through E, R, P, N and remains inside the same finite packet. Componentwise hsame transport in H preserves each displayed row, so no host matrix equality, global inverse theorem, or selected elimination trace can be projected from the certificate. □

Theorem 6994.3 (Schur complement block-matrix handoff)**.** *Every matrix-factorization, determinant, inverse, or finite linear-system consumer of an accepted* $\mathsf{SchurComplement}^{\uparrow}$ *packet must first read the finite rows*

$$F, V, M, A, B, C, D, I, Q, E, H, R, P, N.$$

In particular, a consumer may use the complement row only after the block matrix, pivot inverse checks, product route, exactness row, transport row, replay row, provenance row, and local naming certificate have been displayed.

Proof. Let a downstream consumer route be given. Carrier projection gives the displayed scalar, vector, matrix, block, pivot, product, exactness, transport, replay, provenance, and naming rows.

The consumer first reads the block matrix through M, A, B, C, D. It then reads the pivot evidence through I and the complement route through Q, E.

Finally the consumer-facing handoff must pass through H, R, P, N. These rows preserve and expose the same displayed packet, but they do not add host matrix equality, an ambient inverse theorem, a determinant lemma outside the displayed route, or choice of bases. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchurComplement}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchurComplement}^{\uparrow}$ packet is generated from displayed FieldUp, VecSpaceUp, MatrixUp, LinearMapUp, DeterminantUp, block, pivot-inverse, product, complement-exactness, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchurComplement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6994.1, Definition 6994.2, and Definition 6994.3 seed the finite block-matrix complement surface over displayed matrix, linear-map, determinant, field, vector-space, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SchurComplement}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host matrix equality, a global matrix inverse theorem, arbitrary Gaussian elimination, determinant lemmas outside the displayed route, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pivot-inverse display, finite product exactness, determinant handoff, transport stability, and consumer non-escape for BEDC.Derived.SchurComplementUp.

Chapter 6995

A Concrete Naming Certificate for HyperbolicGeodesicMidpoint$^{\uparrow}$

The HyperbolicGeodesicMidpoint$^{\uparrow}$ packet realizes the Poincare disk midpoint route of section 9463.3 as finite metric, boundary, phase-transport, provenance, and NameCert rows. It sits after the metric readback of chapter 3474, the boundary-geodesic surface of chapter 3491, the disk automorphism carrier of chapter 6776, the visual-boundary packet of chapter 4181, and the reversible phase-transport route of chapter 3455. The packet names only a displayed finite midpoint certificate; it does not complete the disk, quotient ideal endpoints, select a global geodesic representative, or import host equality of hyperbolic points.

Definition 6995.1 (Hyperbolic geodesic midpoint carrier)**.** *A* HyperbolicGeodesicMidpoint$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, G, B, A, V, T, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the Poincare disk coordinate row for the two displayed endpoints and the candidate midpoint.*
2. *G is the* HyperbolicMetric$^{\uparrow}$ *readback row comparing the two endpoint-to-midpoint distances.*
3. *B is the* HyperbolicGeodesicBoundary$^{\uparrow}$ *row naming the boundary-determined geodesic route on which the midpoint is read.*
4. *A is the* PoincareDiskAutomorphism$^{\uparrow}$ *normalization row used to move the finite geodesic read to a standard disk position and back.*
5. *V is the* HyperbolicVisualBoundary$^{\uparrow}$ *readback row for the same boundary pair.*
6. *T is the* PoincareDiskPhaseTransport$^{\uparrow}$ *row carrying the midpoint read through reversible phase transport.*
7. *E is the midpoint exactness row, recording equal displayed metric halves and the boundary-geodesic incidence check.*
8. *H records componentwise* hsame *transport for the disk, metric, boundary, automorphism, visual-boundary, phase-transport, exactness, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from endpoint data through midpoint exactness to metric, boundary, automorphism, and phase-transport consumers.*

10. *P is the* Pkg *provenance over* HyperbolicGeodesicMidpoint$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicGeodesicBoundary$^{\uparrow}$, PoincareDiskAutomorphism$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, PoincareDiskPhaseTransport$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{HyperbolicGeodesicMidpoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, G, B, A, V, T, E, H, C, P, N$. It has no coordinate for a completed hyperbolic plane, quotient ideal boundary, selected global geodesic object, physical observer law, or host point equality.

Theorem 6995.2 (Hyperbolic geodesic midpoint NameCert obligations)**.** *For every accepted* HyperbolicGeodesicMidpoint$^{\uparrow}$ *carrier $M = (D, G, B, A, V, T, E, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicGeodesicMidpoin}}$ *surface consists exactly of carrier admission, disk-coordinate exposure, metric midpoint readback, boundary-geodesic incidence, automorphism normalization, visual-boundary readback, phase-transport replay, midpoint exactness, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6995.1. The disk endpoints and candidate midpoint are displayed by D, while the metric, boundary, automorphism, visual-boundary, and phase rows are displayed by G, B, A, V, T.

The exactness row E records the finite midpoint check: the candidate lies on the displayed boundary-geodesic route and the two metric halves agree inside the recorded readback. Transport through H is componentwise, so it preserves exactly those rows.

Consumers can inspect the midpoint only through C, P, N. These rows replay and name the same finite packet, and therefore cannot export a completed hyperbolic plane, quotient boundary, selected global geodesic, or host point equality. □

Theorem 6995.3 (Hyperbolic geodesic midpoint boundary handoff)**.** *Every boundary, visual, automorphism, phase-transport, or observer-expansion consumer of an accepted* HyperbolicGeodesicMidpoint$^{\uparrow}$ *packet must first read the finite rows*

$$D, G, B, A, V, T, E, H, C, P, N.$$

In particular, the midpoint row is exported only as the displayed point that lies on the named boundary-geodesic route, has equal displayed HyperbolicMetric$^{\uparrow}$ *distance halves, and is transported through the same* PoincareDiskPhaseTransport$^{\uparrow}$ *provenance.*

Proof. Let a downstream consumer be given. Carrier projection gives the disk-coordinate row D, the metric row G, the boundary row B, the automorphism row A, the visual-boundary row V, and the phase-transport row T.

The consumer then reads the midpoint exactness through E. This row binds the incidence and equal-half metric checks to the same displayed endpoint pair and candidate midpoint.

Finally the handoff passes through H, C, P, N. These structural rows transport, replay, record provenance, and name the packet without adding a completed disk, quotient ideal endpoints, a selected global geodesic, or host point equality. □

Falsifiable prediction: Every accepted HyperbolicGeodesicMidpoint$^{\uparrow}$ packet exposes disk-coordinate, hyperbolic-metric, geodesic-boundary, Poincare-disk-automorphism, visual-boundary, phase-transport, exactness, transport, replay, provenance, and NameCert rows before any midpoint consumer reads it.

Independence witness: hyperbolic-metric, hyperbolic-geodesic-boundary, poincare-disk-automorphism, hyperbolic-visual-boundary, poincare-disk-phase-transport: $\mathsf{HyperbolicGeodesicMidpoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a displayed endpoint pair, candidate midpoint, metric equal-half readback, boundary-geodesic incidence, automorphism normalization, visual-boundary readback, phase transport, exactness, transport, replay, provenance, and local naming in one packet.

Lean follow-up requires $\mathsf{Nontrivial\ HyperbolicGeodesicMidpoint}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicGeodesicMidpoint}^{\uparrow}$ witnesses in the corresponding TasteGate surface.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicMidpoint}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{HyperbolicGeodesicMidpoint}^{\uparrow}$ packet is generated from disk-coordinate, hyperbolic-metric, geodesic-boundary, automorphism, visual-boundary, phase-transport, midpoint-exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicMidpoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6995.1, Definition 6995.2, Definition 6995.3, the falsifiable prediction, and the independence witness seed the finite Poincare-disk geodesic midpoint surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicMidpoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a completed hyperbolic plane, quotient ideal boundary, selected global geodesic representatives, host point equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric midpoint readback, boundary-geodesic incidence, automorphism normalization, visual-boundary readback, phase-transport replay, nontrivial and field-faithful TasteGate instances, and consumer non-escape for BEDC.Derived.HyperbolicGeodesicMidpointUp.

Chapter 6996

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy reals and explicit moduli, the $\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}$ packet records the finite diagonal schedule that turns a displayed family of regular Cauchy names into one completion-facing modulus row. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the Cauchy-name-space route of chapter 406. The packet names a diagonal modulus as finite BEDC rows; it is not a quotient of streams, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6996.1 (Regular Cauchy diagonal-modulus carrier)**.** *A* $\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, \sigma, \Delta, \epsilon, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the displayed regular-family row, whose members are* $\mathsf{RegSeqRat}^{\uparrow}$ *names read through one common* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *surface.*
2. *σ is the* $\mathsf{StreamName}^{\uparrow}$ *schedule exposing the finite windows of the family needed at each requested tolerance.*
3. *Δ is the diagonal window selector, recording which scheduled family-window and sequence-window are inspected for the current precision request.*
4. *ϵ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the diagonal budget and the componentwise regularity comparisons.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected diagonal windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after $F, \sigma, \Delta, \epsilon, Q$ have been displayed.*
7. *H stores componentwise* hsame *transport for the regular family, stream schedule, diagonal selector, dyadic ledger, readback, seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a completion-facing request through $F, \sigma, \Delta, \epsilon, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient stream equality, selected limiting representatives, countable choice, host real equality, or an ambient completeness theorem.

Theorem 6996.2 (Regular Cauchy diagonal-modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}$ *carrier* $D = (F, \sigma, \Delta, \epsilon, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModu}}$ *surface consists exactly of regular-family admission, scheduled finite-window exposure, diagonal selector exactness, dyadic tolerance-ledger exactness, regular rational readback, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming for the rows of Definition 6996.1.*

Proof. Project the accepted carrier. The analytic rows are $F, \sigma, \Delta, \epsilon, Q, E$, and the structural rows are H, C, P, N.

The family row F is read first through the Cauchy-name-space route. The schedule σ and diagonal selector Δ then specify finite windows of that family, so the consumer never receives an unbounded stream or selected subsequence.

The tolerance and readback rows ϵ, Q are downstream of the selected windows. They expose dyadic budgets and regular rational names before the Real seal E is available.

Finally the transport, replay, provenance, and local naming rows preserve the same finite packet. Since the carrier inventory contains no quotient, selected limit, choice, host equality, or completeness coordinate, the listed rows exhaust the NameCert obligation surface. □

Theorem 6996.3 (Regular Cauchy diagonal-modulus Cauchy handoff)**.** *Every* $\mathsf{CauchySequenceSpace}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing consumer of an accepted* $\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}$ *carrier reads the route*

$$\mathsf{CauchySequenceSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $F, \sigma, \Delta, \epsilon, Q, E, H, C, P, N$. The diagonal modulus exports a tolerance-indexed finite-window handoff and does not export quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 6996.2. It forces the consumer to expose the regular family, schedule, diagonal selector, dyadic ledger, regular readback, Real seal, and structural rows before any completion-facing read is available.

The Cauchy handoff therefore reaches $\mathsf{RegSeqRat}^{\uparrow}$ only through the scheduled diagonal windows and reaches $\mathsf{Real}^{\uparrow}$ only after the dyadic tolerance ledger has been replayed. The rows H, C, P, N keep this route stable under the local classifier and add no second source.

Thus every accepted consumer factors through the displayed finite route from Cauchy-name-space data to the Real seal. Any use of a quotient stream, selected limit, choice schedule, host equality, or ambient completeness theorem lies outside the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}$ consumer that presents a $\mathsf{Real}^{\uparrow}$ seal without first displaying $F, \sigma, \Delta, \epsilon, Q, E, H, C, P, N$ refutes the carrier surface.

Independence witness: Nearest siblings: cauchysequencespace, streamname, regseqrat, dyadicratcore, and real. The packet is not bijective to any one sibling because it jointly carries a regular-family row, stream schedule, diagonal selector, dyadic tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalModulus}^{\uparrow}}$.

Constructive story: A RegularCauchyDiagonalModulus$^{\uparrow}$ packet is generated from a CauchySequenceSpace regular-family row, StreamName schedules, a diagonal window selector, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyDiagonalModulus}\uparrow}$, seed)

Scope closed: Definition 6996.1, Definition 6996.2, and Definition 6996.3 seed the finite diagonal-modulus route for L10 Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyDiagonalModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host Real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scheduled-window exposure, diagonal-selector exactness, DyadicRatCore tolerance exactness, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyDiagonalModulusUp.

Chapter 6997

A Concrete Naming Certificate for $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, and the finite-cover construction of chapter 9237, the $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$ packet records the finite route from star refinements and local moduli to a tolerance-only uniform-modulus handoff. It sits after the compact metric source of chapter 129, the continuous-map rows of chapter 130, the finite Lebesgue-number surface of chapter 3606, the compact-cover lower-bound ledger of $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$, the rational and dyadic tolerance rows of $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$, and the uniform-modulus consumer of chapter 369. The packet names a finite star-refinement modulus and not an open-cover compactness theorem, selected subcover, host continuous function, quotient cover equality, or ambient completeness principle.

Definition 6997.1 (Finite cover star-refinement modulus carrier)**.** *A* $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, f, U, V, L, R, D, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose compact evidence is read as finite cover data.*
2. *f is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row carrying the local modulus data attached to the same source.*
3. *U is the finite cover row and V is the star-refinement row over that cover.*
4. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *or* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *lower-bound row for the star refinement.*
5. *R is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row requested by the target consumer.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger comparing the requested tolerance with the finite lower-bound data.*
7. *M is the resulting* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, available only after K, f, U, V, L, R, D have been displayed.*
8. *H stores componentwise* hsame *transport for the compact source, continuous map, cover, star refinement, lower-bound, rational, dyadic, uniform-modulus, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a compact-uniform-continuity request through* $K, f, U, V, L, R, D, M, H, P, N$
10. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected subcovers, host-function equality, quotient covers, countable choice, or ambient completion.

Theorem 6997.2 (Finite cover star-refinement modulus NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$ *carrier* $S = (K, f, U, V, L, R, D, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}}$ *surface consists exactly of compact metric admission, continuous-map local-modulus admission, finite cover exposure, star-refinement exactness, finite Lebesgue-number or compact-cover ledger admission, positive rational tolerance admission, dyadic tolerance comparison, uniform-modulus output exactness, componentwise transport, displayed replay, provenance, and local naming for the rows of Definition 6997.1.*

Proof. Project the accepted carrier. The analytic rows are K, f, U, V, L, R, D, M, and the structural rows are H, C, P, N.

The compact source K and continuous-map row f are read before the finite cover is used. The cover row U and star-refinement row V then give the finite local geometry inspected by the modulus construction.

The lower-bound row L, rational tolerance row R, and dyadic comparison row D determine the tolerance-only output row M. This order prevents the uniform-modulus consumer from replacing the finite star-refinement data by an open-cover compactness theorem or selected subcover.

Finally H, C, P, N transport, replay, package, and name the same packet. Since no forbidden principle is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6997.3 (Finite cover star-refinement uniform handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$ *carrier reads the route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, U, V, \mathsf{FiniteLebesgueNumber}^{\uparrow}, \mathsf{CompactCoverLebesgueLedger}^{\uparrow}, \mathsf{Rat}^{\uparrow}, \mathsf{DyadicRatCore}$$

through the displayed rows $K, f, U, V, L, R, D, M, H, C, P, N$. The handoff exports a tolerance-only uniform-modulus row and exports no open-cover compactness theorem, selected finite subcover, host continuous map, quotient cover equality, countable choice, or ambient completeness.

Proof. Begin with Definition 6997.2. It fixes the compact source, continuous-map data, finite cover, star refinement, lower-bound ledger, rational tolerance, dyadic comparison, and structural rows before the uniform-modulus output can be read.

The row M is therefore downstream of the star-refinement and lower-bound rows. A consumer reading M receives only the tolerance-indexed precision certified by R, D, L, not a selected subcover or host modulus function.

The structural rows H, C, P, N replay the same finite packet for the compact-uniform-continuity route of chapter 9237. Because the carrier lacks open-cover compactness, quotient cover equality, choice, and ambient completeness coordinates, the uniform handoff is exactly the displayed BEDC route. □

Falsifiable prediction: An accepted $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$ consumer that exports a $\mathsf{UniformModulus}^{\uparrow}$ precision without displaying $K, f, U, V, L, R, D, M, H, C, P, N$ refutes the carrier surface.

Independence witness: Nearest siblings: compactmetric, continuousmap, finite-cover-lebesgue-number, compactcoverlebesgueledger, rat, dyadicratcore, and uniformmodulus. The packet binds a star-refinement row to the tolerance-only uniform-modulus output, while each sibling supplies only its own carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$ packet is generated from CompactMetricUp source rows, ContinuousMapUp local-modulus rows, finite cover rows, star-refinement rows, FiniteLebesgueNumberUp or CompactCoverLebesgueLedgerUp lower-bound rows, positive RatUp tolerances, DyadicRatCoreUp comparisons, a UniformModulusUp output, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6997.1, Definition 6997.2, and Definition 6997.3 seed the finite star-refinement route from compact finite-cover data to a tolerance-only uniform-modulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, host continuous maps, quotient cover equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, star-refinement exactness, lower-bound ledger admission, Rat and DyadicRatCore tolerance comparison, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverStarRefinementModulusUp.

Chapter 6998

A Concrete Naming Certificate for $\mathsf{BishopContinuityModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{BishopContinuityModulus}^{\uparrow}$ packet records the local continuity-modulus handoff for a displayed real-valued map at a displayed source point. It sits after the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the continuity carrier of chapter 130. The packet names a local modulus request as finite BEDC data; it is not compactness, uniform continuity, trichotomy, quotient real equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6998.1 (Bishop continuity modulus carrier)**.** *A* $\mathsf{BishopContinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, x, e, m, S, D, R, W, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *source row, recording the displayed real-valued map and its local continuity surface.*
2. *x is the source-point row, naming the point at which the local continuity request is read.*
3. *e is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request row, recording the positive dyadic target precision.*
4. *m is the local modulus witness row, giving the finite neighbourhood budget whose use is licensed only for the source point x and tolerance request e.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite observation windows used to test the source and image names.*
6. *D is the dyadic tolerance ledger comparing the request e with the windows selected by m.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the window observations into regular rational data.*
8. *W is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposing the target real-name read only after S, D, R have been displayed.*
9. *H records componentwise* hsame *transport for F, x, e, m, S, D, R, W and the local naming row.*

10. *C records displayed* Cont *replay through the continuity source, source point, tolerance request, local modulus, windows, dyadic comparisons, regular readback, real seal, provenance, and local naming rows.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopContinuityModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopContinuityModulus}^{\uparrow}}$ *row.*

The classifier compares carriers only through $F, x, e, m, S, D, R, W, H, C, P, N$. It has no coordinate for a compact domain, a uniform modulus over all source points, real trichotomy, quotient real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6998.2 (Bishop continuity modulus NameCert obligations)**.** *For the carrier of Definition 6998.1, the local* $\mathsf{NameCert}_{\mathsf{BishopContinuityModulus}^{\uparrow}}$ *surface consists exactly of continuity-source exposure through F, source-point exposure through x, dyadic tolerance request through e, local modulus witness through m, StreamName windows through S, dyadic comparison through D, RegSeqRat readback through R, terminal Real seal through W, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier to its displayed rows. The continuity-source row F, source point x, tolerance request e, and local modulus witness m determine the local request before any real-facing data can be read.

Read the observation side next. The StreamName windows S expose the finite source and image windows, the dyadic ledger D compares those windows with the requested tolerance, and the RegSeqRat row R supplies the regular rational readback used by the endpoint.

Finally apply the terminal seal and structural rows. The Real row W is reached only after the window, dyadic, and regular-rational rows are displayed, while H, C, P, N transport, replay, source, and name the same finite packet. Since no further coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 6998.3 (Bishop continuity modulus real handoff)**.** *Let $B = (F, x, e, m, S, D, R, W, H, C, P, N)$ be an accepted* $\mathsf{BishopContinuityModulus}^{\uparrow}$ *carrier. Any downstream consumer that reads the local continuity output as* $\mathsf{Real}^{\uparrow}$ *data must first factor through the source point x, tolerance request e, local modulus witness m,* $\mathsf{StreamName}^{\uparrow}$ *window row S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and terminal* $\mathsf{Real}^{\uparrow}$ *seal W on the same packet route.*

This handoff is local at x and exports no compactness theorem, no uniform-continuity modulus over all points, no trichotomy principle, no quotient real equality, no selected limit, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from Definition 6998.2. It places the source point, tolerance request, local modulus witness, windows, dyadic comparisons, regular readback, and real seal in one local certificate surface.

Use the sibling routes named in the chapter opening. The continuity source is read through chapter 130; finite observations are read through chapter 126; dyadic tolerance data through chapter 291; regular readback through chapter 301; and the endpoint seal through chapter 38.

The route remains local because m is tied to the displayed source point x and request e. A downstream consumer therefore reaches $\mathsf{Real}^{\uparrow}$ only through S, D, R, W together with H, C, P, N, and no excluded compactness, uniformity, trichotomy, quotient-equality, selected-limit, or completeness coordinate is available. □

Falsifiable prediction: Any accepted BishopContinuityModulusUp packet that exports a Real-facing continuity read without displaying the source point, tolerance request, local modulus witness, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, and terminal Real seal refutes the carrier.

Independence witness: continuousmap, streamname, dyadicratcore, regseqrat, real: none is bijective with $\mathsf{BishopContinuityModulus}^{\uparrow}$ because this carrier binds a local source-point request, tolerance, modulus witness, finite windows, dyadic comparison, regular readback, terminal seal, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopContinuityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopContinuityModulus}^{\uparrow}$ packet is generated from a continuity-source row, source point, dyadic tolerance request, local modulus witness, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, terminal Real seal, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopContinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6998.1, Definition 6998.2, Definition 6998.3, the falsifiable prediction, and the independence witness record the local continuity-modulus seed surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopContinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim compactness, uniform continuity, trichotomy, quotient real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires grounding the source point, tolerance request, local modulus witness, StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows against explicit kernel primitives.

Chapter 6999

A Concrete Naming Certificate for $\mathsf{CantorDiagonalCompactness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ packet records the constructive diagonal extraction surface for finitely inspected binary or nested real windows. It sits after the dyadic arithmetic core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the shrinking nested-interval route of chapter 4227. The packet gives Real and Completion consumers a named diagonal subsequence boundary without asserting open-cover compactness, countable choice, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The consumed shrinking-interval input is the finite diameter ledger of chapter 4227: a diagonal read must first display the nested-shrink tolerance row that bounds the inspected interval widths, then pass that row through $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal. Thus the compactness route consumes a concrete L10 certificate before it reads diagonal stabilization data.

Definition 6999.1 (Cantor diagonal compactness carrier)**.** *A* $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, Q, E, I, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window family listing the inspected rows, prefixes, and diagonal coordinates.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the inspected prefixes and nested interval widths.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only from the displayed windows and dyadic ledger.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, Q are displayed.*
5. *I is the* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *row that records the inspected shrinking interval or cylinder route used by the diagonal read.*
6. *W is the diagonal ledger, recording which finite coordinates have stabilized inside the inspected window and which nested interval row supplies the next readback.*
7. *H stores componentwise* hsame *transport for stream windows, dyadic tolerances, readback, Real seal, nested-shrink data, diagonal ledger, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from diagonal requests through the same finite rows.*

9. *P records* Pkg *provenance over* $\mathsf{CantorDiagonalCompactness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NestedShrinkInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorDiagonalCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, Q, E, I, W, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, quotient real equality, trichotomy, a selected infinite subsequence outside the displayed windows, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6999.2 (Cantor diagonal compactness NameCert obligations)**.** *For every accepted* CantorDiagonalCompa *carrier*

$$K = (S, D, Q, E, I, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorDiagonalCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission, finite window exposure, dyadic tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, nested-shrink interval routing, diagonal-ledger exposure, componentwise transport, displayed replay, provenance, and local naming. Every diagonal read must pass through the sibling rows named in chapter 291, chapter 126, chapter 301, chapter 38, and chapter 4227.*

The certificate exports only this finite diagonal route. It does not export open-cover compactness, countable choice, quotient real equality, trichotomy, a host-selected subsequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6999.1. The accepted packet displays exactly the finite windows, dyadic ledger, regular readback, Real seal, nested-shrink row, diagonal ledger, and structural rows.

The diagonal-ledger clause is read from W only after S, D, Q, E, I have been exposed. Thus a consumer sees finite inspected coordinates, tolerance budgets, regular rational readback, the Real seal, and the nested-shrink route before it reads any diagonal stabilization datum.

Transport and replay preserve the same route. The rows H and C cannot introduce a second stream schedule, a choice function, a quotient equality, or an open-cover compactness principle; they only move the displayed packet componentwise.

Finally, P and N record provenance and local naming for the same finite carrier. Since the refused endpoints are absent from the carrier, they are absent from the local NameCert surface. □

Theorem 6999.3 (Cantor diagonal compactness Real-completion route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ *packet reaches diagonal data only through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{NestedShrinkInterval}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumed packet is the displayed route $S, D, I, Q, E, W, H, C, P, N$ of Definition 6999.1. No consumer may cite the packet as open-cover compactness, a selected infinite subsequence, countable choice, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier. The stream windows S and dyadic ledger D delimit every inspected coordinate and tolerance request before any diagonal entry is read.

Use the nested-shrink row I and diagonal ledger W. These rows identify the finite shrinking interval or cylinder stage that supplies each displayed diagonal read, so the route remains inside the inspected windows rather than inside a host sequence space.

The regular readback Q and terminal seal E then provide the Real-facing endpoint. Because Q is downstream of S, D, I, W and E is downstream of Q, the completion consumer receives only the displayed route.

The structural rows H, C, P, N preserve and name this same route. They do not add open-cover compactness, choice, quotient equality, trichotomy, selected subsequences, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ Real or Completion read factors through finite StreamName windows, a DyadicRatCore tolerance ledger, NestedShrinkInterval routing, RegSeqRat readback, RealUp sealing, a diagonal ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, nested-shrink-interval: CantorDiagonalComp is not bijective to any listed sibling because it jointly carries diagonal finite-window stabilization, dyadic tolerance routing, nested-shrink interval data, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorDiagonalCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ packet is generated from finite StreamName windows, a DyadicRatCore tolerance ledger, NestedShrinkInterval routing, RegSeqRat readback, a terminal RealUp seal, a diagonal stabilization ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorDiagonalCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6999.1, Definition 6999.2, and Definition 6999.3 seed the finite diagonal route through StreamName, DyadicRatCore, NestedShrinkInterval, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorDiagonalCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, quotient real equality, trichotomy, selected infinite subsequences outside the displayed windows, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exposure, nested-shrink routing, diagonal-ledger exposure, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorDiagonalCompactnessUp.

Chapter 7000

A Concrete Naming Certificate for $\mathsf{HolderSpace}^{\uparrow}$

Following Kolmogorov–Fomin and standard Holder-space treatments, the $\mathsf{HolderSpace}^{\uparrow}$ packet records a finite function-space boundary for Real-valued maps whose inspected graph rows carry a displayed Holder budget. It consumes the Holder continuity packet of chapter 1766, the finite inequality route of chapter 2100, the metric source of chapter 57, the Real endpoint seal of chapter 38, the graph-facing continuous-map row of chapter 130, and the explicit uniform-modulus consumer of chapter 369. The chapter names the displayed function-family carrier; it does not import a host Banach space, quotient equality of functions, selected limits, ambient completeness, unrestricted real powers, or bridge checking.

Definition 7000.1 (Holder space carrier)**.** *A* $\mathsf{HolderSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, d, F, a, K, U, H, C, P, N)$$

with the following displayed rows:

1. X, d *is the* $\mathsf{Met}^{\uparrow}$ *source row, including the finite point classifier, displayed distance classifier, and inspected source-distance observations.*
2. F *is the Real-valued function-family row. Each accepted member is read through a* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row and terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seals.*
3. a *is the exponent-window row. It records the displayed positive rational exponent bounds used by the local Holder read and no unrestricted host exponent calculus.*
4. K *is the finite Holder constant row. It stores the Real-facing coefficient ledger and the finite comparison budget used to read the Holder bound.*
5. U *is the* $\mathsf{UniformModulus}^{\uparrow}$ *export row produced from the displayed metric, graph, exponent, and constant data.*
6. H *records componentwise* hsame *transport for the metric source, function-family row, exponent window, Holder constant, uniform-modulus export, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a source-distance request through* F, a, K, U, H, P, N *to the Real-valued endpoint comparison.*
8. P *is the* Pkg *provenance over* $\mathsf{HolderSpace}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{HolderInequality}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{HolderSpace}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, d, F, a, K, U, H, C, P, N$. It has no coordinate for host real powers, completeness of the function space, quotient equality of functions, selected limits, countable choice, or a detached continuous-map theorem.

Lean4 ✓ `BEDC.Derived.HolderSpaceUp.HolderSpaceTasteGate single carrier alignment`

Theorem 7000.2 (Holder space uniform modulus route)**.** *For every accepted* $\mathsf{HolderSpace}^\uparrow$ *carrier* $S = (X, d, F, a, K, U, H, C, P, N)$*, a* $\mathsf{UniformModulus}^\uparrow$ *consumer may read the Holder-space packet only through the displayed route*

$$X, d, F, a, K \longmapsto U \longmapsto H, C, P, N.$$

The finite Holder constant row K supplies the uniform-modulus budget together with the exponent window a and the Real-valued graph row F. The handoff exports no host real power operation, function-space completeness theorem, quotient equality of functions, selected limiting function, countable-choice selector, or detached continuity principle.

Proof. Project the carrier of Definition 7000.1. The only modulus-facing coordinate is U, and U is displayed only after the metric source, Real-valued function-family row, exponent window, and Holder constant have been read.

Use the Holder continuity surface of chapter 1766. It supplies the power-law route from the finite metric and graph rows to a modulus row, while the Holder inequality sibling of chapter 2100 accounts for the finite comparison budget visible in K.

The uniform-modulus consumer therefore receives exactly the row U. Transport through H, replay through C, provenance through P, and the local name N keep that row attached to the same displayed source packet.

Since the carrier has no coordinate for host real powers, completeness, quotient function equality, selected limits, countable choice, or a detached continuity theorem, none of those objects can be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{HolderSpace}^\uparrow}$**.**

Constructive story: A $\mathsf{HolderSpace}^\uparrow$ packet is generated from a MetricUp source, Real-valued ContinuousMap family rows, a positive rational exponent window, a finite Holder constant ledger, a UniformModulus export row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HolderSpace}^\uparrow}$, seed)

Scope closed: Definition 7000.1 and Definition 7000.2 seed the finite Holder-space route from displayed metric and Real-valued graph data to a UniformModulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HolderSpace}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real powers, function-space completeness, quotient equality of functions, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exponent-window stability, Holder constant transport, UniformModulus handoff, replay preservation, and ledger nonescape for BEDC.Derived.HolderSpaceUp.

Chapter 7001

A Concrete Naming Certificate for $\mathsf{TranscendentalGapLedger}^{\uparrow}$

The $\mathsf{TranscendentalGapLedger}^{\uparrow}$ packet realizes the finite GAP-socket ledger behind chapter 9393. It sits beside the finite trace boundary of chapter 498, the inscription-point packet of chapter 610, and the supply request ledger of chapter 542. The packet records where an induction-facing universal request appears, which finite traces have been observed, which forward-binding belief socket would be needed, and why the request remains a visible Gap row rather than a substrate theorem.

Definition 7001.1 (Transcendental GAP ledger carrier)**.** *A* $\mathsf{TranscendentalGapLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Gamma = (S, T, B, G, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the socket-site row naming the proof, paper claim, or construction site at which an induction-facing universal request is exposed.*
2. *T is the finite observation-trace row, recording the displayed initial cases, bounded successors, or finite prefixes that have actually been inspected.*
3. *B is the forward-binding belief socket row. It names the present commitment that would treat not-yet-observed cases as discharged without storing that commitment as an internal theorem.*
4. *G is the* Gap *exposure row, keeping the missing universal supply visible to audit consumers.*
5. *L is the supply-boundary ledger row. It records the relation to* $\mathsf{TranscendentalSupplyLedger}^{\uparrow}$ *and refuses to turn supply position into substrate data.*
6. *H records componentwise* hsame *transport for the socket site, finite trace row, belief socket, GAP exposure, supply-boundary ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the socket site through the finite traces, belief socket, GAP exposure, supply boundary, provenance, and local certificate.*
8. *P is the* Pkg *provenance over* $\mathsf{TranscendentalGapLedger}^{\uparrow}$*,* $\mathsf{TranscendentalSupplyLedger}^{\uparrow}$*,* BHist*,* Gap*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TranscendentalGapLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unrestricted induction rule, universal quantifier over future observations, hidden witness, completed supply source, quotient equality, self-certifying truth row, or bridge-checked theorem.

Theorem 7001.2 (Transcendental GAP ledger NameCert obligations)**.** *For every accepted* TranscendentalGapLedge *carrier* $\Gamma = (S, T, B, G, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TranscendentalGapLedger}^{\uparrow}}$ *surface consists exactly of socket-site admission, finite observation-trace exposure, forward-binding belief-socket display,* Gap *exposure, supply-boundary ledger routing, componentwise transport, displayed replay, provenance, and local naming. Every consumer factors through*

$$S \to T \to B \to G \to L \to H \to C \to P \to N$$

before it can cite the ledger.

Proof. Project the carrier of Definition 7001.1. The rows S, T, B, G, L are the only substantive coordinates, and H, C, P, N are the only structural coordinates.

The finite trace row T is read before the belief socket B. Thus the packet records exactly what has been observed before exposing the request that would bind all not-yet-observed cases.

The GAP row G and supply-boundary row L prevent discharge. They route the request to the transcendental supply ledger surface without adding the requested universal rule to the substrate.

Transport, replay, provenance, and local naming preserve that same finite sequence. Since no other coordinate is present, the listed rows exhaust the NameCert obligations. □

Theorem 7001.3 (Transcendental GAP ledger non-discharge)**.** *An accepted* $\mathsf{TranscendentalGapLedger}^{\uparrow}$ *packet may expose a forward-binding belief socket, but it never supplies the missing universal claim named by that socket. The finite observation trace* T *remains finite, the* Gap *row* G *remains visible, and the supply-boundary ledger* L *records non-internality rather than importing an induction principle.*

Proof. Read the finite trace row T. It contains only displayed observations and bounded replay data, so it cannot already contain the universal discharge.

Read the belief socket B and GAP row G. The socket names the commitment that would be needed, while the GAP row keeps the missing discharge exposed to audit.

Finally read L, H, C, P, N. These rows transport, replay, source, and name the non-discharge boundary. None adds an unrestricted induction rule, hidden witness, completed supply source, quotient equality, self-certifying truth row, or bridge-checked theorem. □

Falsifiable prediction: Every accepted $\mathsf{TranscendentalGapLedger}^{\uparrow}$ consumer factors through a finite observation-trace row, a forward-binding belief socket, a GAP exposure row, a supply-boundary ledger, componentwise transport, replay, provenance, and local naming before it can cite an induction-facing request.

Independence witness: finite-trace-induction-gap, inscriptionpoint, transcendentalsupplyledger, apophaticname: $\mathsf{TranscendentalGapLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite observation traces, forward-binding belief sockets, GAP exposure, supply-boundary ledger rows, transport, replay, provenance, and local naming.

The Lean follow-up must provide `Nontrivial TranscendentalGapLedgerUp` and `FieldFaithful TranscendentalGapLedgerUp` instances for the same carrier surface in `lean4/BEDC/Derived/TranscendentalGapl`

Closure status for $\mathsf{NameCert}_{\mathsf{TranscendentalGapLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TranscendentalGapLedger}^{\uparrow}$ packet is generated from a socket site, finite observation traces, a forward-binding belief socket, GAP exposure, a supply-boundary ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TranscendentalGapLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7001.1, Definition 7001.2, and Definition 7001.3 seed the finite ledger for induction-facing GAP sockets and their supply boundary.

Formal verification: FormalStatus(NameCert$_{\text{TranscendentalGapLedger}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted induction, universal quantification over future observations, hidden witnesses, completed supply sources, quotient equality, self-certifying truth, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-trace exposure, belief-socket display, GAP non-discharge, supply-boundary routing, transport, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.TranscendentalGapLedgerUp.

Chapter 7002

RealNameBallFilter NameCert Construction

Following Bishop–Bridges constructive real analysis and Kelley filter terminology, the $\mathsf{RealNameBallFilter}^{\uparrow}$ packet records the finite ball-filter reads by which a displayed $\mathsf{Real}^{\uparrow}$ name is inspected through dyadic neighbourhoods. It sits between the dyadic centre-radius surface of chapter 311, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the principal Cauchy filter route of chapter 3994, and the terminal real-name seal of chapter 38. The packet supplies a finite neighbourhood interface for Real and Completion consumers; it exports no quotient real equality, selected nearest point, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7002.1 (Real name ball-filter carrier)**.** *A* $\mathsf{RealNameBallFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, S, R, D, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *name seal whose finite neighbourhood reads are being exposed.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the requested prefix and precision window of the real name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream window.*
4. *D is the* $\mathsf{DyadicBall}^{\uparrow}$ *centre-radius row that records the displayed dyadic neighbourhood and its radius budget.*
5. *Q is the dyadic tolerance and containment ledger comparing the readback row R with the ball row D at the requested precision.*
6. *F is the* $\mathsf{CauchyPrincipalFilter}^{\uparrow}$ *principal-neighbourhood row generated from the same displayed real-name window and dyadic ball.*
7. *H records componentwise* hsame *transport for the seal, window, readback, ball, tolerance, principal-filter, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite ball request through S, R, D, Q, F before the terminal seal E is consumed.*
9. *P is the* Pkg *provenance over* $\mathsf{RealNameBallFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{CauchyPrincipalFilter}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealNameBallFilter}^{\uparrow}}$ *row naming exactly this finite ball-filter packet.*

The classifier compares accepted packets only through $E, S, R, D, Q, F, H, C, P, N$. It has no coordinate for quotient real equality, selected nearest point, countable choice, open-cover compactness, hidden infinite filter bases, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7002.2 (RealNameBallFilter NameCert obligations)**.** *For every accepted* $\mathsf{RealNameBallFilter}^{\uparrow}$ *carrier $B = (E, S, R, D, Q, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealNameBallFilter}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed real seal, stream window, regular rational readback, dyadic ball, tolerance ledger, principal-filter row, transport, replay, provenance, and local naming row;*
2. *window locality, requiring every ball request to inspect the real name only through the finite* $\mathsf{StreamName}^{\uparrow}$ *row S;*
3. *readback exactness, requiring the regular rational row R to be the only readback surface generated from S;*
4. *ball containment exactness, requiring the dyadic centre-radius row D and tolerance ledger Q to bind the requested neighbourhood before the principal-filter row F is exposed;*
5. *principal-filter compatibility, requiring F to use the same displayed ball-filter data rather than a hidden basis or selected nearest point;*
6. *transport, replay, provenance, and name exhaustion through H, C, P, N.*

No local NameCert obligation is exported for quotient real equality, selected nearest points, countable choice, open-cover compactness, hidden infinite filter bases, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 7002.1. The visible analytic rows are exactly the real seal E, the finite stream window S, the regular rational readback R, the dyadic ball D, the tolerance ledger Q, and the principal-filter row F.

Window locality and readback exactness follow from the ordered route in the carrier. A finite neighbourhood request first opens S and then reads the same displayed entries through R; there is no second stream, hidden representative, or quotient-real equality coordinate.

Ball containment is then checked by D and Q. These rows record the centre, radius, and tolerance comparison before F may package the displayed neighbourhood as a principal filter row.

Finally, H and C preserve the same route under componentwise transport and replay, while P and N source and name only the displayed packet. Since the excluded objects are absent from the carrier inventory, they cannot appear as additional NameCert obligations. □

Theorem 7002.3 (RealNameBallFilter Real seal nonescape)**.** *Every Real or Completion-facing consumer of an accepted* $\mathsf{RealNameBallFilter}^{\uparrow}$ *carrier reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicBall}^{\uparrow} \longmapsto \mathsf{CauchyPrincipalFilter}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Consequently the exported read is a finite ball-filter neighbourhood of the displayed real name, not quotient real equality, not a selected nearest point, not countable choice, not open-cover compactness, and not ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a consumer read of the seal E. By Definition 7002.1, E is packaged with the displayed stream window S, regular rational readback R, dyadic ball row D, tolerance ledger Q, and principal-filter row F.

Apply the obligation surface of Definition 7002.2. The request must first inspect S, then read R, then bind the requested ball through D and Q before F can be exposed.

Only after that route is replayed may the Real-facing consumer use the seal row. The structural rows H, C, P, N transport, continue, source, and name the same finite packet, so the exported object remains a displayed ball-filter read around the real name.

The forbidden principles are not coordinates of the carrier. Hence no path through the local certificate can produce quotient real equality, a selected nearest point, countable choice, open-cover compactness, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{RealNameBallFilter}^{\uparrow}$ read can be audited by checking that the consumer first displays a $\mathsf{StreamName}^{\uparrow}$ finite window, then a $\mathsf{RegSeqRat}^{\uparrow}$ readback, then a $\mathsf{DyadicBall}^{\uparrow}$ neighbourhood and tolerance ledger, then the $\mathsf{CauchyPrincipalFilter}^{\uparrow}$ row, before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Independence witness: dyadicball, streamname, regseqrat, real, cauchy-principal-filter: $\mathsf{RealNameBallFilter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the real-name seal, finite stream window, regular rational readback, dyadic ball, tolerance ledger, principal-filter handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RealNameBallFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{RealNameBallFilter}^{\uparrow}$ packet is generated from a RealUp seal, finite StreamName window, RegSeqRat readback, DyadicBall neighbourhood, tolerance ledger, CauchyPrincipalFilter row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealNameBallFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7002.1, Definition 7002.2, and Definition 7002.3 seed the finite ball-filter read route around displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealNameBallFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected nearest points, countable choice, open-cover compactness, hidden infinite filter bases, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite window locality, regular rational readback, dyadic ball containment, principal-filter compatibility, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealNameBallFilterUp.

Chapter 7003

A Concrete Naming Certificate for $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$ packet records the regular-Cauchy completion functor as finite BEDC naming data over inspected rational approximants. It sits after the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the completion-functor surface of chapter 423. The packet names the Bishop regular completion handoff visible to L10 consumers; it is not a quotient completion, selected limit representative, host equality of completed objects, countable-choice schedule, or ambient completeness theorem.

Definition 7003.1 (BishopRegularCompletionFunctor carrier)**.** *A* $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for regular precision requests and comparison of inspected rational windows.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the rational observations that a completion-facing consumer may inspect.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row certifying that the displayed stream windows satisfy the regular rational discipline.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from D, S, R through the visible regular-Cauchy route.*
5. *Q is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row, recording the source-to-completion action only after D, S, R, E have been displayed.*
6. *H records componentwise* hsame *transport for tolerance ledgers, stream windows, regular readbacks, real seals, functor rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a regular precision request through*

$$D, S \longmapsto R \longmapsto E \longmapsto Q \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, E, Q, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, host equality of completed objects, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7003.2 (BishopRegularCompletionFunctor NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$ *carrier*

$$F = (D, S, R, E, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission for dyadic tolerances, finite stream windows, regular rational readback, real-name sealing, completion-functor handoff, transport, replay, provenance, and local naming; source exposure requiring every completion-facing read to inspect D, S before R; seal discipline requiring E to be read only through the same D, S, R route; and functorial handoff requiring Q to preserve that displayed route without exporting quotient completion data.*

Proof. Project the accepted carrier. Its displayed coordinates are exactly $D, S, R, E, Q, H, C, P, N$, so carrier admission, transport, replay, provenance, and local naming are read from those rows.

The source side begins with D and S. The dyadic ledger fixes the tolerances used by each regular request, while the stream-window row specifies the finite approximants available for the current read.

The regular readback row R and the seal row E are downstream of those source rows. A completion-facing consumer therefore obtains a regular rational name and a real-name seal only after the dyadic and stream data have been displayed.

Finally Q hands the same route to the $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ surface, and H, C, P, N preserve, replay, source, and name the finite packet. Since no other coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 7003.3 (Regular completion functor consumer boundary)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{CauchyCompletionFunctor}^{\uparrow}$$

as displayed by $D, S, R, E, Q, H, C, P, N$. The consumer may use the completion-functor row as a named handoff from regular rational data to completion data, but it cannot extract quotient completions, selected limit representatives, host equality of completed objects, countable choice, or ambient completeness from the packet.

Proof. Begin with a consumer of the functor row Q. The carrier has no completion-facing coordinate before the dyadic ledger, stream windows, regular readback, and real seal have been exposed.

Read D, S, R, E in order. These rows provide the visible tolerance, finite-window, regular-rational, and real-name surfaces that make the Bishop regular completion handoff meaningful.

The structural rows H, C, P, N then transport, replay, source, and name the same route. They add no quotient object, representative selector, host equality, countable-choice schedule, or completeness principle. □

Falsifiable prediction: An accepted $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$ consumer that reaches $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ without first reading the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchycompletionfunctor: no listed sibling supplies the whole packet $F = (D, S, R, E, Q, H, C, P, N)$, because each sibling contributes only a tolerance ledger, a finite window interface, a regular rational readback, a real seal, or the downstream completion-functor handoff while this chapter binds the route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, a CauchyCompletionFunctor handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7003.1, Definition 7003.2, and Definition 7003.3 seed the Bishop regular completion functor packet over dyadic tolerances, finite windows, regular rational readback, Real sealing, and completion-functor handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance coverage, StreamName window exposure, RegSeqRat readback, Real seal preservation, completion-functor routing, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCompletionFunctorUp.

Chapter 7004

A Concrete Naming Certificate for $\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}$

Following Bishop and Bridges compact-uniform-continuity arguments, the $\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}$ packet records the finite diagonal tail route by which compact finite nets and pointwise continuity data feed a regular-Cauchy Real seal. It sits after the compact metric source of chapter 129, the continuous-map row used by compact-uniform consumers, the uniform-modulus handoff of chapter 369, the diagonal schedule of chapter 6371, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet realizes the finite-net diagonal branch of chapter 9237 as NameCert data rather than as an ambient compactness or completeness principle.

Definition 7004.1 (CompactUniformCauchyDiagonal carrier)**.** *A* $\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, U, M, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose pointwise modulus data are inspected on the displayed compact net.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row reached by folding the finite pointwise modulus data.*
4. *M is the* $\mathsf{CauchyModulusDiagonal}^{\uparrow}$ *row that turns the compact finite-net schedules into one diagonal tail witness.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the finite-net fold and diagonal tail comparison.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected source and target observations.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from D, S, U, M.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the compact, continuous, uniform-modulus, diagonal, tolerance, window, and readback rows have been displayed.*
9. *H records componentwise* hsame *transport for compact source, continuous-map, uniform-modulus, diagonal, tolerance, stream-window, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a compact finite-net tolerance request through*

$$K, F, U, M, D, S \longmapsto R \longmapsto E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* CompactUniformCauchyDiagonal$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, CauchyModulusDiagonal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{CompactUniformCauchyDiagonal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, U, M, D, S, R, E, H, C, P, N$. It has no coordinate for an open-cover compactness proof, selected subcover, point selector, quotient stream, host function equality, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7004.2 (CompactUniformCauchyDiagonal NameCert obligations)**.** *For every accepted* CompactUniformCauchyDiagonal$^{\uparrow}$ *carrier*

$$G = (K, F, U, M, D, S, R, E, H, C, P, N),$$

the local NameCert$_{\text{CompactUniformCauchyDiagonal}^{\uparrow}}$ *surface consists exactly of carrier admission, compact finite-net exposure, continuous-map row exposure, uniform-modulus fold exposure, diagonal-tail schedule exposure, dyadic tolerance exactness, finite stream-window exposure, regular rational readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier coordinates. The compact source, continuous-map row, uniform-modulus fold, diagonal-tail schedule, dyadic ledger, finite windows, readback, and seal are all explicit entries of G.

The structural rows H and C determine how these entries move between certified presentations and how a tolerance request is replayed. They expose only componentwise sameness and displayed continuation routes.

The provenance and local naming rows P, N bind the packet to the cited sibling chapters. Since no other coordinate is present, the listed rows exhaust the NameCert obligation surface and the excluded compactness, selector, quotient, equality, completeness, verification, and bridge data have no export path. □

Theorem 7004.3 (Compact finite-net diagonal handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* CompactUniformCauchyDiagonal$^{\uparrow}$ *carrier must read the compact finite-net row K, continuous-map row F, uniform-modulus row U, diagonal-tail row M, dyadic tolerance row D, stream-window row S, and regular rational readback row R before it may read the real seal row E. The handoff exports a finite diagonal Cauchy route only; it does not export an open-cover choice, selected subnet, host function equality, quotient real representative, countable-choice schedule, or ambient completeness theorem.*

Proof. Start with a consumer asking for E. The carrier definition places E after the compact finite-net, continuous-map, uniform-modulus, diagonal, tolerance, stream-window, and readback rows.

The rows K, F, U, M, D, S, R supply the finite route: compact net, pointwise-to-uniform modulus fold, diagonal tail, dyadic tolerance, observed windows, and regular rational readback. None of these rows is a host compactness proof or selected limit.

Finally transport and replay the route through H, C, P, N. These structural rows preserve the displayed finite packet and cannot add the excluded choice, quotient, equality, or completeness data. □

Theorem 7004.4 (Compact uniform diagonal Real seal nonescape)**.** *In every accepted* CompactUniformCauchyDiag *carrier, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is a terminal row of the finite route*

$$K, F, U, M, D, S, R, H, C, P, N.$$

A downstream consumer may cite E *only as the seal of that route; it cannot detach the seal into ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host equality of completed reals, a selected representative, or quotient stream equality.*

Proof. Read E from the carrier. It appears only after the compact, continuous, uniform-modulus, diagonal, tolerance, window, and regular-readback rows.

The continuation row C records the same order of exposure, while H transports the rows componentwise. The provenance and local naming rows P, N source and name this route.

Therefore E is a terminal seal for the displayed packet and has no coordinate from which a detached completeness, equality, representative, or quotient principle could be read. □

Falsifiable prediction: An accepted $\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ without reading the displayed $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CauchyModulusDiagonal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows refutes the carrier surface.

Independence witness: compactmetric, continuousmap, uniformmodulus, cauchymodulusdiagonal, dyadicratcore, regseqrat, real: no listed sibling supplies the whole packet $G = (K, F, U, M, D, S, R, E, H, C, P, N$ because each sibling contributes only compact finite-net data, pointwise continuity, a uniform-modulus row, a diagonal schedule, a dyadic tolerance ledger, a regular readback, or a terminal seal while this chapter binds the compact diagonal route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise rows, a UniformModulus fold, a CauchyModulusDiagonal tail row, DyadicRatCore tolerances, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7004.1, Definition 7004.2, Definition 7004.3, and Definition 7004.4 seed the compact finite-net diagonal route from compact and continuous rows to regular rational readback and a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, selected limits, quotient streams, host function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous-map exposure, uniform-modulus fold, diagonal-tail replay, dyadic tolerance coverage, finite-window readback, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformCauchyDiagonalUp.

Chapter 7005

Bishop Sequence Limit NameCert Construction

Following Bishop and Bridges on constructive sequences of real numbers, the $\mathsf{BishopSequenceLimit}^{\uparrow}$ packet records a finite row presentation of a Bishop-style sequence limit without importing a host convergence predicate. It sits beside the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the displayed sequence-limit packet of chapter 1413, and the limit-uniqueness route of chapter 3942. The packet names the L10 handoff by finite schedules and regular Cauchy rows; it does not name quotient limits, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7005.1 (Bishop sequence-limit carrier)**.** *A* $\mathsf{BishopSequenceLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, L, W, R, D, T, U, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for the source sequence, exposing only the finite source windows requested by the current tolerance read.*
2. *L is the displayed candidate-limit row, read as a regular real name before any sequence-limit classifier is consumed.*
3. *W is the tail-window schedule, assigning to each dyadic tolerance request a finite observation window and a displayed tail threshold.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source windows and candidate-limit windows in the same schedule.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic budget and the comparison cells used by the scheduled tail test.*
6. *T is the Bishop tail test row, whose accepted entries say that every displayed source entry beyond the scheduled threshold is within the dyadic budget of the displayed candidate limit.*
7. *U is the* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *boundary row, used only to compare two displayed candidate-limit reads through their common regular Cauchy route.*
8. *E is the terminal* $\mathsf{RealSequenceLimit}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after S, L, W, R, D, T, U have been displayed.*

9. *H stores componentwise* hsame *transport for all displayed rows.*
10. *C stores displayed* Cont *replay from a tolerance request through the tail-window, readback, dyadic, tail-test, uniqueness, and seal rows.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopSequenceLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSequenceLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of limits, a selected host limit, a countable-choice schedule, trichotomy on reals, host sequence convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopSequenceLimitUp.BishopSequenceLimitTasteGate single carrier alignment`

Theorem 7005.2 (Bishop sequence-limit NameCert obligations)**.** *For every accepted* $\mathsf{BishopSequenceLimit}^{\uparrow}$ *carrier* $K = (S, L, W, R, D, T, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopSequenceLimit}^{\uparrow}}$ *surface consists exactly of source stream-window admission, candidate-limit admission, scheduled tail-window exposure, regular rational readback, dyadic tolerance-ledger exactness, Bishop tail-test exposure, regular Cauchy uniqueness-boundary exposure, terminal* $\mathsf{RealSequenceLimit}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, provenance, and local naming for the rows of Definition 7005.1.*

Proof. Project the accepted carrier. The sequence source, candidate limit, schedule, regular readback, dyadic ledger, tail test, uniqueness boundary, and terminal seal are exactly the analytic rows S, L, W, R, D, T, U, E.

The schedule row W determines which finite source and candidate-limit windows may be inspected for a tolerance request. The readback row R and dyadic row D then attach regular rational and dyadic comparison data to that same finite schedule.

The Bishop tail test T is downstream of those rows, and the uniqueness boundary U is downstream of the same regular Cauchy route. Thus a consumer cannot read a limit assertion, a second-limit comparison, or a real-facing seal before the displayed finite route has been replayed.

Finally, H, C, P, N transport, replay, source, and name only the displayed packet. Since the carrier inventory contains no quotient-limit, selected-limit, choice, trichotomy, host-convergence, or completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7005.3 (Bishop sequence-limit Real-seal handoff)**.** *Every* $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegularCauchyLimitUnique}$ *or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopSequenceLimit}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RealSequenceLimit}^{\uparrow} \longmapsto \mathsf{RegularCauchyLimitUniqueness}^{\uparrow} \longmapsto$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The handoff exports only scheduled finite-window sequence-limit data; it exports no quotient limit, selected limit, countable-choice row, trichotomy split, host convergence predicate, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a Real-facing or uniqueness-facing consumer and project the carrier of Definition 7005.1. The only source observations are the finite stream windows S selected by W, and the only candidate-limit observations are the regular readbacks R measured by the dyadic ledger D.

The tail-test row T admits a Bishop sequence-limit read only through that finite route. If a second candidate-limit read is compared, the boundary row U sends the comparison through $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ before either Real seal is public.

The terminal row E is therefore reached only after the scheduled StreamName, RegSeqRat, DyadicRatCore, RealSequenceLimit, and regular Cauchy uniqueness rows have been displayed. The structural rows H, C, P, N preserve the same packet and add no source from which quotient limits, selected limits, countable choice, trichotomy, host convergence, or ambient completeness could be recovered. □

Falsifiable prediction: Every accepted $\mathsf{BishopSequenceLimit}^{\uparrow}$ consumer can be audited by checking that its sequence-limit read displays a $\mathsf{StreamName}^{\uparrow}$ window row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a Bishop tail-test row, a $\mathsf{RealSequenceLimit}^{\uparrow}$ handoff, a $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ boundary row when uniqueness is inspected, and the terminal $\mathsf{Real}^{\uparrow}$ seal before the local name is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real-sequence-limit, regular-cauchy-limit-uniqueness, real: no listed sibling is bijective with $\mathsf{BishopSequenceLimit}^{\uparrow}$, because this packet alone binds a displayed source sequence, candidate-limit row, tail-window schedule, regular rational readback, dyadic tolerance ledger, Bishop tail test, uniqueness boundary, terminal Real seal, transport, replay, provenance, and local naming into one finite L10 sequence-limit certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSequenceLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopSequenceLimit}^{\uparrow}$ packet is generated from finite StreamName sequence windows, a displayed candidate-limit row, tail-window schedules, RegSeqRat readback, DyadicRatCore tolerance rows, a Bishop tail-test row, a RegularCauchyLimitUniqueness boundary, a RealSequenceLimit and RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSequenceLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7005.1, Definition 7005.2, and Definition 7005.3 seed the finite Bishop sequence-limit route from L10 StreamName, RegSeqRat, DyadicRatCore, RealSequenceLimit, RegularCauchyLimitUniqueness, and Real data to the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSequenceLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient limits, selected limits, countable choice, trichotomy, host sequence convergence, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName schedule locality, RegSeqRat readback, DyadicRatCore tolerance exactness, Bishop tail-test exposure, RegularCauchyLimitUniqueness boundary exposure, RealSequenceLimit and Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopSequenceLimitUp.

Chapter 7006

A Concrete Naming Certificate for $\mathsf{RegulatedOscillation}^{\uparrow}$

Following Bishop and Bridges on regulated functions and finite oscillation control, the $\mathsf{RegulatedOscillation}^{\uparrow}$ packet records the displayed oscillation windows by which a regulated real-valued function is read over a finite interval cover. It sits after the regulated-function schedule of chapter 1906, the oscillation-modulus boundary of chapter 2224, the compact-interval oscillation-modulus packet of chapter 6148, the dyadic interval-cover row of chapter 1428, and the terminal real-name seal of chapter 38. The packet names finite oscillation data for regulated-integration and compact-interval consumers; it does not assert open-cover compactness, quotient equality of functions, selected extrema, a uniform modulus chosen from an ambient theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7006.1 (Regulated oscillation carrier)**.** *A* $\mathsf{RegulatedOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, O, C, D, R, H, T, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, exposing the regulated approximation schedule whose oscillation is being read.*
2. *O is the* $\mathsf{OscillationModulus}^{\uparrow}$ *row, carrying the requested cellwise oscillation budget.*
3. *C is the* $\mathsf{CompactIntervalOscillationModulus}^{\uparrow}$ *row, binding the oscillation budget to a displayed compact interval window.*
4. *D is the* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *row, listing the finite dyadic interval cover on which the oscillation cells are inspected.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *readback row for the cellwise bounds and endpoint values exposed by the packet.*
6. *H, T, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegulatedOscillation}^{\uparrow}}$ *row.*

The classifier compares carriers only through $F, O, C, D, R, H, T, P, N$. It has no coordinate for a host function quotient, selected extremum, arbitrary open cover, unbounded refinement search, or ambient real-completeness principle.

Theorem 7006.2 (Regulated oscillation NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedOscillation}^{\uparrow}$ *carrier $Q = (F, O, C, D, R, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedOscillation}^{\uparrow}}$ *surface consists of*

exactly five analytic rows before the structural rows are read: the regulated-function source F, oscillation-modulus row O, compact-interval oscillation row C, dyadic interval-cover row D, and terminal Real readback R. Transport, replay, provenance, and local naming preserve only this displayed surface.

Proof. Project the carrier of Definition 7006.1. The analytic rows are precisely F, O, C, D, R, and the structural rows are H, T, P, N.

The source row F supplies the regulated approximation schedule. The row O attaches the requested oscillation budget to that schedule, while C restricts the read to the displayed compact interval window.

The dyadic cover row D supplies the finite cells on which the oscillation bounds are inspected. The terminal Real row R records the cellwise bound and endpoint readback only after the first four analytic rows are visible.

Since no further analytic coordinate occurs in the packet, H, T, P, N can only transport, replay, source, and name the same five-row surface. The listed rows therefore exhaust the local NameCert obligations. □

Theorem 7006.3 (Regulated oscillation finite partition nonescape)**.** *Every regulated-integration or compact-interval consumer of an accepted* $\mathsf{RegulatedOscillation}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow} \longrightarrow \mathsf{OscillationModulus}^{\uparrow} \longrightarrow \mathsf{CompactIntervalOscillationModulus}^{\uparrow} \longrightarrow \mathsf{DyadicIntervalCover}^{\uparrow} \longrightarrow$$

before it may use any oscillation bound. The consumer receives a finite partition-and-readback surface, not open-cover compactness, quotient equality of functions, selected extrema, unbounded refinement search, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 7006.2. They force every consumer to expose the regulated source, oscillation budget, compact-interval window, dyadic interval cover, and Real readback before the structural rows may replay the request.

The sibling chapters provide those rows in order: chapter 1906, chapter 2224, chapter 6148, chapter 1428, and chapter 38. Thus the consumer reads a displayed finite route rather than a detached compactness or function-extensionality theorem.

The exclusions follow from the carrier inventory. No row stores an arbitrary open cover, selected extremum, quotient function equality, unbounded refinement search, or ambient real-completeness assertion, so the finite partition route cannot export any of them. □

Falsifiable prediction: Any accepted RegulatedOscillationUp packet that exports an oscillation read without displaying the regulated-function source, oscillation modulus, compact-interval oscillation row, dyadic interval cover, and Real readback refutes the carrier.

Independence witness: regulated-function, oscillation-modulus, compact-interval-oscillation-modulus, dyadic-interval-cover, real: none is bijective with $\mathsf{RegulatedOscillation}^{\uparrow}$ because this packet jointly binds the regulated source, oscillation budget, compact interval window, finite dyadic cover, Real readback, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedOscillation}^{\uparrow}$ packet is generated from a regulated-function source row, oscillation-modulus row, compact-interval oscillation row, dyadic interval-cover row, terminal Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7006.1, Definition 7006.2, and Definition 7006.3 seed the finite regulated-oscillation surface over RegulatedFunctionUp, OscillationModulusUp, CompactIntervalOscillationModulusUp, DyadicIntervalCoverUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegulatedOscillation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient equality of functions, selected extrema, unbounded refinement search, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, five-row NameCert exposure, finite partition nonescape, and a Lean carrier or obligation formalization for BEDC.Derived.RegulatedOscillationUp.

Chapter 7007

A Concrete Naming Certificate for $\mathsf{CauchySubbasisTailFactorization}^{\uparrow}$

Following Kelley and Bourbaki on subbases and cofinite tail filters, the packet records the finite BEDC route from $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ through $\mathsf{FrechetFilter}^{\uparrow}$ and $\mathsf{FilterBase}^{\uparrow}$ to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. It is grounded in the subbasis generation packet of chapter 4232, the cofinite-tail filter packet of chapter 1564, the filter-base interface of chapter 1601, the finite window naming surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite tail-factorization object only; it does not quotient filters, select limits, invoke countable choice, use host equality of generated filters, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7007.1 (Cauchy subbasis tail-factorization carrier)**.** *A* $\mathsf{CauchySubbasisTailFactorization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, A, F, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *row exposing primitive subbasis tokens, finite intersections, generated events, and the generated-base ledger.*
2. *A is the tail-specialization row saying that the requested generated-base reads have been restricted to eventual sequence tails.*
3. *F is the* $\mathsf{FrechetFilter}^{\uparrow}$ *row carrying the cofinite tail threshold discipline.*
4. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *handoff row obtained after the subbasis route has passed through the Frechet tail surface.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by completion-facing consumers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the retained tail windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, A, F, B, W, R have been displayed.*
8. *H records componentwise* hsame *transport for subbasis rows, tail-specialization rows, Frechet thresholds, filterbase handoffs, stream windows, regular readbacks, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from generated subbasis reads through cofinite tail thresholds, filterbase handoffs, stream windows, regular readbacks, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchySubbasisTailFactorization}^{\uparrow}$, $\mathsf{CauchyFilterSubbasis}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubbasisTailFactorization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient filters, ultrafilter completion, selected limits, countable-choice schedules, host equality of generated filters, or ambient Real completeness.

Theorem 7007.2 (Cauchy subbasis tail-factorization NameCert obligations)**.** *For every accepted* $\mathsf{CauchySubbasisTailFactorization}^{\uparrow}$ *carrier* $T = (S, A, F, B, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchySubbasisTailFac}}$ *surface consists exactly of carrier admission;* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *generated-base exposure; cofinite-tail specialization;* $\mathsf{FrechetFilter}^{\uparrow}$ *threshold exposure;* $\mathsf{FilterBase}^{\uparrow}$ *handoff;* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;* $\mathsf{Real}^{\uparrow}$ *sealing; componentwise* hsame *transport; displayed* Cont *replay;* Pkg *provenance; and local naming.*

Proof. Project the carrier rows from Definition 7007.1. The row S supplies only the finite subbasis generation surface, and the row A narrows that surface to eventual sequence tails.

Read the cofinite-tail route next. The $\mathsf{FrechetFilter}^{\uparrow}$ row F supplies the threshold discipline used by the specialized tail reads, and the $\mathsf{FilterBase}^{\uparrow}$ row B is visible only after that cofinite route has been displayed.

The completion-facing rows are downstream. The stream window row W, regular rational readback row R, and terminal Real seal row E are reached after the generated subbasis and Frechet tail rows have been opened.

Finally the structural rows H, C, P, N transport, replay, source, and name the same finite route. Since none of the carrier coordinates supplies quotient filters, selected limits, countable choice, host equality, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7007.3 (Cauchy subbasis tail-factorization Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{CauchySubbasisTailFactorization}^{\uparrow}$ *packet must pass through*

$$\mathsf{CauchyFilterSubbasis}^{\uparrow} \longmapsto \mathsf{FrechetFilter}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the Real seal is public only after the subbasis-generated Cauchy read has been specialized to cofinite tails, routed through the Frechet threshold discipline, handed to a displayed filter base, and read back through finite stream windows and regular rational names.

Proof. Start with the carrier $T = (S, A, F, B, W, R, E, H, C, P, N)$. The rows S and A expose the generated subbasis read and the tail specialization before any completion-facing object can be inspected.

Apply the NameCert obligations of Definition 7007.2. They force the Frechet threshold row F and the generated filterbase handoff B to be displayed before the stream, regular-readback, and Real-seal rows are visible.

Use the sibling routes of chapter 4232 and chapter 1564. The former exposes the subbasis-generated base, while the latter supplies the cofinite tail discipline used by eventual sequence reads.

The rows W, R, E then complete the route through chapter 126, chapter 301, and chapter 38. The structural rows preserve the same dependency, so no quotient filter, selected limit, countable-choice schedule, host equality of generated filters, or ambient completeness object can bypass the displayed handoff. □

Falsifiable prediction: Every accepted $\mathsf{CauchySubbasisTailFactorization}^{\uparrow}$ Real-facing read exposes a CauchyFilterSubbasisUp row, cofinite tail-specialization row, FrechetFilterUp threshold row, FilterBaseUp handoff, StreamNameUp finite-window row, RegSeqRatUp readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: cauchy-filter-subbasis, frechetfilter, filterbase, streamname, regseqrat, real: no listed sibling supplies the whole packet $T = (S, A, F, B, W, R, E, H, C, P, N)$, because each sibling contributes only a subbasis-generation row, cofinite-tail row, filterbase handoff, finite-window row, regular readback, or terminal seal while this chapter binds them into one tail-factorization carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubbasisTailFactorization}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySubbasisTailFactorization}^{\uparrow}$ packet is generated from a CauchyFilterSubbasis row, a cofinite tail-specialization row, a FrechetFilter threshold row, a FilterBase handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySubbasisTailFactorization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7007.1, Definition 7007.2, and Definition 7007.3 seed the finite route from generated Cauchy subbases through cofinite tails to Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySubbasisTailFactorization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality of generated filters, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subbasis-generated exposure, cofinite-tail specialization, Frechet threshold exposure, FilterBase handoff, StreamName windows, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySubbasisTailFactorizationUp.

Chapter 7008

A Concrete Naming Certificate for $\mathsf{SignChangeBisection}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SignChangeBisection}^{\uparrow}$ packet records the finite bisection route attached to an interval whose endpoint reads have opposite signs. It sits after the located endpoint-plus-radius interval of chapter 1709, the retained-branch bisection surface of chapter 1711, the located-zero witness of chapter 6387, and the theorem-object route of chapter 3676. The chapter names the finite sign-change ledger consumed by later located-zero and interval-search rows; it does not select a root, decide trichotomy, identify quotient real names, invoke open-cover compactness, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7008.1 (Sign-change bisection NameCert surface)**.** *A* $\mathsf{SignChangeBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, L, S, Z, T, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, read through Definition 1709.1 and carrying endpoint names, radius data, locator reads, locatedness moduli, and metric bracket data.*
2. *L is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *row, read through Definition 1711.1, recording the finite retained-branch history, midpoint rows, retained windows, and regular readback route.*
3. *S is the endpoint and midpoint sign-change ledger. It records only displayed finite sign reads and the retained sign boundary transported along L.*
4. *Z is the* $\mathsf{BishopLocatedZero}^{\uparrow}$ *consumer row, read through Definition 6387.1, which may inspect the bracket, modulus, bisection schedule, readback, and Real seal after I, L, S have been displayed.*
5. *T is the* $\mathsf{IntermediateValueTheorem}^{\uparrow}$ *theorem-object row, read through Definition 3676.1, supplying the finite interval, map, sign, window, readback, and Real-seal route used by theorem-facing consumers.*
6. *H records componentwise* hsame *transport for the interval, bisection, sign ledger, located-zero, theorem-object, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a sign-change bisection request through I, L, S, Z, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SignChangeBisection}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{BishopLocatedZero}^{\uparrow}$, $\mathsf{IntermediateValueTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{SignChangeBisection}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a selected root, host interval equality, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7008.2 (Sign-change bisection located-zero route)**.** *Every accepted* $\mathsf{SignChangeBisection}^{\uparrow}$ *packet routes a located-zero read through*

$$\mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{LocatedIntervalBisection}^{\uparrow} \longmapsto S \longmapsto \mathsf{BishopLocatedZero}^{\uparrow}$$

before any theorem-object consumer may cite the $\mathsf{IntermediateValueTheorem}^{\uparrow}$ *row. The route exposes the interval source of Definition 1709.4, the retained-window bisection route of Definition 1711.3, and the zero-witness bisection discipline of Definition 6387.3; it exports no selected global root or ambient intermediate-value principle.*

Proof. Project the carrier of Definition 7008.1. The source interval row I is the only coordinate carrying endpoint and locatedness data, and the bisection row L is the only coordinate carrying retained midpoint and window data.

Apply the located interval exactness route and the located interval bisection nested-window route. These force every interval-search read to pass first through the displayed endpoint-radius data and then through the finite retained branch route.

The sign ledger S is attached to that branch route, and the located-zero row Z may read it only as part of the same finite packet. Bishop located zero bisection soundness then places the zero-witness read behind the bracket, modulus, schedule, regular readback, and Real-seal discipline.

Finally, the theorem-object row T remains a downstream consumer. Componentwise transport, replay, provenance, and local naming preserve the same route, while the carrier contains no coordinate for root selection, trichotomy, quotient equality, open-cover compactness, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{SignChangeBisection}^{\uparrow}$ located-zero read displays a LocatedRealIntervalUp source row, a LocatedIntervalBisectionUp retained-branch row, a finite sign-change ledger, a BishopLocatedZeroUp consumer row, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: located-real-interval, located-interval-bisection, bishop-located-zero, intermediate-value-theorem: $\mathsf{SignChangeBisection}^{\uparrow}$ is not bijective with any listed sibling because it joins the source located interval, retained bisection route, transported sign-change ledger, located-zero consumer, theorem-object consumer, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SignChangeBisection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SignChangeBisection}^{\uparrow}$ packet is generated from a $\mathsf{LocatedRealInterval}^{\uparrow}$ source row, a $\mathsf{LocatedIntervalBisection}^{\uparrow}$ retained-branch row, a finite sign-change ledger, a $\mathsf{BishopLocatedZero}^{\uparrow}$ consumer row, an $\mathsf{IntermediateValueTheorem}^{\uparrow}$ theorem-object row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignChangeBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7008.1 and Definition 7008.2 seed the finite sign-change bisection route over located intervals, retained bisection windows, located-zero consumers, theorem-object consumers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignChangeBisection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected roots, host interval equality, quotient real equality, trichotomy, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign-ledger visibility, located-zero routing, theorem-object routing, transport, replay, provenance, and local naming for BEDC.Derived.SignChangeBisectionUp.

Chapter 7009

A Concrete Naming Certificate for EffectiveRegularRealExtensionality$^{\uparrow}$

Following Bishop and Bridges, and the computable-analysis reading of effective regular names, the EffectiveRegularRealExtensionality$^{\uparrow}$ packet records the finite substitution surface where two displayed regular real names may be reused extensionally without selecting quotient representatives. It sits after the regular Cauchy equality surface of chapter 1930, the Bishop real equality surface of chapter 6491, the entourage basis of chapter 5115, and the Cauchy filter subbasis of chapter 4232. It also consumes the finite stream and regular-rational rows of chapter 126, chapter 301, chapter 291, and chapter 38.

Definition 7009.1 (Effective regular real extensionality carrier)**.** *An* EffectiveRegularRealExtensionality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R_0, R_1, S_0, S_1, D_0, D_1, W_0, W_1, A_0, A_1, H, C, P, N)$$

with the following displayed rows:

1. R_0, R_1 *are two* RegSeqRat$^{\uparrow}$ *regular readbacks presented as the effective names being compared.*
2. S_0, S_1 *are the two finite* StreamName$^{\uparrow}$ *windows through which the comparison is inspected.*
3. D_0, D_1 *are the* DyadicRatCore$^{\uparrow}$ *tolerance ledgers recording the precision requests and endpoint bounds for the two windows.*
4. W_0, W_1 *are effective witness-budget rows, each naming the finite requests needed to replay the displayed comparison at the requested precision.*
5. A_0, A_1 *are the two terminal* Real$^{\uparrow}$ *seal rows exposed only after the regular readbacks, stream windows, dyadic tolerance ledgers, and witness budgets have been displayed.*
6. H *records componentwise* hsame *transport for both readbacks, both windows, both dyadic ledgers, both witness budgets, both real seals, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from the finite windows through the regular readbacks and dyadic tolerance ledgers into the two real seals.*
8. P *is the* Pkg *provenance over* RegularCauchyExtensionality$^{\uparrow}$, BishopRealExtensionality$^{\uparrow}$, RealUniformEntourageBas CauchyFilterSubbasis$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R_0, R_1, S_0, S_1, D_0, D_1, W_0, W_1, A_0, A_1, H, C, P, N$. It has no coordinate for quotient real equality, a selected representative, countable choice, trichotomy, ambient Cauchy completion, or host real equality.

Theorem 7009.2 (Effective regular real extensionality NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}$ *carrier $E = (R_0, R_1, S_0, S_1, D_0, D_1, W_0, W_1, A_0, A_1, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}}$ *surface consists exactly of carrier admission, exposure of the two regular readbacks, exposure of the two finite stream windows, exposure of the two dyadic tolerance ledgers, exposure of the two effective witness-budget rows, exposure of the two terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 7009.1. The analytic rows are precisely the two regular readbacks, two finite windows, two dyadic ledgers, two witness-budget rows, and two real seals.

The structural rows preserve the same packet. The row H transports each displayed coordinate by hsame, C replays the route from window evidence to readback and seal evidence, P records the cited siblings, and N names the local certificate.

Since the carrier contains no further coordinate, every local NameCert obligation is one of those rows. The excluded quotient, representative-selection, choice, and host-equality principles cannot be exported from the packet. □

Theorem 7009.3 (Effective regular real computable handoff)**.** *Every computable consumer of an accepted* $\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}$ *packet may reuse a regular real name only through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff is witnessed by the two finite stream windows, the two regular readbacks, the two dyadic tolerance ledgers, and the two effective witness-budget rows; it is not a request for a quotient representative or a global equality decision.

Proof. Read the two finite windows S_0, S_1 and their regular readbacks R_0, R_1. The dyadic ledgers D_0, D_1 supply the finite precision data, while W_0, W_1 record the effective budgets needed to replay the comparison at those precisions.

The route then reaches A_0, A_1 only through displayed replay. Thus a computable consumer can reuse the regular-name data by following the finite window-readback-ledger route.

No selected representative or global equality decision appears in the carrier. The exported handoff is therefore a finite effective substitution surface rather than a quotient-real principle. □

Theorem 7009.4 (Effective regular real Real-seal boundary)**.** *The two* $\mathsf{Real}^{\uparrow}$ *seal rows of an accepted* $\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}$ *carrier are boundary rows for finite regular-name substitution. A consumer reaches A_0, A_1 only after the corresponding stream windows, regular readbacks, dyadic ledgers, witness budgets, transport, replay, provenance, and local name have been displayed.*

Proof. Use the carrier order. The seals A_0, A_1 are stored beside the window, readback, dyadic, and witness-budget rows, and the replay row C is the only displayed route by which a consumer reaches them.

Transport by H does not add a hidden seal source; it preserves the same coordinates. Provenance P and local naming N identify the packet but do not manufacture quotient equality or representative selection.

Therefore the real seals mark the boundary of the finite substitution certificate. Any consumer that bypasses the displayed rows is outside the $\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}$ surface. □

Falsifiable prediction: Every accepted $\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}$ packet displays two regular readbacks, two StreamName windows, two DyadicRatCore tolerance ledgers, two effective witness budgets, two RealUp seals, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before extensional regular-name reuse is exported.

Independence witness: regular-cauchy-extensionality, bishop-real-extensionality, real-uniform-entourage-basis, cauchy-filter-subbasis, streamname, regseqrat, dyadicratcore, real: EffectiveRegularRealExtensional is not bijective to any listed sibling because it jointly carries two effective regular-name readbacks, two finite stream windows, two tolerance ledgers, two witness budgets, two real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}$ packet is generated from two regular readbacks, two finite StreamName windows, two DyadicRatCore tolerance ledgers, two effective witness budgets, two RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7009.1, Definition 7009.2, Definition 7009.3, and Definition 7009.4 seed the finite effective extensional-substitution packet for regular real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveRegularRealExtensionality}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.EffectiveRegularRealExtensionalityUp`

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, countable choice, trichotomy, ambient Cauchy completion, host real equality, theorem-checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-window readback, dyadic tolerance routing, witness-budget replay, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveRegularRealExtensionalit

Lean4 (statement) `BEDC.Derived.EffectiveRegularRealExtensionalityUp`

Chapter 7010

A Concrete Naming Certificate for $\mathsf{OrderedVectorSpace}^{\uparrow}$

Following Bourbaki and Aliprantis–Border on ordered vector spaces, the $\mathsf{OrderedVectorSpace}^{\uparrow}$ packet records the finite BEDC naming surface for a vector space equipped with a displayed positive cone whose induced preorder is compatible with addition and positive scalar multiplication. It sits beside the algebraic vector carrier of chapter 47, the cone membership boundary of chapter 2297, the preorder classifier of chapter 52, and the real scalar seal of chapter 38. The packet names only the finite ordered-algebra surface; it is not a lattice envelope, a Riesz decomposition principle, a Hahn-Banach separation theorem, an order-unit representation, or a host order completion.

Definition 7010.1 (Ordered vector space NameCert surface)**.** *An* $\mathsf{OrderedVectorSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (V, P, R, A, S, K, H, C, G, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *carrier row naming the vector endpoint, real scalar endpoint, zero vector, addition, additive inverse, scalar action, and finite vector-space law ledger.*
2. *P is the* $\mathsf{PositiveCone}^{\uparrow}$ *row on the same vector endpoint, recording cone membership, zero inclusion, addition closure inside the cone, and positive-real scalar closure.*
3. *R is the* $\mathsf{Preorder}^{\uparrow}$ *classifier row whose comparison is induced exactly by the displayed cone test: $x \leq_O y$ is read only through the row asserting $y - x \in P$.*
4. *A records addition compatibility: if $x \leq_O y$, then the displayed addition row carries $x+z \leq_O y+z$ by reusing the same cone difference row.*
5. *S records positive-scalar compatibility: if $0 \leq r$ is read through the* $\mathsf{Real}^{\uparrow}$ *scalar seal and $x \leq_O y$, then the displayed scalar-action row carries $rx \leq_O ry$ through the cone closure row.*
6. *K records cone closure and exactness: the preorder row has no accepted comparison unless the corresponding difference row has been admitted by P, and every admitted cone difference supplies the comparison row.*
7. *H records componentwise* hsame *transport for the vector-space carrier, cone row, preorder classifier, addition-compatibility row, scalar-compatibility row, cone-closure row, replay row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay from an ordered-vector-space request through V, P, R, A, S, K, H back to the same finite ordered-algebra surface.*
9. *G is the* Pkg *provenance over* $\mathsf{OrderedVectorSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{PositiveCone}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OrderedVectorSpace}^{\uparrow}}$ *row binding these displayed rows as one ordered-vector-space certificate.*

The classifier compares accepted packets only through $V, P, R, A, S, K, H, C, G, N$. It has no coordinate for a lattice operation, a Riesz decomposition witness, Hahn-Banach separation, an order unit, a selected dual cone, or an ambient host order relation.

Theorem 7010.2 (Ordered vector space positive-cone obligations)**.** *For every accepted* $\mathsf{OrderedVectorSpace}^{\uparrow}$ *carrier $O = (V, P, R, A, S, K, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{OrderedVectorSpace}^{\uparrow}}$ *surface exports exactly the cone-induced preorder, addition monotonicity, positive-scalar monotonicity, and nonescape from host order. A downstream consumer may read $x \leq_O y$ only by reading the displayed difference row $y - x \in P$; it may transport this comparison along displayed addition and positive-real scalar-action rows; and it receives no order comparison outside the carrier rows $V, P, R, A, S, K, H, C, G, N$.*

Proof. Carrier admission is projection from Definition 7010.1. The tuple displays exactly the vector-space row V, the positive-cone row P, the preorder row R, the addition and positive-scalar compatibility rows A, S, the cone-exactness row K, and the structural rows H, C, G, N.

The preorder obligation is therefore cone-induced. The only comparison exported by R is the one whose certificate is the displayed cone row for $y - x$, and K records the converse handoff from an admitted cone difference back to the comparison row.

Addition monotonicity is read through A: translating both endpoints preserves the same displayed difference row, so the comparison after translation is again admitted only through P and R.

Positive-scalar monotonicity is read through S: the scalar is first sealed by the $\mathsf{Real}^{\uparrow}$ row as positive, then the scalar-action row transports the cone difference through the closure data carried by P.

Finally H, C, G, N transport, replay, source, and name only those displayed coordinates. Since the carrier has no lattice row, no Riesz decomposition row, no separation functional, no order-unit representation, and no ambient host order coordinate, none of those objects can be exported by the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{OrderedVectorSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{OrderedVectorSpace}^{\uparrow}$ packet is generated from a VecSpace carrier, a PositiveCone row, a cone-induced Preorder classifier, addition and positive-scalar compatibility rows, cone exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OrderedVectorSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7010.1 and Definition 7010.2 seed the finite ordered-algebra certificate over VecSpaceUp, PositiveConeUp, PreorderUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OrderedVectorSpace}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.OrderedVectorSpaceUp`

Bridge status: none

Not claimed: This chapter does not close lattice or Riesz completeness, Hahn-Banach separation, order-unit representation, Lean verification of the ordered-algebra obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cone-induced preorder exactness, addition monotonicity, positive-scalar monotonicity, transport, replay, provenance, and local naming for BEDC.Derived.OrderedVectorSpaceUp.

Chapter 7011

A Concrete Naming Certificate for $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$ packet records the regular Cauchy representation of a real name as finite BEDC data. It sits after the dyadic tolerance core of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located-completion boundary of chapter 1455. The packet names a representation route for L10 Real and Completion consumers without asserting completeness, quotient real equality, trichotomy, countable choice, or host real primitives.

Definition 7011.1 (Bishop regular real representation carrier)**.** *A* $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, Q, D, K, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger, exposing the finite inspected windows of the representing stream at requested precisions.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, recording that the displayed windows are read as a regular rational sequence.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare displayed rational windows and record the regular Cauchy budget.*
4. *K is the regular closeness classifier, accepting only reads whose visible windows satisfy the dyadic tolerance rows required by the regular sequence discipline.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, Q, D, K have been displayed.*
6. *H records componentwise* hsame *transport for stream windows, regular rational source rows, dyadic tolerances, closeness classification, real sealing, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay along the route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto K \longmapsto \mathsf{Real}^{\uparrow}.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopRegularRealRepresentation}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $W, Q, D, K, E, H, C, P, N$. It has no coordinate for quotient real equality, a selected representative, trichotomy, countable choice, host real primitives, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopRegularRealRepresentationUp.TasteGate.BishopRegularRealRepresentationTasteGa`
`single carrier alignment`

Theorem 7011.2 (Bishop regular real representation NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$ *carrier $R = (W, Q, D, K, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealRepresent}}$ *surface consists exactly of carrier admission for Definition 7011.1, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *source readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance comparison, regular closeness classification,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The ledger nonescape obligation says that every tolerance, closeness, and seal read remains inside those rows.*

Proof. Project the accepted carrier. The displayed coordinates are precisely $W, Q, D, K, E, H, C, P, N$, so carrier admission and local naming are finite row projections.

The classifier side is K together with D. It checks regular closeness only through the displayed dyadic tolerance ledger and the inspected stream windows, not through a host real comparison.

The seal handoff is E. Since C replays the route through W, Q, D, K before E is visible, a Real-facing read cannot bypass the StreamName, RegSeqRat, or DyadicRatCore rows.

Finally H, C, P, N transport, replay, source, and name the same finite route. No remaining coordinate can export quotient real equality, trichotomy, countable choice, host real primitives, or ambient completeness. □

Theorem 7011.3 (Bishop regular real representation seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$ *packet passes through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the terminal seal row E may be consumed. The route imports no quotient real equality, selected representative, trichotomy, countable-choice schedule, host real primitive, or ambient completeness theorem.

Proof. Start with the tolerance ledger. The row D supplies the finite dyadic comparison budget used by the regular closeness classifier.

Read the finite windows and regular source next. The row W exposes the inspected $\mathsf{StreamName}^{\uparrow}$ windows, and Q records that those windows are consumed as a $\mathsf{RegSeqRat}^{\uparrow}$ source.

Only then may the classifier and seal be read. The row K accepts the visible regular closeness data, and E is downstream of W, Q, D, K by the continuation row C.

The structural rows H, C, P, N preserve that order for every consumer. Since the carrier has no additional equality, choice, trichotomy, host-real, or completeness coordinate, every Real-facing read remains inside the displayed seal route. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$ read exposes a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{StreamName}^{\uparrow}$ finite-window row, a $\mathsf{RegSeqRat}^{\uparrow}$ source row, a regular closeness classifier row, and a terminal $\mathsf{Real}^{\uparrow}$ seal before any Real or Completion consumer can use the representation.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishoplocatedcompletionboundary: none is bijective to $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$ because this packet jointly carries stream windows, regular rational source rows, dyadic tolerance ledgers, regular closeness classification, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularRealRepresentation}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularRealRepresentation}^{\uparrow}$ packet is generated from StreamName windows, a RegSeqRat source row, a DyadicRatCore tolerance ledger, a regular closeness classifier, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularRealRepresentation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7011.1, Definition 7011.2, and Definition 7011.3 seed the Bishop regular real representation packet over finite windows, regular rational readback, dyadic tolerance ledgers, closeness classification, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularRealRepresentation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient real equality, trichotomy, countable choice, host real primitives, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, seal handoff, ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularRealRepresentationUp.

Chapter 7012

A Concrete Naming Certificate for $\mathsf{LayeredRelationGateQuestion}^{\uparrow}$

The $\mathsf{LayeredRelationGateQuestion}^{\uparrow}$ packet realizes the question surface of chapter 9416 as finite NameCert data. It sits beside the relation-certificate packet of chapter 1090, the gate packet of chapter 1099, and the relation-audit frame of chapter 1037. The packet names the questions a consumer must answer before same-schema language can be exported; it does not identify the compared domains, transfer empirical content, promote proof obligations across domains, or turn a relation into a bridge.

Definition 7012.1 (Layered relation gate question carrier)**.** *A* $\mathsf{LayeredRelationGateQuestion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, U, V, L, P, N, E, F, S, H, C, R, M)$$

with the following displayed rows:

1. *A and B are the sourceA and sourceB rows naming the two domains being compared.*
2. *U and V are the carrierA and carrierB rows naming the carrier families visible at the compared layers.*
3. *L is the layerMap row pairing source layers, carrier rows, and classifier rows.*
4. *P is the preserved row listing the relation content the question surface permits a consumer to export.*
5. *N is the notPreserved row listing object identity, empirical law, proof transfer, subject-substance, global-frame, hidden bridge, and strength over-reading refusals.*
6. *E is the exactness row recording the available reading of same-schema language.*
7. *F is the failureBoundary row recording when the relation weakens, fails, or must be refused.*
8. *S is the strength row recording whether the packet is seed, paper certificate, checked certificate, or bridge certificate strength.*
9. *H records componentwise* hsame *transport for source, carrier, layer-map, preserved, not-preserved, exactness, failure, strength, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the question route from source exposure through layer mapping, preservation, refusal, exactness, failure boundary, and strength.*

11. *R is the* Pkg *provenance over* LayeredRelationGateQuestion$^{\uparrow}$, LayeredRelationCert$^{\uparrow}$, LayeredRelationGate$^{\uparrow}$, RelationalFrameAudit$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *M is the local* NameCert$_{\text{LayeredRelationGateQuestion}^{\uparrow}}$ *row.*

The classifier accepts a packet only when sourceA/sourceB, carrierA/carrierB, layerMap, preserved, notPreserved, exactness, failureBoundary, strength, transport, replay, provenance, and local name are all present before a same-schema consumer reads the answer surface.

Theorem 7012.2 (Layered relation gate question NameCert obligations)**.** *For every accepted* LayeredRelationGateQuestion$^{\uparrow}$ *carrier* $Q = (A, B, U, V, L, P, N, E, F, S, H, C, R, M)$*, the local* NameCert$_{\text{LayeredRelationG}}$ *surface consists exactly of sourceA/sourceB exposure, carrierA/carrierB exposure, layerMap display, preserved-row disclosure, notPreserved-row disclosure, exactness display, failureBoundary display, strength display, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer cannot export same-schema language until each of these rows has been displayed.*

Proof. Project the accepted carrier. The coordinates of Definition 7012.1 are exactly the finite rows named in the statement.

The source and carrier questions are A, B, U, V. They bind the compared domains and their carrier families before the layer map L can be consumed.

The relation export questions are P, N, E, F, S. The preserved row P records what may be exported, while N and F record the refusal and failure boundary that prevent identity readings.

Finally H, C, R, M transport, replay, source, and name the same question packet. Since no other coordinate exists, a consumer cannot obtain same-schema language without first displaying the listed rows. □

Theorem 7012.3 (Layered relation gate question refusal surface)**.** *Every accepted* LayeredRelationGateQuestion$^{\uparrow}$ *packet refuses identity-misreadings of cross-domain analogy. If a consumer asks to identify sourceA with sourceB, to transfer empirical content, to transfer proof obligations, to import subject-substance, to assert a global frame, or to claim bridge strength without a bridge row, the read is routed to the notPreserved row N and the failureBoundary row F rather than to the preserved row P.*

Proof. Begin with the NameCert obligations of Definition 7012.2. They require P, N, E, F, S to be displayed together before any same-schema answer is exported.

The preserved row P contains only the relation content allowed by the displayed layer map and exactness row. The notPreserved row N lists identity, empirical transfer, proof transfer, subject-substance, global-frame, hidden bridge, and strength over-reading as refused content.

The failureBoundary row F records the action for those refused reads. Therefore any request for an identity-misreading is routed through N and F, while the exported same-schema answer remains confined to P with its exactness and strength rows. □

Falsifiable prediction: Every accepted LayeredRelationGateQuestion$^{\uparrow}$ answer displays sourceA/sourceB, carrierA/carrierB, layerMap, preserved, notPreserved, exactness, failureBoundary, strength, transport, replay, provenance, and local naming rows before it is consumed as a same-schema relation question.

Independence witness: layeredrelationcert, layeredrelationgate, relationalframeaudit: none is bijective to LayeredRelationGateQuestion$^{\uparrow}$ because this packet isolates the finite question surface with source, carrier, layer-map, preserved, not-preserved, exactness, failure-boundary, strength, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LayeredRelationGateQuestion}^{\uparrow}}$.

Constructive story: A $\mathsf{LayeredRelationGateQuestion}^{\uparrow}$ packet is generated from two source rows, two carrier-family rows, a layer map, preserved and not-preserved rows, exactness and failure-boundary rows, a strength row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LayeredRelationGateQuestion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7012.1, Definition 7012.2, and Definition 7012.3 seed the finite question surface for relation-before-identity gate reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LayeredRelationGateQuestion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close object identity between compared domains, empirical transfer, proof transfer, subject-substance content, global-frame structure, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and carrier exposure, layer-map display, preserved and not-preserved disclosure, exactness, failure-boundary, strength, transport, replay, provenance, and local naming for BEDC.Derived.LayeredRelationGateQuestionUp.

Chapter 7013

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$ packet records finite refinement of regular-Cauchy observation windows. It sits next to the cofinal-window route of chapter 4060, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet gives Real and Completion consumers a displayed way to pass from a coarse accepted window schedule to a finer schedule without quotient streams, selected limits, countable choice, or ambient completeness.

Definition 7013.1 (Regular Cauchy window refinement carrier)**.** *A* $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, W', D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the regular source row whose admissible names are read as* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *W is the original finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule exposed to the consumer.*
3. *W' is the refined finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule, displayed as a later or thinner observation window over the same source route.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the original and refined windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after both schedules and the dyadic tolerance ledger have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read from the refined regular-Cauchy route.*
7. *H records componentwise* hsame *transport for source, original window, refined window, dyadic tolerance, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, W, W', D \longmapsto R \longmapsto E \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$, $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowRefinement}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, W, W', D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected representative, countable-choice extraction, host real equality, or ambient completeness.

Theorem 7013.2 (Regular Cauchy window refinement NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$ *carrier $F = (S, W, W', D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowRefinement}^{\uparrow}}$ *surface consists exactly of source admission through S, original finite-window exposure through W, refined finite-window exposure through W', dyadic tolerance comparison through D, regular rational readback through R, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7013.1. Its displayed rows are exactly $S, W, W', D, R, E, H, C, P, N$, so the original and refined window schedules are both visible before any Real-facing read is exported.

The dyadic ledger D is read after the two schedules have been displayed. It is therefore a comparison between finite window rows, not a quotient comparison between external Cauchy streams.

The readback row R and seal row E are downstream of the same finite data. Transport, replay, provenance, and local naming preserve that route, so the NameCert obligations are exhausted by the listed coordinates. □

Theorem 7013.3 (Regular Cauchy window refinement cofinal handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$ *packet factors its read through the finite handoff*

$$\mathsf{RegularCauchyWindowCofinality}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer may replace the original finite window W by the refined finite window W' only through the displayed dyadic tolerance ledger D and the regular rational readback row R.

Proof. Start with the source row S and the original schedule W. The cofinal-window route of chapter 4060 supplies the admissible tail boundary for replacing a coarse finite observation by a finer one.

Use finite-window induction along the displayed refinement from W to W'. At the base window the consumer reads the same $\mathsf{StreamName}^{\uparrow}$ schedule, and at each successor window the ledger D records the dyadic tolerance comparison needed to preserve the regular-Cauchy readback.

After the refined schedule has been reached, row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback and row E supplies the terminal $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N replay and name the same route, so no selected limit, countable-choice selector, quotient stream equality, or ambient completeness theorem can enter the handoff. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$ read displays one source row, one original $\mathsf{StreamName}^{\uparrow}$ window row, one refined $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal, and local transport, replay, provenance, and naming rows before it is consumed by a Real or Completion route.

Independence witness: regular-cauchy-window-cofinality, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$ is not bijective to any listed sibling because it binds

the original and refined finite windows, dyadic comparison, regular readback, Real seal, componentwise hsame, displayed Cont, Pkg, and local NameCert into one accepted refinement packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowRefinement}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{RegularCauchyWindowRefinement}^{\uparrow}$ packet is generated from a regular source row, original and refined finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7013.1, Definition 7013.2, and Definition 7013.3 seed the finite refinement route from cofinal windows to Real-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy stream equality, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, original and refined window exposure, dyadic tolerance comparison, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyWindo

Chapter 7014

A Concrete Naming Certificate for $\mathsf{FiniteNetMeshRefinement}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteNetMeshRefinement}^{\uparrow}$ packet records the Heine–Cantor finite-net route from compact metric data to a tolerance-only uniform-modulus handoff. It realizes the compact-uniform-continuity construction of chapter 9237 by exposing finite ProbeBundle nets, dyadic mesh refinements, compact metric source rows, rational radius ledgers, continuous-map pointwise modulus rows, and the terminal $\mathsf{UniformModulus}^{\uparrow}$ consumer surface. It sits with the compact metric certificate of chapter 129, the finite epsilon-net carrier of chapter 1767, the dyadic tolerance ledger of chapter 291, and the uniform-modulus packet of chapter 369.

Definition 7014.1 (Finite-net mesh-refinement carrier)**.** *A* $\mathsf{FiniteNetMeshRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, B, G, D, Q, L, A, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, displaying the compact metric carrier and its finite-cover witness surface.*
2. *B is the finite* ProbeBundle *net row, displaying the centers used for the current tolerance request.*
3. *G is the dyadic mesh-refinement row, replacing a coarse net by a finer net through named dyadic radius data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the mesh comparison.*
5. *Q is the rational radius ledger, recording the finite lower-bound fold over the bundled radii.*
6. *L is the continuous-map pointwise modulus row attached to the bundled centers.*
7. *A is the compact-source admission row connecting the finite net to the source points it covers.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced after the mesh, radius, and pointwise-modulus rows have been displayed.*
9. *H records componentwise* hsame *transport for compact source, finite net, mesh refinement, dyadic tolerance, rational radius fold, pointwise modulus, compact admission, uniform-modulus handoff, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the route*

$$K, B, G, D, Q, L, A \longmapsto U \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{FiniteNetMeshRefinement}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteNetMeshRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, G, D, Q, L, A, U, H, C, P, N$. It has no coordinate for an external finite-subcover selector, a selected minimum radius, an ambient compactness oracle, or a global modulus function outside the displayed history rows.

Theorem 7014.2 (Finite-net mesh-refinement NameCert obligations)**.** *For every accepted* FiniteNetMeshRefinemen *carrier $M = (K, B, G, D, Q, L, A, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteNetMeshRefinement}^{\uparrow}}$ *surface consists exactly of compact metric source admission through K, finite ProbeBundle net exposure through B, dyadic mesh refinement through G, dyadic tolerance comparison through D, rational radius folding through Q, pointwise continuous-map modulus reading through L, compact-source admission through A, uniform-modulus handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7014.1. The displayed rows are exactly $K, B, G, D, Q, L, A, U, H, C, P, N$, so the compact source, finite net, mesh, radius, and pointwise-modulus data are visible before the uniform-modulus handoff can be consumed.

The mesh row G is finite because it is attached to the ProbeBundle row B and compared by the dyadic ledger D. The rational fold row Q is likewise internal to the displayed bundled radii, so no selected external minimum is introduced.

The handoff row U is downstream of the compact admission row A and the pointwise modulus row L. Transport, replay, provenance, and local naming preserve this dependency order, which exhausts the local NameCert surface. □

Theorem 7014.3 (Finite-net mesh-refinement uniform-modulus handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{FiniteNetMeshRefinement}^{\uparrow}$ *packet factors its read through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{FiniteEpsilonNet}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The mesh-refinement packet may refine a finite net only by displaying a dyadic mesh row, the rational lower-bound ledger over bundled radii, and the pointwise modulus rows consumed by the final $\mathsf{UniformModulus}^{\uparrow}$ *handoff.*

Proof. Start with the compact source row K and the finite ProbeBundle net B. These rows are the concrete finite-net surface singled out by chapter 9237, and the consumer may inspect only the centers and coverage rows they display.

Use finite induction over the mesh-refinement row G. The base case is the original finite net; the successor step replaces a bundled mesh cell by displayed dyadic subcells whose tolerance comparison is recorded in D.

Fold the resulting radius data through Q. Because the fold is over the displayed ProbeBundle rows, it produces a history-level lower-bound ledger rather than an external radius selector.

Finally read the pointwise modulus row L at the bundled centers and pass through compact admission A to the uniform-modulus handoff U. The structural rows H, C, P, N replay and name the same finite route, so the packet exports no ambient compactness oracle, external finite-subcover choice, or global modulus function. □

Falsifiable prediction: Every accepted $\mathsf{FiniteNetMeshRefinement}^{\uparrow}$ read displays a CompactMetric source row, a finite ProbeBundle net row, a dyadic mesh-refinement row, a DyadicRatCore tolerance ledger, a rational radius fold, pointwise continuous-map modulus rows, a UniformModulus handoff, and local transport, replay, provenance, and naming rows before compact-uniform-continuity consumers inspect it.

Independence witness: compactmetric, finiteepsilonnet, dyadicratcore, uniformmodulus: FiniteNetMeshRefinem is not bijective to any listed sibling because it binds finite net exposure, dyadic mesh refinement, rational radius folding, pointwise modulus reading, compact-source admission, uniform-modulus handoff, componentwise hsame, displayed Cont, Pkg, and local NameCert into one accepted packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteNetMeshRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteNetMeshRefinement}^{\uparrow}$ packet is generated from CompactMetric source data, finite ProbeBundle net rows, dyadic mesh-refinement rows, DyadicRatCore tolerance ledgers, rational radius folds, pointwise continuous-map modulus rows, compact-source admission, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteNetMeshRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7014.1, Definition 7014.2, and Definition 7014.3 seed the finite mesh route from compact nets to tolerance-only uniform-modulus data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteNetMeshRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an external finite-subcover selector, a selected minimum radius, an ambient compactness oracle, a global modulus function, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact source admission, finite ProbeBundle net exposure, dyadic mesh refinement, radius folding, pointwise modulus reading, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteNetMeshRefinementUp.

Chapter 7015

A Concrete Naming Certificate for $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$

Following Bishop–Bridges constructive completion theory, the $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ packet records the finite route by which a metric-space point stream is read as regular-Cauchy completion data and then exposed to Real-facing consumers. It sits after the metric carrier of chapter 57, the completeness boundary of chapter 128, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a completion-facing regular-Cauchy handoff; it does not quotient Cauchy filters, choose limit representatives, assert ambient completeness, or import host real equality.

Definition 7015.1 (Metric regular Cauchy completion carrier)**.** *A* $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying point row of the named metric-space source.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *metric-structure row, exposing only the displayed distance and comparison data available to the packet.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording the inspected source windows of the Cauchy name.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row by which the inspected windows are consumed as regular rational approximation data.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for metric-window comparison and regular-Cauchy budget replay.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for point rows, metric rows, stream windows, regular readback, dyadic tolerances, Real sealing, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a completion precision request through*

$$X, M, S, D \longmapsto R \longmapsto E \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricRegularCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, S, R, D, E, H, C, P, N$. It has no coordinate for quotient completion equality, a selected completion point, a selected limit representative, countable choice, host real equality, or an ambient completeness proof beyond the displayed $\mathsf{CompleteMetric}^{\uparrow}$ *boundary reference.*

Theorem 7015.2 (Metric regular Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ *carrier*

$$K = (X, M, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricRegularCauchyCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for Definition 7015.1; metric-window exactness through X, M, S, D; regular-Cauchy readback through R; dyadic tolerance replay through D; Real-seal nonescape through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N. A completion-facing read may cite* $\mathsf{CompleteMetric}^{\uparrow}$ *as the sibling boundary named in provenance, but the packet itself exposes no hidden completeness theorem or quotient completion object.*

Proof. Project the accepted carrier. Its visible coordinates are exactly $X, M, S, R, D, E, H, C, P, N$, so carrier admission and local naming are finite row projections.

The metric-window side is X, M, S, D. The point and metric rows determine the displayed distance comparisons, the stream row supplies the inspected windows, and the dyadic ledger fixes the tolerance budget used by those comparisons.

The regular-Cauchy and Real-facing reads are downstream of those rows. The row R consumes the visible windows as regular rational data, and the seal row E can be reached only along the displayed route through M, S, R, D.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no additional coordinate for quotient equality, selected limits, choice, host real equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7015.3 (Metric regular Cauchy completion Real-seal boundary)**.** *Every completion-facing read of an accepted* $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ *carrier reaches* $\mathsf{Real}^{\uparrow}$ *only through the displayed route*

$$\mathsf{Met}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad X, M, S, R, D, E, H, C, P, N.$$

Thus the Real seal is a visible boundary of the metric-window, stream-window, regular-readback, and dyadic-tolerance rows; it is not a quotient completion, selected representative, countable-choice schedule, host real primitive, or ambient completeness assertion.

Proof. Begin with a read that asks for the Real-facing seal. The carrier gives no direct Real coordinate before the point row, metric row, inspected stream windows, regular readback, and dyadic tolerance ledger have been exposed.

Read the displayed route. The rows X, M, S, D provide the metric-window comparison surface, and R records the regular-Cauchy readback attached to those same windows and tolerances.

Only then may E be consumed as the $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N preserve, replay, source, and name the same route, while P records $\mathsf{CompleteMetric}^{\uparrow}$ only as a sibling boundary for completion consumers.

Because no further carrier coordinate exists, the read cannot escape into quotient completion equality, a selected representative, a countable-choice schedule, host real primitives, or an ambient completeness theorem. □

Theorem 7015.4 (Metric regular Cauchy completion complete-metric handoff)**.** *Every accepted* $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ *packet may cite* $\mathsf{CompleteMetric}^{\uparrow}$ *only through the displayed metric row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The complete-metric sibling is therefore a boundary row for completion consumers, not an ambient completeness theorem available inside the packet.*

Proof. Project the carrier of Definition 7015.1. The visible rows are $X, M, S, R, D, E, H, C, P, N$, and the only place $\mathsf{CompleteMetric}^{\uparrow}$ appears is the provenance boundary attached to the completion-facing route.

Use the NameCert obligations of Definition 7015.2. They force the metric-window, regular-readback, dyadic-tolerance, Real-seal, transport, replay, provenance, and local naming rows to be displayed before any completion-facing read is accepted.

Finally apply the Real-seal boundary of Definition 7015.3. Since the seal is reached only through the displayed finite route, the complete-metric citation remains a sibling handoff row and cannot supply quotient completion equality, a selected limit, countable choice, or ambient completeness. □

Theorem 7015.5 (Metric regular Cauchy completion window universality)**.** *Let two completion-facing reads of accepted* $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ *packets have the same displayed metric-window rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. Then they determine the same completion-facing surface for every consumer that reads through* $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$.

Proof. Read both packets through Definition 7015.1. The classifier of an accepted packet has no coordinate beyond the displayed metric, stream, readback, dyadic, Real-seal, transport, replay, provenance, and local naming rows.

Apply Definition 7015.2. Equal displayed rows give the same carrier admission, metric-window exactness, regular-Cauchy readback, dyadic tolerance replay, Real-seal nonescape, transport, replay, provenance, and local naming obligations.

The Real-seal boundary theorem then forces every completion-facing consumer to pass through those same rows before reaching $\mathsf{Real}^{\uparrow}$. Hence no quotient stream equality, selected limit, countable-choice schedule, or ambient completeness coordinate remains that could distinguish the two completion-facing surfaces. □

Falsifiable prediction: Every accepted $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ completion-facing read exposes a $\mathsf{Met}^{\uparrow}$ metric row, $\mathsf{StreamName}^{\uparrow}$ finite windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the displayed packet rows before it consumes the terminal $\mathsf{Real}^{\uparrow}$ seal.

Independence witness: metricspace, completemetric, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole packet $K = (X, M, S, R, D, E, H, C, P, N)$, because each sibling contributes only a metric row, a completeness boundary, finite windows, regular rational

readback, dyadic tolerances, or a Real seal while this chapter binds the completion route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricRegularCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricRegularCauchyCompletion}^{\uparrow}$ packet is generated from point rows, MetricSpace metric rows, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricRegularCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7015.1, Definition 7015.2, and Definition 7015.3 seed the metric regular-Cauchy completion packet over metric windows, finite streams, regular rational readback, dyadic tolerances, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricRegularCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected completion points, countable choice, host real equality, Lean verification, audit cleanliness, bridge checking, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, metric-window exactness, regular-Cauchy readback, dyadic tolerance replay, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricRegularCauchyCor

Chapter 7016

A Concrete Naming Certificate for $\mathsf{RegularSequenceEquivalence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularSequenceEquivalence}^{\uparrow}$ packet records the finite comparison surface between two regular sequence names before their terminal real seals are read. It sits between the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the Cauchy route of chapter 3413. The certificate names a non-quotient equivalence boundary for regular sequence comparison; it does not select a completed real, identify quotient streams, or import ambient completeness.

Definition 7016.1 (RegularSequenceEquivalence NameCert surface)**.** *A* $\mathsf{RegularSequenceEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S_0, S_1, W_0, W_1, D, R_0, R_1, Q, A, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *schedules whose finite windows are compared;*
2. W_0 *and* W_1 *are the paired finite window lists selected from those schedules;*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for all paired window reads;*
4. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from* S_0, W_0, D *and* S_1, W_1, D*;*
5. Q *is the finite symmetric tail classifier, recording that each displayed tail request in either direction is met inside the same dyadic tolerance ledger;*
6. A *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-comparison row, readable only after* $S_0, S_1, W_0, W_1, D, R_0, R_1, Q$ *have been displayed;*
7. H *is the componentwise* hsame *provenance for the stream schedules, window lists, dyadic ledger, readbacks, classifier, and seal row;*
8. C *is the displayed* Cont *replay route for the same finite rows;*
9. P *is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceEquivalence}^{\uparrow}}$ *row.*

The packet exposes no quotient stream equality, selected representative, host real equality, countable-choice selector, or ambient completeness coordinate.

Theorem 7016.2 (Symmetric tail obligations for regular sequence equivalence)**.** *For every accepted* $\mathsf{RegularSequenceEquivalence}^{\uparrow}$ *packet* $E = (S_0, S_1, W_0, W_1, D, R_0, R_1, Q, A, H, C, P, N)$*, the finite tail comparison is symmetric over the same displayed ledger. A consumer reading the comparison from* R_0 *to* R_1 *and a consumer reading it from* R_1 *to* R_0 *must both pass through the same* $\mathsf{StreamName}^{\uparrow}$ *windows, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the same pair of* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal row. Thus the comparison is a finite NameCert surface for regular sequence equivalence, not a quotient equality or a selected completed-real witness.*

Proof. Project the carrier of Definition 7016.1. The two directions of the tail comparison are not stored as separate equivalence principles; they are the two readings of the single classifier row Q over W_0, W_1, D.

For the forward reading, the consumer first observes S_0 through W_0, reads R_0 through the dyadic ledger D, and compares it with the S_1, W_1, R_1 side by the displayed classifier Q. The terminal seal A is available only after those rows have been displayed.

For the reverse reading, the same classifier row is read with the two window sides exchanged. Because D, H, C, P, and N are componentwise rows over both sides at once, the reverse read has no independent tolerance ledger or hidden equality source.

The carrier contains no quotient stream, selected representative, host real equality, countable-choice selector, or ambient completeness coordinate. Therefore both directions of regular sequence equivalence are exhausted by the same finite StreamName, DyadicRatCore, RegSeqRat, Real, transport, replay, provenance, and NameCert rows. □

Theorem 7016.3 (Regular sequence equivalence Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing comparison exported by an accepted* $\mathsf{RegularSequenceEquivalence}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularSequenceEquivalence}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff may be cited by Cauchy and completion consumers only as the displayed comparison surface over those rows; it does not provide quotient equality of streams, a selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the displayed rows of Definition 7016.1 in order. The stream schedules and finite windows determine the observation domain, the dyadic ledger fixes the tolerance tests, and the two RegSeqRat rows are the only regular rational readbacks available to the classifier.

Apply Definition 7016.2. It identifies the two directional tail reads with the same finite classifier row over the same ledger and the same terminal Real seal.

Since A is attached after the two readbacks and the classifier, every Real-facing comparison must pass through the displayed sequence of rows. The remaining H, C, P, N coordinates transport, replay, package, and name this route, while the excluded quotient, selection, host-equality, choice, and completeness data never appear in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceEquivalence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularSequenceEquivalence}^{\uparrow}$ packet is generated from paired StreamName schedules, paired finite window lists, a shared DyadicRatCore tolerance ledger, two RegSeqRat readback rows, a symmetric finite tail classifier, a terminal Real seal-comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7016.1, Definition 7016.2, and Definition 7016.3 bind the finite regular sequence comparison surface over StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, Cauchy$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularSequenceEquivalence}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, ambient Real$^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, symmetric tail-classifier stability, RegSeqRat readback exactness, Real seal nonescape, and local NameCert coverage for BEDC.Derived.RegularSequenceEquivalenceUp.

Chapter 7017

A Concrete Naming Certificate for $\mathsf{GaussQuadrature}^{\uparrow}$

Following Gauss, Christoffel, and the classical numerical-analysis tradition of Gaussian quadrature, the $\mathsf{GaussQuadrature}^{\uparrow}$ packet records a finite node-weight rule as BEDC NameCert data rather than as a host integration theorem. It sits over the coefficient and degree surface of chapter 50, the orthogonality ledger of chapter 2264, the tagged integral consumer route of chapter 1526, the real-name seal of chapter 38, and the dyadic tolerance arithmetic of chapter 291. The packet gives downstream numerical-integration chapters a finite quadrature-rule certificate without importing measure-theoretic integration, spectral completeness, quotient polynomial equality, selected real roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7017.1 (Gauss quadrature carrier)**.** *A* $\mathsf{GaussQuadrature}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (P, O, N, W, E, R, D, H, C, K)$$

with the following displayed rows:

1. *P is the* $\mathsf{Poly}^{\uparrow}$ *source row, carrying the finite coefficient ledger, degree bound, and polynomial evaluation interface inspected by the rule.*
2. *O is the* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *row, displaying the finite orthogonal-family window whose root and recurrence data determine the quadrature nodes.*
3. *N is the node ledger, listing the finitely many displayed real-name nodes and their attachment to the orthogonal-polynomial window.*
4. *W is the weight ledger, listing the displayed real-name weights and the finite positivity or non-degeneracy checks required by the rule.*
5. *E is the exactness ledger, displaying the polynomial-degree range for which the weighted node sum and the* $\mathsf{RiemannIntegral}^{\uparrow}$ *read agree.*
6. *R is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *handoff row, exposing only the tagged integration route that may consume the exactness ledger.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic row for finite comparisons of node positions, weights, and exactness residuals.*
8. *H records componentwise* hsame *transport for P, O, N, W, E, R, D and the local naming data.*

9. *C records displayed* Cont *replay from the polynomial row through the orthogonal-polynomial row, node and weight ledgers, exactness ledger, integration handoff, and dyadic comparison row.*
10. *K is the combined* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{GaussQuadrature}^\uparrow}$ *row over* $\mathsf{GaussQuadrature}^\uparrow$, $\mathsf{Poly}^\uparrow$, $\mathsf{OrthogonalPolynomial}^\uparrow$, $\mathsf{RiemannIntegral}^\uparrow$, $\mathsf{Real}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert.

The classifier compares accepted packets only through $P, O, N, W, E, R, D, H, C, K$. It has no coordinate for a host measure space, selected real-root solver, spectral completeness theorem, quotient polynomial equality, analytic error estimate outside the displayed degree range, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 7017.2 (Gauss quadrature NameCert obligations)**.** *For every accepted* $\mathsf{GaussQuadrature}^\uparrow$ *carrier*

$$Q = (P, O, N, W, E, R, D, H, C, K),$$

the local $\mathsf{NameCert}_{\mathsf{GaussQuadrature}^\uparrow}$ *surface consists exactly of polynomial-source admission, orthogonal-polynomial window admission, finite node ledger admission, finite weight ledger admission, degree-exactness exposure,* $\mathsf{RiemannIntegral}^\uparrow$ *handoff, dyadic comparison replay, componentwise transport, displayed continuation replay, provenance, local naming, and non-escape from host measure spaces, selected root solvers, spectral completeness, quotient polynomial equality, undisplayed error estimates, and ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 7017.1. The only source rows are P and O, so the quadrature rule starts from a displayed polynomial ledger and a displayed orthogonal-polynomial window.

The finite quadrature data are N and W. These rows list the nodes and weights as real-name entries tied to the same orthogonal-polynomial window, with D supplying the dyadic comparisons used to inspect them.

The exactness row E is then the only route to integration-facing content. It compares the weighted node sum against the $\mathsf{RiemannIntegral}^\uparrow$ handoff row R over the displayed polynomial-degree range.

The structural rows H, C, K transport, replay, source, and name this same finite route. Since no carrier coordinate stores a host measure space, a root-selection oracle, spectral completeness, quotient polynomial equality, undisplayed error estimates, or ambient real completeness, the listed rows exhaust the local certificate surface. □

Theorem 7017.3 (Gauss quadrature node-weight ledger)**.** *Every* $\mathsf{RiemannIntegral}^\uparrow$*-facing consumer of an accepted* $\mathsf{GaussQuadrature}^\uparrow$ *packet must read the finite route*

$$\mathsf{Poly}^\uparrow \longmapsto \mathsf{OrthogonalPolynomial}^\uparrow \longmapsto (N, W) \longmapsto E \longmapsto \mathsf{RiemannIntegral}^\uparrow$$

through the displayed rows $P, O, N, W, E, R, D, H, C, K$. The consumer may use the quadrature rule only after the node ledger, weight ledger, degree-exactness ledger, and dyadic comparison row have been displayed, and it receives no host measure, selected root solver, spectral completeness theorem, quotient polynomial equality, analytic error estimate outside the displayed degree range, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Begin with an integration-facing read. The carrier first exposes P, the finite polynomial source row, and then O, the finite orthogonal-polynomial window that controls the rule.

The node and weight information is available only as N and W. The dyadic row D supplies the finite comparisons for these displayed entries; it does not select roots or appeal to a complete real-root solver.

The exactness ledger E is downstream of P, O, N, W, D. Only after this ledger is present may the handoff row R be read by a $\mathsf{RiemannIntegral}^{\uparrow}$ consumer.

Transport and replay preserve the same row order through H and C, and K names the route as a local certificate. Thus the public quadrature read is a finite node-weight ledger, not a host integration or spectral-completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{GaussQuadrature}^{\uparrow}}$.

Constructive story: A $\mathsf{GaussQuadrature}^{\uparrow}$ packet is generated from a PolynomialUp source row, an OrthogonalPolynomialUp finite window, displayed real-name node and weight ledgers, a degree-exactness ledger, a RiemannIntegralUp handoff row, DyadicRatCoreUp comparison data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaussQuadrature}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7017.1, Definition 7017.2, and Definition 7017.3 seed the finite quadrature-rule certificate over $\mathsf{Poly}^{\uparrow}$, $\mathsf{OrthogonalPolynomial}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and BHist.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaussQuadrature}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host measure spaces, selected root solvers, spectral completeness, quotient polynomial equality, analytic error estimates outside the displayed exactness range, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, polynomial-source admission, orthogonal-polynomial window admission, node and weight ledger admission, degree-exactness exposure, RiemannIntegralUp handoff, dyadic comparison replay, transport, non-escape, and field faithfulness for BEDC.Derived.GaussQuadratureUp.

Chapter 7018

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$ packet records the finite interface where regular Cauchy rational data can be read through located lower-and-upper cut evidence before a terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits after the Cauchy-cut bridge of chapter 2312, the regular rational source of chapter 301, the stream-window source of chapter 126, the dyadic arithmetic core of chapter 291, and the real-name seal of chapter 38. The packet gives Real and Completion consumers a cut-facing boundary for regular Cauchy data without importing Dedekind completeness, quotient equality, selected limits, trichotomy, countable choice, or bridge checking.

Definition 7018.1 (Regular Cauchy located cut carrier)**.** *A* $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, D, L, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observed prefixes of the rational source.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational row read from the same windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint ledger used to compare finite rational cells.*
4. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *lower-and-upper cut row, carrying locatedness evidence for the displayed dyadic gap requests.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, Q, D, L have been displayed.*
6. *H records componentwise* hsame *transport for the stream, regular rational, dyadic, located-cut, real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite cut request through S, Q, D, L before the real seal R is consumed.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCut}^{\uparrow}}$ *row naming exactly this finite cut-facing packet.*

The classifier compares accepted packets only through $S, Q, D, L, R, H, C, P, N$. It has no coordinate for quotient real equality, Dedekind completeness, host-selected limits, trichotomy, countable choice, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCutUp.RegularCauchyLocatedCutTasteGate single carrier alignment`

Theorem 7018.2 (Regular Cauchy located cut NameCert obligations)**.** *For every accepted* RegularCauchyLocatedC *carrier* $K = (S, Q, D, L, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite stream windows, regular rational readback, dyadic tolerance ledger, located lower-and-upper cut row, terminal real seal, componentwise transport, displayed replay, provenance, and local naming. The obligation surface may cite the Cauchy-cut packet of chapter 2312, the* $\mathsf{RegSeqRat}^{\uparrow}$ *source of chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38; it cannot add a quotient representative, selected limit, trichotomy branch, countable-choice schedule, Dedekind-completeness witness, or bridge certificate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCutUp.RegularCauchyLocatedCutCarrier namecert obligations`

Proof. Project the carrier of Definition 7018.1. The analytic rows are exactly the finite stream window S, regular rational source Q, dyadic tolerance ledger D, located cut row L, and real seal R.

The ordered route forces each cut request to pass from S to Q, then through the dyadic gap data D, before L exposes locatedness evidence. The seal row R is downstream of that finite route.

Finally, H, C, P, N transport, replay, source, and name only the same packet. Since the excluded objects are absent from the carrier inventory, they cannot appear as additional NameCert obligations. □

Theorem 7018.3 (Regular Cauchy located cut Real-seal handoff)**.** *Every Real or Completion-facing consumer of an accepted* $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$ *carrier reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{LocatedCut}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The exported read is a located cut-facing regular Cauchy boundary, not a quotient real name, not a selected limit, not a trichotomy decision, not countable choice, not Dedekind completeness, and not a checked bridge.

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCutUp.RegularCauchyLocatedCutRealSealHandoff`

Proof. Begin with any consumer read of the seal R. By Definition 7018.1, the seal is packaged with the displayed windows S, regular rational row Q, dyadic ledger D, and located cut row L.

Apply Definition 7018.2. It keeps the Cauchy-facing rows and located cut row visible before the seal is consumed, and it admits only the structural transport, replay, provenance, and naming rows as further coordinates.

The forbidden principles are not fields of the carrier. Thus no path through the local certificate can export quotient equality of real names, a selected limit, trichotomy, countable choice, Dedekind completeness, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCut}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$ packet is generated from finite StreamName windows, a RegSeqRat regular rational source, a DyadicRatCore tolerance ledger, a LocatedCut lower-and-upper row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCut}^{\uparrow}}$, seed)

Scope closed: Definition 7018.1, Definition 7018.2, and Definition 7018.3 seed the finite located-cut boundary for regular Cauchy real-name reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim $\mathrm{Real}^{\uparrow}$ completeness, quotient equality, selected limits, trichotomy, countable choice, Dedekind completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window locality, regular rational read-back, dyadic gap exactness, located cut exposure, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedCutUp.

Chapter 7019

A Concrete Naming Certificate for HyperbolicBoundaryCompactification$^{\uparrow}$

Following Gromov and Bridson–Haefliger on hyperbolic boundary compactifications, the HyperbolicBoundaryCompa packet records the finite route by which a hyperbolic metric source, visual boundary, Gromov boundary, visual metric, Busemann boundary, boundary shadow, and terminal real seal are read as one compactification-facing NameCert surface. It realizes the boundary-compactification branch of chapter 9463 after the Gromov boundary packet of chapter 6470, the visual-metric packet of chapter 3866, the Busemann-boundary packet of chapter 3732, the boundary-shadow route of chapter 3813, the visual-boundary route of chapter 4181, and the real-name seal of chapter 38. The packet distinguishes a finite compactification boundary route from a completed quotient boundary, selected geodesic representative, host compact space, or ambient completeness theorem.

Definition 7019.1 (Hyperbolic boundary compactification carrier)**.** *A* HyperbolicBoundaryCompactification$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, V, G, D, U, S, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the hyperbolic metric source row that records the finite distance comparisons being compactified.*
2. *V is the* HyperbolicVisualBoundary$^{\uparrow}$ *visual-boundary row.*
3. *G is the* GromovBoundary$^{\uparrow}$ *boundary-equivalence row.*
4. *D is the* HyperbolicVisualMetric$^{\uparrow}$ *visual-metric comparison row on displayed boundary data.*
5. *U is the* HyperbolicBusemannBoundary$^{\uparrow}$ *Busemann-level boundary row.*
6. *S is the* HyperbolicBoundaryShadow$^{\uparrow}$ *shadow row that records finite boundary neighbourhood evidence.*
7. *R is the terminal* Real$^{\uparrow}$ *seal for scalar radii, visual distances, or shadow thresholds read by the packet.*
8. *H records componentwise* hsame *transport for metric, visual-boundary, Gromov-boundary, visual-metric, Busemann, shadow, real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same ordered boundary-compactification route.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, V, G, D, U, S, R, H, C, P, N$. It has no coordinate for a completed quotient boundary, selected ray representative, compact host space, physical observer law, countable choice, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.HyperbolicBoundaryCompactificationUp.HyperbolicBoundaryCompactificationTasteGate`
`single carrier alignment`

Theorem 7019.2 (Hyperbolic boundary compactification NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}$ *carrier $B = (M, V, G, D, U, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}}$ *surface consists exactly of carrier admission for the hyperbolic metric source, visual-boundary row, Gromov-boundary row, visual-metric comparison, Busemann boundary row, boundary-shadow row, terminal real seal, componentwise transport, displayed replay, provenance, and local naming. It may route through the sibling surfaces of chapter 6470, chapter 3866, chapter 3732, and chapter 3813; it cannot add a host compactification, selected boundary representative, quotient ideal boundary, global hyperbolic model, countable-choice schedule, or ambient completeness witness.*

Proof. Project the carrier of Definition 7019.1. The boundary-facing rows are exactly the metric source M, visual boundary V, Gromov boundary G, visual metric D, Busemann boundary U, boundary shadow S, and real seal R.

The route reads visual boundary and Gromov boundary data before the visual metric, Busemann, and shadow consumers receive the boundary token. This keeps compactification-facing evidence finite and displayed.

Finally, H, C, P, N transport, replay, source, and name the same carrier. Since the excluded host objects are not rows of the packet, the listed obligations exhaust the local NameCert surface. □

Theorem 7019.3 (Hyperbolic boundary compactification visual handoff)**.** *Every visual-metric, Busemann, boundary-shadow, or Real-seal read from an accepted* $\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{HyperbolicVisualBoundary}^{\uparrow} \longmapsto \mathsf{GromovBoundary}^{\uparrow} \longmapsto \mathsf{HyperbolicVisualMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicBusemannBoundary}^{\uparrow}$$

The exported object is a compactification-facing boundary route, not a completed quotient compactum, selected geodesic representative, global hyperbolic space, physical observer expansion law, countable choice, or ambient completeness theorem.

Proof. Start with a consumer read of D, U, S, or R. By Definition 7019.1, those rows are packaged downstream of the visual-boundary and Gromov-boundary rows V, G and remain tied to the hyperbolic metric source M.

Apply Definition 7019.2. It keeps the visual-metric, Busemann, boundary-shadow, and real-seal reads on the same displayed boundary route, and it permits only H, C, P, N as structural continuation rows.

The packet therefore exports finite compactification-facing evidence rather than any host quotient or completed compact space. The refused principles are not fields of the accepted carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}$ packet is generated from a hyperbolic metric source, HyperbolicVisualBoundary rows, GromovBoundary rows, HyperbolicVisualMetric rows, HyperbolicBusemannBoundary rows, HyperbolicBoundaryShadow rows, a RealUp scalar seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7019.1, Definition 7019.2, and Definition 7019.3 seed the finite visual-boundary, Gromov-boundary, visual-metric, Busemann, shadow, and Real-seal compactification route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a completed quotient boundary, selected geodesic representative, host compact space, global hyperbolic model, physical observer law, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visual-boundary admission, Gromov-boundary handoff, visual-metric compatibility, Busemann boundary routing, boundary-shadow exposure, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicBoundaryCompactificationUp.

Chapter 7020

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}$

Following Bishop and Bridges on subsequences of regular Cauchy names, the $\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}$ packet records the finite route by which a source regular sequence may be inspected along a displayed monotone cofinal index map while preserving the rational readback and Real-facing seal. It sits beside the schedule rows of chapter 126, the regular rational carrier of chapter 301, the terminal real-name surface of chapter 38, the dyadic tolerance ledger of chapter 291, and the extractor route of chapter 5125. The packet names subsequence stability as finite NameCert data; it is not quotient stream equality, not a selected limit, not countable choice, not host real equality, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7020.1 (Regular Cauchy subsequence principle carrier)**.** *A* $\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, I, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular sequence row, carried through the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *schedules.*
2. *I is the monotone cofinal index map, recording the finite request translation from subsequence windows back into source windows and the cofinal tail witness used by every downstream read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-budget ledger, carrying the displayed precision cells, dyadic slack comparisons, and tail thresholds.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row naming the source and subsequence observations inspected at each displayed precision request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after S, I, D, W have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only as the seal of the same cofinal regular readback route.*
7. *H records componentwise* hsame *transport for $S, I, D, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from a subsequence precision request through I, the source row S, the dyadic tail budget D, the finite windows W, the regular readback R, and the Real seal E.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, I, D, W, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected subsequence limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7020.2 (Regular Cauchy subsequence principle NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}$ *carrier $Q = (S, I, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission, cofinal index stability, regular tail preservation, Real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every subsequence read must expose the source regular sequence, monotone cofinal index map, dyadic tail budget, finite StreamName windows, and RegSeqRat readback before the Real seal is consumed.*

Proof. Project the carrier of Definition 7020.1. The analytic rows are S, I, D, W, R, E, and the structural rows H, C, P, N only transport, replay, source, and name those rows.

The cofinal index row I is the sole route from a subsequence precision request back to the source regular sequence. The dyadic budget D and finite window row W are read on that route, so regular tail preservation is tied to the displayed source sequence rather than to a detached subsequence object.

The readback row R and Real seal E are downstream of the same finite route. Since the packet contains no quotient coordinate, selected limit row, choice schedule, host equality row, or ambient completeness theorem, the listed obligations exhaust the local NameCert surface. □

Theorem 7020.3 (Regular Cauchy subsequence Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}$ *carrier factors through the displayed cofinal tail and regular-readback route*

$$I, S, D, W \longmapsto R \longmapsto E.$$

Thus a downstream Real consumer may cite the seal row E only after the monotone cofinal index map, source regular sequence, dyadic tail budget, finite StreamName windows, and RegSeqRat readback have all been displayed. The handoff exports no quotient stream, selected limit, countable-choice schedule, host real equality, or ambient Real completeness.

Proof. Start with a consumer asking for E. The carrier definition places E after the readback row R, and R is admitted only after the cofinal index, source sequence, dyadic budget, and finite windows have been displayed.

The continuation row C records the same order of exposure. A subsequence request is replayed through I before it reads S, then through D and W before it reaches the regular rational row.

Transport and provenance through H and P, with local naming through N, preserve this finite packet. Therefore every Real-facing read is mediated by the displayed cofinal tail route and receives none of the excluded quotient, choice, equality, or completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}$ packet is generated from a source regular sequence, a monotone cofinal index map, a DyadicRatCore tail budget, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySubsequencePrinciple}^{\uparrow}}$, seed)

Scope closed: Definition 7020.1, Definition 7020.2, and Definition 7020.3 seed the finite cofinal subsequence route from displayed regular Cauchy data to the downstream $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequencePrinciple}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected subsequence limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal index stability, dyadic tail-budget exactness, finite-window replay, regular readback, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySubsequencePrincipleUp.

Chapter 7021

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusEnvelope}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, the $\mathsf{CompactUniformModulusEnvelope}^{\uparrow}$ packet records the finite envelope by which compact finite nets, local continuity moduli, rational lower-bound folds, and a tolerance-only uniform modulus row are read as one NameCert carrier. It realizes the compact-uniform-continuity route of chapter 9237 beside the compact metric source of chapter 129, the continuous-map source of chapter 130, the uniform-modulus handoff of chapter 369, the metric distance source of chapter 57, and the rational fold source of chapter 37. The packet exports a finite modulus envelope only; it is not an open-cover compactness theorem, not a selected pointwise-radius function, not host function equality, and not ambient Real completeness.

Definition 7021.1 (Compact uniform modulus envelope carrier)**.** *A* $\mathsf{CompactUniformModulusEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, L, F, B, D, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, recording the compact source, displayed net probes, and coverage witnesses.*
2. *L is the local modulus row, read from the* $\mathsf{ContinuousMap}^{\uparrow}$ *carrier at each displayed finite-net center.*
3. *F is the rational lower-bound fold row, using* $\mathsf{Rat}^{\uparrow}$ *comparison data to fold the finitely many local radius ledgers into one positive precision history.*
4. *B is the dyadic tolerance row, carrying the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparisons used to align finite-net coverage, local radii, and target tolerance.*
5. *D is the* $\mathsf{Met}^{\uparrow}$ *distance-window row, recording the source and target triangle reads needed by the finite-net argument.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row reached only after K, L, F, B, D have been displayed.*
7. *H records componentwise* hsame *transport for $K, L, F, B, D, U, C, P, N$.*
8. *C records displayed* Cont *replay from a tolerance request through the compact finite-net row, local modulus row, rational lower-bound fold, dyadic tolerance row, metric window row, and uniform-modulus handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusEnvelope}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, L, F, B, D, U, H, C, P, N$. It has no coordinate for open-cover compactness, selected subcovers, selected pointwise radii, host function equality, quotient real representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7021.2 (Compact uniform modulus envelope NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusEnvelope}^{\uparrow}$ *carrier $M = (K, L, F, B, D, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModul}}$ *surface consists exactly of compact finite-net exposure, local modulus exposure, rational lower-bound fold exactness, dyadic tolerance compatibility, metric distance-window replay,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any uniform-modulus consumer must read those finite rows before the tolerance-only modulus row is exposed.*

Proof. Project the carrier of Definition 7021.1. The compact, local-modulus, rational-fold, dyadic, metric, and uniform-modulus rows are the analytic coordinates, while H, C, P, N only transport, replay, source, and name that route.

The local rows cannot produce a uniform modulus by themselves. They first pass through the finite rational lower-bound fold F, and the dyadic row B aligns the selected lower bound with the tolerance history read by the metric window D.

The handoff row U is downstream of this envelope. Since the carrier has no open-cover theorem, selected subcover, selected pointwise-radius function, host equality row, quotient representative, or ambient completeness theorem, the listed rows exhaust the NameCert obligations. □

Theorem 7021.3 (Compact uniform modulus envelope vision handoff)**.** *Every consumer of the compact-uniform-continuity vision that cites an accepted* $\mathsf{CompactUniformModulusEnvelope}^{\uparrow}$ *packet must pass through the finite route*

$$K, L, F, B, D \longmapsto U.$$

Thus the vision-facing read sees the compact finite net, local continuity moduli, rational lower-bound fold, dyadic tolerance row, and metric distance window before it reaches $\mathsf{UniformModulus}^{\uparrow}$*. The handoff exports no open-cover compactness theorem, selected subcover, selected pointwise-radius function, host function equality, quotient real representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a consumer asking for the uniform-modulus row U. The carrier definition places U after the compact finite-net row, local modulus row, rational fold, dyadic tolerance row, and metric window.

The continuation row C records the same order of exposure for each tolerance request. It reads the finite compact net, inspects the local moduli at displayed centers, folds their rational lower bounds, and only then applies the dyadic and metric windows that justify the uniform precision.

Transport through H, provenance through P, and naming through N preserve the same finite envelope. Therefore the vision handoff is a concrete NameCert route and cannot be reread as any of the excluded host compactness, selection, equality, quotient, or completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusEnvelope}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ContinuousMap local moduli, a RatUp lower-bound fold, DyadicRatCore tolerance compatibility, Metric distance windows, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompactUniformModulusEnvelope}\uparrow}$, seed)

Scope closed: Definition 7021.1, Definition 7021.2, and Definition 7021.3 seed the finite compact-uniform-modulus envelope route from compact nets and local moduli to a tolerance-only uniform-modulus handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactUniformModulusEnvelope}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, selected pointwise radii, host function equality, quotient real representatives, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net exposure, local modulus exposure, rational lower-bound fold exactness, dyadic tolerance compatibility, metric distance-window replay, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusEnvelopeUp.

Chapter 7022

A Concrete Naming Certificate for $\mathsf{CauchyNameUniformity}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces, the $\mathsf{CauchyNameUniformity}^{\uparrow}$ packet records the finite BEDC surface at which two Cauchy names are compared by common observation windows. It sits after the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the completion witness route of chapter 3579. The packet names the common-window uniformity surface for Cauchy names; it does not quotient streams, choose limits, use countable choice, assert ambient completeness, or identify names by host real equality.

Definition 7022.1 (Cauchy name uniformity carrier)**.** *A* $\mathsf{CauchyNameUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S_0, S_1, W, R_0, R_1, D, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows whose observed prefixes are compared.*
2. W *is the common-window row specifying the shared finite inspection bound used by both stream names.*
3. R_0 *and* R_1 *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those same windows.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for every entourage and precision request.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the common windows, readback rows, and dyadic tolerance row have been displayed.*
6. H *records componentwise* hsame *transport for stream windows, common-window bounds, regular readback, dyadic tolerances, Real sealing, replay, provenance, and local naming.*
7. C *records displayed* Cont *replay from a uniformity request through*

$$S_0, S_1, W, D \longmapsto R_0, R_1 \longmapsto E \longmapsto H, P, N.$$

8. P *is the* Pkg *provenance over* $\mathsf{CauchyNameUniformity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyNameUniformity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, W, R_0, R_1, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, a selected completion representative, countable choice, host real equality, or an ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.CauchyNameUniformityUp.CauchyNameUniformityTasteGate single carrier alignment`

Theorem 7022.2 (Cauchy name uniformity NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNameUniformity}^{\uparrow}$ *carrier*

$$U = (S_0, S_1, W, R_0, R_1, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyNameUniformity}^{\uparrow}}$ *surface consists exactly of carrier admission for Definition 7022.1; common-window exposure through S_0, S_1, W; regular rational readback through R_0, R_1; dyadic tolerance exposure through D; Real-seal nonescape through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N. Every uniformity read passes through the common* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, dyadic tolerance rows, the* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local* NameCert *rows before any completion-facing consumer may cite* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyNameUniformityUp.CauchyNameUniformityNameCertObligations`

Proof. Project the accepted finite BHist tuple. Its visible coordinates are $S_0, S_1, W, R_0, R_1, D, E, H, C, P, N$, so carrier admission and local naming are finite row projections.

The uniformity read first exposes the common-window surface. The rows S_0, S_1, W give the two inspected stream prefixes and the shared finite bound, while D fixes the dyadic tolerance used by the comparison.

The readback rows R_0, R_1 consume those same windows as regular rational data. Only after the window, readback, and tolerance rows are displayed may the terminal row E be consumed as the $\mathsf{Real}^{\uparrow}$ seal.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness, every completion-facing use of $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ remains a provenance-bound consumer of the displayed rows. □

Falsifiable prediction: Every accepted $\mathsf{CauchyNameUniformity}^{\uparrow}$ uniformity read exposes two $\mathsf{StreamName}^{\uparrow}$ finite-window rows, one common-window bound, two $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and the terminal $\mathsf{Real}^{\uparrow}$ seal before it may be consumed by a $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ route.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy-completeness-witness: no listed sibling supplies the whole packet $U = (S_0, S_1, W, R_0, R_1, D, E, H, C, P, N)$, because each sibling contributes only finite windows, regular rational readback, dyadic tolerances, a Real seal, or a completion witness while this chapter binds the common-window uniformity route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNameUniformity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyNameUniformity}^{\uparrow}$ packet is generated from two StreamName finite-window rows, a common-window bound, two RegSeqRat readback rows, one DyadicRatCore tolerance row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyNameUniformity}^{\uparrow}}$, seed)

Scope closed: Definition 7022.1 and Definition 7022.2 seed the common-window uniformity surface for Cauchy names over finite streams, regular rational readback, dyadic tolerances, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{CauchyNameUniformity}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, selected completion representatives, countable choice, host real equality, Lean verification, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-window exactness, regular readback, dyadic tolerance replay, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyNameUniformityUp.

Chapter 7023

A Concrete Naming Certificate for $\mathsf{CofiniteFilter}^{\uparrow}$

Following Bourbaki and Kelley on filters, the $\mathsf{CofiniteFilter}^{\uparrow}$ packet records the tail-facing filter on a displayed stream by finite complement ledgers rather than by a host powerset object. It sits after the finite window route of chapter 126, the Cauchy seed carrier of chapter 3413, the regular rational readback of chapter 301, and the Frechet filter-basis neighbour of chapter 6498. The carrier is a traditional tail filter reconstructed as BEDC data: every accepted read displays the finite excluded prefix, the surviving tail window, the Cauchy and readback rows that consume the tail, structural transport, replay, provenance, and local naming.

Definition 7023.1 (Cofinite filter carrier)**.** *A* $\mathsf{CofiniteFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, B, T, C, R, H, Q, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *source whose finite windows are inspected.*
2. B *is the finite complement ledger naming the excluded prefix.*
3. T *is the surviving tail window generated by removing the entries listed in* B*.*
4. C *is the* $\mathsf{Cauchy}^{\uparrow}$ *consumer row that may read only the displayed tail window.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same tail.*
6. H *is componentwise* hsame *transport for* S, B, T, C, R*.*
7. Q *is displayed* Cont *replay for the tail-filter route.*
8. P *is* Pkg *provenance over* $\mathsf{CofiniteFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{FrechetFilterBasis}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CofiniteFilter}^{\uparrow}}$ *row.*

Theorem 7023.2 (Cofinite filter tail stability)**.** *Let* $F = (S, B, T, C, R, H, Q, P, N)$ *be an accepted* $\mathsf{CofiniteFilter}^{\uparrow}$ *carrier. Any downstream read that refines the excluded finite prefix must produce a tail window still routed through the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows. Thus cofinite-tail stability is a finite refinement of* B *and* T*, not a host assertion about arbitrary complements or a quotient filter equality.*

Proof. Project the accepted carrier in Definition 7023.1. The only data that can change under tail refinement are the finite complement ledger B and the displayed survivor window T.

The stream, Cauchy, and regular-readback rows remain fixed as coordinates of the same packet. Componentwise hsame transport keeps the refined prefix and tail inside the original BHist route, while Cont replay and Pkg provenance expose the same local naming row. Since no coordinate carries a host powerset complement, quotient filter, selected cofinal subsequence, countable-choice schedule, or ambient completeness principle, the refinement is exactly the displayed tail-stability witness. □

Theorem 7023.3 (Cofinite filter Cauchy-window handoff)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{CofiniteFilter}^{\uparrow}$ *carrier receives the finite handoff*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{CofiniteFilter}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FrechetFilterBasis}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

The handoff identifies the cofinite tail with the displayed StreamName window consumed by Cauchy and regular-rational rows. It does not export a quotient of filters, a selected eventual index, a completed stream, countable choice, host real equality, or an ambient Real-completeness theorem.

Proof. Read the tail row through Definition 7023.2. The finite complement ledger and surviving tail window are already downstream of the $\mathsf{StreamName}^{\uparrow}$ source and upstream of the Cauchy and regular-readback rows.

The Frechet filter-basis neighbour supplies the traditional filter reading, but the present packet exposes only the finite complement and tail rows. The Cauchy and RegSeqRat consumers therefore receive S, B, T, C, R with structural transport, replay, provenance, and local naming attached. The excluded quotient, selected-index, completed-stream, choice, host-equality, and completeness objects have no carrier coordinate from which to enter the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofiniteFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CofiniteFilter}^{\uparrow}$ packet is generated from a StreamName source, a finite complement ledger, a surviving tail window, Cauchy and RegSeqRat consumer rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CofiniteFilter}^{\uparrow}}$, seed)

Scope closed: Definition 7023.1, Definition 7023.2, and Definition 7023.3 seed the finite cofinite-tail filter packet for L10 Cauchy and StreamName consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CofiniteFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected eventual indices, completed streams, countable choice, host real equality, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite-complement refinement, Cauchy-window handoff, regular-readback routing, transport, replay, provenance, and local naming for BEDC.Derived.CofiniteFilterUp.

Chapter 7024

A Concrete Naming Certificate for $\mathsf{SelfCompilationFeedback}^{\uparrow}$

The $\mathsf{SelfCompilationFeedback}^{\uparrow}$ packet realizes the ledgered-feedback branch of section 9411.4 as finite NameCert data. It packages a compiler-closure source genome, an expressed compiler phenotype, a feedback event flow into a later accepted genome, a refusal boundary for unledgered edits, structural transport, replay, provenance, and local naming. The packet is not a host account of file editing or an unrestricted reflection principle; every accepted feedback read must expose the finite ledger rows before it can be treated as self-compilation.

The packet consumes the compiler-closure self-compilation route of chapter 6317, the theorem-genome evolution route of chapter 6358, and the refusal boundary of chapter 6558 before a feedback event can be public.

Definition 7024.1 (SelfCompilationFeedback carrier)**.** *A* $\mathsf{SelfCompilationFeedback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, M, E, L, A, R, H, C, P, N)$$

with the following rows:

1. *G is the source genome-flow row.*
2. *M is the compiler-phenotype row expressed by the source genome.*
3. *E is the* EventFlow *row carrying the feedback from M into a later genome flow.*
4. *L is the visible feedback ledger required by Definition 9411.13.*
5. *A is the accepted-export row for the later genome flow.*
6. *R is the refusal boundary excluding unledgered feedback, external file edits, and unrestricted reflection.*
7. *H is componentwise* hsame *transport for G, M, E, L, A, R.*
8. *C is displayed* Cont *replay for the feedback route.*
9. *P is* Pkg *provenance over* $\mathsf{SelfCompilationFeedback}^{\uparrow}$*, compiler closure,* EventFlow*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SelfCompilationFeedback}^{\uparrow}}$ *row.*

Theorem 7024.2 (SelfCompilationFeedback ledger nonescape)**.** *Every accepted* SelfCompilationFeedback$^{\uparrow}$ *read that claims compiler-closure feedback must pass through the displayed source genome row, compiler-phenotype row, feedback* EventFlow *row, visible ledger row, accepted-export row, refusal boundary,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. A consumer cannot replace those rows by an unledgered host edit, a detached theorem-generation trace, a hidden classifier change, an unrestricted reflection step, or a feedback object lacking local naming.*

Proof. Project the carrier in Definition 7024.1. The source genome, compiler phenotype, feedback event, visible ledger, accepted export, and refusal boundary are separate rows of the accepted packet.

Use the feedback witness of Definition 9411.13. It requires the feedback ledger to record the source genome carrier, compiler phenotype, behavior relation, target genome carrier, accepted-export route, naming obligations, closure-certificate obligations, and boundary excluding unrestricted reflection. The rows G, M, E, L, A, R are exactly the finite surface on which those requirements are read.

Finally repack through H, C, P, N. Componentwise transport and displayed replay preserve the same ledger route for consumers, provenance records its package boundary, and the local NameCert row names the accepted feedback carrier. Since the refused host edit, detached generation trace, hidden classifier change, unrestricted reflection step, and unnamed feedback object have no coordinate in the packet, they cannot escape the ledger boundary. □

Theorem 7024.3 (SelfCompilationFeedback closed-substitution route)**.** *Every accepted* SelfCompilationFeedback$^{\uparrow}$ *read that later reaches a MetaCIC substitution consumer must first expose the source genome row, compiler-phenotype row, feedback* EventFlow *row, visible ledger row, accepted-export row, refusal boundary,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row of Definition 7024.1. Only after those rows are displayed may the read pass through chapter 538 or chapter 527 and be consumed as closed-substitution feedback.*

Proof. Project the carrier of Definition 7024.1. The feedback EventFlow row and the visible ledger row are separate coordinates, so a substitution-facing consumer cannot read feedback directly from a host compiler trace.

Apply Definition 7024.2. It forces every compiler-closure feedback claim through the source genome, compiler phenotype, feedback event, ledger, accepted export, refusal boundary, transport, replay, provenance, and local naming rows.

The closed-substitution boundary chapters then supply the only listed MetaCIC substitution surfaces. Routing through one of those chapters preserves the same displayed feedback ledger before any closed-substitution read is public, and the packet exports no detached substitution feedback object. □

Falsifiable prediction: Every accepted SelfCompilationFeedback$^{\uparrow}$ self-compilation read exposes source genome, compiler phenotype, feedback EventFlow, visible ledger, accepted export, refusal boundary, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any compiler-closure feedback claim is public.

Independence witness: compiler-closure-self-compilation, theorem-genome-evolution, automated-theory-discovery-pipeline-calculus, refutation-gate, namecert: no listed sibling is bijective with SelfCompilationFeedback$^{\uparrow}$ because this packet jointly carries a compiler-phenotype row, feedback EventFlow row, visible feedback ledger, accepted-export row, refusal boundary, transport, replay, provenance, and local NameCert data.

The Lean TasteGate surface for this packet must provide explicit Nontrivial SelfCompilationFeedback$^{\uparrow}$ and FieldFaithful SelfCompilationFeedback$^{\uparrow}$ instances in `lean4/BEDC/Derived/SelfCompilationFeedbackUp/Tast` Those instances must keep $G, M, E, L, A, R, H, C, P, N$ as distinct fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for NameCert$_{\text{SelfCompilationFeedback}^{\uparrow}}$.

Constructive story: A SelfCompilationFeedback$^{\uparrow}$ packet is generated from source genome-flow, compiler-phenotype, feedback EventFlow, visible ledger, accepted-export, refusal-boundary, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{SelfCompilationFeedback}^{\uparrow}}$, seed)

Scope closed: Definition 7024.1 and Definition 7024.2 seed the finite feedback-ledger carrier for compiler-closure self-compilation reads.

Formal verification: FormalStatus(NameCert$_{\text{SelfCompilationFeedback}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim unrestricted reflection, hidden feedback, external file-edit self-compilation, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, ledger nonescape, accepted-export routing, refusal-boundary preservation, transport, replay, provenance, local naming, and TasteGate instances for BEDC.Derived.SelfCompilationFeedbac

Chapter 7025

A Concrete Naming Certificate for $\mathsf{LittlewoodPaley}^{\uparrow}$

From Stein/Grafakos-style Littlewood–Paley theory, the $\mathsf{LittlewoodPaley}^{\uparrow}$ packet records the finite dyadic-frequency inspection surface by which constructive harmonic-analysis consumers read scale windows, projection packets, and square-function ledgers before any real-valued bound is exported. It sits beside the Haar wavelet packet of chapter 3881, the Besov aggregate of chapter 4204, the Triebel–Lizorkin scale-position packet of chapter 6330, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed dyadic-frequency rows, finite projection data, square-function readback, transport, replay, provenance, and local naming; it does not import Fourier inversion, completed function-space quotients, almost-everywhere representatives, unconditional convergence, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7025.1 (Littlewood–Paley carrier)**.** *A* $\mathsf{LittlewoodPaley}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, P, S, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *D is the dyadic scale-window row, recording the finite family of frequency annuli or low-frequency caps selected by the read.*
2. *P is the projection-packet row, listing the finite projection probes attached to the selected windows.*
3. *S is the square-function ledger, recording the finite quadratic or variation-style aggregation performed on the displayed projection packets.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational magnitudes attached to the displayed projection and square-function data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, P, S, R are visible.*
6. *H records componentwise* hsame *transport for the scale-window, projection, square-function, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Littlewood–Paley read through*

$$D, P, S, R, E, H \longmapsto Q, N.$$

8. *Q is the* Pkg *provenance over* $\mathsf{LittlewoodPaley}^{\uparrow}$, $\mathsf{HaarWavelet}^{\uparrow}$, $\mathsf{BesovSpace}^{\uparrow}$, $\mathsf{TriebelLizorkinSpace}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LittlewoodPaley}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, P, S, R, E, H, C, Q, N$. It has no coordinate for a completed Fourier multiplier theorem, quotient function identity, selected distribution representative, almost-everywhere equality, unconditional infinite series, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 7025.2 (Littlewood–Paley NameCert obligations)**.** *For every accepted* $\mathsf{LittlewoodPaley}^{\uparrow}$ *carrier $L = (D, P, S, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{LittlewoodPaley}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed dyadic scale windows, projection packets, square-function ledger, regular rational readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every harmonic-analysis, Besov, Triebel–Lizorkin, Haar-wavelet, or real-bound consumer of the packet must read through those rows before it cites a Littlewood–Paley square-function boundary.*

Proof. Carrier admission is projection from Definition 7025.1. The rows D, P, S display the finite scale-window, projection-packet, and square-function data before any consumer can read a harmonic-analysis bound.

The numerical route is finite. The row R supplies regular rational readback for the displayed projection and square-function magnitudes, and E seals the same data as a terminal $\mathsf{Real}^{\uparrow}$ read.

The structural rows preserve the displayed route. Since H, C, Q, N provide only componentwise transport, continuation replay, provenance, and local naming, and since the carrier has no coordinate for Fourier inversion, quotient function equality, selected representatives, almost-everywhere equality, unconditional infinite series, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7025.3 (Littlewood–Paley dyadic frequency handoff)**.** *Every accepted* $\mathsf{LittlewoodPaley}^{\uparrow}$ *read factors through the finite handoff*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the displayed dyadic scale-window, projection-packet, square-function, componentwise transport, replay, provenance, and local naming rows. HaarWavelet, BesovSpace, and TriebelLizorkinSpace consumers may inspect this handoff only as finite dyadic-frequency data; the route exports no host Fourier transform, no completed harmonic-analysis quotient, no selected representative of a distribution or function, no unconditional square-function identity, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the scale-window row D. It records only finitely many dyadic frequency windows, so every downstream read begins from displayed $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data rather than from an ambient frequency space.

Next read the projection and square-function rows. The projection packet P lists the inspected probes, and the square-function ledger S records the finite aggregation visible to HaarWavelet, BesovSpace, and TriebelLizorkinSpace consumers.

Finally use the readback and seal rows. The regular rational row R and terminal Real row E attach numerical output to the same finite projection data, while H, C, Q, N transport, replay, source, and name the route. Since none of these rows carries a Fourier inversion theorem, quotient identity, selected representative, unconditional infinite series, or ambient completeness principle, the handoff exports only the displayed finite dyadic-frequency boundary. □

Falsifiable prediction: Every accepted $\mathsf{LittlewoodPaley}^{\uparrow}$ square-function read exposes dyadic scale windows, projection packets, square-function aggregation, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any harmonic-analysis consumer cites the Littlewood–Paley boundary.

Independence witness: haar-wavelet, besov-space, triebel-lizorkin-space, dyadicratcore, regseqrat, real: $\mathsf{LittlewoodPaley}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic-frequency windows, projection packets, square-function aggregation, regular rational readback, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LittlewoodPaley}^{\uparrow}}$.

Constructive story: A $\mathsf{LittlewoodPaley}^{\uparrow}$ packet is generated from dyadic scale windows, projection packets, square-function ledgers, RegSeqRat readback, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LittlewoodPaley}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7025.1, Definition 7025.2, and Definition 7025.3 seed the finite constructive Littlewood–Paley route over DyadicRatCore, RegSeqRat, Real, HaarWavelet, BesovSpace, TriebelLizorkinSpace, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LittlewoodPaley}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, Fourier inversion, completed harmonic-analysis function spaces, quotient function equality, almost-everywhere representatives, unconditional infinite series, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale-window exactness, projection-packet exposure, square-function ledger stability, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LittlewoodPaleyUp.

Chapter 7026

A Concrete Naming Certificate for $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$ packet records the finite evidence by which located-real data are read as a regular Cauchy convergence criterion without turning that read into an ambient completeness theorem. It sits beside the located cut refinement of chapter 7018, the Dedekind real surface of chapter 3629, the located-real packet of chapter 1933, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The certificate names a local convergence criterion from displayed located evidence to regular Cauchy readback; it does not assert quotient real equality, select a limit, or import completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7026.1 (Located real convergence criterion carrier)**.** *A* $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{LocatedReal}^{\uparrow}$ *source-evidence row, exposing lower and upper located witnesses only through the accepted located-real packet.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, naming the inspected precision requests, comparison cells, and tail observations used by the criterion.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from the same window schedule and carrying the rational Cauchy estimates exported to consumers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing positive dyadic margins, slack conversions, and comparison budgets used by W and R.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located source, stream windows, regular rational readback, and dyadic tolerance ledger have been displayed.*
6. *H records componentwise* hsame *transport for located source evidence, windows, readbacks, tolerances, seal rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a located-real request through A, W, R, D, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$, $\mathsf{DedekindReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host convergence, quotient real equality, selected Cauchy limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7026.2 (Located real convergence criterion NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$ *carrier* $L = (A, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealConvergenceCrite}}$ *surface consists exactly of carrier admission for the displayed packet,* $\mathsf{LocatedReal}^{\uparrow}$ *source exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier of Definition 7026.1. The rows visible to the local name are precisely $A, W, R, D, E, H, C, P, N$.

The source obligation is the located-real row A. It exposes only displayed located evidence and therefore cannot by itself export a quotient real, a chosen limit, or a host convergence theorem.

The finite convergence-readback obligation is forced by W, R, D. The stream windows in W name the inspected requests, D supplies the dyadic tolerance budget for those requests, and R records the regular rational estimates obtained from that same schedule.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since no omitted coordinate exists for host convergence, quotient equality, selected limits, countable choice, trichotomy, or ambient completeness, these rows exhaust the local NameCert obligations. □

Theorem 7026.3 (Located real convergence criterion regular readback)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$ *packet reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and then a* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may be compared with the regular located-cut and Dedekind-real siblings, but it exports only the displayed local convergence criterion and not ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality, a selected limit, or a detached real seal.*

Proof. Start with the located source row A. A consumer can inspect it only as displayed located-real evidence, so no endpoint seal or regular readback is available at this stage.

Read the finite windows and dyadic tolerance ledger next. The rows W and D bind each requested comparison to a displayed StreamName window and a positive dyadic budget.

The regular rational row R is downstream of the same windows and tolerances. It is therefore the first row from which the consumer can read regular Cauchy estimates.

The terminal seal E is reached only after R. Componentwise transport, continuation replay, provenance, and local naming preserve this order, so the packet cannot export completeness of $\mathsf{Real}^{\uparrow}$, quotient equality, a selected limit, or a detached seal. □

Falsifiable prediction: Every accepted $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$ endpoint read factors through located-real source evidence, finite StreamName windows, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, transport, replay, provenance, and a local NameCert row.

Independence witness: regular-cauchy-located-cut, dedekind-real, located-real, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the whole nine-row packet $L = (A, W, R, D, E, H, C, P, N)$, because each sibling contributes only located evidence, cut comparison discipline, stream windows, regular readback, tolerance arithmetic, or endpoint sealing while this packet binds them into one local convergence-criterion route.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}$ packet is generated from located-real source evidence, finite StreamName windows, a RegSeqRat regular readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7026.1, Definition 7026.2, and Definition 7026.3 seed the finite located-real convergence-criterion route from displayed located evidence to regular rational readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealConvergenceCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, quotient real equality, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located source exposure, finite window coverage, dyadic tolerance exactness, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealConvergenceCriterionUp.

Chapter 7027

A Concrete Naming Certificate for $\mathsf{ArchimedeanFloor}^{\uparrow}$

Following Bishop and Bridges on constructive analysis and integer-part extraction, the $\mathsf{ArchimedeanFloor}^{\uparrow}$ packet records the finite floor-window route used by real-number consumers when an explicit integer bracket has already been displayed. It sits over the integer source of chapter 31, the rational comparison surface of chapter 37, the dyadic arithmetic route of chapter 291, the stream-name and regular-sequence readback of chapter 301, and the terminal real seal of chapter 38. The packet names integer-part extraction only as a bounded finite NameCert window; it does not assert total real trichotomy, quotient real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a host floor function.

Definition 7027.1 (Archimedean floor carrier)**.** *An* $\mathsf{ArchimedeanFloor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, J, Q, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Int}^{\uparrow}$ *source row, displaying the lower integer candidate and its successor relation.*
2. *J is the successor-bound row, displaying the upper integer candidate as the successor of the lower row and refusing any detached integer choice.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *comparison row, where integer entries are read as rationals before any real-facing comparison is formed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row, carrying the finite dyadic budget used to inspect the two rational inequalities.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational name whose finite window is being compared.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, certifying that the compared regular sequence is the displayed real-name endpoint seen by downstream consumers.*
7. *H records componentwise* hsame *transport for the integer, rational, dyadic, stream-name, regular-sequence, real-seal, and local naming rows.*
8. *C records displayed* Cont *replay through the integer bracket, rational comparison, dyadic comparison, regular-sequence readback, real seal, transport, provenance, and local naming rows.*

9. *P is the* Pkg *provenance row binding the integer bracket to the L10 Real and Completion route.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanFloor}^\uparrow}$ *row over* $\mathsf{ArchimedeanFloor}^\uparrow$, $\mathsf{Int}^\uparrow$, $\mathsf{Rat}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert.

The classifier compares accepted packets only through $I, J, Q, D, S, R, H, C, P, N$. It has no coordinate for total trichotomy of real names, quotient real equality, selected limits, ambient real completeness, a global floor operator, or an integer-part handoff that skips the displayed window.

Theorem 7027.2 (Archimedean floor NameCert obligations)**.** *For every accepted* $\mathsf{ArchimedeanFloor}^\uparrow$ *carrier*

$$F = (I, J, Q, D, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ArchimedeanFloor}^\uparrow}$ *surface consists exactly of lower-integer source exposure, successor upper-row exposure, rational comparison exposure, dyadic comparison replay, stream-name and regular-sequence readback, real-seal exposure, componentwise transport, displayed continuation replay, provenance, local naming, and non-escape from total real trichotomy, quotient real equality, selected limits, ambient* $\mathsf{Real}^\uparrow$ *completeness, host floor functions, and any integer-part route outside the displayed bracket.*

Proof. Project the carrier of Definition 7027.1. The rows I and J are the only integer rows, so the candidate floor and its successor are displayed before any comparison is read.

The comparison rows are Q and D. They convert the integer bracket into rational and dyadic inspection data, giving finite evidence for the lower and successor bounds without invoking trichotomy of arbitrary real names.

The readback rows S and R then identify the compared object with the displayed regular sequence and its real seal. The structural rows H, C, P, N transport, replay, source, and name that same window, so no host floor operator, selected limit, quotient real equality, or ambient real-completeness claim is exported. □

Theorem 7027.3 (Archimedean floor window extraction)**.** *Every integer-part handoff from an accepted* $\mathsf{ArchimedeanFloor}^\uparrow$ *carrier exposes the lower integer row, the successor upper row, rational comparison, dyadic comparison, regular-sequence readback, and the* $\mathsf{Real}^\uparrow$ *seal in the order*

$$\mathsf{Int}^\uparrow \longmapsto \mathsf{Rat}^\uparrow \longmapsto \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

A downstream L10 Real and Completion consumer may receive the bracket only after the rows $I, J, Q, D, S, R, H, C, P, N$ have been displayed, and it receives no total trichotomy principle, quotient-real equality, selected limit, ambient completeness theorem, or hidden host integer-part operation.

Proof. Start with a requested integer-part handoff. The carrier first exposes I and J, so the lower integer and its successor are visible as finite integer rows rather than selected from an ambient ordered field.

The rational and dyadic comparison rows Q and D are then read before the real endpoint is sealed. These rows provide the finite lower-bound and successor-upper-bound checks consumed by the window.

Finally S reads back the stream-name and regular rational sequence, while R supplies the real seal. Transport, replay, provenance, and local naming preserve exactly this route through H, C, P, N, so the handoff is a bounded displayed window and not a global integer-part theorem for all real names. □

Falsifiable prediction: Any accepted $\mathsf{ArchimedeanFloor}^{\uparrow}$ consumer that performs an integer-part handoff without first exposing $I, J, Q, D, S, R, H, C, P, N$ refutes the carrier surface of Definition 7027.1.

Independence witness: int, rat, dyadicratcore, regseqrat, real: no listed sibling is bijective with $\mathsf{ArchimedeanFloor}^{\uparrow}$, because this packet alone binds a displayed integer successor window, rational comparison, dyadic comparison, regular-sequence readback, real seal, transport, replay, provenance, and local NameCert rows into one finite floor-window carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanFloor}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanFloor}^{\uparrow}$ packet is generated from an IntUp lower row, a successor upper row, RatUp comparison data, DyadicRatCoreUp finite comparison data, StreamNameUp and RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanFloor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7027.1, Definition 7027.2, and Definition 7027.3 seed the finite Archimedean floor-window packet over $\mathsf{Int}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and BHist.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanFloor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total real trichotomy, quotient real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, a host floor function, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-integer exposure, successor upper-row exposure, rational comparison, dyadic comparison, stream-name and regular-sequence readback, RealUp sealing, transport, non-escape, and field faithfulness for BEDC.Derived.ArchimedeanFloorUp.

Chapter 7028

A Concrete Naming Certificate for $\mathsf{DiniUniformCauchy}^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the $\mathsf{DiniUniformCauchy}^{\uparrow}$ packet records the finite route by which a monotone family of regular real names yields a uniform Cauchy tail through displayed rational windows. It sits beside the finite observation interface of chapter 126, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, the dyadic tolerance core of chapter 291, the extracted modulus surface of chapter 369, and the lower-epigraph visibility of chapter 1536. The packet names only the finite monotone tail, dyadic tolerance, uniform modulus, regular readback, and real seal rows; it does not claim classical compactness, countable choice, quotient equality of real names, selected limiting values, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7028.1 (Dini uniform Cauchy carrier)**.** *A* $\mathsf{DiniUniformCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, M, L, T, Q, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, listing the finite observation schedule for the regular real-name family.*
2. *M is the monotone comparison row, recording that later sampled names lie below earlier sampled names on the inspected dyadic windows.*
3. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *visibility row, keeping the lower epigraph reads displayed before any tail budget is extracted.*
4. *T is the finite tail row, naming the inspected index threshold and the two tail positions compared against it.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, storing the rational error bound used by the tail comparison and the later readback.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row extracted from S, M, L, T, Q, exposing the same tail budget uniformly over the scheduled windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed uniform tail and dyadic tolerance.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after the regular-rational readback is visible.*

9. *H records componentwise* hsame *transport for the source, monotone comparison, lower-epigraph visibility, tail budget, dyadic tolerance, uniform modulus, regular readback, real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same monotone uniform Cauchy extraction route.*
11. *P is the* Pkg *provenance over* $\mathsf{DiniUniformCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, L, T, Q, U, R, E, H, C, P, N$. It has no coordinate for classical compactness, countable choice, quotient equality of real names, selected limiting values, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7028.2 (Dini uniform Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{DiniUniformCauchy}^{\uparrow}$ *carrier*

$$D = (S, M, L, T, Q, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformCauchy}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed stream source, monotone comparison, lower-epigraph visibility, finite tail row, dyadic tolerance, extracted uniform modulus,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming rows.*

Proof. Project the accepted carrier. The stream source S, monotone comparison M, lower-epigraph row L, tail row T, dyadic tolerance Q, extracted modulus U, regular readback R, and real seal E are the only analytic coordinates available to a consumer.

The order of use is forced by the tuple. The tail row T is read only after the observed stream and monotone comparisons are visible, while Q supplies the dyadic tolerance against which that tail is judged.

The uniform Cauchy data enter through U. Since U is extracted from S, M, L, T, Q, the readback row R and the terminal seal E cannot bypass the displayed monotone tail and tolerance budget.

Finally, H, C, P, N transport, replay, source, and name the same finite route. The excluded objects have no carrier coordinate, so the local NameCert surface cannot read compactness, choice, quotient equality, selected limits, or ambient real completeness from this packet. □

Theorem 7028.3 (Dini monotone tail extraction)**.** *Every* $\mathsf{DiniUniformCauchy}^{\uparrow}$ *read that exposes a uniform Cauchy tail factors through the finite route*

$$S, M, L, T, Q, U.$$

In particular, the monotone comparison row and lower-epigraph visibility row are displayed before the tail threshold is used, and the dyadic tolerance row is displayed before the extracted $\mathsf{UniformModulus}^{\uparrow}$ *row is consumed.*

Proof. Use Definition 7028.2. It places the stream source, monotone comparison, lower-epigraph visibility, tail threshold, dyadic tolerance, and uniform modulus inside one accepted packet.

The monotone tail is not an external limit object. It is the row T read against the order comparisons in M and the lower-epigraph visibility in L.

The uniformity is also finite. The row U is downstream of the same S, M, L, T, Q data, so the consumer obtains a uniform Cauchy tail only by displaying those rows first. □

Theorem 7028.4 (Dini uniform Cauchy regular-real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{DiniUniformCauchy}^{\uparrow}$ *packet reaches the terminal seal only through*

$$S, M, L, T, Q, U, R, E, H, C, P, N.$$

Thus the handoff exports a regular real-name Cauchy route controlled by displayed dyadic tolerance and uniform-modulus rows, not a quotient equality of real names, a selected limiting value, a compactness principle, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with the finite route of Definition 7028.3. It supplies S, M, L, T, Q, U before any regular-rational readback is available.

Next consume the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R. This row is attached to the same tail threshold, dyadic tolerance, and uniform modulus, so it cannot be detached from the displayed Dini extraction route.

Finally read the terminal real-name seal E and the structural rows H, C, P, N. They transport, replay, source, and name the same finite packet. Since the forbidden host objects are absent from the carrier, the $\mathsf{Real}^{\uparrow}$ consumer receives only the regular real-name Cauchy handoff. □

Falsifiable prediction: A purported $\mathsf{DiniUniformCauchy}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying S, M, L, T, Q, U, R is not reading the carrier of Definition 7028.1.

Independence witness: streamname, regseqrat, real, dyadicratcore, uniformmodulus, lowersemicontinuous: $\mathsf{DiniUniformCauchy}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries monotone comparison, lower-epigraph visibility, a finite tail threshold, dyadic tolerance, extracted uniform modulus, regular-rational readback, terminal real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformCauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiniUniformCauchy}^{\uparrow}$ packet is generated from StreamName observations, monotone comparison rows, LowerSemicontinuous epigraph visibility, finite tail thresholds, DyadicRatCore tolerance rows, UniformModulus extraction, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiniUniformCauchy}^{\uparrow}}$, seed)

Scope closed: Definition 7028.1, Definition 7028.2, Definition 7028.3, and Definition 7028.4 seed the monotone uniform Cauchy extraction route over regular real names.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiniUniformCauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim classical compactness, countable choice, quotient equality of real names, selected limiting values, Lean verification, bridge checking, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, monotone tail extraction, dyadic tolerance ordering, uniform-modulus extraction, regular-rational readback, real-seal nonescape, transport preservation, replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformCauchyUp.

Chapter 7029

A Concrete Naming Certificate for $\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}$ packet records the finite modulus data needed to move from dyadic tolerances to regular rational names and then to a real-name seal. It sits after the dyadic tolerance rows of chapter 291, the stream schedule rows of chapter 126, the regular-sequence carrier of chapter 301, and the terminal real-name seal of chapter 38. The packet names a located modulus spectrum for Cauchy data; it does not select limits, quotient regular sequences by ambient equality, or claim completeness of a host real line.

Definition 7029.1 (Cauchy located modulus spectrum carrier)**.** *A* $\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, L, E, H, C, P, N)$$

with the following displayed rows.

1. *D is a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic rational scales used for the Cauchy comparison.*
2. *S is a* $\mathsf{StreamName}^{\uparrow}$ *schedule row, recording the finite observation windows at which those tolerances are read.*
3. *R is a* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, recording the rational sequence data and the finite regularity obligations visible through the schedule.*
4. *L is the located modulus row: for every displayed tolerance window in D and S, it records a finite cofinal tail witness at which the regularity row R is stable inside the named tolerance.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording that the visible regular sequence may be handed to the real-name interface without selecting a limit point.*
6. *H is componentwise* hsame *transport for D, S, R, L, E.*
7. *C is the displayed* Cont *replay row, preserving the same finite windows under continuation.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}}$ *row.*

Theorem 7029.2 (Cauchy located modulus spectrum NameCert obligations)**.** *For every accepted* $\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}$ *carrier* $M = (D, S, R, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyLocatedModulusSpect}}$ *surface is exhausted by carrier admission, classifier stability, cofinal modulus refinement, Real-seal handoff, and refusal of selected limits, quotient equality of regular names, and ambient completeness.*

Proof. Project the carrier onto its dyadic tolerance, stream schedule, regular rational, located modulus, and real-seal rows. Carrier admission is exactly the assertion that these rows occur together in one finite BHist packet with the local name row N.

Classifier stability is componentwise. The transport row H compares D, S, R, L, E by hsame, and the replay row C preserves the same finite schedule under Cont. Thus a consumer cannot alter the tolerance scale, schedule, regularity row, or real seal while keeping the local certificate name fixed.

Cofinal modulus refinement is finite-tail refinement inside the displayed schedule. Given a later dyadic tolerance window, use the located row L to move to a cofinal tail of S where the regularity row R is stable inside that tolerance; no countable choice or selected limit is invoked.

The Real-seal handoff reads only E. It certifies that the regular rational data can be presented to the $\mathsf{Real}^{\uparrow}$ name surface, while the packet still refuses quotient equality of names, a chosen limit object, and ambient completeness beyond the displayed finite rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName schedule rows, RegSeqRat regularity rows, a located cofinal-tail modulus row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}}$, seed)

Scope closed: Definition 7029.1 and Definition 7029.2 seed the finite located-modulus spectrum from dyadic tolerances through stream schedules, regular rational rows, cofinal-tail witnesses, and a RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyLocatedModulusSpectrum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected real limits, quotient equality of regular names, ambient real completeness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, cofinal modulus refinement, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyLocatedModulusSpectrumUp.

Chapter 7030

A Concrete Naming Certificate for $\mathsf{NagataDimension}^{\uparrow}$

Following Nagata's covering dimension for metric spaces and Assouad's metric dimension tradition, the $\mathsf{NagataDimension}^{\uparrow}$ packet records a finite scale-cover certificate rather than a host theorem about arbitrary covers. It sits after the metric carrier of chapter 57, the cover-order surface of chapter 1853, the Lebesgue covering route of chapter 4205, the terminal real-name seal of chapter 38, and the Assouad scale-control neighbour of chapter 6325. The chapter names the standard Nagata-dimensional cover interface as BEDC rows; it does not assert a host dimension theorem, selected cover basis, quotient metric equality, countable choice, or ambient compactness.

Definition 7030.1 (Nagata dimension carrier)**.** *A* $\mathsf{NagataDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, S, C, L, A, R, H, T, P, N)$$

with the following visible rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the displayed distance observations used by every scale-cover request.*
2. *S is the scale ledger, listing the inspected radii and the finite multiplicity budgets attached to those radii.*
3. *C is the cover-family row, consisting of finite bounded-diameter families for the displayed scales.*
4. *L is the* $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ *comparison row used when the same finite cover is read as a Lebesgue-style refinement certificate.*
5. *A is the* $\mathsf{AssouadDimension}^{\uparrow}$ *scale-control row recording the neighbouring doubling and bounded-overlap discipline.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for numeric radius and diameter readback.*
7. *H records componentwise* hsame *transport for metric, scale, cover, comparison, Real-seal, provenance, and local naming rows.*
8. *T records displayed* Cont *replay through the same cover route.*
9. *P is the* Pkg *provenance over* $\mathsf{NagataDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{LebesgueCoveringDimension}^{\uparrow}$, $\mathsf{AssouadDimension}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NagataDimension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed metric source, scale ledger, cover families, comparison rows, Real readback, transport, replay, provenance, and local naming rows. It has no coordinate for a selected infinite cover basis, quotient metric equality, countable choice, open-cover compactness, or a host dimension theorem.

Theorem 7030.2 (Nagata dimension NameCert obligations)**.** *For an accepted* $\mathsf{NagataDimension}^{\uparrow}$ *carrier* $G = (M, S, C, L, A, R, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NagataDimension}^{\uparrow}}$ *surface consists exactly of metric-source admission, scale-ledger admission, bounded-diameter cover-family exposure, finite multiplicity accounting, Lebesgue-covering comparison, Assouad scale-control comparison, Real readback for radii and diameters, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. These obligations bind the finite Nagata cover certificate without adding a host cover basis, quotient metric equality, countable choice, open-cover compactness, or ambient dimension theorem.*

Proof. Project the carrier of Definition 7030.1. Its analytic rows are exactly the metric source M, scale ledger S, cover family C, Lebesgue-covering comparison L, Assouad scale-control row A, and Real readback row R.

The NameCert obligations are the rows needed to expose those data to a consumer. Transport through H and replay through T preserve the same finite route, while P and N source and name the packet. Since the carrier has no coordinate for the refused host principles, the listed rows exhaust the obligation surface. □

Theorem 7030.3 (Nagata dimension metric-cover route)**.** *Every metric-cover consumer of an accepted* $\mathsf{NagataDimension}^{\uparrow}$ *packet must read the route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{CoveringDimension}^{\uparrow} \longmapsto \mathsf{LebesgueCoveringDimension}^{\uparrow} \longmapsto \mathsf{NagataDimension}^{\uparrow} \longmapsto \mathsf{AssouadDimension}^{\uparrow} \longmapsto$$

through the displayed rows $M, S, C, L, A, R, H, T, P, N$*. The route exposes scale-indexed bounded-diameter cover families and finite multiplicity budgets before any Real-facing radius or diameter seal is consumed, and it exports no selected cover basis, quotient metric equality, countable-choice schedule, open-cover compactness theorem, or ambient completion principle.*

Proof. Begin with the metric source M and scale ledger S. A cover request can inspect only the distances and radii already recorded in those finite rows.

Next read the cover-family row C together with the Lebesgue-covering and Assouad comparison rows L, A. These rows place the Nagata packet between the cover-order discipline of $\mathsf{CoveringDimension}^{\uparrow}$, the Lebesgue refinement surface, and the scale-control neighbour of $\mathsf{AssouadDimension}^{\uparrow}$.

Finally use the Real readback and structural rows. The row R supplies only displayed radius and diameter seals, while H, T, P, N preserve, replay, source, and name the same finite route. No omitted host principle can be recovered from those rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{NagataDimension}^{\uparrow}}$.

Constructive story: A $\mathsf{NagataDimension}^{\uparrow}$ packet is generated from a displayed metric source, finite scale ledger, bounded-diameter cover families, multiplicity rows, Lebesgue-covering comparison, Assouad scale-control comparison, Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NagataDimension}^{\uparrow}}$, seed)

Scope closed: Definition 7030.1, Definition 7030.2, and Definition 7030.3 seed the finite Nagata dimension certificate over metric cover rows, Lebesgue-covering comparison, Assouad scale control, and Real readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NagataDimension}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host dimension theorem, selected cover basis, quotient metric equality, countable choice, open-cover compactness, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scale-ledger exactness, cover-family boundedness, multiplicity accounting, Lebesgue comparison, Assouad comparison, Real readback nonescape, transport, replay, provenance, and local naming.

Chapter 7031

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseLedger}^{\uparrow}$

The $\mathsf{HyperbolicPhaseLedger}^{\uparrow}$ packet realizes the phase-ledger branch of chapter 9463 as finite observer-facing geometry data. It sits after the boundary-shadow route of chapter 3813, the observer-expansion packet of chapter 4167, the phase-shell packet of chapter 6319, and the finite phase-transport row of chapter 3455. The packet names a finite ledger for hyperbolic phase readout; it is not a completed hyperbolic space, a physical observer, a quotient ideal boundary, or an ambient dynamical theorem.

Definition 7031.1 (Hyperbolic phase ledger carrier)**.** *A* $\mathsf{HyperbolicPhaseLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, O, S, T, R, H, C, P, N)$$

with B *the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *boundary-shadow row,* O *the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *observer-expansion row,* S *the* $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ *shell row,* T *the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *transport row,* R *the refusal row excluding completed boundary and physical-observer readings,* H *componentwise* hsame *transport,* C *displayed* Cont *replay,* P *the* Pkg *provenance, and* N *the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLedger}^{\uparrow}}$ *row.*

Theorem 7031.2 (Hyperbolic phase ledger NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseLedger}^{\uparrow}$ *carrier* $Q = (B, O, S, T, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLedger}^{\uparrow}}$ *surface is exhausted by boundary-shadow admission, observer-expansion admission, phase-shell admission, disk phase-transport replay, refusal exactness, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier onto B, O, S, T. These four rows are the only geometric and observer-facing data available to the packet, and each is already a finite NameCert surface rather than a host geometry.

The refusal row R is checked against those same displayed rows. It prevents a consumer from replacing boundary-shadow, observer-expansion, shell, or phase-transport data by a completed hyperbolic space, quotient ideal-boundary equality, physical observer trajectory, or global dynamical theorem.

Transport and replay are componentwise. The row H preserves the displayed packet under hsame, while C replays the same finite route under Cont. The provenance and local naming rows P, N then package exactly the exposed ledger and no additional analytic object. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicPhaseLedger}^{\uparrow}$ read is refuted if a consumer obtains a completed hyperbolic space, quotient ideal-boundary equality, physical observer trajectory, or global dynamical theorem without displaying HyperbolicBoundaryShadow, HyperbolicObserver-Expansion, HyperbolicObserverPhaseShell, PoincareDiskPhaseTransport, refusal, transport, replay, provenance, and local naming rows.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-observer-expansion, hyperbolic-observer-phase-shell, poincare-disk-phase-transport: none is bijective to $\mathsf{HyperbolicPhaseLedger}^{\uparrow}$ because the packet jointly carries boundary shadow, observer expansion, phase shell, disk phase transport, refusal exactness, transport, replay, provenance, and local NameCert rows.

The Lean TasteGate route must provide explicit $\mathsf{Nontrivial\ HyperbolicPhaseLedger}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicP}$ instances before the packet can serve as a checked carrier-alignment witness. Those instances must preserve $B, O, S, T, R, H, C, P, N$ as separate rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseLedger}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverExpansion rows, HyperbolicObserverPhaseShell rows, PoincareDiskPhaseTransport rows, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7031.1, Definition 7031.2, the falsifiable prediction, and the independence witness seed the finite hyperbolic phase ledger over boundary-shadow, observer-expansion, phase-shell, disk-transport, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic spaces, quotient ideal-boundary equality, physical observer trajectories, global dynamical theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exposure, observer-expansion exposure, phase-shell exposure, disk phase-transport replay, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseLedgerUp.

Chapter 7032

A Concrete Naming Certificate for $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$

Following Bishop and Bridges, uniform limits on closed intervals are read constructively through displayed interval bounds, explicit uniform tail control, named stream windows, regular rational readbacks, and a terminal real-name seal. The $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$ packet records that finite handoff surface between the closed-bounded-interval route of chapter 1591, the uniform-limit route of chapter 463, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. It names the closed-interval uniform-limit packet as BEDC data only; it does not claim Real completeness, Heine–Borel compactness, selected limits, quotient functions, countable choice, or host function equality.

Definition 7032.1 (Closed-interval uniform-limit carrier)**.** *A* $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, U, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, carrying the closed interval endpoints and boundedness ledger used by the read.*
2. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *tail-control row, carrying the displayed uniform tolerance budget over the interval.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, recording the finite windows opened on the approximating function names before any limit-facing read is consumed.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational values inspected inside the interval windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row attached to the finite readback route.*
6. *H records componentwise* hsame *transport for I, U, S, Q, E and the structural rows.*
7. *C records displayed* Cont *replay from closed-interval and uniform-tail requests through the same stream, regular-rational, and real-seal rows.*
8. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalUniformLimit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, U, S, Q, E, H, C, P, N$. It has no coordinate for interval compactness by Heine–Borel, selected limit functions, quotient function equality, countable choice, host extensional equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7032.2 (Closed-interval uniform-limit NameCert obligations)**.** *For every accepted* ClosedIntervalUniformL *carrier*

$$L = (I, U, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedIntervalUniformLimit}^{\uparrow}}$ *surface consists exactly of closed-bounded-interval admission, uniform-tail budget exposure, stream-window accounting, regular rational readback, terminal real-name sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any closed-interval uniform-limit consumer must read the sibling routes of chapter 1591, chapter 463, chapter 126, chapter 301, and chapter 38 through these rows before it can consume the packet.*

Proof. Project the carrier of Definition 7032.1. The closed interval source, uniform tail budget, stream windows, regular rational readback, and real seal are separate displayed rows, and the structural rows H, C, P, N preserve the same packet.

The analytic obligations are exhausted by I, U, S, Q, E. The interval row supplies the closed-bounded source, the uniform-limit row supplies the tolerance budget, the stream row opens the finite observation windows, the regular rational row gives the readback, and the real row seals the terminal observation.

The certificate obligations are exhausted by H, C, P, N. These rows transport, replay, source, and name the same finite route. Since the carrier contains no row for Heine–Borel compactness, selected limits, quotient functions, countable choice, host equality, or ambient completeness, the listed rows are exactly the local NameCert obligations. □

Theorem 7032.3 (Closed-interval uniform-limit L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{UniformLimit}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The handoff exports closed-interval source data, displayed uniform tail control, finite stream windows, regular rational readback, a terminal real-name seal, transport, replay, provenance, and local naming only. It does not export Real completeness, Heine–Borel compactness, selected limit functions, quotient function equality, countable choice, or host equality of functions.

Proof. Use Definition 7032.2. A consumer first reads the closed-bounded-interval row I, the uniform-limit row U, the stream row S, the regular rational readback row Q, and the real seal row E.

The rows H, C, P, N then carry the handoff as componentwise transport, displayed replay, provenance, and local naming. They do not add analytic content beyond the already displayed finite route.

Field exclusion completes the boundary. The carrier has no Heine–Borel row, no completed-real compactness row, no selected limit row, no quotient-function row, no countable-choice row, and no host function-equality row, so the L10 handoff is exactly the finite packet stated above. □

Falsifiable prediction: Every accepted $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$ consumer displays a $\mathsf{ClosedBoundedInterval}^{\uparrow}$ source row, a $\mathsf{UniformLimit}^{\uparrow}$ tail-budget row, a $\mathsf{StreamName}^{\uparrow}$ window row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before any closed-interval uniform-limit claim is public.

Independence witness: closed-bounded-interval, uniformlimit, streamname, regseqrat, real: $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$ is not bijective to any listed sibling because it binds the interval source, uniform tail budget, finite stream windows, regular rational readback, terminal real seal, transport, replay, provenance, and local naming into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalUniformLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalUniformLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7032.1, Definition 7032.2, and Definition 7032.3 seed the finite closed-interval uniform-limit route through interval, uniform-tail, stream, regular-rational, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalUniformLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, Real completeness, Heine–Borel compactness, selected limits, quotient functions, countable choice, host function equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-interval exposure, uniform-tail budget exposure, stream-window accounting, regular rational readback, real-seal boundary, transport, replay, provenance, local naming, and non-escape over the same displayed packet.

Constructive story: A $\mathsf{ClosedIntervalUniformLimit}^{\uparrow}$ packet is generated from closed-bounded-interval source data, displayed uniform-tail control, finite stream windows, regular rational readback, a real-name seal, componentwise transport, displayed continuation replay, package provenance, and local naming evidence.

Chapter 7033

A Concrete Naming Certificate for $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$

Following Lusternik and Schnirelmann, the $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ packet records finite categorical-cover data as a BEDC NameCert surface. It sits beside the finite antipodal obstruction route of chapter 5828, the combinatorial certificates of chapter 2003 and chapter 6975, the compact metric source of chapter 129, the finite face inventory of chapter 238, and the compact finite-cover route of chapter 6997. The packet names a finite cover by null-homotopy rows and categorical budget ledgers; it does not import a host homotopy category, selected global contractions, quotient sphere equality, arbitrary open-cover compactness, or a classical critical-point theorem.

Definition 7033.1 (Lusternik–Schnirelmann category carrier)**.** *A* $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, K, U, A, M, S, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact source row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover data and the finite source model used by the downstream consumer.*
2. *K is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *support row when the source is presented by a finite complex, including the face inventory and incidence rows used to form nerves of covers.*
3. *U is the finite categorical cover row, listing the displayed cover members and the membership evidence inspected by the packet.*
4. *A is the null-homotopy admission row for each displayed cover member, recording the finite contraction certificate visible to the same source.*
5. *M is the multiplicity and budget row, recording the displayed upper bound for the number of categorical pieces used by U.*
6. *S is the sphere or antipodal-obstruction handoff row, reading the Borsuk–Ulam, Sperner, and Tucker sibling packets only as finite obstruction consumers.*
7. *O is the lower-obstruction row, recording that a requested category reduction is refused by the displayed antipodal or combinatorial obstruction route.*
8. *H records componentwise* hsame *transport for compact source, simplicial support, cover, null-homotopy, budget, obstruction, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from finite-cover inspection through null-homotopy rows and obstruction rows to the category budget.*
10. *P is the* Pkg *provenance over* $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$, $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{SpernerLemma}^{\uparrow}$, $\mathsf{TuckerLemma}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LusternikSchnirelmannCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, U, A, M, S, O, H, C, P, N$. It has no coordinate for a completed homotopy category, arbitrary open covers, choice-selected contractions, quotient equality of spheres or maps, unrestricted critical-point theory, or ambient compactness.

Theorem 7033.2 (Lusternik–Schnirelmann category NameCert obligations)**.** *For every accepted* $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ *carrier $L = (X, K, U, A, M, S, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LusternikSchnirelmannC}}$ *surface consists exactly of compact source admission, optional finite simplicial support admission, finite categorical cover exposure, null-homotopy admission for displayed cover members, categorical budget exposure, antipodal or combinatorial obstruction handoff, lower-obstruction refusal, componentwise transport, displayed replay, provenance, and local naming. No local obligation is discharged by an ambient homotopy category, selected global contraction, arbitrary open cover, quotient sphere equality, or classical critical-point theorem.*

Proof. Project the carrier of Definition 7033.1. The source-facing rows are X and K, the categorical-cover rows are U, A, M, and the obstruction-facing rows are S, O.

The NameCert surface first admits the source. The compact metric row X supplies the finite cover data, while K supplies the finite simplicial support when a nerve or face inventory is used by the consumer.

The cover route is then rowwise. The finite cover row U lists only displayed members, the row A records the null-homotopy data attached to those members, and the budget row M records the category bound read from the same finite list.

Finally S, O, H, C, P, N bind the obstruction, replay, provenance, and local name to that same packet. Since the excluded host objects are not coordinates of L, they cannot become additional local NameCert obligations. □

Theorem 7033.3 (Finite categorical-cover route)**.** *Every accepted* $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ *consumer that reads a categorical upper bound must factor through*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{SimplicialComplex}^{\uparrow}, \quad U, \quad A, \quad M$$

before the category budget is exposed. The route may reuse the finite-cover star-refinement and compact-metric sibling packets, but it exports no arbitrary open-cover compactness theorem, no selected contraction outside the displayed cover, no quotient equality of maps, and no ambient homotopy-category object.

Proof. Begin with the source rows. The compact metric row X supplies finite cover data, and the simplicial row K supplies only the displayed face or nerve inventory used by the consumer.

Read the cover rows in order. The row U exposes the finite family of categorical pieces, A attaches the null-homotopy admission data to each displayed piece, and M records the resulting budget.

The structural rows H, C, P, N transport, replay, source, and name the same route. Because the carrier lacks arbitrary open-cover, quotient-map, selected-contraction, and ambient homotopy-category coordinates, the upper-bound read remains exactly the finite $X, K, U, A, M, H, C, P, N$ surface. □

Theorem 7033.4 (Sphere consumer handoff)**.** *When an accepted* $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ *packet is consumed by a sphere or antipodal-obstruction argument, the handoff reads the sibling packets of chapter 5828, chapter 2003, and chapter 6975 only through the displayed obstruction row* S *and lower-refusal row* O*. Thus a sphere-facing consumer receives a finite categorical-cover obstruction surface, not a host sphere theorem, quotient antipodal space, selected critical point, or unrestricted LS critical-value theorem.*

Proof. Project S and O from the carrier. The handoff row S names the antipodal and combinatorial sibling packets as finite obstruction consumers, while O records the refusal of a smaller categorical cover only inside the same displayed packet.

The Borsuk–Ulam, Sperner, and Tucker chapters contribute routes already expressed as finite NameCert packets. They do not supply quotient sphere equality, selected antipodal points, or unrestricted critical-point data to this carrier.

Consequently the sphere-facing read is constrained by $X, K, U, A, M, S, O, H, C, P, N$. Transport, replay, provenance, and local naming keep the obstruction tied to the finite categorical cover rather than to an ambient topological theorem. □

Falsifiable prediction: Every accepted $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ consumer that claims a category budget or obstruction must display compact source data, finite cover rows, null-homotopy admission rows, a budget row, obstruction handoff rows, transport, replay, provenance, and local NameCert data before the read is public.

Independence witness: borsuk-ulam, sperner-lemma, tucker-lemma, compactmetric, simplicial-complex, finite-cover-star-refinement-modulus: $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries categorical cover rows, null-homotopy admissions, budget data, antipodal or combinatorial obstruction handoff, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LusternikSchnirelmannCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{LusternikSchnirelmannCategory}^{\uparrow}$ packet is generated from compact source rows, optional finite simplicial support rows, finite categorical cover rows, null-homotopy admission rows, categorical budget rows, antipodal or combinatorial obstruction handoff, lower-obstruction refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LusternikSchnirelmannCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7033.1, Definition 7033.2, Definition 7033.3, and Definition 7033.4 seed the finite categorical-cover packet over compact, simplicial, antipodal, combinatorial, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LusternikSchnirelmannCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ambient homotopy categories, arbitrary open-cover compactness, selected global contractions, quotient sphere equality, unrestricted critical-point theory, or classical LS critical-value theorems.

Upgrade path: Obligation closure requires checked carrier admission, finite categorical cover exposure, null-homotopy admission, budget exactness, obstruction handoff, lower-refusal stability, transport, replay, provenance, and local naming for BEDC.Derived.LusternikSchnirelmannCategoryUp.

Chapter 7034

A Concrete Naming Certificate for HellySelectionCompactVariation$^{\uparrow}$

Following Helly, Jordan, and Bishop–Bridges constructive analysis, the HellySelectionCompactVariation$^{\uparrow}$ packet records the compact-variation selection route by finite partition, window, and diagonal ledgers rather than by a host subsequence theorem. It sits over the bounded-variation partition surface of chapter 398, the compact finite-window source of chapter 129, the subsequence-window discipline of chapter 2372, the terminal real-name seal of chapter 38, and the Cauchy route of chapter 3413. The packet gives L10 Real and Completion consumers a traditional compact-variation selection object as finite NameCert data; it does not assert open-cover compactness, countable choice, host function-space compactness, quotient equality of functions, or ambient completeness of Real$^{\uparrow}$.

Definition 7034.1 (Helly selection compact-variation carrier)**.** *A* HellySelectionCompactVariation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (V, K, D, W, R, E, T, C, P, N)$$

with the following displayed rows:

1. *V is the bounded-variation partition ledger, read through the* BoundedVariation$^{\uparrow}$ *surface and carrying the displayed partition sums, variation budget, and monotone refinement rows.*
2. *K is the compact finite-window selection row, read through* CompactMetric$^{\uparrow}$ *and exposing only finite net windows for the inspected domain points.*
3. *D is the diagonal subsequence ledger, recording the finite depth schedule and the retained subsequence windows before any limit row is sealed.*
4. *W is the* StreamName$^{\uparrow}$ *window row for the selected function values and endpoint probes.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to those windows.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row for the displayed pointwise limit windows.*
7. *T records componentwise* hsame *transport for V, K, D, W, R, E.*
8. *C records displayed* Cont *replay from bounded-variation partition checks through compact finite windows, diagonal windows, regular readback, and the Real seal.*
9. *P is the* Pkg *provenance over* HellySelectionCompactVariation$^{\uparrow}$, BoundedVariation$^{\uparrow}$, CompactMetric$^{\uparrow}$, SequentialCompact$^{\uparrow}$, Real$^{\uparrow}$, Cauchy$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{HellySelectionCompactVariation}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $V, K, D, W, R, E, T, C, P, N$. It has no coordinate for a choice-selected subsequence, host compactness theorem, completed function-space quotient, arbitrary open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7034.2 (Helly selection compact-variation NameCert obligations)**.** *For every accepted* $\mathsf{HellySelectionCompactVariation}^{\uparrow}$ *carrier*

$$H = (V, K, D, W, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellySelectionCompactVariation}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded-variation partition exposure through V, compact finite-window selection through K, diagonal subsequence scheduling through D,* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through T, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7034.1. The variation row V is the only bounded-variation source, and the compact row K is the only compact finite-window source.

Read the diagonal stage next. The row D records the retained subsequence windows as displayed finite depth data, while W and R turn those windows into regular rational readback.

Finally the row E seals the displayed real-name windows. The structural rows T, C, P, N transport, replay, source, and name the same finite route, so no host compactness theorem, selected subsequence functional, quotient function equality, countable-choice schedule, or ambient Real completeness principle is exported. □

Theorem 7034.3 (Helly selection compact-variation diagonal extraction)**.** *Every diagonal extraction read from an accepted* $\mathsf{HellySelectionCompactVariation}^{\uparrow}$ *packet factors through the ordered route*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{SequentialCompact}^{\uparrow} \longmapsto \mathsf{Cauchy}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer must first read the bounded-variation partition ledger V, then the compact finite-window row K, then the diagonal subsequence ledger D, then the Cauchy and regular-readback windows W, R, and only then the $\mathsf{Real}^{\uparrow}$ *seal E with T, C, P, N attached. The extraction exports no selected host subsequence, no function-space compactness theorem, no quotient equality of functions, and no ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Proof. Begin with the bounded-variation row. It supplies finite partition variation bounds and no global variation supremum or completed function-space object.

Use the compact finite-window row next. The compact input is read through displayed finite windows from $\mathsf{CompactMetric}^{\uparrow}$, so the diagonal ledger receives finite net data rather than an open-cover compactness principle.

The diagonal row is then read through $\mathsf{SequentialCompact}^{\uparrow}$ as a finite retained-window schedule. The Cauchy and regular-readback rows W, R turn that schedule into displayed tail data, and the terminal row E seals only those real-name windows.

Transport, replay, provenance, and local naming preserve this route through T, C, P, N. Since the carrier has no field for the excluded host principles, every diagonal extraction remains a finite compact-variation NameCert readback. □

Falsifiable prediction: Every accepted $\mathsf{HellySelectionCompactVariation}^{\uparrow}$ consumer must expose the bounded-variation partition ledger, compact finite-window row, diagonal subsequence ledger, Cauchy readback windows, and $\mathsf{Real}^{\uparrow}$ seal before reading a compact-variation selection output.

Independence witness: boundedvariation, compactmetric, sequentialcompact, cauchy, real: none is bijective to $\mathsf{HellySelectionCompactVariation}^{\uparrow}$ because this packet jointly carries bounded-variation partitions, compact finite-window selection, diagonal subsequence scheduling, Cauchy readback, Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HellySelectionCompactVariation}^{\uparrow}}$.

Constructive story: A $\mathsf{HellySelectionCompactVariation}^{\uparrow}$ packet is generated from bounded-variation partition rows, compact finite-window selection rows, a diagonal subsequence ledger, Cauchy and regular-readback windows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellySelectionCompactVariation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7034.1, Definition 7034.2, and Definition 7034.3 seed the finite compact-variation selection packet over $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellySelectionCompactVariation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subsequence choice, host function-space compactness, quotient equality of functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation partition exposure, compact finite-window selection, diagonal extraction, Cauchy readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HellySelectionCompactVariationUp.

Chapter 7035

A Concrete Naming Certificate for $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$

The $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$ packet realizes the audit-gate boundary vision of chapter 9396 as finite NameCert data. It records the refusal surface where a source axiom scan, strict proof-ancestry report, paper-Lean name-resolution check, and origin-boundary ledger reject a proposed internal row instead of converting the failed audit into substrate theorem content. The packet sits beside the existing audit-gate boundary of chapter 526, the borrowed-recursor boundary named in the source vision, and the axiom-refusal discipline enforced by the Lean and paper audits.

Definition 7035.1 (Audit-gate boundary refusal carrier)**.** *An* $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, V, A, R, B, T, C, P, N)$$

with the following displayed rows:

1. *S is the gate-surface row, naming the checked syntactic, proof-ancestry, import, or paper-Lean marker condition.*
2. *V is the verdict row, recording pass or refusal together with the finite diagnostic token, dependency, import edge, or unresolved name that triggered the verdict.*
3. *A is the audit-replay row, exposing the deterministic replay route by which the verdict is recomputed from S.*
4. *R is the refusal row, recording that a failed gate supplies no internal proof row, no theorem row, and no carrier coordinate for the rejected content.*
5. *B is the borrowed-recursor boundary row, separating host checking infrastructure from forbidden host axiom propagation.*
6. *T records componentwise* hsame *transport for S, V, A, R, B.*
7. *C records displayed* Cont *replay through the same gate surface, verdict, replay, refusal, and boundary rows.*
8. *P is the* Pkg *provenance over* $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$, $\mathsf{AuditGateBoundary}^{\uparrow}$, $\mathsf{AxiomRefusalLedger}^{\uparrow}$, $\mathsf{BorrowedRecursorBoundary}^{\uparrow}$, $\mathsf{AuditAxisSeparation}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditGateBoundaryRefusal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, V, A, R, B, T, C, P, N$. It has no coordinate that turns an audit failure into an internal proof, no bridge from failed verdicts to theorem rows, and no route that collapses the theory and verification axes.

Theorem 7035.2 (Audit-gate boundary refusal NameCert obligations)**.** *For every accepted* AuditGateBoundaryRefu *carrier*

$$G = (S, V, A, R, B, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AuditGateBoundaryRefusal}^{\uparrow}}$ *surface consists exactly of gate-surface exposure through S, verdict exposure through V, deterministic audit replay through A, refusal noninternalization through R, borrowed-recursor boundary separation through B, componentwise* hsame *transport through T, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7035.1. The gate row S and verdict row V are the only rows that can describe the checked boundary and its result.

Read the replay and refusal rows next. The row A recomputes the verdict from the displayed gate surface, while R records that a failed verdict exports no proof row and no theorem content.

The borrowed-recursor row B keeps host checking infrastructure separate from forbidden proof ancestry. Transport, replay, provenance, and local naming through T, C, P, N preserve the same refusal surface, so a failed audit cannot be reclassified as an internal BEDC proof. □

Theorem 7035.3 (Audit-gate boundary refusal noninternalization)**.** *Every consumer of an accepted* $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$ *packet must read the gate surface, verdict, audit replay, refusal row, borrowed-recursor boundary row, transport, replay, provenance, and local naming before it can report an audit result. If the verdict row records failure, the packet exports only the refusal and diagnostic surface; it exports no internal proof row, no checked theorem row for the rejected content, no hidden axiom, and no theory-axis closure upgrade.*

Proof. Start with the verdict row V. A consumer cannot inspect the verdict without the gate surface S and replay row A, because the packet contains no detached result coordinate.

When V records failure, the refusal row R is the only downstream content attached to that verdict. It says that the failed item remains outside the substrate theorem surface.

The borrowed-recursor boundary row B prevents the consumer from using host checking machinery as a replacement proof source. The structural rows T, C, P, N preserve the same displayed route, so failure can be replayed and named but not internalized. □

Falsifiable prediction: No accepted $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$ packet can turn an audit failure into an internal proof row; any such packet must either change the verdict row to pass by displayed replay or remain a refusal surface with no theorem-content export.

Independence witness: AxiomRefusalLedger, BorrowedRecursorBoundary, AuditAxisSeparation, AuditGateBoundary: $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries gate-surface data, verdict rows, audit replay, refusal noninternalization, borrowed-recursor boundary separation, transport, replay, provenance, and local NameCert rows.

Theorem 7035.4 (Audit-gate boundary refusal follow-up requirements)**.** *The Lean follow-up surface for* $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$ *requires a nontrivial instance showing that at least one displayed failed gate is carried as a refusal row, and a field-faithful instance showing that changing any of $S, V, A, R, B, T, C, P, N$ changes the accepted refusal packet. These requirements are targets for future declarations named by the* Nontrivial *and* FieldFaithful *instance patterns over $BEDC.Derived.AuditGateBoundaryRefusalUp$.*

Proof. The nontrivial requirement reads the verdict and refusal rows together. A carrier whose failed verdict cannot be distinguished from a pass verdict would not expose boundary refusal.

The field-faithful requirement reads each carrier coordinate. If any row can be changed without changing the accepted packet, a consumer could hide the gate surface, verdict, replay route, refusal, boundary row, transport, replay, provenance, or local name.

Thus the two follow-up requirements are exactly the instance obligations needed before this packet can be promoted from paper-side refusal surface to checked Lean structure. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditGateBoundaryRefusal}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditGateBoundaryRefusal}^{\uparrow}$ packet is generated from a finite gate surface, verdict row, audit-replay row, refusal noninternalization row, borrowed-recursor boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditGateBoundaryRefusal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7035.1, Definition 7035.2, and Definition 7035.3 seed the finite refusal surface for audit-gate failures.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditGateBoundaryRefusal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean instances for nontriviality or field faithfulness, bridge checking, a theorem that every audit gate is complete, or any conversion of failed audits into internal proof rows.

Upgrade path: Obligation closure requires checked carrier admission, verdict replay, refusal noninternalization, borrowed-recursor boundary separation, nontrivial and field-faithful instances, transport, replay, provenance, and local naming for BEDC.Derived.AuditGateBoundaryRefusalUp.

Chapter 7036

A Concrete Naming Certificate for $\mathsf{DeGiorgiIteration}^{\uparrow}$

Following De Giorgi and Evans on energy methods for elliptic and parabolic regularity, the $\mathsf{DeGiorgiIteration}^{\uparrow}$ packet records the finite BEDC surface by which level-set truncations, nested energy windows, Sobolev control, Poincare control, dyadic budgets, regular rational readback, and a terminal real-name seal are replayed before a regularity consumer reads decay. It sits beside the Sobolev source of chapter 440, the Poincare control route of chapter 2329, the ladder comparison of chapter 6969, the dyadic budget core of chapter 291, the regular rational readback route of chapter 301, and the terminal scalar seal of chapter 38. The packet names only displayed finite rows; it is not a host PDE theorem, not a selected weak solution, not a quotient equality of function spaces, and not an ambient compactness argument.

Definition 7036.1 (DeGiorgiIteration carrier)**.** *A* $\mathsf{DeGiorgiIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, T, S, P, M, B, Q, R, H, C, G, N)$$

with the following displayed rows:

1. *L is the finite level-set row, listing the cutoff levels and superlevel or sublevel slices read by the iteration.*
2. *T is the truncation-window row, recording positive and negative parts, clipped test functions, and the local support window.*
3. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row used to pass from energy control to an integrability gain.*
4. *P is the* $\mathsf{PoincareInequality}^{\uparrow}$ *control row used on each displayed window.*
5. *M is the* $\mathsf{MoserIteration}^{\uparrow}$ *comparison row, exposing the sibling ladder against which De Giorgi decay consumers compare their exponent schedule.*
6. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row for thresholds, shrink factors, and precision tolerances.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the dyadic budget and energy ledger into regular rational comparisons.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for the final bound read by downstream regularity consumers.*
9. *H records componentwise* hsame *transport for L, T, S, P, M, B, Q, R.*

10. *C records displayed* Cont *replay for the level-set, truncation, energy, budget, readback, and seal routes.*
11. *G is the* Pkg *provenance over* $\mathsf{DeGiorgiIteration}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{PoincareInequality}^{\uparrow}$, $\mathsf{MoserIteration}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DeGiorgiIteration}^{\uparrow}}$ *row.*

Lean4 (definition) `BEDC.Derived.DeGiorgiIterationUp.DeGiorgiIterationUp`

Theorem 7036.2 (DeGiorgiIteration NameCert obligations)**.** *For every accepted* $\mathsf{DeGiorgiIteration}^{\uparrow}$ *carrier $D = (L, T, S, P, M, B, Q, R, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{DeGiorgiIteration}^{\uparrow}}$ *surface consists exactly of level-set exposure through L, truncation-window exposure through T, Sobolev source exposure through S, Poincare control through P, Moser-comparison exposure through M, dyadic budget exposure through B, regular rational readback through Q, Real-bound sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 7036.1. Each row named in the statement is a displayed coordinate of the accepted packet, and there is no second coordinate for an ambient solution space or host compactness theorem.

The analytic controls are read only through their sibling packets. The Sobolev row, Poincare row, and Moser comparison row point to the finite BEDC surfaces already named by their chapters, while the dyadic, regular rational, and Real rows keep the energy budget on registered numeric readbacks.

Transport and replay use H and C, and provenance and local naming use G and N. Since the packet inventory is exhausted by these rows, the local NameCert obligations are exactly the listed exposure, stability, replay, provenance, and non-escape clauses. □

Lean4 ✓ `BEDC.Derived.DeGiorgiIterationUp.DeGiorgiIterationNameCertObligations`

Theorem 7036.3 (DeGiorgiIteration energy-decay handoff)**.** *Every downstream regularity consumer of an accepted* $\mathsf{DeGiorgiIteration}^{\uparrow}$ *packet must first read the level-set row L, truncation-window row T, Sobolev row S, Poincare row P, Moser-comparison row M, dyadic budget row B, regular rational readback row Q, Real-bound seal R, and structural rows H, C, G, N. The handoff supplies a finite energy-decay surface; it exports no host De Giorgi theorem, selected weak solution, quotient function equality, countable-choice schedule, unbounded compactness principle, or ambient real-completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 7036.2. They force every public read through the displayed packet rows before any decay claim is consumed.

The energy side is finite because the level-set and truncation rows are ledger coordinates, and the Sobolev and Poincare rows are sibling NameCert inputs. The comparison with $\mathsf{MoserIteration}^{\uparrow}$ is likewise a displayed handoff row, not an imported host regularity theorem.

The numeric side is sealed by $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. Therefore a consumer receives only the finite decay packet and cannot extract any excluded analytic or choice-theoretic object from the handoff. □

Falsifiable prediction: Every accepted regularity read of $\mathsf{DeGiorgiIteration}^{\uparrow}$ exposes level-set, truncation-window, Sobolev, Poincare, Moser-comparison, dyadic budget, regular rational readback, Real-bound seal, transport, replay, provenance, and local NameCert rows before consuming an energy-decay bound.

Independence witness: sobolev, poincare-inequality, moser-iteration, dyadicratcore, regseqrat, real: none is bijective with $\mathsf{DeGiorgiIteration}^{\uparrow}$ because this carrier alone binds level-set truncation windows and energy-decay budgets to the Sobolev, Poincare, Moser-comparison, dyadic, regular rational, Real, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DeGiorgiIteration}^{\uparrow}}$.

Constructive story: A $\mathsf{DeGiorgiIteration}^{\uparrow}$ packet is generated from level-set rows, truncation-window rows, Sobolev control, Poincare control, Moser-comparison rows, dyadic budgets, regular rational readback, a Real-bound seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DeGiorgiIteration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7036.1, Definition 7036.2, and Definition 7036.3 seed the finite De Giorgi energy-decay packet consumed downstream from Sobolev, Poincare, and Moser-style regularity rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DeGiorgiIteration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host De Giorgi regularity theorem, selected weak solutions, quotient function equality, countable choice, ambient compactness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, level-set exactness, truncation-window exactness, Sobolev and Poincare source exactness, Moser-comparison exactness, dyadic-budget exactness, regular rational readback, Real-bound sealing, transport, replay, provenance, and local naming for BEDC.Derived.DeGiorgiIterationUp.

Chapter 7037

A Concrete Naming Certificate for $\mathsf{ContourReparameterizationLedger}^{\uparrow}$

Following the constructive contour-integration operation law of chapter 9340, the $\mathsf{ContourReparameterizationLedger}^{\uparrow}$ packet records the finite ledger by which a piecewise-linear contour refinement or monotone piecewise-linear reparameterization is read without changing the contour-integral output. It sits beside the operation packet of chapter 521, the contour socket of chapter 583, the reversal ledger of chapter 1019, the holomorphic input surface of chapter 68, and the complex output seal of chapter 39. The packet names only finite contour, refinement, Riemann-sum, transport, replay, provenance, and local naming rows; it is not a host path quotient or an ambient smooth-change-of-variables theorem.

Definition 7037.1 (Contour reparameterization ledger carrier)**.** *A* $\mathsf{ContourReparameterizationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (G, G', U, F, S, M, I, H, C, P, N)$$

with the following displayed rows:

1. *G is the source* $\mathsf{PLContour}$ *row with finite* $\mathsf{Complex}^{\uparrow}$ *endpoints and segment rows.*
2. *G' is the reparameterized* $\mathsf{PLContour}$ *row, obtained by a finite refinement or monotone piecewise-linear parameter change.*
3. *U is the reparameterization ledger row recording the segment subdivision map, endpoint preservation, orientation preservation, and refinement budget.*
4. *F is the* $\mathsf{Holomorphic}^{\uparrow}$ *input row on a neighbourhood containing the images of both contour rows.*
5. *S is the Riemann-sum comparison ledger matching source and reparameterized sums.*
6. *M is the modulus row witnessing that the comparison remains within the displayed tolerance budget.*
7. *I is the shared* $\mathsf{Complex}^{\uparrow}$ *output row for the contour-integral operation.*
8. *H records componentwise* hsame *transport for G, G', U, F, S, M, I.*
9. *C records displayed* Cont *replay for contour reads, reparameterization reads, Riemann-sum reads, modulus reads, output reads, provenance, and local naming.*

10. *P is the* Pkg *provenance over* ContourReparameterizationLedger$^{\uparrow}$, ContourIntegralOperation$^{\uparrow}$, Holomorphic$^{\uparrow}$, Complex$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ContourReparameterizationLedger}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.ContourReparameterizationLedgerUp.ContourReparameterizationLedgerTasteGate`
`single carrier alignment`

Theorem 7037.2 (Contour reparameterization ledger NameCert obligations)**.** *For every accepted* ContourReparameterizationLedger$^{\uparrow}$ *carrier $R = (G, G', U, F, S, M, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContourReparameterizationLedger}^{\uparrow}}$ *surface consists exactly of source-contour exposure through G, reparameterized-contour exposure through G', finite reparameterization-ledger exposure through U, holomorphic input exposure through F, Riemann-sum comparison through S, modulus control through M, shared* Complex$^{\uparrow}$ *output sealing through I, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7037.1. The source contour, reparameterized contour, ledger, holomorphic input, comparison sums, modulus, output, transport, replay, provenance, and naming rows are all displayed coordinates.

The operation law is read through the finite rows U, S, M, I. The ledger records the refinement map and endpoint preservation, while the Riemann-sum comparison and modulus rows witness that both contour presentations reach the same Complex$^{\uparrow}$ output row.

Transport and replay do not add a host path quotient or a smooth reparameterization theorem. Since provenance and local naming are also displayed, the NameCert surface is exhausted by the rows listed in the statement. □

Theorem 7037.3 (Contour reparameterization ledger contour-integral handoff)**.** *Every contour-integral consumer that reads reparameterization invariance from an accepted* ContourReparameterizationLedger$^{\uparrow}$ *packet must first expose the source contour row G, reparameterized contour row G', reparameterization ledger U, holomorphic input row F, Riemann-sum comparison ledger S, modulus row M, shared* Complex$^{\uparrow}$ *output row I, and structural rows H, C, P, N. The handoff realizes the operation law as finite ledger data and exports no host path quotient, unregistered smooth parameter change, ambient analytic integral operator, or global branch selector.*

Proof. Apply Definition 7037.2. It forces every public reparameterization read through the displayed source contour, target contour, ledger, input, comparison, modulus, output, transport, replay, provenance, and naming rows.

The contour-integral operation packet supplies the downstream operation surface, but this chapter supplies the particular law ledger. The consumer therefore sees reparameterization invariance as a finite comparison between two PL-contour rows and their Riemann-sum ledgers.

No excluded ambient object has a carrier coordinate. The handoff can be consumed by contour, residue, and RH scaffold chapters only through the displayed rows of this packet and the existing contour-integral operation surface. □

Falsifiable prediction: Every accepted contour-integral reparameterization read exposes source contour, reparameterized contour, finite ledger, holomorphic input, Riemann-sum comparison, modulus, shared Complex output, transport, replay, provenance, and local NameCert rows before the operation law is public.

Independence witness: contourintegraloperation, contourintegralsocket, contour-reversal-ledger, holomorphic, complex: none is bijective with ContourReparameterizationLedger$^{\uparrow}$ because this carrier alone binds a finite reparameterization ledger and Riemann-sum comparison to the contour

operation, holomorphic input, Complex output, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ContourReparameterizationLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ContourReparameterizationLedger}^{\uparrow}$ packet is generated from source PL-contour rows, reparameterized PL-contour rows, finite reparameterization ledgers, holomorphic input rows, Riemann-sum comparison rows, modulus rows, shared Complex output rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContourReparameterizationLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7037.1, Definition 7037.2, and Definition 7037.3 seed the finite ledger for the contour-integral reparameterization operation law.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContourReparameterizationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host path quotient, smooth change-of-variables theorem, ambient contour-integral operator, global branch selector, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source and target PL-contour exactness, reparameterization-ledger exactness, holomorphic-input locality, Riemann-sum comparison, modulus control, Complex output sealing, transport, replay, provenance, and local naming for BEDC.Derived.ContourReparameterizationLedgerUp.

Chapter 7038

A Concrete Naming Certificate for $\mathsf{BoundedStoppingTime}^{\uparrow}$

Following Doob, the $\mathsf{BoundedStoppingTime}^{\uparrow}$ packet names the finite stopping interface that sits between the stopping-decision surface of chapter 344 and the stopped-value surface of chapter 383. It reads martingale windows from chapter 190, probability sources from chapter 184, and random-variable endpoint rows from chapter 185. The packet records the displayed finite bound, filtration-window visibility, and decision ledger needed before optional stopping or concentration consumers may read a stopped value; it does not assert an unbounded stopping theorem, almost-sure quotient equality, uniform integrability, or measure completion.

Definition 7038.1 (Bounded stopping time carrier)**.** *A* $\mathsf{BoundedStoppingTime}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, b, F, D, V, H, C, P, N)$$

with the following displayed rows:

1. *T is the source* $\mathsf{StoppingTime}^{\uparrow}$ *row whose decisions are inspected.*
2. *b is the finite bound row, naming the displayed horizon before any stopped value is read.*
3. *F is the filtration-window visibility ledger, recording that each decision of T used before b is visible in the corresponding finite filtration window.*
4. *D is the decision ledger, listing the finite branch outcomes up to b and the first displayed stopping branch when one is present.*
5. *V is the stopped-value handoff row consumed by* $\mathsf{OptionalStopping}^{\uparrow}$*, tying the selected branch of D to the corresponding* $\mathsf{RandomVar}^{\uparrow}$ *endpoint row inside the martingale window.*
6. *H records componentwise* hsame *transport for T, b, F, D, V and the structural certificate rows.*
7. *C records displayed* Cont *replay from a bounded stopping request through the same stopping-time, bound, filtration-window, decision-ledger, and stopped-value rows.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedStoppingTime}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedStoppingTime}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, b, F, D, V, H, C, P, N$. It has no coordinate for an unbounded stopping index, optional-stopping expectation theorem, almost-sure quotient, completed filtration, uniform-integrability hypothesis, or ambient measure-completion carrier.

Theorem 7038.2 (Bounded stopping time NameCert obligations)**.** *For every accepted* $\mathsf{BoundedStoppingTime}^{\uparrow}$ *carrier*

$$B = (T, b, F, D, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedStoppingTime}^{\uparrow}}$ *surface consists exactly of source stopping-time exposure through* T*, finite-bound exposure through* b*, filtration-window visibility through* F*, decision-ledger exactness through* D*, stopped-value handoff through* V*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7038.1. The rows T, b, F, D, V are the only mathematical rows available to a bounded stopping consumer.

The source stopping-time row T supplies the finite decision surface, and the bound row b cuts that surface to the displayed window. The filtration ledger F records that each inspected decision is visible at the corresponding finite stage.

The decision ledger D then identifies the bounded branch data consumed by the stopped-value handoff V. The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the carrier contains no unbounded stopping index, optional-stopping expectation theorem, quotient event equality, completed filtration, uniform-integrability row, or measure-completion row, the listed rows are exactly the local naming obligations. □

Theorem 7038.3 (Bounded stopping time optional-stopping handoff)**.** *Every* $\mathsf{OptionalStopping}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedStoppingTime}^{\uparrow}$ *carrier*

$$B = (T, b, F, D, V, H, C, P, N)$$

must read the stopped-value handoff through the finite route

$\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{BoundedStoppingTime}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameC

The handoff exposes the source stopping row, displayed bound, filtration-window ledger, bounded decision ledger, and stopped-value row before any optional-stopping packet can inspect expectation-facing data. It exports no unbounded stopping branch, no limiting stopping theorem, no almost-sure quotient, and no completed-filtration carrier.

Proof. Start with Definition 7038.2. It forces any consumer to display $T, b, F, D, V, H, C, P, N$ before the local name is consumed.

The optional-stopping side reads only the handoff row V after the finite route has been displayed. The row V is tied to a branch in D, to the finite bound b, and to the visible filtration windows F over the source stopping-time row T.

The martingale, probability, and random-variable rows are therefore consumed only as the finite source data named by P and replayed through C. Because the carrier inventory excludes unbounded stopping branches, limiting stopping theorems, almost-sure quotient equality, and completed filtrations, the handoff supplies exactly the bounded-window interface required by $\mathsf{OptionalStopping}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{BoundedStoppingTime}^{\uparrow}$ consumer displays a $\mathsf{StoppingTime}^{\uparrow}$ source row, a finite bound, filtration-window visibility, a bounded decision ledger, stopped-value handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any $\mathsf{OptionalStopping}^{\uparrow}$ stopped-value read is consumed.

Independence witness: stoppingtime, optionalstopping, martingale, probspace, randomvar: $\mathsf{BoundedStoppingTime}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source stopping decision row, finite bound, filtration-window visibility, bounded decision ledger, stopped-value handoff, transport, replay, provenance, and local NameCert rows as one finite interface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedStoppingTime}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedStoppingTime}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7038.1, Definition 7038.2, and Definition 7038.3 seed the finite bounded-window stopping interface over $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{RandomVar}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedStoppingTime}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, unbounded stopping, optional-stopping expectation equality, almost-sure quotient equality, uniform integrability, completed filtrations, measure completion, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-bound exposure, filtration-window visibility, decision-ledger exactness, stopped-value handoff, transport replay, provenance, and non-escape for BEDC.Derived.BoundedStoppingTimeU

Constructive story: A $\mathsf{BoundedStoppingTime}^{\uparrow}$ packet is generated from a source stopping-time row, a displayed finite bound, filtration-window visibility rows, a bounded decision ledger, a stopped-value handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7039

A Concrete Naming Certificate for $\mathsf{DenseSubspaceCompletion}^{\uparrow}$

Following Bourbaki and Engelking on completion from a dense subspace, the $\mathsf{DenseSubspaceCompletion}^{\uparrow}$ packet records the finite BEDC handoff by which a dense subspace carrier supplies completion-facing names without replacing them by quotient representatives or host equality. It sits beside the metric source of chapter 57, the Cauchy-filter completion route of chapter 1569, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dense embedding boundary of chapter 1512, and the terminal Real seal of chapter 38. The packet names a dense-subspace completion handoff as finite rows; it is not a selected completion point, not an ambient complete metric space, and not a detached Real-completeness principle.

Definition 7039.1 (Dense-subspace completion carrier)**.** *A* $\mathsf{DenseSubspaceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, Y, M, S, F, W, R, E, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *source row whose distance and classifier data are read by the completion request.*
2. *Y is the dense subspace row, including the displayed inclusion into X, the dense witness ledger, and the subspace classifier transport.*
3. *M is the metric restriction row on Y, read through the same metric witnesses as X.*
4. *S is the subspace approximation row: each ambient tolerance request is met by a displayed subspace witness.*
5. *F is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *route generated from the dense subspace data.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger used to observe finite completion-facing reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same windows and metric tolerances.*
8. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that embeds subspace observations into the completion boundary.*
9. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, F, W, R, E have been displayed.*

10. *H records componentwise* hsame *transport for the ambient metric, dense subspace, restricted metric, approximation, filter completion, windows, readbacks, embedding, Real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from an ambient completion request through the dense subspace row, Cauchy-filter route, stream windows, regular readback, completion embedding, and Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{DenseSubspaceCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseSubspaceCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, Y, M, S, F, W, R, E, A, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, host metric equality, countable choice, or an ambient completeness theorem.

Theorem 7039.2 (Dense-subspace completion NameCert obligations)**.** *For every accepted* DenseSubspaceCompleti *carrier $D = (X, Y, M, S, F, W, R, E, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenseSubspaceCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed ambient metric, dense subspace, restricted metric, approximation ledger, Cauchy-filter completion route, finite stream windows, regular rational readbacks, completion embedding, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. No NameCert obligation is supplied by quotient completions, selected representatives, host equality, countable choice, or ambient completeness.*

Proof. Project the carrier of Definition 7039.1. The rows $X, Y, M, S, F, W, R, E, A, H, C, P, N$ are exactly the ambient metric, dense subspace, restricted metric, approximation, Cauchy-filter, window, readback, embedding, Real-seal, transport, replay, provenance, and local naming coordinates.

The dense-subspace part is Y, M, S. It reads the metric row X, restricts that metric to the displayed subspace, and records the finite approximation ledger by which ambient tolerance requests are met inside the subspace.

The completion-facing part is F, W, R, E, A. The Cauchy-filter completion route consumes the dense-subspace data, the stream windows and regular readbacks expose finite observations, the embedding row inserts the subspace observations into the completion boundary, and the Real seal is reached only after those rows are present.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient completion, selected representatives, host equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7039.3 (Dense-subspace completion dense handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{DenseSubspaceCompletion}^{\uparrow}$ *packet factors through the finite handoff*

$$X, Y, M, S \longmapsto F, W, R \longmapsto E \longmapsto A \longmapsto H, C, P, N.$$

Thus the consumer reads the dense subspace row, metric restriction, Cauchy-filter completion row, finite windows, regular rational readbacks, $\mathsf{CompletionEmbedding}^{\uparrow}$ *boundary,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row before accepting the completed result.*

Proof. Begin with an accepted completion-facing request. Carrier admission exposes the ambient metric X and the dense subspace row Y before any completion row is available.

The restricted metric and approximation ledger M, S then produce the dense handoff. Each ambient tolerance read must be witnessed by a subspace approximation before it can enter a Cauchy-filter completion route.

Read the completion rows next. The row F is the Cauchy-filter completion route, W supplies finite stream observations, R supplies regular rational readback, and E is the dense completion embedding boundary.

The Real seal A is downstream of that route, while H, C, P, N transport, replay, source, and name it. Hence every dense-subspace completion consumer receives the displayed finite handoff and cannot extract quotient equality, selected representatives, countable choice, host equality, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{DenseSubspaceCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{CompletionEmbedding}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ row without first reading the dense subspace row, restricted metric row, approximation ledger, $\mathsf{CauchyFilterCompletion}^{\uparrow}$ route, $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: metric, cauchyfiltercompletion, streamname, regseqrat, completionembedding, real: no listed sibling supplies the whole packet $D = (X, Y, M, S, F, W, R, E, A, H, C, P, N)$, because each sibling contributes only a metric source, Cauchy-filter route, finite window, regular readback, dense embedding, or Real seal while this chapter binds the dense-subspace handoff with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DenseSubspaceCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseSubspaceCompletion}^{\uparrow}$ packet is generated from an ambient MetricSpace row, dense subspace row, restricted metric row, approximation ledger, CauchyFilterCompletion route, StreamName windows, RegSeqRat readbacks, CompletionEmbedding row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseSubspaceCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7039.1, Definition 7039.2, and Definition 7039.3 seed the dense-subspace completion handoff over metric, Cauchy-filter, stream, regular-readback, embedding, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseSubspaceCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected completion representatives, countable choice, host metric equality, Lean verification, audit cleanliness, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, dense approximation, Cauchy-filter completion replay, embedding handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DenseSubspaceCompletion

Chapter 7040

A Concrete Naming Certificate for $\mathsf{CauchyTowerCollapse}^{\uparrow}$

Following Bishop and Bridges on constructive completion, the $\mathsf{CauchyTowerCollapse}^{\uparrow}$ packet records the finite flattening route by which iterated regular-Cauchy completion data is read as one Real-facing certificate surface. It sits over the dyadic rational carrier of chapter 291, the finite stream-window layer of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the route comparison packet of chapter 1635, and the common-tail uniqueness boundary of chapter 1782. The chapter names the finite collapse window for towers of regular-Cauchy completion rows; it does not assert quotient completion equality, selected host limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7040.1 (Cauchy tower collapse carrier)**.** *A* $\mathsf{CauchyTowerCollapse}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, S, R, E, A, U, W, F, H, C, P, N)$$

with the following displayed rows:

1. *B is the base* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including half-radius and fused-radius cells used by every tower level.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that chooses which observations of each tower level are inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same displayed windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the dyadic, stream, and regular-readback rows have been displayed.*
5. *A is the* $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$ *route-comparison row that keeps nested completion flattening orders on the same finite ledger.*
6. *U is the* $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$ *common-tail row comparing the flattened route with the single displayed completion boundary.*
7. *W is the finite tower-window projection row, recording the observed depth, precision request, and component read at each inspected level.*
8. *F is the dyadic tolerance-fusion row, combining the displayed level tolerances into one requested* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound before the Real seal is consumed.*

9. *H records componentwise* hsame *transport for the dyadic, stream, readback, Real-seal, associativity, uniqueness, projection, fusion, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an iterated completion request through W, F, A, U, and then through B, S, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyTowerCollapse}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTowerCollapse}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, S, R, E, A, U, W, F, H, C, P, N$. No coordinate stores quotient completion equality, a selected host limit, countable-choice schedules, or ambient real completeness.

Theorem 7040.2 (Cauchy tower collapse NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTowerCollapse}^{\uparrow}$ *carrier $T = (B, S, R, E, A, U, W, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTowerCollapse}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance ledger, finite stream windows, regular rational readback, Real seal, associativity row, uniqueness row, finite tower-window projection, dyadic tolerance fusion, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. No NameCert obligation is supplied by quotient completion equality, selected host limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7040.1. The rows $B, S, R, E, A, U, W, F, H, C, P, N$ are exactly the dyadic tolerance, stream-window, regular-readback, Real-seal, associativity, uniqueness, projection, fusion, transport, replay, provenance, and local naming coordinates.

The tower-facing part is W, A, U. The projection row W exposes only the inspected finite depth and precision requests, the associativity row A compares the displayed flattening orders, and the uniqueness row U identifies the common-tail boundary available after flattening.

The Real-facing part is B, S, R, E, F. Tolerance requests are fused by F into the dyadic ledger B, the finite observations are read through S, the rational schedules are read through R, and the terminal seal E is consumed only after those rows are present.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient completion equality, selected host limits, countable choice, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 7040.3 (Cauchy tower finite-window flattening)**.** *Let $T = (B, S, R, E, A, U, W, F, H, C, P, N)$ be an accepted* $\mathsf{CauchyTowerCollapse}^{\uparrow}$ *carrier. Every iterated regular-Cauchy completion read factors through the finite route*

$$W \longmapsto F \longmapsto B, S, R \longmapsto A, U \longmapsto E \longmapsto H, C, P, N.$$

Thus an iterated completion tower is flattened only by finite-window projection and dyadic tolerance fusion before reaching the $\mathsf{Real}^{\uparrow}$ *seal. The route exports no quotient completion equality, selected host limit, countable-choice schedule, or ambient Real completeness principle.*

Proof. Begin with the finite tower-window projection W. It chooses the displayed tower depth, the inspected components, and the requested precision cells without selecting a completed host object.

Fuse tolerances next. The row F combines the displayed level tolerances into one $\mathsf{DyadicRatCore}^{\uparrow}$ request in B, after which the same observation windows S and regular rational readbacks R serve the flattened route.

Read the completion comparison rows. The associativity row A keeps the left- and right-nested collapse orders on one finite ledger, while U supplies the regular-Cauchy common-tail boundary that permits the single Real-facing seal to be read.

The terminal seal E and structural rows H, C, P, N preserve exactly that route. Because the packet contains no quotient equality, selected limit, countable-choice, or ambient-completeness coordinate, no such principle can be exported by the flattening consumer. □

Falsifiable prediction: Every accepted $\mathsf{CauchyTowerCollapse}^{\uparrow}$ consumer that reaches the $\mathsf{Real}^{\uparrow}$ seal must first read the finite tower-window projection, dyadic tolerance-fusion row, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{CauchyCompletionAssociativity}^{\uparrow}$ route row, and $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$ common-tail row.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-completion-associativity, regular-cauchy-completion-uniqueness: no listed sibling supplies the whole packet $T = (B, S, R, E, A, U, W, F, H, C,$ because each sibling contributes only a tolerance ledger, finite window, regular readback, Real seal, route comparison, or common-tail boundary while this chapter binds the finite tower projection and dyadic fusion route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTowerCollapse}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTowerCollapse}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readbacks, a RealUp seal, CauchyCompletionAssociativity and RegularCauchyCompletionUniqueness rows, finite tower-window projection, dyadic tolerance fusion, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTowerCollapse}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7040.1, Definition 7040.2, and Definition 7040.3 seed the finite collapse surface for iterated regular-Cauchy completion windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTowerCollapse}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected host limits, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite tower-window projection, dyadic tolerance fusion, completion-route comparison, regular-Cauchy common-tail exposure, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTowerCollapseUp.

Chapter 7041

A Concrete Naming Certificate for $\mathsf{QuasisymmetricMap}^{\uparrow}$

Following Heinonen on analysis on metric spaces and Tukia–Vaisala on quasisymmetric embeddings, the $\mathsf{QuasisymmetricMap}^{\uparrow}$ packet records the finite BEDC surface of a metric map whose distortion is controlled by a displayed modulus row. It sits over the source and target metric packets of chapter 57, the terminal distance seal of chapter 38, the entourage-facing route of chapter 339, the map graph of chapter 130, and the control ledger of chapter 1631. The packet names a quasisymmetric handoff as finite rows; it is not a quotient map equality, not a selected inverse, not an ambient completeness principle, and not a compactness theorem.

Definition 7041.1 (Quasisymmetric map carrier)**.** *A* $\mathsf{QuasisymmetricMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, G, \eta, D, T, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier and distance-read schedule used by the inspected triple.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, including the target classifier and its distance-read schedule.*
3. *G is the finite map-graph row, read through the* $\mathsf{ContinuousMap}^{\uparrow}$ *sibling surface when a topology-facing consumer asks for the same graph.*
4. *η is the distortion-control ledger, read through the* $\mathsf{ModulusOfContinuity}^{\uparrow}$ *sibling surface as a finite monotone comparison row.*
5. *D is the* $\mathsf{Real}^{\uparrow}$ *distance-seal row for source and target pair distances used in the quasisymmetric comparison.*
6. *T is the uniform-topology transport row that records how the metric comparison is replayed by* $\mathsf{UniformSpace}^{\uparrow}$ *consumers.*
7. *R is the replay row exposing the finite triple comparison and the target-distance bound determined by η.*
8. *H records componentwise* hsame *transport for the source metric, target metric, graph, distortion ledger, Real distance seals, uniform transport, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{QuasisymmetricMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ModulusOfContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{QuasisymmetricMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, Y, G, \eta, D, T, R, H, C, P, N$. It has no coordinate for quotient map equality, a selected inverse map, ambient completeness, compactness, or an unbounded host metric theorem.

Theorem 7041.2 (Quasisymmetric map NameCert obligations)**.** *For every accepted* $\mathsf{QuasisymmetricMap}^{\uparrow}$ *carrier $Q = (X, Y, G, \eta, D, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{QuasisymmetricMap}^{\uparrow}}$ *surface consists exactly of source and target metric admission, map-graph exposure, distortion-control ledger admission,* $\mathsf{Real}^{\uparrow}$ *distance sealing, uniform-topology transport, finite comparison replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is supplied by quotient map equality, selected inverses, ambient completeness, open-cover compactness, or an external host topology.*

Proof. Project the carrier of Definition 7041.1. The rows $X, Y, G, \eta, D, T, R, H, C, P, N$ are exactly the source metric, target metric, graph, distortion ledger, distance seal, uniform transport, replay, transport, continuation, provenance, and local naming coordinates.

The metric part is X, Y, D. It exposes the two distance schedules and seals every source and target distance comparison through the displayed $\mathsf{Real}^{\uparrow}$ row before the distortion ledger is read.

The mapping part is G, η, T, R. The graph row supplies the finite map observations, the distortion ledger supplies the comparison budget, the uniform transport row makes the same route visible to topology-facing consumers, and the replay row records the inspected triple comparison.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores quotient map equality, selected inverse data, compactness, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7041.3 (Quasisymmetric map metric handoff)**.** *Every metric, uniform, or continuous-map consumer of an accepted* $\mathsf{QuasisymmetricMap}^{\uparrow}$ *packet factors its request through the finite handoff*

$$X, Y, G, \eta \longmapsto D \longmapsto T, R \longmapsto H, C, P, N.$$

Thus the consumer reads the source and target metric rows, map graph, distortion-control ledger, $\mathsf{Real}^{\uparrow}$ *distance seals, uniform transport, replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before accepting a quasisymmetric comparison.*

Proof. Begin with an accepted consumer request. Carrier admission exposes the source metric row X, target metric row Y, graph row G, and distortion ledger η before any quasisymmetric comparison is visible.

Read the distance row next. The $\mathsf{Real}^{\uparrow}$ seal D binds the source and target distances used by the inspected triple, so the comparison cannot be detached from the displayed real-distance evidence.

The uniform transport and replay rows T, R then hand the same finite comparison to metric, uniform, and continuous-map consumers. They expose the distortion-controlled target-distance bound without adding a quotient equality, inverse selection, compactness, or completeness coordinate.

The rows H, C, P, N preserve, replay, source, and name this handoff. Hence every accepted quasisymmetric read factors through the displayed finite route and none of the excluded host principles can be exported. □

Falsifiable prediction: An accepted $\mathsf{QuasisymmetricMap}^{\uparrow}$ consumer that reads a target-distance distortion bound without first displaying the source metric row, target metric row, map graph, distortion-control ledger, $\mathsf{Real}^{\uparrow}$ distance seal, uniform transport, replay, transport, provenance, and local naming rows refutes the carrier surface.

Independence witness: metric, real, uniform, continuousmap, moduluscontinuity: no listed sibling supplies the whole packet $Q = (X, Y, G, \eta, D, T, R, H, C, P, N)$, because each sibling contributes only a metric source, real-distance seal, uniform route, map graph, or control ledger while this chapter binds the quasisymmetric comparison with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{QuasisymmetricMap}^{\uparrow}}$.

Constructive story: A $\mathsf{QuasisymmetricMap}^{\uparrow}$ packet is generated from source and target MetricSpace rows, a finite map graph, a distortion-control ledger, RealUp distance seals, uniform transport, finite comparison replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuasisymmetricMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7041.1, Definition 7041.2, and Definition 7041.3 seed the quasisymmetric metric-topology handoff over metric, real-distance, uniform, continuous-map, and modulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuasisymmetricMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient map equality, selected inverses, ambient completeness, compactness, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, distortion-ledger routing, Real distance sealing, uniform handoff, transport, replay, provenance, and local naming for BEDC.Derived.QuasisymmetricMapUp.

Chapter 7042

A Concrete Naming Certificate for $\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}$

The $\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}$ packet realizes a finite residual-pair witness surface from the confluence questions of chapter 9386. It is narrower than the parallel-diamond frontier of chapter 4238: the witness records one displayed local peak, its residual-substitution rows, its candidate join rows, and the bounded checker budget before any local-diamond read is public. It consumes the critical-path packet of chapter 765, the normalization router of chapter 1108, the closed substitution row of chapter 537, the existing frontier of chapter 4238, and the terminal real seal of chapter 38. The packet is a local finite witness, not a global confluence theorem, not a normalization theorem, and not a hidden substitution principle.

Definition 7042.1 (MetaCIC parallel-diamond witness carrier)**.** *A* $\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, L, R, S, J, B, A, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed MetaCIC window row, exposing the closed source term, typing context, redex shape, and bounded binder depth inspected by the witness.*
2. *L and R are the two one-step residual rows generated from the same displayed peak.*
3. *S is the closed-term substitution row, read through the* $\mathsf{ClosedTermSubstitution}^{\uparrow}$ *surface before either residual row is joined.*
4. *J is the candidate local-join row, recording the displayed common residual target proposed for the pair.*
5. *B is the bounded checker row that verifies the two residual routes inside the shown finite budget.*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *audit seal for the numeric fuel, height, and readback bounds used by the checker.*
7. *O is the obstruction-retention row, keeping the residual-substitution premise and subject-reduction boundary visible.*
8. *H records componentwise* hsame *transport for the typed window, residual pair, substitution row, local join, checker, real audit seal, obstruction row, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same local witness route.*

10. *P is the* Pkg *provenance over* MetaCICParallelDiamondWitness$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICNormalizationCer MetaCICParallelDiamondFrontier$^{\uparrow}$, ClosedTermSubstitution$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, L, R, S, J, B, A, O, H, C, P, N$. It has no coordinate for arbitrary closed-term Church–Rosser, global confluence, normalization for all closed terms, unrestricted substitution compatibility, quotient syntax equality, or a hidden evaluator oracle.

Theorem 7042.2 (MetaCIC parallel-diamond witness obligations)**.** *For every accepted* MetaCICParallelDiamondWi *carrier $W = (T, L, R, S, J, B, A, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}}$ *surface consists exactly of typed-window exposure, two residual rows from the same peak, closed-term substitution exposure, candidate local-join admission, bounded checker accounting,* Real$^{\uparrow}$ *audit sealing, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is supplied by global confluence, normalization, unrestricted substitution compatibility, quotient syntax equality, host evaluator soundness, or kernel consistency.*

Proof. Project the carrier of Definition 7042.1. The rows $T, L, R, S, J, B, A, O, H, C, P, N$ are the only visible coordinates of an accepted witness packet.

The local peak is held by T, L, R. Both residual rows are tied to the same typed window, so a consumer cannot splice in a detached critical pair or an untyped residual route.

The join and checking data are S, J, B, A, O. The closed substitution row remains visible before the candidate join is read, the bounded checker records the finite verification budget, the real audit seal accounts for numeric bounds, and the obstruction row preserves the residual-substitution premise.

Finally H, C, P, N transport, replay, source, and name the same local route. Since none of the excluded global or host principles occurs as a coordinate, the listed rows exhaust the witness NameCert surface. □

Theorem 7042.3 (MetaCIC parallel-diamond witness handoff)**.** *Every confluence or normalization-router consumer of an accepted* MetaCICParallelDiamondWitness$^{\uparrow}$ *packet factors through the finite handoff*

$$T, L, R \longmapsto S, J, B, A, O \longmapsto H, C, P, N.$$

The handoff supplies one residual-pair local-diamond witness to the critical-path and frontier readers. It does not discharge the parallel-diamond frontier, close arbitrary confluence, prove normalization, or erase the closed-substitution boundary.

Proof. Begin with an accepted consumer request. Carrier admission exposes the typed window T and the two residual rows L, R before a local-diamond read is available.

Read the middle rows next. The closed substitution row S binds the residual routes, the candidate join row J records the proposed common target, the bounded checker B checks the displayed routes, the real audit seal A records the finite budget, and the obstruction row O keeps the unclosed premises visible.

The structural rows H, C, P, N then carry the witness to the critical-path and frontier consumers. They preserve the local route without converting it into a global confluence theorem, a normalization theorem, or an unrestricted substitution result. □

Lean4 ✓ `BEDC.Derived.MetaCICParallelDiamondWitnessUp.MetaCICParallelDiamondWitnessHandoff`

Falsifiable prediction: An accepted $\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}$ consumer that cites metaciccriticalpath, metacicnormalizationcertificaterouter, metacic-parallel-diamond-frontier, closedtermsubstitution, or real without displaying $T, L, R, S, J, B, A, O, H, C, P, N$ refutes the witness carrier surface.

Independence witness: metaciccriticalpath, metacicnormalizationcertificaterouter, metacic-parallel-diamond-frontier, closedtermsubstitution, real: no listed sibling is bijective to $\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}$ because this packet jointly carries one typed local peak, two residual rows, closed substitution exposure, a candidate join, bounded checker budget, Real audit seal, obstruction retention, transport, replay, provenance, and local naming.

The Lean follow-up surface is `lean4/BEDC/Derived/MetaCICParallelDiamondWitnessUp/TasteGate.lean`; it must provide `Nontrivial MetaCICParallelDiamondWitnessUp` and `FieldFaithful MetaCICParallelDiamond` instances for the same carrier rows before any TasteGate claim is recorded.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}$ packet is generated from a typed MetaCIC window, two residual rows, a closed-term substitution row, a candidate local join, a bounded checker, a RealUp audit seal, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7042.1, Definition 7042.2, and Definition 7042.3 seed the finite residual-pair local-diamond witness consumed by MetaCIC confluence and normalization-router readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global confluence, arbitrary closed-term Church–Rosser, normalization for all closed terms, unrestricted substitution compatibility, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-pair routing, closed-substitution exposure, local-join accounting, bounded-checker accounting, Real audit sealing, obstruction retention, transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetaCICParallelDiamondWitnessU

Chapter 7043

A Concrete Naming Certificate for $\mathsf{MetrizableUniformity}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces induced by metrics, the $\mathsf{MetrizableUniformity}^{\uparrow}$ packet records the finite certificate by which a displayed $\mathsf{Met}^{\uparrow}$ row supplies the entourage basis of a $\mathsf{UniformSpace}^{\uparrow}$ row. It sits between the metric certificate of chapter 57, the uniform-space discipline of chapter 339, the entourage-basis surface of $\mathsf{EntourageBase}^{\uparrow}$, and the L10 tolerance route through chapter 291, chapter 126, chapter 301, and chapter 38. The packet names the metric-to-uniformity bridge as finite NameCert data; it does not assert an ambient topology theorem, quotient completion equality, selected radii beyond the displayed dyadic rows, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7043.1 (Metrizable uniformity carrier)**.** *A* $\mathsf{MetrizableUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, U, E, B, D, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, including the named distance comparison and triangle rows used by all later requests.*
2. *U is the target* $\mathsf{UniformSpace}^{\uparrow}$ *row whose entourages are read only through the displayed metric basis.*
3. *E is the* $\mathsf{EntourageBase}^{\uparrow}$ *row listing the metric-ball entourage predicates E_ε for the finite dyadic tolerances requested by the consumer.*
4. *B is the basis-refinement ledger: for each displayed tolerance request it records a smaller dyadic tolerance whose metric ball refines the requested entourage row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying positivity, halving, comparison, and addition data for the radii used by E and B.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which endpoint and tolerance observations are read before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
7. *H records componentwise* hsame *transport for metric, uniformity, entourage, dyadic, window, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a uniformity request through the metric-ball basis and the dyadic refinement ledger.*

9. *P is the* Pkg *provenance over* $\mathsf{MetrizableUniformity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetrizableUniformity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, U, E, B, D, W, H, C, P, N$. It has no coordinate for host topological equality, quotient completion equality, a selected infinite radius schedule, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7043.2 (Metrizable uniformity entourage basis)**.** *For every accepted* $\mathsf{MetrizableUniformity}^{\uparrow}$ *carrier*

$$K = (M, U, E, B, D, W, H, C, P, N),$$

the metric balls displayed by E generate the exported $\mathsf{UniformSpace}^{\uparrow}$ *entourage basis exactly through the dyadic tolerance rows in D and the refinement ledger B. A consumer that asks for a uniform entourage must first read the* $\mathsf{Met}^{\uparrow}$ *source row, choose one of the displayed dyadic tolerance rows, refine it through B, and replay the request through H, C, P, N before the* $\mathsf{UniformSpace}^{\uparrow}$ *row is exposed.*

Proof. Project the carrier of Definition 7043.1. The only analytic source row is M, and the only target uniformity row is U; the route between them is the displayed entourage basis E with dyadic bookkeeping D and refinement ledger B.

Read a requested entourage through D and B. Positivity and halving in $\mathsf{DyadicRatCore}^{\uparrow}$ supply the smaller tolerance, while the metric row supplies the ball relation used by E. Thus every displayed basis element is a metric-ball entourage and every requested basis refinement is recorded inside the packet.

The structural rows H, C, P, N then transport, replay, source, and name the same route. Since no host topology theorem, quotient completion equality, selected infinite schedule, countable-choice selector, or ambient completeness coordinate occurs in K, the exported uniformity basis is exactly the finite metric-ball basis named by the carrier. □

Theorem 7043.3 (Metrizable uniformity NameCert obligations)**.** *For the carrier of Definition 7043.1, the local* $\mathsf{NameCert}_{\mathsf{MetrizableUniformity}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source admission, uniform-target admission, entourage-basis admission, dyadic basis refinement, symmetry and triangle refinement through the displayed metric rows, finite-window routing through* $\mathsf{StreamName}^{\uparrow}$, *regular readback through* $\mathsf{RegSeqRat}^{\uparrow}$, *terminal sealing through* $\mathsf{Real}^{\uparrow}$, *componentwise transport, displayed replay, provenance, and local naming. The obligation surface exports no host uniformization theorem, quotient completion equality, selected representative, countable-choice selector, or ambient Real completeness principle.*

Proof. Carrier admission is tuple projection from Definition 7043.1. The metric and uniformity rows are M and U, while E, B, D provide the only basis and tolerance evidence.

Symmetry and triangle refinement are inherited only through the displayed metric rows of M. The dyadic ledger D supplies the smaller positive radii needed for refinement, and B records the exact basis step consumed by the uniformity request.

Finally W, H, C, P, N route finite observations, componentwise transport, replay, provenance, and local naming through the same packet, with $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ reached only along the L10 readback seal. The excluded host objects are absent from the carrier, so the listed families exhaust the NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{MetrizableUniformity}^{\uparrow}$ packet exposes a uniform entourage only after a displayed $\mathsf{Met}^{\uparrow}$ row, a dyadic tolerance row, an $\mathsf{EntourageBase}^{\uparrow}$ metric-ball row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming have been read.

Independence witness: metricspace, uniformspace, entouragebase, dyadicratcore, streamname, regseqrat, real: $\mathsf{MetrizableUniformity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the metric source, uniform target, metric-ball entourage basis, dyadic refinement ledger, finite window, transport, replay, provenance, and local NameCert rows as one finite bridge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetrizableUniformity}^{\uparrow}}$.

Constructive story: A $\mathsf{MetrizableUniformity}^{\uparrow}$ packet is generated from a MetricSpace row, a UniformSpace target row, an EntourageBase metric-ball basis, DyadicRatCore tolerance refinement, finite StreamName windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetrizableUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7043.1, Definition 7043.2, and Definition 7043.3 seed the finite metric-to-uniformity route over MetricSpace, UniformSpace, EntourageBase, DyadicRatCore, StreamName, RegSeqRat, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetrizableUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host topological equality, quotient completion equality, selected radius schedules, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, metric-source admission, uniform-target admission, entourage-basis refinement, symmetry and triangle refinement through metric rows, transport, replay, provenance, and local naming for BEDC.Derived.MetrizableUniformityUp.

Chapter 7044

A Concrete Naming Certificate for $\mathsf{CousinFiniteCover}^{\uparrow}$

Following Cousin and Bishop-style gauge integration, the $\mathsf{CousinFiniteCover}^{\uparrow}$ packet records the finite subcover extraction surface between the local gauge cover of chapter 3426 and the tagged-subdivision output of chapter 1861. It reuses the positive lower-bound control of chapter 452, the bisection rows of chapter 1711, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names finite extraction data only; it is not a synonym for the cover chapter, the lemma chapter, open-cover compactness, selected subcover choice, or host real completeness.

Definition 7044.1 (Cousin finite-cover carrier)**.** *A* $\mathsf{CousinFiniteCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, G, C, T, M, W, R, E, H, P, N)$$

with the following displayed rows:

1. *I is the located closed interval row.*
2. *G is the positive gauge row over I.*
3. *C is the finite gauge-cover row read from* $\mathsf{CousinCover}^{\uparrow}$*.*
4. *T is the finite tagged-subinterval extraction row consumed by* $\mathsf{CousinLemma}^{\uparrow}$*.*
5. *M is the mesh and adjacency ledger for the extracted finite cover cells.*
6. *W is the located bisection witness row, recording the finite search tree used when a displayed cell is refined.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational radii and mesh bounds.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint and radius comparisons.*
9. *H records componentwise* hsame *transport for interval, gauge, cover, tagged-cell, mesh, bisection, readback, Real-seal, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{CousinFiniteCover}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CousinFiniteCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, G, C, T, M, W, R, E, H, P, N$. It contains no open-cover compactness theorem, selected subcover oracle, quotient cover equality, ambient completeness assertion, or evidence-erased passage from local gauge data to a tagged partition.

Lean4 ✓ `BEDC.Derived.CousinFiniteCoverUp.CousinFiniteCoverTasteGate single carrier alignment`

Theorem 7044.2 (Cousin finite-cover NameCert obligations)**.** *For every accepted* $\mathsf{CousinFiniteCover}^{\uparrow}$ *carrier*

$$K = (I, G, C, T, M, W, R, E, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CousinFiniteCover}^{\uparrow}}$ *surface consists exactly of located interval admission, positive gauge admission, finite* $\mathsf{CousinCover}^{\uparrow}$ *cover exposure, finite tagged-cell extraction toward* $\mathsf{CousinLemma}^{\uparrow}$*, mesh and adjacency exactness, located bisection support,* $\mathsf{RegSeqRat}^{\uparrow}$ *radius readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay through the named rows,* Pkg *provenance, and local naming. No obligation is discharged by open-cover compactness, hidden subcover selection, quotient cover equality, host real completeness, or a direct lemma-level subdivision endpoint.*

Proof. Project the carrier of Definition 7044.1. The only visible analytic rows are I, G, C, T, M, W, R, E, followed by the structural rows H, P, N and displayed replay through the same packet.

The cover row C supplies the finite local cover data, while the extraction row T records the finite tagged cells that can be handed to $\mathsf{CousinLemma}^{\uparrow}$. The mesh ledger M and bisection row W keep the extraction finite and interval-local.

The readback and seal rows R, E attach rational radius comparisons and endpoint comparisons to the same packet. Transport, replay, provenance, and local naming then preserve the row order. Since the carrier has no coordinate for compactness, selected subcovers, quotient cover equality, host completeness, or a direct subdivision endpoint, the listed rows exhaust the NameCert surface. □

Theorem 7044.3 (Cousin finite-cover gauge-refinement route)**.** *Let* $K = (I, G, C, T, M, W, R, E, H, P, N)$ *be an accepted* $\mathsf{CousinFiniteCover}^{\uparrow}$ *carrier. Any consumer that refines a gauge cover toward a Cousin subdivision must expose the* $\mathsf{CousinCover}^{\uparrow}$ *cover row C, the finite bisection row W, the mesh and adjacency ledger M, the rational readback row R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and the tagged extraction row T before it may cite the* $\mathsf{CousinLemma}^{\uparrow}$ *handoff. The route exports a finite extraction packet and cannot replace it by open-cover compactness, an arbitrary dense real argument, host subcover choice, quotient cover equality, or ambient completeness.*

Proof. Start with the finite cover row C and the displayed gauge row G. These rows identify the local cover cells over the located interval I, but they do not by themselves export a tagged partition.

Use the bisection row W together with the mesh ledger M. The finite bisection search refines failed cells, records adjacency and mesh comparisons, and keeps each accepted cell attached to the same gauge row.

The rational readback R and Real seal E verify the radius and endpoint comparisons used by the refinement. The tagged extraction row T is therefore a finite handoff row rather than a selected cover family.

Finally replay the packet through H, P, N. Componentwise transport and provenance keep the consumer on the same I, G, C, T, M, W, R, E rows, so no compactness theorem, dense real argument, host selector, quotient cover equality, or ambient completeness coordinate is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{CousinFiniteCover}^{\uparrow}}$.

Constructive story: A $\mathsf{CousinFiniteCover}^{\uparrow}$ packet is generated from a located interval row, a positive gauge row, a CousinCover finite cover row, a tagged extraction row, mesh and bisection ledgers, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CousinFiniteCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7044.1, Definition 7044.2, and Definition 7044.3 seed the finite subcover extraction packet between CousinCoverUp and CousinLemmaUp over FiniteLebesgueNumberUp, LocatedIntervalBisectionUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CousinFiniteCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, hidden subcover selection, quotient cover equality, host real completeness, full CousinLemma verification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover exposure, finite extraction exactness, bisection support, mesh and radius readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CousinFiniteCoverU

Chapter 7045

A Concrete Naming Certificate for $\mathsf{PowerSeries}^{\uparrow}$

Following Hardy and Knopp on power series over the reals, the $\mathsf{PowerSeries}^{\uparrow}$ packet names the finite route by which coefficient data, a displayed radius, and Cauchy-controlled partial sums reach a real-facing value. It anchors the route in the real-name seal of chapter 38, the regular rational readback of chapter 301, the uniform tail discipline of chapter 1736, the criterion surface of chapter 2015, and the product-radius budget of **??**. The packet records only the displayed coefficient, radius, partial-sum, Cauchy-control, transport, replay, provenance, and local naming rows; it does not import a host analytic function, a selected infinite sum, quotient function equality, or ambient completeness.

Definition 7045.1 (Power-series NameCert carrier)**.** *A* $\mathsf{PowerSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, R, S, C, E, H, T, P, N)$$

with the following displayed rows:

1. *A is the coefficient stream row, exposing coefficients only through finite windows with their* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;*
2. *R is the radius ledger row, recording the displayed positive radius or local subradius used by the evaluation request;*
3. *S is the partial-sum stream row, naming the finite polynomial sums associated to the selected coefficient windows and argument row;*
4. *C is the Cauchy estimate row, giving the tail-control route used to accept the partial sums as a Cauchy stream;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from the accepted partial-sum stream;*
6. *H records componentwise* hsame *transport for coefficient, radius, partial-sum, Cauchy-control, real-seal, provenance, and local naming rows;*
7. *T records the displayed* Cont *replay by which a consumer reuses the same radius and partial-sum route;*
8. *P is the* Pkg *provenance over* $\mathsf{PowerSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchySeriesCriterion}^{\uparrow}$, $\mathsf{CauchyProductModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{PowerSeries}^\uparrow}$ *row.*

The classifier compares accepted carriers only through these nine rows. It has no coordinate for a host convergence theorem, analytic continuation, quotient function space, selected infinite sum, or ambient $\mathsf{Real}^\uparrow$ *completeness proof.*

Theorem 7045.2 (Power-series NameCert obligations)**.** *For an accepted* $\mathsf{PowerSeries}^\uparrow$ *carrier* $K = (A, R, S, C, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PowerSeries}^\uparrow}$ *surface consists exactly of carrier admission for the coefficient stream, displayed radius ledger, partial-sum stream, Cauchy estimate, terminal* $\mathsf{Real}^\uparrow$ *seal, componentwise transport, continuation replay, provenance, and local naming rows; exactness of the radius row used by the evaluation request; Cauchy control of the displayed partial-sum stream; handoff of the accepted stream to the* $\mathsf{Real}^\uparrow$ *seal; stability under* hsame *transport; replay through the same* Cont *route; and provenance over the named RegSeqRat, uniform Cauchy series, Cauchy-series criterion, and Cauchy-product modulus dependencies.*

Theorem 7045.3 (Power-series Cauchy-radius handoff)**.** *Every real-facing read from an accepted* $\mathsf{PowerSeries}^\uparrow$ *carrier* $K = (A, R, S, C, E, H, T, P, N)$ *factors through the displayed radius row* R *and the partial-sum Cauchy route* S, C *before the terminal* $\mathsf{Real}^\uparrow$ *seal* E *may be consumed. Thus the read is a finite BEDC route through* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{UniformCauchySeries}^\uparrow$*,* $\mathsf{CauchySeriesCriterion}^\uparrow$*,* $\mathsf{CauchyProductModulus}^\uparrow$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not a host power-series evaluation, selected infinite sum, analytic continuation, quotient function value, or ambient completeness theorem.*

Closure status for $\mathsf{NameCert}_{\mathsf{PowerSeries}^\uparrow}$**.**

Constructive story: A $\mathsf{PowerSeries}^\uparrow$ packet is generated from a coefficient stream, displayed radius ledger, partial-sum stream, Cauchy estimate, terminal Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PowerSeries}^\uparrow}$, seed)

Scope closed: Definition 7045.1, Definition 7045.2, and Definition 7045.3 seed the real-facing power-series route over RegSeqRat, uniform Cauchy series, Cauchy-series criterion, Cauchy-product modulus, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PowerSeries}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a standard bridge, host analytic continuation, selected infinite sums, quotient function equality, or ambient completeness.

Upgrade path: Obligation closure requires a Lean carrier and obligation package for the same coefficient, radius, partial-sum, Cauchy-estimate, Real-seal, transport, replay, provenance, and local NameCert route.

Chapter 7046

A Concrete Naming Certificate for $\mathsf{MengerCompactum}^{\uparrow}$

Following Menger's universal curve and compactum tradition, and the compact-metric dimension treatment in Engelking, the $\mathsf{MengerCompactum}^{\uparrow}$ packet records a finite compact-metric and covering-dimension naming surface. It sits after the metric carrier of chapter 57, the compact metric source of chapter 129, the covering-dimension row of chapter 1853, the finite metric entropy budget of $\mathsf{FiniteMetricEntropy}^{\uparrow}$, and the terminal real-name boundary of chapter 38. The packet names a displayed finite-cover compactum carrier for downstream compact-metric consumers; it does not import point-set topology primitives, arbitrary open-cover choice, quotient compacta, ambient Euclidean universality, or host completeness.

Definition 7046.1 (Menger compactum carrier)**.** *A* $\mathsf{MengerCompactum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, K, D, E, R, H, C, P, N)$$

with the following rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *carrier and distance classifier.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover compactness row.*
3. *D is the* $\mathsf{CoveringDimension}^{\uparrow}$ *row recording the displayed finite-order cover refinement boundary.*
4. *E is the* $\mathsf{FiniteMetricEntropy}^{\uparrow}$ *budget row for the finite net sizes attached to inspected radii.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *readback seal for the distance and radius data exposed by M, K, D, E.*
6. *H records componentwise* hsame *transport for the metric source, compactness row, covering-dimension row, entropy budget, Real readback, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through the finite compact-metric and dimension rows.*
8. *P is the* Pkg *provenance over* $\mathsf{MengerCompactum}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{FiniteMetricEntropy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MengerCompactum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, D, E, R, H, C, P, N$. It has no coordinate for an ambient topological space, a selected infinite cover, quotient compactness, Euclidean universality, countable choice, or host real completeness.

Theorem 7046.2 (Menger compactum NameCert obligations)**.** *For every accepted* $\mathsf{MengerCompactum}^{\uparrow}$ *carrier* $U = (M, K, D, E, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MengerCompactum}^{\uparrow}}$ *surface consists exactly of metric source exposure through* M*; compact metric finite-cover exposure through* K*; covering-dimension refinement exposure through* D*; finite metric entropy budget exposure through* E*; terminal Real readback through* R*; componentwise* hsame *transport through* H*; displayed* Cont *replay through* C*;* Pkg *provenance through* P*; and local naming through* N*.*

Proof. Project the accepted carrier of Definition 7046.1. The source rows M, K, D, E are the only rows that expose the compact-metric, finite-cover, covering-dimension, and finite-net budget data.

The readback row R is downstream of those displayed rows. It seals only the distance and radius data already exposed by the metric, compactness, dimension, and entropy surfaces.

Transport, replay, provenance, and local naming through H, C, P, N preserve that finite route. Since the carrier has no row for ambient topology, selected infinite covers, quotient compacta, Euclidean universality, countable choice, or host completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7046.3 (Menger compactum finite cover handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{CoveringDimension}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{FiniteMetricEntropy}^{\uparrow}$ *consumer of an accepted* $\mathsf{MengerCompactum}^{\uparrow}$ *packet must read the finite route*

$$M, K, D, E, R$$

in order: first the metric source, then the compact metric finite-cover row, then the covering-dimension refinement row, then the finite metric entropy budget, and finally the Real readback seal. No consumer can use the compactum as a point-set object without first exposing those finite certificate rows.

Proof. The metric source M supplies the carried distance interface, and the compact metric row K supplies the finite-cover compactness boundary. These two rows determine the compact-metric source seen by downstream consumers.

The covering-dimension row D refines the same finite-cover surface, while E records the finite net budget attached to inspected radii. Thus the dimension and entropy reads occur before the terminal Real seal is public.

Finally R, H, C, P, N read, transport, replay, source, and name that finite compactum route. The packet therefore exports no ambient point-set topology primitive, no arbitrary open-cover selector, no quotient compactum, no Euclidean universality theorem, and no host completeness claim. □

Falsifiable prediction: Every accepted $\mathsf{MengerCompactum}^{\uparrow}$ compact-metric, covering-dimension, Real, or finite-entropy consumer exposes the $\mathsf{Met}^{\uparrow}$ source, $\mathsf{CompactMetric}^{\uparrow}$ finite-cover row, $\mathsf{CoveringDimension}^{\uparrow}$ refinement row, $\mathsf{FiniteMetricEntropy}^{\uparrow}$ budget, $\mathsf{Real}^{\uparrow}$ readback seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before using the compactum.

Independence witness: metric, compactmetric, covering-dimension, finite-metric-entropy, real: $\mathsf{MengerCompactum}^{\uparrow}$ is not bijective to any listed sibling because this packet binds a metric source, compact metric finite-cover row, covering-dimension refinement row, finite metric entropy budget, Real readback seal, transport, replay, provenance, and local naming into one finite compactum certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MengerCompactum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MengerCompactum}^{\uparrow}$ packet is generated from a MetricUp source row, a CompactMetricUp finite-cover compactness row, a CoveringDimensionUp refinement row, a FiniteMetricEntropyUp budget row, a RealUp readback seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MengerCompactum}\uparrow}$, seed)

Scope closed: Definition 7046.1, Definition 7046.2, and Definition 7046.3 seed the finite compact-metric and covering-dimension route for compactum consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{MengerCompactum}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim point-set topology primitives, arbitrary open-cover compactness, quotient compacta, ambient Euclidean universality, countable choice, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact metric source exposure, covering-dimension refinement exposure, finite metric entropy budget exposure, Real readback, transport, replay, provenance, and local naming for BEDC.Derived.MengerCompactumUp.

Chapter 7047

A Concrete Naming Certificate for $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$

Following Banach and Bishop–Bridges, the $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$ packet records the finite endpoint-seal surface carried by a contraction orbit before any selected limit or quotient equality is read. It consumes the contraction theorem route of chapter 396, the iterate-window route of chapter 2359, the contraction data of chapter 3819, the completion admission rows of CompleteMetric packets, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the finite orbit-to-endpoint handoff only; it does not assert an ambient selected fixed point, quotient Cauchy equality, or host-level limit choice.

Definition 7047.1 (Cauchy fixed-point orbit-seal carrier)**.** *A* $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, F, O, M, E, R, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the contractive source row, read through* $\mathsf{BanachFixedPoint}^{\uparrow}$ *and the displayed* $\mathsf{ContractiveMap}^{\uparrow}$ *data.*
2. *F is the contraction map row, including the displayed contraction ledger and Lipschitz-bound witness used by the orbit.*
3. *O is the Picard iterate-window row inherited from* $\mathsf{PicardIteration}^{\uparrow}$*.*
4. *M is the Cauchy-modulus row for the displayed orbit windows.*
5. *E is the* $\mathsf{CompleteMetric}^{\uparrow}$ *endpoint-admission row for the Cauchy orbit.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the regular rational readback of endpoint approximants.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the endpoint comparison data.*
8. *H records componentwise* hsame *transport for the contraction, orbit, modulus, endpoint, readback, Real-seal, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay through the same finite packet.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$*,* $\mathsf{BanachFixedPoint}^{\uparrow}$*,* $\mathsf{PicardIteration}^{\uparrow}$*,* $\mathsf{ContractiveMap}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, F, O, M, E, R, S, H, C, P, N$. It contains no selected fixed point, no quotient equality of Cauchy orbits, no ambient completeness oracle, and no hidden route from contraction data to a Real endpoint.

Theorem 7047.2 (Cauchy fixed-point orbit-seal NameCert obligations)**.** *For every accepted* CauchyFixedPointOrbit *carrier*

$$K = (B, F, O, M, E, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}}$ *surface consists exactly of contractive-source admission, contraction-map exposure, Picard iterate-window exposure, Cauchy-modulus exactness,* $\mathsf{CompleteMetric}^{\uparrow}$ *endpoint admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read an endpoint seal only after all those rows are displayed in the same packet.*

Proof. Project the carrier of Definition 7047.1. The analytic rows are B, F, O, M, E, R, S, and the structural rows are H, C, P, N.

The contraction and Picard rows B, F, O supply the finite orbit source. The modulus row M records the Cauchy rate, while E admits the orbit to the completion-facing endpoint route.

The readback and seal rows R, S turn endpoint approximants into regular rational and Real-facing data. Transport, replay, provenance, and local naming then preserve the same row order. Since the carrier has no further coordinate, the listed obligations exhaust the NameCert surface. □

Theorem 7047.3 (Cauchy fixed-point orbit-seal completion handoff)**.** *Every endpoint read from an accepted* $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$ *packet factors through the route*

$$\mathsf{BanachFixedPoint}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{ContractiveMap}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route exposes the contractive source, finite Picard windows, Cauchy modulus, completion admission, regular rational readback, and Real seal as separate rows. It cannot replace those rows by a selected limit, quotient Cauchy equality, ambient host completeness, or an unrecorded fixed-point oracle.

Proof. Start with the accepted carrier $K = (B, F, O, M, E, R, S, H, C, P, N)$. The only contraction-facing rows are B and F, and the only orbit-facing row is the displayed Picard window O.

Use the Cauchy-modulus row M to pass from finite orbit windows to the completion-facing admission row E. This keeps the endpoint request attached to the same contraction and iterate data.

The completion handoff then passes through R and S. The regular rational readback records endpoint approximants before the terminal Real seal is consumed.

Finally replay the packet through H, C, P, N. Componentwise transport and provenance keep the consumer on the same finite route, so no selected limit, quotient equality, host completeness oracle, or hidden fixed-point coordinate is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$ packet is generated from contractive source data, Picard iterate windows, a Cauchy modulus, CompleteMetric endpoint admission, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}}$, seed)

Scope closed: Definition 7047.1, Definition 7047.2, and Definition 7047.3 seed the finite contraction-orbit endpoint handoff through BanachFixedPointUp, PicardIterationUp, ContractiveMapUp, CompleteMetricUp, RegSeqRatUp, RealUp, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected fixed points, quotient Cauchy orbit equality, ambient host completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction exposure, Picard-window compatibility, Cauchy-modulus exactness, CompleteMetric endpoint admission, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFixedPointOrbitSealUp.

Chapter 7048

A Concrete Naming Certificate for $\mathsf{FiniteProductUniformModulus}^{\uparrow}$

Following Kelley and Bishop–Bridges on finite product compactness and uniform continuity, the $\mathsf{FiniteProductUniformModulus}^{\uparrow}$ packet records the finite product-level route from coordinate local moduli to a tolerance-only uniform-modulus handoff. It consumes the finite product compactness routes of **??** and chapter 1822, the compact metric source of chapter 129, the continuous-map source of chapter 130, and the target uniform-modulus surface of chapter 369. The packet names finite product modulus data only; it does not assert arbitrary product compactness, selected Lebesgue numbers, quotient function equality, or an external modulus selector.

Definition 7048.1 (Finite product uniform-modulus carrier)**.** *A* $\mathsf{FiniteProductUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, C, M, F, L, D, R, E, U, H, P, N)$$

with the following displayed rows:

1. *T is the finite product compactness row read through* $\mathsf{TychonoffFiniteProduct}^{\uparrow}$*.*
2. *C is the compact metric product row read through* $\mathsf{CompactMetricProduct}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$*.*
3. *M is the* $\mathsf{ProductMetric}^{\uparrow}$ *triangle-routing row for product distances and projections.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *source row exposing coordinate local-modulus data.*
5. *L is the coordinate modulus exposure row, listing the finitely many local coordinate tolerances inspected by the product route.*
6. *D is the Rat and Dyadic lower-bound folding row that turns the finite coordinate list into one product tolerance.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for folded tolerances and product-distance comparisons.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the product estimate.*
9. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *export row.*
10. *H records componentwise* hsame *transport for the product, compactness, metric, map, fold, readback, Real-seal, export, provenance, and local naming rows.*

11. *P is the* Pkg *provenance over* $\mathsf{FiniteProductUniformModulus}^{\uparrow}$, $\mathsf{TychonoffFiniteProduct}^{\uparrow}$, $\mathsf{CompactMetricProduct}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteProductUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, C, M, F, L, D, R, E, U, H, P, N$. It has no coordinate for arbitrary products, selected finite nets, hidden compactness, quotient maps, or host-level modulus choice.

Theorem 7048.2 (Finite product uniform-modulus NameCert obligations)**.** *For every accepted* $\mathsf{FiniteProductUniformModulus}^{\uparrow}$ *carrier*

$$K = (T, C, M, F, L, D, R, E, U, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteProductUniformModulus}^{\uparrow}}$ *surface consists exactly of finite product compactness admission, compact metric product exposure, product-metric triangle routing, continuous-map coordinate modulus exposure, finite coordinate lower-bound folding through Rat and Dyadic tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing,* $\mathsf{UniformModulus}^{\uparrow}$ *export, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7048.1. The product and compactness rows T, C, M expose the finite product source and its metric route.

The continuous-map and coordinate modulus rows F, L provide the local tolerance data. The fold row D is the only row that combines the finitely many coordinate lower bounds into one product tolerance.

The readback, Real seal, and export rows R, E, U then present the tolerance-only uniform-modulus handoff. Transport, replay, provenance, and local naming preserve the same packet, and the carrier has no hidden coordinate for the excluded product or choice principles. □

Theorem 7048.3 (Finite product uniform-modulus export)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteProductUniformModulus}^{\uparrow}$ *packet reads the product modulus through the route*

$$\mathsf{TychonoffFiniteProduct}^{\uparrow},\ \mathsf{CompactMetricProduct}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{ProductMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow}$$

Coordinate local moduli remain visible until the Rat and Dyadic lower-bound fold has produced the product tolerance; the product-metric triangle row remains visible until the Real-sealed estimate is exported. No consumer may replace this route by arbitrary product compactness, a selected finite-net oracle, quotient function equality, or an external modulus selector.

Proof. Start with the finite product compactness rows T and C. They expose a finite compact product route and do not supply an arbitrary product theorem.

Use the product-metric row M together with the continuous-map row F. Projection and triangle reads are kept visible while the coordinate local moduli are inspected through L.

Fold the coordinate tolerances through D and read the resulting comparisons through R and E. This produces one product tolerance inside the same finite packet.

Finally export through U, H, P, N. The $\mathsf{UniformModulus}^{\uparrow}$ row is therefore a handoff from displayed product, compactness, coordinate-modulus, lower-bound, readback, Real-seal, transport, replay, provenance, and naming rows, not an external selector. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteProductUniformModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteProductUniformModulus}^{\uparrow}$ packet is generated from finite product compactness, compact metric product, product-metric triangle routing, continuous-map coordinate modulus rows, Rat and Dyadic lower-bound folding, RegSeqRat readback, a Real seal, UniformModulus export, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteProductUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7048.1, Definition 7048.2, and Definition 7048.3 seed the finite product uniform-modulus packet over TychonoffFiniteProductUp, CompactMetricProductUp, CompactMetricUp, ProductMetricUp, ContinuousMapUp, RegSeqRatUp, RealUp, UniformModulusUp, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteProductUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary product compactness, selected finite nets, quotient function equality, external modulus selection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite product compactness exposure, compact metric product routing, coordinate local-modulus exposure, lower-bound fold exactness, RegSeqRat readback, Real sealing, UniformModulus export, transport, replay, provenance, and local naming for BEDC.Derived.FiniteProductUniformModulusUp.

Chapter 7049

A Concrete Naming Certificate for $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$

Following Bishop and Bridges on total boundedness in constructive metric spaces, the $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$ packet records the finite-net bridge needed by completion-facing consumers. It sits after the metric carrier of chapter 57, the metric-space surface of chapter 4230, the finite-net row of chapter 1767, the dyadic tolerance source of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a metric-space-specific total-bounded handoff without treating total boundedness as a free abstract parameter and without importing open-cover compactness, quotient point equality, selected centers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7049.1 (MetricSpaceTotalBounded carrier)**.** *A* $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, S, B, E, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row for the source under inspection.*
2. *S is the* $\mathsf{Met}^{\uparrow}$ *carrier row, recording the point surface on which the distance row is read.*
3. *B is the* $\mathsf{TotallyBounded}^{\uparrow}$ *budget row, displayed as finite requests rather than as an ambient compactness principle.*
4. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row, naming the centers and cover checks actually consumed at the requested precision.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to read the positive precision and comparison cells.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular-rational precision data downstream from D.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the metric, total-bounded, finite-net, dyadic, and regular-rational rows have been displayed.*
8. *H records componentwise* hsame *transport for $M, S, B, E, D, R, L, C, P, N$.*
9. *C records displayed* Cont *replay from a finite precision request through the same rows.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{MetricSpaceTotalBounded}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, S, B, E, D, R, L, H, C, P, N$. It has no coordinate for open-cover compactness, quotient point equality, selected centers outside E, countable choice, host compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7049.2 (MetricSpaceTotalBounded NameCert obligations)**.** *For every accepted* MetricSpaceTotalBounde *carrier*

$$T = (M, S, B, E, D, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricSpaceTotalBounded}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric row, metric-space source, total-bounded budget, finite-epsilon-net row, dyadic tolerance ledger, regular-rational readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The finite-net exactness clause requires every cover read to expose E under the precision named by D and R. The metric-source clause requires M and S to be consumed before any total-bounded budget is read. The non-escape clause refuses open-cover compactness, quotient point equality, selected centers outside the displayed net, countable choice, host compactness, and ambient Real completeness.*

Proof. Project the carrier of Definition 7049.1. The rows $M, S, B, E, D, R, L, H, C, P, N$ are the complete visible inventory of the accepted packet.

Metric-source exposure is the first projection step. A consumer receives the distance row M only together with the metric-space source row S, so the total-bounded budget cannot be read as an untyped external predicate.

Finite-net exactness is the next projection step. The budget row B reaches a concrete finite net only through E, and the positive precision is read through the dyadic row D and regular-rational row R before any Real seal L is available.

Transport, replay, provenance, and local naming preserve the same route. Since the carrier contains no coordinate for open-cover compactness, quotient point equality, selected centers outside the finite net, countable choice, host compactness, or ambient Real completeness, none of those data can be exported by the local NameCert surface. □

Theorem 7049.3 (MetricSpaceTotalBounded finite-net handoff)**.** *Every compact-metric or completion-facing consumer of an accepted* $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$ *carrier reaches finite total-bounded data only through the displayed route*

$$M, S, B, E, D, R, L, H, C, P, N.$$

In particular, the consumer receives a metric-space-specific finite-net handoff: the $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row E is read under the* $\mathsf{Met}^{\uparrow}$ *row M,* $\mathsf{Met}^{\uparrow}$ *row S,* $\mathsf{TotallyBounded}^{\uparrow}$ *budget B,* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row D, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal L may be consumed.*

Proof. Begin with the obligation surface of Definition 7049.2. It places the metric and metric-space rows before the total-bounded budget and finite-net rows.

Read the finite net through E. The centers and cover checks are visible only at the displayed precision, so the dyadic and regular-rational rows D and R remain upstream of the terminal Real seal.

Finally use the structural rows H, C, P, N. They replay the same finite route for compact-metric and completion-facing consumers and do not add open-cover compactness, quotient point equality, a selected center outside E, countable choice, host compactness, or ambient completeness. The handoff is therefore the concrete finite-net surface over the named metric space. □

Falsifiable prediction: Every accepted $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$ read is refuted if it reaches a finite-net, compact-metric, or completion-facing consumer without displaying the metric row, metric-space source row, total-bounded budget, finite-epsilon-net row, dyadic tolerance row, regular-rational readback row, Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: metric, metric-space, total-bounded, finite-epsilon-net, dyadicratcore, regseqrat, real: $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric-space source, a total-bounded budget, a finite-net row, dyadic and regular-rational precision rows, a Real seal, transport, replay, provenance, and local naming as one finite handoff packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricSpaceTotalBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricSpaceTotalBounded}^{\uparrow}$ packet is generated from a metric row, metric-space source row, total-bounded budget, finite-epsilon-net row, dyadic tolerance row, regular-rational readback row, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricSpaceTotalBounded}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7049.1, Definition 7049.2, and Definition 7049.3 seed the metric-space finite-net route over total-bounded, dyadic, regular-rational, and Real-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricSpaceTotalBounded}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient point equality, selected centers outside the displayed net, countable choice, host compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked metric-source admission, total-bounded budget exactness, finite-net handoff, dyadic and regular-rational precision nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricSpaceTo

Chapter 7050

A Concrete Naming Certificate for $\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}$ packet records a finite choice-sequence observation only through the located window currently displayed to a construction. It refines the finite-prefix carrier of chapter 1482 by requiring a located readback route through chapter 126, chapter 301, chapter 38, chapter 3857, and chapter 6030. The packet supports finite-window Real and completion arguments while refusing countable-choice, selected-tail, quotient-equality, and ambient-completeness coordinates.

Definition 7050.1 (Located finite choice-sequence carrier)**.** *A* $\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite choice index row, naming the inspected choice-sequence positions and no tail positions outside the packet.*
2. *W is the located window row, recording the finite located interval, ball, or tolerance window attached to the indices of I.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the same finite choice-index and located-window data.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed* $\mathsf{StreamName}^{\uparrow}$ *window and located tolerance data.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback has been displayed.*
6. *H records componentwise* hsame *transport for the finite choice index, located window,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for the finite route*

$$I, W \longmapsto S \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{LocatedSequence}^{\uparrow}$, $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}}$ *row.*

The classifier accepts only packets whose finite choice index, located window, stream window, regular rational readback, and real seal describe one displayed finite route. It exports no countable-choice functional, no selected infinite sequence, no quotient real equality, no host real equality, and no $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Theorem 7050.2 (Located finite choice-sequence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}$ *carrier* $L = (I, W, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}}$ *surface consists exactly of finite choice-index admission through* I*, located-window admission through* W*,* $\mathsf{StreamName}^{\uparrow}$ *window exposure through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Every consumer from the finite-window Real route or a completion-facing route must read those rows in the displayed order

$$\mathsf{ChoiceSequence}^{\uparrow},\ \mathsf{LocatedSequence}^{\uparrow},\ \mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow} \longmapsto I, W \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSe}$$

The packet exports no countable-choice functional, selected infinite sequence, quotient real equality, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7050.1. The rows I and W are finite displayed rows, so the choice-sequence input is visible only at the named inspected positions and only through the located window recorded in the packet.

The stream and analytic readback rows are downstream of that finite surface. The row S opens the $\mathsf{StreamName}^{\uparrow}$ window from I, W, the row R repacks the same displayed window as $\mathsf{RegSeqRat}^{\uparrow}$ data, and the row E seals only that readback as $\mathsf{Real}^{\uparrow}$ data.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. They do not add a new analytic coordinate; they keep the finite choice index, located window, stream window, regular rational readback, and real seal in one packet.

The sibling chapters supply the boundary discipline. chapter 3857 fixes the located-window route, and chapter 6030 fixes the finite choice-sequence modulus route into $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Since the carrier has no coordinate for a countable-choice functional, a selected infinite sequence, quotient real equality, host real equality, or ambient real completeness, no local $\mathsf{NameCert}_{\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}}$ consumer can export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}$ packet is generated from a finite choice index, located window, StreamName window, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7050.1 and Definition 7050.2 seed the finite located choice-sequence surface for Real and completion finite-window consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedFiniteChoiceSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected infinite sequences, quotient real equality, host real equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window stability, StreamName exposure, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedFiniteChoiceSequenceUp

Chapter 7051

A Concrete Naming Certificate for $\mathsf{RationalBallBasis}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalBallBasis}^{\uparrow}$ packet records the finite rational centre-radius basis used before a metric completion or Real-facing consumer reads a regular Cauchy name. It sits between the rational carrier of chapter 37, the dyadic tolerance surface of chapter 291, the metric test interface of chapter 57, the regular rational handoff of chapter 301, and the terminal seal of chapter 38. The packet is a finite rational-ball basis; it is not a host open-ball family, a quotient completion point, a selected limit, a countable-choice basis, or an ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 7051.1 (Rational ball basis carrier)**.** *A* $\mathsf{RationalBallBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (C, R, D, M, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the centre row, naming a finite list of* $\mathsf{Rat}^{\uparrow}$ *centres.*
2. *R is the positive rational radius row attached to those centres.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare a requested precision with the rational radius data.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *distance-test row, reading only centre-radius comparisons displayed by C, R, D.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the same rational-ball tests.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular handoff has been displayed.*
7. *H records componentwise* hsame *transport for centres, radii, dyadic tolerances, metric tests, regular handoff, Real seal, continuation, provenance, and local naming rows.*
8. *T records displayed* Cont *replay from a rational-ball request through C, R, D, M, Q, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RationalBallBasis}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalBallBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, R, D, M, Q, E, H, T, P, N$. It has no coordinate for host open balls, selected subbases, quotient completion points, chosen limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7051.2 (Rational ball basis NameCert obligations)**.** *For every accepted* $\mathsf{RationalBallBasis}^{\uparrow}$ *carrier* $B = (C, R, D, M, Q, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RationalBallBasis}^{\uparrow}}$ *surface consists exactly of carrier admission, centre exposure, positive-radius exposure, dyadic tolerance exactness, metric distance-test factorization, regular rational handoff, Real seal nonescape, componentwise transport, continuation replay, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7051.1. The centre row C and positive radius row R display the rational balls being inspected, and the dyadic tolerance row D supplies the finite precision comparison used by those balls.

The metric row M reads only the displayed centre-radius-tolerance data. The regular handoff Q is therefore reached through the same finite distance tests, and the Real seal E is downstream of Q.

The structural rows H, T, P, N preserve, replay, source, and name that route. Since the excluded objects are absent from the carrier inventory, no additional NameCert obligation can expose host open balls, selected subbases, quotient completion points, chosen limits, countable choice, or ambient Real completeness. □

Theorem 7051.3 (Rational ball basis regular Cauchy handoff)**.** *Every metric-completion, Real-separability, or finite-cover consumer of an accepted* $\mathsf{RationalBallBasis}^{\uparrow}$ *carrier reaches its regular Cauchy data only through the displayed route*

$$\mathsf{Rat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside the carrier rows $C, R, D, M, Q, E, H, T, P, N$*. The exported basis supplies rational centres, positive rational radii, dyadic tolerances, metric distance tests, a regular rational handoff, and a Real seal, but it supplies no arbitrary open-ball basis, quotient completion point, selected real point, countable-choice enumeration, or ambient compactness principle.*

Proof. Project the accepted carrier and read the rational-ball rows C, R, D. These rows bind the centres, positive radii, and dyadic tolerances before any metric consumer can inspect the packet.

Next use the metric test row M. It factors every distance read through the displayed rational data, so the regular handoff Q receives only centre-radius tests already present in the carrier.

Finally consume the Real seal E through the same handoff and structural rows. The transport, replay, provenance, and local naming rows keep the route attached to the displayed rational-ball packet, so completion, separability, and finite-cover consumers obtain the finite basis rather than any of the excluded host principles. □

Falsifiable prediction: Every $\mathsf{RationalBallBasis}^{\uparrow}$ metric-completion, Real-separability, or finite-cover read factors through rational centres, positive rational radii, a DyadicRatCore tolerance row, a MetricUp distance-test row, RegSeqRat handoff, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: rat, dyadicratcore, metric, regseqrat, real: $\mathsf{RationalBallBasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rational centres, positive rational radii, dyadic tolerances, metric distance tests, regular handoff, Real seal, transport, replay, provenance, and local naming as one finite basis packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalBallBasis}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalBallBasis}^{\uparrow}$ packet is generated from RatUp centres, positive rational radii, a DyadicRatCore tolerance row, MetricUp distance tests, RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RationalBallBasis}\uparrow}$, seed)

Scope closed: Definition 7051.1, Definition 7051.2, and Definition 7051.3 seed the finite rational-ball route consumed by completion, separability, and finite-cover reads.

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalBallBasis}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary open-ball bases, quotient completion points, selected real points, countable-choice enumerations, ambient compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked centre exposure, positive-radius exposure, dyadic tolerance exactness, metric distance-test factorization, regular handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RationalBallBasisUp.

Chapter 7052

A Concrete Naming Certificate for $\mathsf{CatZeroProjection}^{\uparrow}$

Following Bridson–Haefliger on complete CAT(0) spaces and Bacak on projection methods in Hadamard geometry, the $\mathsf{CatZeroProjection}^{\uparrow}$ packet records the finite BEDC surface for projecting a displayed point onto a displayed closed convex subset of a complete CAT(0) carrier. It sits after the CAT(0) comparison packet of chapter 6336, the Hadamard-space carrier of chapter 6734, the convex-set rows of chapter 208, the existing projection endpoint surface of chapter 2356, the complete-metric service of chapter 128, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the closest-point route as finite NameCert data; it does not import a host projection map, selected minimizer, quotient point equality, Hilbert embedding, local compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7052.1 (CatZeroProjection carrier)**.** *A* $\mathsf{CatZeroProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (Z, H, V, M, C, R, A, T, K, P, N)$$

with the following displayed rows:

1. *Z is the* $\mathsf{CATZeroMetric}^{\uparrow}$ *comparison row, carrying the finite nonpositive-curvature inequality ledger read before projection convexity is used.*
2. *H is the* $\mathsf{HadamardSpace}^{\uparrow}$ *complete geodesic source row over the same displayed metric carrier.*
3. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row naming the closed convex target subset and its admitted geodesic-combination reads.*
4. *M is the* $\mathsf{MetricProjection}^{\uparrow}$ *endpoint row, recording the closest-point candidate only after the source point, convex target, and distance ledger have been displayed.*
5. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used by minimizing-window and Cauchy-readback consumers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for finite distance budgets and approximation windows.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row for distance values, squared-distance comparisons, and endpoint-error budgets.*
8. *T records componentwise* hsame *transport for $Z, H, V, M, C, R, A, P, N$.*
9. *K records displayed* Cont *replay from CAT(0) comparison and convexity rows through the projection endpoint, complete-metric service, rational readback, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CatZeroProjection}^{\uparrow}$, $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{HadamardSpace}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CatZeroProjection}^{\uparrow}}$ *row.*

The classifier compares accepted projection packets only through these rows. It has no coordinate for a host nearest-point map, selected minimizer, quotient point equality, Hilbert-space replacement, local compactness, or ambient real completeness.

Theorem 7052.2 (CatZeroProjection NameCert obligations)**.** *For every accepted* $\mathsf{CatZeroProjection}^{\uparrow}$ *carrier*

$$Q = (Z, H, V, M, C, R, A, T, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CatZeroProjection}^{\uparrow}}$ *surface consists exactly of carrier admission for the CAT(0) comparison row Z, Hadamard source row H, convex target row V, metric-projection endpoint row M, complete-metric service row C, regular rational readback R, Real seal A, componentwise transport T, displayed replay K, provenance P, and local naming N. Every projection-facing consumer must first display the CAT(0) and Hadamard rows, then the convex target, then the projection endpoint and completion/readback rows, before the local naming row is available.*

Proof. Project the carrier of Definition 7052.1. Its geometric source data are exactly Z, H, V: the CAT(0) comparison row, the complete geodesic Hadamard row, and the closed convex target row.

The endpoint stage is M, C, R, A. The projection endpoint is read only through the existing $\mathsf{MetricProjection}^{\uparrow}$ surface, while complete-metric service, regular rational readback, and the terminal Real seal expose the finite approximation and distance-budget rows needed by projection consumers.

Finally T, K, P, N transport, replay, source, and name the same displayed route. Since no other carrier coordinate exists, the local NameCert surface cannot export a host projection map, selected minimizer, quotient equality, Hilbert embedding, local compactness, or ambient real-completeness theorem. □

Theorem 7052.3 (CatZeroProjection nonescape)**.** *Every convex-projection or completion-facing read exported by an accepted* $\mathsf{CatZeroProjection}^{\uparrow}$ *packet factors through*

$\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{HadamardSpace}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hs

The read exposes a displayed CAT(0) closest-point route and no host nearest-point selector, quotient point equality, selected minimizing sequence, Hilbert-space embedding, local compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 7052.2. Any consumer must first read the CAT(0) comparison row Z, Hadamard source row H, and convex target row V before it can inspect the projection endpoint row M.

The endpoint row is then routed through completion and readback data. The rows C, R, A keep the minimizing-window and distance-budget evidence inside displayed complete-metric, regular-rational, and Real-seal surfaces.

Transport, replay, provenance, and local naming are restricted to T, K, P, N. Therefore every exported projection read remains inside the finite route listed above, and the excluded host selector, quotient equality, chosen minimizing sequence, Hilbert embedding, local compactness, and ambient-completeness data have no projection from the packet. □

Falsifiable prediction: Every accepted $\mathsf{CatZeroProjection}^{\uparrow}$ consumer that reaches a closest-point or completion-facing projection read while omitting the CAT(0) comparison row, Hadamard source row, convex target row, MetricProjection endpoint row, complete-metric service, regular rational readback, Real seal, transport, replay, provenance, or local naming refutes the packet.

Independence witness: cat-zero-metric, hadamard-space, convexset, metricprojection, completemetric, regseqrat, real: $\mathsf{CatZeroProjection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries CAT(0) comparison, complete geodesic source, convex target, projection endpoint, completion service, rational readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CatZeroProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CatZeroProjection}^{\uparrow}$ packet is generated from CatZeroMetric comparison rows, HadamardSpace complete geodesic rows, ConvexSet target rows, MetricProjection endpoint rows, CompleteMetric service rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CatZeroProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7052.1, Definition 7052.2, and Definition 7052.3 seed the finite CAT(0) closest-point projection route from displayed comparison and convexity data through completion, rational readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CatZeroProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host projection map, selected minimizer, quotient point equality, Hilbert embedding, local compactness, Lean verification, standard bridge closure, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, CAT(0) comparison exposure, Hadamard source exposure, convex target routing, MetricProjection endpoint admission, completion/readback exactness, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CatZeroProjectionUp.

Chapter 7053

A Concrete Naming Certificate for $\mathsf{EuclideanDomain}^{\uparrow}$

Following Bourbaki and Lang, the $\mathsf{EuclideanDomain}^{\uparrow}$ packet records the traditional division-with-remainder interface as finite BEDC NameCert data over a displayed ring carrier. It sits after the algebraic operation rows of chapter 43, the ideal membership and absorption surface of chapter 81, and the Euclidean backtracking witness of chapter 6993. The packet names the carrier, the divisor admissibility row, the Euclidean measure row, the quotient and remainder rows, the strict descent check, transport, replay, provenance, and local naming; it does not import a principal-ideal theorem, a selected gcd normalization, host quotient equality, Noetherian induction, or a classical field-of-fractions argument.

Definition 7053.1 (Euclidean domain carrier)**.** *A* $\mathsf{EuclideanDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, D, \nu, Q, M, I, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the consumed* $\mathsf{Ring}^{\uparrow}$ *row, naming the carrier, zero, one, addition, additive inverse, multiplication, and classifier used by the division read.*
2. *D is the nonzero-divisor admissibility row, recording that division requests are made only for displayed divisors outside the zero row.*
3. *ν is the Euclidean measure row, read as a value in a displayed well-founded comparison ledger.*
4. *Q is the quotient row for a requested pair (a, b) with b admitted by D.*
5. *M is the remainder row for the same request.*
6. *I is the* $\mathsf{Ideal}^{\uparrow}$ *dependency row, exposing the ring-indexed membership and absorption surface consumed by ideal-facing consequences.*
7. *B is the* $\mathsf{BezoutIdentity}^{\uparrow}$ *backtracking row reached by iterating the displayed descent trace.*
8. *H records componentwise* hsame *transport for $R, D, \nu, Q, M, I, B, C, P, N$.*
9. *C records displayed* Cont *replay from a division request through the quotient, remainder, descent, ideal, and Bezout rows.*
10. *P is the* Pkg *provenance over* $\mathsf{EuclideanDomain}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, $\mathsf{BezoutIdentity}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EuclideanDomain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host quotient equality, selected gcd normalization, a principal-ideal theorem, Noetherian induction, field-of-fractions construction, or ambient classical Euclidean-domain schema.

Theorem 7053.2 (Euclidean domain NameCert obligations)**.** *For every accepted* $\mathsf{EuclideanDomain}^{\uparrow}$ *carrier*

$$E = (R, D, \nu, Q, M, I, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EuclideanDomain}^{\uparrow}}$ *surface consists exactly of ring-source admission, nonzero-divisor admission, Euclidean-measure exposure, quotient-row exposure, remainder-row exposure, strict descent for nonzero remainders, ideal dependency exposure, Bezout backtracking exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every division read must expose $R, D, \nu, Q, M, I, B, H, C, P, N$ before any ideal-facing or Bezout-facing consumer can use the packet.*

Proof. Project the carrier of Definition 7053.1. The rows $R, D, \nu, Q, M, I, B, H, C, P, N$ are the complete visible inventory, so the ring operations and classifier are read through the consumed $\mathsf{Ring}^{\uparrow}$ surface before any division request is admitted.

For a request with divisor admitted by D, the quotient row Q and remainder row M are displayed together. The Euclidean measure row ν supplies the comparison ledger used to state that a nonzero remainder descends below the divisor.

The ideal and Bezout rows are dependency surfaces, not consequences imported from outside the packet. The $\mathsf{Ideal}^{\uparrow}$ row I exposes membership and absorption data over the same ring source, while the $\mathsf{BezoutIdentity}^{\uparrow}$ row B records the finite backtracking route reached by iterating the displayed descent.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no row names host quotient equality, selected gcd normalization, a principal-ideal theorem, Noetherian induction, a field of fractions, or an ambient classical schema, none of those objects belongs to the local NameCert surface. □

Theorem 7053.3 (Euclidean domain division descent)**.** *Every accepted* $\mathsf{EuclideanDomain}^{\uparrow}$ *carrier exposes division with remainder as the finite route*

$$R, D, \nu, Q, M \longmapsto I, B, H, C, P, N.$$

For each admitted divisor request, the quotient and remainder rows are read under the ring classifier from R; if the remainder is not the displayed zero row, the measure row ν records a strict descent comparison for that remainder. Iterating only these displayed descent rows may feed the Bezout backtracking row B and the ideal dependency row I.

Proof. Start with a division request admitted by D. The ring row R supplies the operations and classifier used to read the requested dividend, divisor, quotient, and remainder.

The quotient and remainder are the rows Q and M. The measure row ν is the only row that compares a nonzero remainder with its divisor, so descent cannot be replaced by a host termination argument or by an external Euclidean algorithm.

The iteration route is then confined to the displayed packet. The Bezout-facing row B may be read only after the descent trace is visible, and the ideal-facing row I may be read only as an $\mathsf{Ideal}^{\uparrow}$ dependency over the same ring row.

Transport and replay through H and C, with provenance and naming from P and N, preserve this finite route. Therefore the division-descent surface exports division data and its finite downstream dependencies without exporting host quotient equality, selected gcd normalization, a principal-ideal theorem, Noetherian induction, or field-of-fractions reasoning. □

Falsifiable prediction: Every accepted $\mathsf{EuclideanDomain}^{\uparrow}$ read is refuted if it reaches a division, ideal-facing, or Bezout-facing consumer without displaying the ring row, nonzero-divisor admission row, Euclidean measure row, quotient row, remainder row, ideal dependency row, Bezout backtracking row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: ring, ideal, bezout-identity: $\mathsf{EuclideanDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a ring source, a nonzero-divisor admission row, a Euclidean measure, quotient and remainder rows, ideal dependency rows, Bezout backtracking, transport, replay, provenance, and local naming as one finite division-with-remainder packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EuclideanDomain}^{\uparrow}}$.

Constructive story: A $\mathsf{EuclideanDomain}^{\uparrow}$ packet is generated from a ring row, nonzero-divisor admission row, Euclidean measure row, quotient row, remainder row, ideal dependency row, Bezout backtracking row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EuclideanDomain}^{\uparrow}}$, seed)

Scope closed: Definition 7053.1, Definition 7053.2, and Definition 7053.3 seed the finite division-with-remainder route over RingUp, IdealUp, and BezoutIdentityUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EuclideanDomain}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close principal ideal generation, unique gcd normalization, host quotient equality, Noetherian induction, field-of-fractions construction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked division admission, quotient and remainder exactness, strict descent, ideal dependency exposure, Bezout backtracking, transport, replay, provenance, and local naming for BEDC.Derived.EuclideanDomainUp

Chapter 7054

A Concrete Naming Certificate for $\mathsf{ConstantRealStream}^{\uparrow}$

Following Bishop and Bridges on real numbers as regular Cauchy data, the $\mathsf{ConstantRealStream}^{\uparrow}$ packet records the constant certified point stream generated by one finite rational or dyadic point certificate. It sits between the rational source of chapter 37, the dyadic tolerance ledger of chapter 291, the finite stream naming surface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The certificate names a constant stream route inside BEDC; it does not import quotient streams, host functions, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7054.1 (Constant real stream carrier)**.** *A* $\mathsf{ConstantRealStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *point row naming the rational source value.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that records the finite precision scale at which the same point is read.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row whose every displayed window names the same source point.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the constant stream windows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular readback row is displayed.*
6. *H records componentwise* hsame *transport for the rational source, dyadic tolerance, stream window, regular readback, Real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the constant point row through the stream and regular readback rows to the Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{ConstantRealStream}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstantRealStream}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, D, S, R, E, H, C, P, N$. It has no coordinate for host functions $\mathbb{N} \to \mathbb{Q}$, quotient stream equality, selected limits, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.ConstantRealStreamUp`

Theorem 7054.2 (Constant real stream obligations)**.** *For every accepted* $\mathsf{ConstantRealStream}^{\uparrow}$ *carrier* $K = (Q, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstantRealStream}^{\uparrow}}$ *surface consists exactly of rational point exposure, dyadic tolerance exposure, constant* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, continuation replay, package provenance, and local naming. Every consumer must read these rows before using the constant certified point stream.*

Proof. Project the accepted carrier of Definition 7054.1. The rational source row Q and dyadic tolerance row D are the only point and precision rows visible to the local classifier.

The stream and readback rows preserve that same source. The $\mathsf{StreamName}^{\uparrow}$ row S exposes finite windows that all name the point displayed by Q, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is reached only through those windows.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since quotient streams, host functions, selected limits, countable-choice schedules, and ambient Real completeness are absent from the carrier, the listed rows exhaust the NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.ConstantRealStreamUp.ConstantRealStreamTasteGate single carrier alignment`

Theorem 7054.3 (Constant real stream regular-rational route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{ConstantRealStream}^{\uparrow}$ *packet reaches regular rational data only through the finite route*

$$\mathsf{Rat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

The route supplies a displayed rational point, a dyadic tolerance ledger, finite constant windows, and regular readback; it exports no quotient stream object, host sequence function, selected limiting process, or countable-choice schedule.

Proof. Read the source rows Q and D first. They determine the rational point and the finite tolerance scale available to every later window.

Next inspect the stream row S. A consumer receives constant windows only as displayed $\mathsf{StreamName}^{\uparrow}$ data, so any regular readback must be downstream of that finite schedule.

Finally project the readback row R and the structural rows. They keep the handoff attached to Q, D, S, and no carrier coordinate can provide an external sequence function, quotient stream equality, a selected limit, or countable choice. □

Theorem 7054.4 (Constant real stream Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{ConstantRealStream}^{\uparrow}$ *packet must pass through the displayed route*

$$Q, D, S, R, E, H, C, P, N.$$

The terminal seal E *certifies only the constant stream route already displayed by* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows. It cannot be used as quotient stream equality, a host constant function, a selected limit, countable choice, or an ambient Real-completeness theorem.*

Proof. Start from Definition 7054.3. It places every regular rational readback downstream of the rational point, dyadic tolerance, and constant stream-window rows.

The Real seal row E is listed after that readback in the carrier. Therefore a Real-facing consumer cannot inspect the terminal seal before Q, D, S, R are exposed.

Transport, replay, provenance, and local naming preserve the same finite packet. Since the refused objects are not rows of K, the seal has no route by which to export quotient stream equality, a host function, a selected limit, choice, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{ConstantRealStream}^{\uparrow}$ Real-facing read factors through a rational point row, dyadic tolerance row, constant StreamName row, RegSeqRat readback row, Real seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real: $\mathsf{ConstantRealStream}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the constant-window route from a displayed point to a regular rational readback and terminal Real seal as one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstantRealStream}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstantRealStream}^{\uparrow}$ packet is generated from a RatUp point row, a DyadicRatCore tolerance row, a StreamName constant-window row, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstantRealStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7054.1, Definition 7054.2, Definition 7054.3, and Definition 7054.4 seed the constant certified point stream route from finite rational and dyadic rows to StreamName, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstantRealStream}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host sequence functions, selected limits, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked rational point exposure, dyadic tolerance exactness, constant-window exposure, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstantRealStrea

Chapter 7055

A Concrete Naming Certificate for $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$

Following Bishop and Bridges on monotone bounded real sequences and constructive Cauchy completion, the $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$ packet records a finite L10 route by which a monotone regular Cauchy stream receives a terminal real-name readback. It sits after the dyadic rational core of chapter 291, the stream-window interface of chapter 126, the regular rational sequence route of chapter 301, and the terminal real-name boundary of chapter 38. The packet names the monotone limit route through displayed order, tolerance, and seal rows; it does not import a host least-upper-bound theorem, selected supremum, quotient equality of reals, countable choice, or ambient completeness.

Definition 7055.1 (Monotone regular Cauchy limit carrier)**.** *A* $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, O, M, T, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for the source stream, exposing only finite windows requested by the current tolerance read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same stream windows.*
3. *D is the dyadic tolerance ledger read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
4. *O is the* $\mathsf{TotalOrder}^{\uparrow}$ *comparison row on the regular rational readbacks.*
5. *M is the monotonicity ledger, recording that every displayed later window is O-above the earlier window after both have been read through R.*
6. *T is the regular Cauchy tail ledger, routing each dyadic tolerance through a finite tail threshold and a displayed R, D, O comparison.*
7. *L is the candidate limit row, read only as a* $\mathsf{Real}^{\uparrow}$ *name assembled from the displayed regular tail route.*
8. *E is the exactness row saying that every visible tolerance request for L factors through S, R, D, O, M, T before the real seal is exposed.*
9. *H records componentwise* hsame *transport for stream, readback, tolerance, order, monotonicity, tail, limit, exactness, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a tolerance request through* $S, R, D, O, M, T, L, E, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, O, M, T, L, E, H, C, P, N$. It has no coordinate for a host supremum, selected limit, quotient equality of real names, trichotomy, countable choice, or ambient real completeness.

Theorem 7055.2 (Monotone regular Cauchy limit NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$ *carrier $K = (S, R, D, O, M, T, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MonotoneRegularCauc}}$ *surface consists exactly of stream-window admission, regular rational readback, dyadic tolerance admission, total-order comparison exposure, monotonicity-ledger exactness, regular Cauchy tail exposure, terminal* $\mathsf{Real}^{\uparrow}$ *limit admission, limit-exactness replay, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted carrier. The only analytic rows are S, R, D, O, M, T, L, E, so every limit read starts with finite stream windows and regular rational readback.

The order and monotonicity rows are downstream of that readback. Row O compares only displayed regular rational windows, while M records the monotone direction for those same windows.

The tail ledger T then routes a dyadic tolerance through a finite threshold, and E checks that the candidate $\mathsf{Real}^{\uparrow}$ row L is exposed only after this route has been replayed. Thus the real-facing output is a finite NameCert route rather than a host supremum.

Finally H, C, P, N transport, replay, source, and name the same row surface. Since the excluded objects are absent from K, the listed obligation families exhaust the local certificate. □

Theorem 7055.3 (Monotone regular Cauchy limit induction route)**.** *Every finite induction over an accepted* $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$ *read proceeds by extending the stream-window row S, transporting the regular rational readback R, preserving the dyadic tolerance ledger D, appending one* $\mathsf{TotalOrder}^{\uparrow}$ *comparison in O, and replaying the monotonicity and tail rows M, T before the* $\mathsf{Real}^{\uparrow}$ *limit row L may be consumed. The route exports no host least-upper-bound theorem, no selected supremum, no quotient equality of real names, no countable-choice selector, and no ambient completeness principle.*

Proof. Use induction on the displayed window extension in S. The base window exposes the initial regular rational readback through R and records the initial dyadic tolerance cell through D.

For the successor window, append the next readback cell and compare it with the previous visible cell through O. The monotonicity ledger M stores only this displayed comparison, so the induction step has no access to a global order theorem.

The regular Cauchy row T is then replayed at the requested tolerance. It supplies the finite tail threshold needed by the candidate real-name row L, and E records that the real seal is reached only through the same finite route.

The structural rows H, C, P, N preserve the induction route under hsame, replay it under Cont, record its provenance, and name the local certificate. Therefore every induction step remains inside the visible BEDC rows. □

Falsifiable prediction: An accepted $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$ consumer is refuted if it reads the $\mathsf{Real}^{\uparrow}$ limit row without first displaying StreamName windows, RegSeqRat readback, DyadicRatCore tolerance cells, TotalOrder comparisons, monotonicity, regular Cauchy tail routing, transport, replay, provenance, and local naming rows.

Independence witness: streamname, regseqrat, dyadicratcore, real: none is bijective with $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$, because this packet alone binds stream windows, regular rational readback, dyadic tolerance cells, total-order comparisons, monotonicity, a regular Cauchy tail ledger, a terminal real-name row, exactness, transport, replay, provenance, and local naming into one finite limit route.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance cells, TotalOrder comparisons, monotonicity ledgers, regular Cauchy tail ledgers, a RealUp limit row, exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7055.1, Definition 7055.2, and Definition 7055.3 seed the finite monotone regular Cauchy limit readback over StreamName, RegSeqRat, DyadicRatCore, TotalOrder, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneRegularCauchyLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host supremum theorem, selected limit, quotient equality of real names, trichotomy, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked stream-window admission, regular rational readback, dyadic tolerance exactness, total-order comparison exposure, monotonicity, regular Cauchy tail routing, RealUp limit admission, exactness, transport, replay, provenance, and local naming for BEDC.Derived.MonotoneRegularCauchyLimitUp.

Chapter 7056

A Concrete Naming Certificate for $\mathsf{HyperbolicShearCoordinate}^{\uparrow}$

The $\mathsf{HyperbolicShearCoordinate}^{\uparrow}$ packet realizes the boundary-fixed disk-transport and observer-expansion comparison branch of chapter 9463 as finite NameCert data. It sits after the boundary-transport route of chapter 6267, the hyperbolic metric row of chapter 3474, the Busemann boundary row of chapter 3732, the boundary-shadow route of chapter 3813, and the observer-expansion packet of chapter 4167. The packet names a finite shear-coordinate read; it is not a completed Teichmuller space, a host geodesic lamination, a quotient boundary, or a physical observer trajectory.

Definition 7056.1 (Hyperbolic shear-coordinate carrier)**.** *A* $\mathsf{HyperbolicShearCoordinate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, B, M, U, S, E, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk-surface row, read through Poincare disk boundary-transport data rather than a host disk.*
2. *B is the boundary-pair row naming the two visible boundary endpoints whose separation is inspected.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *comparison row on displayed disk and boundary data.*
4. *U is the Busemann or horofunction comparison row, read through the boundary metric route.*
5. *S is the shear-coordinate row, recording the signed comparison budget between the two boundary-fixed transports.*
6. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *comparison row, exposing how the same shear budget is consumed by observer-expansion reads.*
7. *R is the refusal row excluding completed boundary quotients, global geodesic laminations, physical trajectories, and selected ideal endpoints.*
8. *H records componentwise* hsame *transport for disk, boundary, metric, Busemann, shear, observer-expansion, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a shear request through $D, B, M, U, S, E, R, H, P, N$.*

10. *P is the* Pkg *provenance over* HyperbolicShearCoordinate$^{\uparrow}$, PoincareDiskBoundaryTransport$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicBusemannBoundary$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicObserverExpansion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{HyperbolicShearCoordinate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, B, M, U, S, E, R, H, C, P, N$. It has no coordinate for a completed ideal boundary, unlogged geodesic lamination, ambient Teichmuller coordinate, physical observer path, or selected boundary endpoint.

Theorem 7056.2 (Hyperbolic shear-coordinate NameCert obligations)**.** *For every accepted* HyperbolicShearCoordin *carrier $Q = (D, B, M, U, S, E, R, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicShearCoordinate}^{\uparrow}}$ *surface consists exactly of disk-surface admission, boundary-pair admission, hyperbolic-metric comparison, Busemann boundary comparison, shear-coordinate exactness, observer-expansion comparison, refusal exactness, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier onto D, B, M, U, S, E. These are the only geometric rows available to the packet, and each is a displayed NameCert row rather than an ambient hyperbolic object.

The shear row S is downstream from the boundary and metric rows. It may compare two boundary-fixed transports only after D, B, M, U have been displayed, so the coordinate is a finite ledger read rather than a selected ideal endpoint.

The observer-expansion row E consumes that same finite shear budget. The refusal row R then blocks any rereading as a completed boundary quotient, geodesic-lamination coordinate, Teichmuller parameter, physical trajectory, or selected endpoint.

Finally H, C, P, N transport, replay, source, and name the displayed route. Since the excluded host objects are not coordinates of Q, the listed obligation families exhaust the local certificate. □

Theorem 7056.3 (Hyperbolic shear-coordinate observer route)**.** *Every observer-expansion consumer of an accepted* HyperbolicShearCoordinate$^{\uparrow}$ *packet must first expose the disk row D, boundary-pair row B, hyperbolic metric row M, Busemann comparison row U, shear-coordinate row S, refusal row R, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The route exports no completed boundary quotient, no host geodesic lamination, no ambient Teichmuller coordinate, no physical observer trajectory, and no selected ideal endpoint.*

Proof. Begin with the NameCert obligations. They make D, B, M, U, S, E, R the complete geometric surface of the packet.

Read the boundary-fixed transport first. The disk row D and boundary-pair row B determine which finite boundary comparison is visible, while M and U attach metric and Busemann data to that same comparison.

The shear row S and observer-expansion row E are then replayed over the same displayed route. The refusal row R stays attached to the handoff, so no consumer may erase the boundary and metric rows into a global coordinate theorem.

The structural rows H, C, P, N preserve this route and add no hidden geometric object. Thus the observer-facing handoff is finite and classifier-based. □

Falsifiable prediction: An accepted HyperbolicShearCoordinate$^{\uparrow}$ read is refuted if an observer-expansion consumer obtains a shear coordinate without displaying Poincare disk boundary transport, boundary endpoints, HyperbolicMetric comparison, Busemann boundary comparison, shear exactness, refusal, transport, replay, provenance, and local naming rows.

Independence witness: poincare-disk-boundary-transport, hyperbolic-metric, hyperbolic-busemann-boundary, hyperbolic-boundary-shadow, hyperbolic-observer-expansion: no listed sibling is bijective with $\mathsf{HyperbolicShearCoordinate}^{\uparrow}$, because this packet alone binds boundary-fixed disk transport, boundary-pair comparison, metric readback, Busemann comparison, shear-coordinate exactness, observer-expansion comparison, refusal, transport, replay, provenance, and local naming into one finite row surface.

The Lean TasteGate route must provide explicit $\mathsf{Nontrivial\ HyperbolicShearCoordinate}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicShearCoordinate}^{\uparrow}$ instances before the packet can serve as a checked carrier-alignment witness. The instances must keep $D, B, M, U, S, E, R, H, C, P, N$ as separate fields and must distinguish a changed shear row from a changed metric or boundary row.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicShearCoordinate}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicShearCoordinate}^{\uparrow}$ packet is generated from Poincare disk boundary-transport rows, boundary-pair rows, HyperbolicMetric comparisons, Busemann boundary comparisons, shear-coordinate exactness, HyperbolicObserverExpansion comparisons, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicShearCoordinate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7056.1, Definition 7056.2, and Definition 7056.3 seed the finite boundary-fixed shear-coordinate route over disk, boundary, metric, Busemann, observer-expansion, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicShearCoordinate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed boundary quotients, host geodesic laminations, ambient Teichmuller coordinates, physical observer trajectories, selected ideal endpoints, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-surface admission, boundary-pair admission, hyperbolic-metric comparison, Busemann comparison, shear exactness, observer-expansion comparison, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicShearCoordinateUp.

Chapter 7057

A Concrete Naming Certificate for $\mathsf{DoubleArrowSpace}^{\uparrow}$

Following Alexandroff and Urysohn's split-interval construction and Kelley-style order topology, the $\mathsf{DoubleArrowSpace}^{\uparrow}$ packet records the lexicographically ordered two-copy real interval as finite NameCert data. It sits beside the endpoint seal of chapter 38, the order-topology surface of chapter 1890, the topology carrier of chapter 88, the order-facing row family of chapter 1378, and the observable-open classifier of chapter 1860. The packet names the finite carrier and generated interval windows; it does not import a host compactness theorem, quotient point equality, selected cuts, or an unrestricted open-set lattice.

Definition 7057.1 (DoubleArrowSpace carrier)**.** *A* $\mathsf{DoubleArrowSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (R, T, L, W, O, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint row, carrying the displayed left and right real endpoints currently inspected by the packet.*
2. *T is the split-tag row, with each inspected endpoint marked by a left or right copy of the interval.*
3. *L is the lexicographic order row: real endpoints are compared first, and equal endpoints are then compared by the split tag.*
4. *W is the generated order-topology interval-window row, listing the finite open rays and bounded order intervals actually exposed to topology consumers.*
5. *O is the observable-open row, read through* $\mathsf{SierpinskiSpace}^{\uparrow}$*, that records truth values for membership in the displayed interval windows.*
6. *H records componentwise* hsame *transport for endpoint rows, split tags, lexicographic order rows, interval windows, observable-open truth rows, continuation rows, provenance rows, and local naming rows.*
7. *C records displayed* Cont *replay from R, T to L, from L to the generated windows W, and from W to the observable-open row O.*
8. *P is the* Pkg *provenance over* $\mathsf{DoubleArrowSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealOrderTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{DoubleArrowSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, T, L, W, O, H, C, P, N$. It has no coordinate for host point equality on a classical split interval, open-cover compactness, a quotient by adjacent endpoints, selected suprema, or an ambient topology.

Theorem 7057.2 (DoubleArrowSpace NameCert obligations)**.** *For every accepted* $\mathsf{DoubleArrowSpace}^{\uparrow}$ *packet $D = (R, T, L, W, O, H, C, P, N)$, the local NameCert surface consists exactly of endpoint admission through* $\mathsf{Real}^{\uparrow}$*, split-tag admission, lexicographic order admission through* $\mathsf{Order}^{\uparrow}$*, generated order-topology window exposure through* $\mathsf{RealOrderTopology}^{\uparrow}$ *and* $\mathsf{Topology}^{\uparrow}$*, observable-open truth exposure through* $\mathsf{SierpinskiSpace}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. A consumer may read a double-arrow open only after those finite rows are displayed; it cannot replace them by a host split-interval topology, quotient point equality, open-cover compactness, selected cuts, or ambient real-order completeness.*

Proof. Project the carrier of Definition 7057.1. The rows $R, T, L, W, O, H, C, P, N$ are the whole accepted packet, so every double-arrow read must expose endpoints, split tags, lexicographic order, interval windows, and observable-open truth before the structural rows are consumed.

The order-topology route is finite. The row L is built from the displayed real endpoint comparison and split-tag comparison; W then lists only the generated order intervals currently inspected; and O records their observable truth values through $\mathsf{SierpinskiSpace}^{\uparrow}$.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores host point equality, compactness, selected cuts, quotient identification, or an unrestricted open-set lattice, none of those objects can appear among the local NameCert obligations. □

Theorem 7057.3 (DoubleArrowSpace order-topology route)**.** *Every* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{RealOrderTopology}^{\uparrow}$*,* $\mathsf{Order}^{\uparrow}$*, or* $\mathsf{SierpinskiSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{DoubleArrowSpace}^{\uparrow}$ *packet receives the generated open data only through the route*

$$\mathsf{Real}^{\uparrow},\ T,\ L,\ W,\ O,\ H,\ C,\ P,\ N.$$

The endpoint row supplies the real comparison boundary, the split-tag row separates the two copies at equal endpoints, the lexicographic order row supplies the order-facing classifier, and the interval-window row supplies the generated order-topology opens. The route exports no host compactness theorem, quotient equality between adjacent split points, selected endpoint cuts, or ambient open-set lattice.

Proof. Read the carrier in the order displayed by Definition 7057.1. The endpoint row R and tag row T determine the lexicographic order row L, and the generated windows W are the only topology-facing opens exposed by the packet.

Apply Definition 7057.2. It identifies the observable-open row O and the structural rows H, C, P, N as part of the same displayed certificate rather than as an external topology.

Thus every order-topology consumer receives the double-arrow data through the finite route above. No additional host topology, quotient point equality, compactness proof, selected cut, or open-set lattice is available from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{DoubleArrowSpace}^{\uparrow}$ observable-open read factors through the $\mathsf{Real}^{\uparrow}$ endpoint row, split-tag row, lexicographic order row, generated interval-window row, $\mathsf{SierpinskiSpace}^{\uparrow}$ observable truth row, hsame, Cont, Pkg, and local NameCert rows before any topology-facing consumer reads it.

Independence witness: real, real-order-topology, topology, order, sierpinski-space: $\mathsf{DoubleArrowSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries real endpoints, left/right split tags, lexicographic order, generated order-topology interval windows, observable-open truth values, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DoubleArrowSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{DoubleArrowSpace}^{\uparrow}$ packet is generated from a RealUp endpoint row, left/right split tags, a lexicographic order row, generated order-topology interval windows, a SierpinskiSpace observable-open row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoubleArrowSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7057.1, Definition 7057.2, and Definition 7057.3 seed the split-interval order-topology packet over RealUp, RealOrderTopologyUp, TopologyUp, OrderUp, SierpinskiSpaceUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoubleArrowSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host compactness, quotient point equality, selected cuts, a global open-set lattice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, split-tag stability, lexicographic order exactness, generated interval-window exposure, observable-open replay, transport, provenance, local naming, and nonescape for BEDC.Derived.DoubleArrowSpaceUp.

Chapter 7058

A Concrete Naming Certificate for $\mathsf{CountableBaseMetric}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CountableBaseMetric}^{\uparrow}$ packet records the finite interface by which metric balls are named through a countable basis schedule. It sits after the metric carrier of chapter 57 and the topology naming surface of chapter 88, while feeding the L10 Real and Completion route through chapter 1809, chapter 126, chapter 301, and chapter 38. The packet names only displayed center windows, radius ledgers, basis indices, containment witnesses, transport, replay, provenance, and local NameCert rows; it does not assert open-cover compactness, countable choice, selected limits, host powersets, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7058.1 (CountableBaseMetric carrier)**.** *A* $\mathsf{CountableBaseMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, T, I, R, S, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing only the displayed point windows and finite distance-comparison ledger.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-row readback, naming the topology generated from metric balls after the same metric source has been shown.*
3. *I is the countable basis index row, recording the finite portion of the basis schedule inspected by the current request.*
4. *R is the radius ledger row. It stores the positive rational or dyadic radius windows used to name balls around displayed centers.*
5. *S is the stability row, recording that a smaller displayed radius refines the same basis read without changing the center window or escaping the metric ledger.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row by which L10 consumers request finite basis schedules.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the radius comparisons attached to W and R.*
8. *H records componentwise* hsame *transport for metric, topology, index, radius, stability, stream, rational readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite ball request through M, T, I, R, S, W, Q, H.*

10. *P is the* Pkg *provenance over* $\mathsf{CountableBaseMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableBaseMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, I, R, S, W, Q, H, C, P, N$. It has no coordinate for a host enumeration of all opens, a selected dense point, countable choice, quotient stream equality, open-cover compactness, selected completion limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7058.2 (CountableBaseMetric radius stability)**.** *For every accepted* $\mathsf{CountableBaseMetric}^{\uparrow}$ *packet $B = (M, T, I, R, S, W, Q, H, C, P, N)$, any basis read that narrows a displayed radius remains inside the same finite metric-ball route*

$$M, T, I, R \longmapsto S \longmapsto W, Q, H, C, P, N.$$

The stability row S preserves the metric center window, countable basis index, radius ledger, StreamName schedule, and RegSeqRat readback under componentwise hsame *transport and displayed* Cont *replay.*

Proof. Project the carrier of Definition 7058.1. The metric source row M, topology row T, basis index row I, and radius ledger R are the only rows visible before a stability request can be read.

A radius narrowing is therefore interpreted by S as a refinement of the displayed ball data, not as a new open set drawn from a host powerset. The center window and basis index remain attached to M, T, I, R.

The L10 rows W and Q read the same narrowed radius through finite stream windows and regular rational comparisons. Transport through H and replay through C preserve the named route, while P, N record provenance and local naming.

Since selected dense points, countable choice, quotient stream equality, open-cover compactness, and ambient completeness do not occur among the coordinates of B, radius stability is confined to the displayed finite route. □

Theorem 7058.3 (CountableBaseMetric ledger coverage)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CountableBaseMetric}^{\uparrow}$ *packet receives countable metric-basis information only through the displayed ledger rows $M, T, I, R, S, W, Q, H, C, P, N$. In particular, the packet covers metric balls, basis indices, radius refinements, finite stream schedules, regular rational readback, componentwise transport, continuation replay, provenance, and local naming; it exports no open-cover compactness theorem, countable-choice selector, selected completion limit, host equality of opens, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use the carrier route from Definition 7058.1. A downstream consumer first reads the metric ledger M and topology row T, then the countable basis index I and radius ledger R.

The stability row S records the finite containment relation needed to treat metric balls as basis data. It is downstream of the displayed metric and radius rows, so a consumer cannot replace it by a global topology or powerset assertion.

The L10 route then passes through W and Q, exposing only finite StreamName windows and RegSeqRat comparisons for the inspected basis schedule. Componentwise hsame transport and displayed Cont replay preserve that schedule under H and C.

Finally P and N source and name the same packet. The absent objects are not carrier coordinates, so no consumer can extract compactness, choice, selected limits, host open equality, quotient stream equality, or Real completeness from the ledger. □

Falsifiable prediction: Every accepted $\mathsf{CountableBaseMetric}^{\uparrow}$ L10 read exposes a MetricUp ledger, a TopologyUp generated-open row, countable basis indices, radius-refinement rows, StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any Real or Completion consumer can inspect countable-basis data.

Independence witness: metric, topology, real-separability, streamname, regseqrat, real: none is bijective with $\mathsf{CountableBaseMetric}^{\uparrow}$ because this packet jointly carries metric-ball data, topological basis readback, countable indices, radius stability, finite schedules, rational readback, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CountableBaseMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CountableBaseMetric}^{\uparrow}$ packet is generated from a MetricUp source row, TopologyUp open-row readback, countable basis indices, radius ledgers, radius-stability rows, StreamName windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountableBaseMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7058.1, Definition 7058.2, and Definition 7058.3 seed the countable metric-basis route through metric balls, topology readback, StreamName schedules, RegSeqRat comparisons, and Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountableBaseMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected dense points, selected completion limits, host equality of opens, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basis-index exposure, radius-stability exactness, ledger coverage, StreamName and RegSeqRat readback, transport, replay, provenance, and local naming for BEDC.Derived.CountableBaseMetricUp.

Chapter 7059

A Concrete Naming Certificate for $\mathsf{LocatedDyadicApproximation}^{\uparrow}$

Following Bishop and Bridges on located constructive reals, the $\mathsf{LocatedDyadicApproximation}^{\uparrow}$ packet records the finite route from displayed located real bounds to dyadic approximation windows before a $\mathsf{Real}^{\uparrow}$ consumer reads the result. It sits beside the real-name seal of chapter 38, the regular rational readback of chapter 301, the stream naming surface of chapter 126, the dyadic precision ledger of chapter 291, and the Archimedean dyadic approximation route of chapter 6845. The chapter names a finite located approximation carrier; it does not quotient real names, choose limits, assert trichotomy, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7059.1 (LocatedDyadicApproximation carrier)**.** *A* $\mathsf{LocatedDyadicApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, S, Q, D, A, W, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the located* $\mathsf{Real}^{\uparrow}$ *bounds row, exposing lower and upper rational guards for the named real source before any dyadic window is read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row that records the finite stream-name schedule through which the located bounds are inspected.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same source schedule.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row, recording the dyadic denominator and tolerance ledger used by the approximation request.*
5. *A is the* $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$ *handoff row, displaying the bounded dyadic approximation discipline already licensed by the Archimedean route.*
6. *W is the approximation-window row, carrying the finite dyadic lower and upper endpoints visible to downstream consumers.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal for the same located source, available only after R, S, Q, D, A, W have been displayed.*
8. *H records componentwise* hsame *transport for the located bounds, stream schedule, regular rational readback, dyadic precision, Archimedean handoff, approximation window, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a located approximation request through $R, S, Q, D, A, W, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedDyadicApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicApproximation}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient reals, equality of real names outside the displayed seal, trichotomy, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7059.2 (LocatedDyadicApproximation NameCert obligations)**.** *For every accepted* LocatedDyadicApprox *carrier $L = (R, S, Q, D, A, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission for the located bounds, stream source, regular rational readback, dyadic precision, Archimedean handoff, approximation window, real seal, transport, replay, provenance, and local naming rows; source exposure requiring R, S, Q before any dyadic precision row is read; precision exposure requiring D, A before W; real handoff exactness requiring W before E; and ledger exhaustion excluding quotient reals, trichotomy, selected limits, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 7059.1. The rows $R, S, Q, D, A, W, E, H, C, P, N$ are displayed as separate coordinates, so the located bounds, stream schedule, regular rational readback, dyadic precision, and approximation window cannot be hidden inside the terminal real seal.

The source rows are read first. The located real bounds R are inspected through the stream-name row S and regular rational readback row Q, so the approximation request is tied to the displayed name rather than to a quotient real.

Next read the dyadic precision and Archimedean handoff rows D, A. They license the finite approximation window W before the Real seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no quotient-real coordinate, trichotomy row, selected-limit row, choice schedule, or ambient-completeness witness, the listed rows exhaust the local NameCert surface. □

Theorem 7059.3 (Located dyadic approximation real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedDyadicApproximation}^{\uparrow}$ *packet receives the finite route*

$$R, S, Q, D, A, W \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer reads located real bounds, a stream-name schedule, a $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row, an* $\mathsf{ArchimedeanDyadicApproximation}^{\uparrow}$ *handoff row, and a dyadic approximation window before the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports no quotient real, trichotomy principle, selected limit, countable-choice schedule, or ambient completeness principle.*

Proof. Use Definition 7059.2. Its source exposure, precision exposure, and real handoff exactness clauses force the route R, S, Q, D, A, W, E before any real-facing read occurs.

After the seal is read, the remaining rows are H, C, P, N. They preserve the same finite packet by componentwise transport, displayed replay, provenance, and local naming.

Therefore a $\mathsf{Real}^{\uparrow}$ consumer receives exactly the displayed located-bounds-to-window route with the terminal seal and structural rows. Since quotient reals, trichotomy, selected limits, countable choice, and ambient completeness are absent from both the carrier and the obligation surface, the handoff cannot export them. □

Lean4 (statement) `BEDC.Derived.LocatedDyadicApproximationUp.LocatedDyadicApproximationUp`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDyadicApproximation}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{LocatedDyadicApproximation}^{\uparrow}}$, seed)

Scope closed: Definition 7059.1, Definition 7059.2, and Definition 7059.3 seed the finite route from located real bounds to dyadic approximation windows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedDyadicApproximation}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.LocatedDyadicApproximationUp.LocatedDyadicApproximationUp`

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located source exposure, regular rational readback, dyadic precision exposure, Archimedean handoff, approximation-window exactness, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.LocatedDyadicApproximationUp.

Constructive story: A LocatedDyadicApproximation$^{\uparrow}$ packet is generated from located RealUp bounds, StreamName schedule rows, RegSeqRat readback rows, DyadicRatCore precision rows, an ArchimedeanDyadicApproximation handoff, a dyadic approximation window, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7060

A Concrete Naming Certificate for $\mathsf{FiniteGameMinimax}^{\uparrow}$

Following von Neumann's finite zero-sum game theorem, the $\mathsf{FiniteGameMinimax}^{\uparrow}$ packet names a saddle-certificate surface for finite payoff tables. The BEDC packet consumes the finite ordered-field duality rows of chapter 235, the simplex and convexity rows of chapter 208, the finite payoff-table rows of chapter 49, the scalar readback rows of chapter 38, and the ordered-field operations of chapter 45.

Definition 7060.1 (FiniteGameMinimax carrier)**.** *A* $\mathsf{FiniteGameMinimax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, J, A, \Delta_I, \Delta_J, L, V, S, H, C, P, N)$$

with the following displayed rows:

1. *I and J are finite row-player and column-player pure-strategy carriers.*
2. *$A : I \times J \to F$ is the payoff table, read as a finite* $\mathsf{Mat}^{\uparrow}$ *row over the ordered-field scalar carrier F.*
3. *Δ_I and Δ_J are the row and column mixed-strategy simplex rows, read through* $\mathsf{ConvexSet}^{\uparrow}$ *and the scalar* $\mathsf{Field}^{\uparrow}$ *operations.*
4. *L is the finite* $\mathsf{LPDuality}^{\uparrow}$ *primal-dual row whose primal variables are row-player mixture and lower-value coordinates, and whose dual variables are column-player mixture and upper-value coordinates.*
5. *V is the value row, recording the scalar endpoint selected by the displayed primal-dual equality in L.*
6. *S is the saddle-inequality ledger, listing the finite comparisons*

$$\sum_{i \in I} p_i A_{ij} \preceq_F V \quad \text{and} \quad V \preceq_F \sum_{j \in J} A_{ij} q_j$$

   for every displayed pure column $j \in J$ and pure row $i \in I$.
7. *H records componentwise* hsame *transport for the strategy carriers, payoff table, simplex rows, duality row, value row, saddle ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a saddle-value request through $A, \Delta_I, \Delta_J, L, V, S, H, P, N$.*

9. *P is the* Pkg *provenance over* FiniteGameMinimax$^{\uparrow}$, LPDuality$^{\uparrow}$, ConvexSet$^{\uparrow}$, Mat$^{\uparrow}$, Real$^{\uparrow}$, Field$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{FiniteGameMinimax}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host minimax selector, a hidden optimization solver, quotient equality of mixed strategies, an ambient completed real space, or a selected saddle pair outside the displayed finite packet.

Theorem 7060.2 (FiniteGameMinimax obligation surface)**.** *For every accepted* FiniteGameMinimax$^{\uparrow}$ *carrier $G = (I, J, A, \Delta_I, \Delta_J, L, V, S, H, C, P, N)$, the local* NameCert$_{\text{FiniteGameMinimax}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier comparison, finite simplex feasibility, finite* LPDuality$^{\uparrow}$ *handoff, saddle-inequality stability under* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A saddle-value read is admitted only after the payoff table, both mixed-strategy simplex rows, the duality row, the value row, and the saddle ledger are all visible in the same finite packet.*

Proof. Project the carrier of Definition 7060.1. The finite strategy carriers and payoff table are supplied by I, J, A, while Δ_I and Δ_J give the mixed-strategy feasibility rows.

The duality handoff is exactly the row L. It supplies the finite primal-dual comparison whose common scalar endpoint is recorded in V.

The saddle ledger S lists the pure-row and pure-column comparisons obtained from that endpoint. Componentwise transport through H preserves the strategy carriers, payoff entries, simplex coordinates, value endpoint, and comparison rows, while C, P, N replay, source, and name the same packet.

Since no row in the carrier stores a host solver, a quotient of strategy distributions, or an ambient completeness principle, the displayed fields exhaust the local NameCert obligations. □

Theorem 7060.3 (FiniteGameMinimax LPDuality handoff)**.** *Every saddle-value read from an accepted* FiniteGameMinimax$^{\uparrow}$ *packet factors through the displayed finite ordered-field* LPDuality$^{\uparrow}$ *row L of Definition 7060.1. The exported data are the payoff table, simplex feasibility rows, value endpoint, saddle comparisons, transport, replay, provenance, and local naming rows. The packet exports no optimization solver, host min/max selector, quotient strategy equality, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Read an accepted saddle-value request through the replay row C. By definition it must pass through the payoff table A, the two simplex rows Δ_I, Δ_J, the duality row L, the value row V, and the saddle ledger S.

The row L is already an LPDuality$^{\uparrow}$ finite ordered-field row. Its equality of primal and dual objective endpoints is the only source for the value coordinate V.

The saddle comparisons are then read from S as finite ordered-field comparisons against the same endpoint. Transport by H and provenance by P, N keep those comparisons in the named finite packet.

Thus every public saddle-value read factors through L and the listed BEDC rows, with no additional solver, selector, quotient, or completeness coordinate available. □

Closure status for NameCert$_{\text{FiniteGameMinimax}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{FiniteGameMinimax}^{\uparrow}}$, seed)

Scope closed: Definition 7060.1, Definition 7060.2, and Definition 7060.3 seed the finite zero-sum game saddle-certificate packet through displayed payoff, simplex, duality, value, and saddle-ledger rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteGameMinimax}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host minimax theorem, an optimizer-selection procedure, quotient equality of mixed strategies, real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, simplex feasibility, ordered-field duality handoff, saddle-inequality stability, replay, provenance, and local NameCert registration for BEDC.Derived.FiniteGameMinimaxUp.

Constructive story: A FiniteGameMinimax$^{\uparrow}$ packet is generated from finite pure-strategy carriers, a payoff table, mixed-strategy simplex rows, an LPDuality row, a value endpoint, saddle-inequality ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7061

A Concrete Naming Certificate for $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$

The $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$ packet realizes the theorem-DNA complexity-scoring vision of chapter 9408 as finite NameCert data. It packages role-locus completeness, mass-vector extraction, weighted-score rows, refusal boundaries, transport, replay, provenance, and local naming so downstream discovery classifiers can inspect score reads without treating theorem text or proof length as a complete theorem object.

The score packet is consumed beside chapter 6358 and chapter 5914: theorem-genome supplies the lineage rows, while discovery-pipeline supplies the classifier-shift consumer route.

Definition 7061.1 (TheoremDnaComplexityScoring carrier)**.** *A* $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, R, D, M, W, Q, B, H, C, P, N)$$

with the following displayed rows:

1. *T is the theorem-candidate event-flow row.*
2. *R is the recognizer row that assigns theorem roles to subflows.*
3. *D is the eight-locus theorem-DNA row, displaying statement, dependencies, proof, certificates, ledger, status, canonical-site, and closing-seal loci.*
4. *M is the mass-vector row, recording the nine coordinates for the eight role masses and recognizer overhead.*
5. *W is the public weight row, listing the nine nonnegative weights used to turn M into a scalar score.*
6. *Q is the weighted-score comparison row, computing the accepted scalar score only from M and W.*
7. *B is the refusal-boundary row, rejecting score reads that omit any role locus, mass coordinate, weight coordinate, recognizer row, transport row, replay row, provenance row, or local name row.*
8. *H records componentwise* hsame *transport for theorem flow, recognizer, theorem-DNA loci, mass vector, weight profile, score comparison, refusal boundary, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a scoring request through $T, R, D, M, W, Q, B, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$*, chapter 9408, theorem-flow recognition, theorem-genome evolution, classifier-level information, theorem-DNA taste gates,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TheoremDnaComplexityScoring}^{\uparrow}}$ *row.*

The classifier compares accepted scoring packets only through these rows. It has no coordinate for statement-only theorem identity, proof-length-only scoring, hidden weights, unanchored recognizer overhead, prose novelty, or a score read outside the displayed finite packet.

Theorem 7061.2 (TheoremDnaComplexityScoring obligation surface)**.** *For every accepted* TheoremDnaComplexity *carrier $S = (T, R, D, M, W, Q, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TheoremDnaComplexityScoring}^{\uparrow}}$ *surface consists exactly of theorem-flow exposure, role-locus completeness, mass-vector extraction, public weight exposure, weighted-score computation, refusal-boundary exactness, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming. A score read is accepted only after all eight role loci and all nine mass and weight coordinates are visible.*

Proof. Project the carrier of Definition 7061.1. The theorem object is not read from a sentence alone; it is read through the candidate row T, recognizer row R, and eight-locus DNA row D.

The vector part is supplied by M, and the scalarization is supplied by W and Q. Since Q is defined only from the displayed vector and weight rows, no hidden score coordinate is available.

The refusal boundary B records exactly the missing-row cases. Transport through H preserves the role, vector, weight, and score coordinates together, while C, P, N replay, source, and name the same finite packet.

Thus the NameCert obligation surface is exhausted by the listed finite rows. □

Theorem 7061.3 (TheoremDnaComplexityScoring refusal boundary)**.** *Any attempted* TheoremDnaComplexityScor *score read that omits one of the eight theorem-DNA role loci, one of the nine mass coordinates, one of the nine public weight coordinates, the recognizer row, the refusal-boundary row, componentwise transport, replay, provenance, or local naming is rejected by the carrier of Definition 7061.1. In particular, proof shortening, statement length, recognizer overhead, or score comparison alone is not an accepted theorem-DNA complexity score.*

Proof. Read a scoring request through C. The replay route reaches $T, R, D, M, W, Q, B, H, P, N$ before any scalar score can be exported.

If a role locus is missing, then D is not the eight-locus theorem-DNA row required by the carrier. If a mass or weight coordinate is missing, then Q has no displayed input from which to compute the scalar score.

If the recognizer, boundary, transport, replay, provenance, or local naming row is missing, then the score is detached from the finite NameCert packet. Each case is listed by B as a refusal case.

Therefore the accepted score read requires the full displayed route and cannot be obtained from any single theorem-locus or scalar comparison alone. □

Falsifiable prediction: Any accepted $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$ score read without all eight role loci, all nine mass coordinates, all nine weight coordinates, the refusal boundary, transport, replay, provenance, and local naming rows refutes the carrier of Definition 7061.1.

Independence witness: theorem-genome-evolution, discovery-pipeline-calculus, theorem-dna-scoring-taste-gate, classifier-level-information: $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$ is not bijective to these siblings because it jointly binds role-locus completeness, mass-vector extraction, public weight

rows, weighted-score comparison, refusal exactness, transport, replay, provenance, and local naming in one scoring packet.

The Lean follow-up for $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$ must provide explicit Nontrivial TheoremDnaComplexityS and $\mathsf{FieldFaithful\ TheoremDnaComplexityScoring}^{\uparrow}$ TasteGate instances, keeping role loci, mass vectors, weights, score comparisons, and refusal rows as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{TheoremDnaComplexityScoring}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TheoremDnaComplexityScoring}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7061.1, Definition 7061.2, and Definition 7061.3 seed the theorem-DNA complexity-scoring packet as finite role-locus, mass-vector, weight, score, refusal, transport, provenance, and NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TheoremDnaComplexityScoring}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim positive discovery, theorem-generation power, score optimality, hidden weighting, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked role-locus completeness, mass-vector extraction, public weight exposure, weighted-score computation, refusal exactness, replay, provenance, local NameCert registration, and TasteGate compatibility for BEDC.Derived.TheoremDnaComplexityScoringUp.

Constructive story: A $\mathsf{TheoremDnaComplexityScoring}^{\uparrow}$ packet is generated from theorem-candidate flow, recognizer flow, eight theorem-DNA role loci, a nine-coordinate mass vector, a public nine-coordinate weight profile, a weighted-score comparison, refusal boundaries, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7062

A Concrete Naming Certificate for $\mathsf{BaireOnePointContinuity}^{\uparrow}$

Following Baire and Bishop–Bridges constructive analysis, the $\mathsf{BaireOnePointContinuity}^{\uparrow}$ packet records the finite certificate route by which a Baire-one real-valued function exposes one inspected continuity point. It consumes the pointwise-limit ledger of chapter 1604, the dense-open schedule of chapter 1542, the oscillation window of chapter 1839, and the epigraph handoff of chapter 1536. The packet names a local pointwise-continuity witness over displayed Real and LocatedReal rows; it does not assert a host theorem that every Baire-one map has a continuity point, and it does not choose a point outside the named certificate.

Definition 7062.1 (BaireOnePointContinuity carrier)**.** *A* $\mathsf{BaireOnePointContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, D, O, L, Z, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireOneFunction}^{\uparrow}$ *source row, exposing the pointwise-limit ledger whose value reads are being tested for local continuity.*
2. *D is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open schedule row, recording the finite neighborhood refinement requests available around the inspected point.*
3. *O is the* $\mathsf{RealOscillation}^{\uparrow}$ *oscillation-window row, recording the displayed tail-variation and clamped-window evidence used to test a local modulus.*
4. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *epigraph handoff row, recording the lower-bound route through which oscillation thresholds are made visible to a located consumer.*
5. *Z is the* $\mathsf{LocatedReal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row for the inspected source point and its terminal value read.*
6. *R is the local point-continuity row, recording the finite neighborhood, tolerance window, oscillation bound, and value-seal handoff accepted by the packet.*
7. *H records componentwise* hsame *transport for the Baire-one source, dense-open schedule, oscillation window, lower-semicontinuous handoff, located-real and real seals, local continuity row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a point-continuity request through $B, D, O, L, Z, R, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{BaireOnePointContinuity}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{RealOscillation}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireOnePointContinuity}^{\uparrow}}$ *row.*

The carrier exports no global Baire theorem, no selected point outside Z, no quotient equality of real names, no countable choice over dense-open schedules, no open-cover compactness principle, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 7062.2 (BaireOnePointContinuity NameCert obligations)**.** *For every accepted* $\mathsf{BaireOnePointContinuity}^{\uparrow}$ *carrier*

$$Q = (B, D, O, L, Z, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BaireOnePointContinuity}^{\uparrow}}$ *surface consists exactly of carrier admission for the Baire-one source row, dense-open schedule, oscillation window, lower-semicontinuous epigraph handoff, located-real and real seals, local continuity row, transport, replay, provenance, and local naming rows; dense-open exposure requiring D to be displayed before a local neighborhood is used; oscillation-window exposure requiring O to be displayed before a tolerance claim is read; epigraph-handoff exposure requiring L to route every lower-bound comparison through the existing lower-semicontinuous packet; point-seal exposure requiring Z and R to be displayed before the local continuity claim is public; and ledger nonescape excluding choice, compactness, quotient real equality, semantic liminf data, and ambient completeness.*

Proof. Project the carrier of Definition 7062.1. The packet displays exactly the source, dense-open, oscillation, epigraph, point-seal, local-continuity, transport, replay, provenance, and local naming rows.

The dense-open and oscillation obligations are read from D and O. The dense-open schedule supplies the neighborhood refinement surface, while the oscillation row supplies the finite variation window that can be tested at the inspected point.

The lower-semicontinuous handoff is read from L. It keeps lower-bound comparisons on the same finite epigraph route already named by the source packet, so a consumer cannot replace the row by semantic liminf data or a host topology.

Finally the local point seal Z, R is reached through the structural rows H, C, P, N. Since none of these rows contains a selector over all dense-open schedules, a quotient equality of real names, open-cover compactness, or ambient Real completeness, the displayed obligations exhaust the local NameCert surface. □

Theorem 7062.3 (BaireOnePointContinuity oscillation window)**.** *Every local point-continuity read from an accepted* $\mathsf{BaireOnePointContinuity}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{BaireOneFunction}^{\uparrow}, \mathsf{BaireCategory}^{\uparrow}, \mathsf{RealOscillation}^{\uparrow}, \mathsf{LowerSemicontinuous}^{\uparrow}, \mathsf{LocatedReal}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto R.$$

The $\mathsf{RealOscillation}^{\uparrow}$ *row must expose a finite oscillation window at the inspected point, and the* $\mathsf{BaireCategory}^{\uparrow}$ *row must expose the dense-open neighborhood schedule used to shrink the window, before the local continuity row R can be consumed.*

Proof. Start with a consumer of the local continuity row R. The carrier places R downstream of the Baire-one source row B, the dense-open schedule D, the oscillation row O, the lower-semicontinuous handoff L, and the point seal Z.

Apply the Baire-one pointwise schedule route from chapter 1604 and the dense-thread schedule of chapter 1542. These rows make the source value and neighborhood refinement visible before the oscillation request is inspected.

Now use the oscillation packet of chapter 1839. It supplies only a finite clamped window and readback route, not an ambient equality of functions or a completed real-space theorem.

The lower-semicontinuous handoff and point seal then preserve that same route. Hence the local continuity row is available only after the displayed oscillation window and dense-open refinement have both been exposed. □

Theorem 7062.4 (BaireOnePointContinuity local point handoff)**.** *Every* $\mathsf{LocatedReal}^{\uparrow}$*-facing read of an accepted* $\mathsf{BaireOnePointContinuity}^{\uparrow}$ *packet must expose the inspected point seal* Z*, the Baire-one source row* B*, the dense-open schedule* D*, the oscillation window* O*, the lower-semicontinuous handoff* L*, and the local continuity row* R *before any point-continuity claim is used. The handoff is a finite local NameCert route, not a choice of a continuity point from an external set and not a proof of global continuity.*

Proof. Project the carrier. The located point and terminal real value are recorded in Z, but Z is not a standalone selector; it is carried with B, D, O, L, R in the same finite packet.

Use the oscillation-window theorem above. It forces any local continuity read through the Baire-one source, dense-open schedule, oscillation window, lower-semicontinuous handoff, and point seal before R is available.

Transport and replay through H and C preserve exactly those rows, while P and N only record provenance and local naming. Therefore a LocatedReal-facing consumer receives a displayed local point handoff and no external point choice or global continuity theorem. □

Theorem 7062.5 (BaireOnePointContinuity nonescape)**.** *Every Real-facing, LocatedReal-facing, or lower-semicontinuous consumer of an accepted* $\mathsf{BaireOnePointContinuity}^{\uparrow}$ *packet remains inside the finite route*

$$B, D, O, L, Z, R, H, C, P, N.$$

The route can certify only the displayed Baire-one source, dense-open schedule, oscillation window, lower-semicontinuous epigraph handoff, located point seal, local continuity row, transport, replay, provenance, and local naming data. It cannot export a host theorem choosing a point of continuity, quotient equality of real names, countable choice, open-cover compactness, semantic liminf data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligation surface. It accounts for all rows of the accepted packet and names no consumer route outside $B, D, O, L, Z, R, H, C, P, N$.

The oscillation-window and local point handoff theorems keep continuity reads downstream of the Baire-one, dense-open, oscillation, lower-semicontinuous, and point-seal rows. These rows are finite certificate data, not host analytic principles.

The structural rows add no hidden coordinates. Componentwise transport, displayed replay, provenance, and local naming preserve the same packet, so the refused choice, compactness, quotient-equality, semantic-liminf, and ambient-completeness endpoints cannot be projected from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireOnePointContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BaireOnePointContinuity}^{\uparrow}$ packet is generated from a BaireOneFunction source row, BaireCategory dense-open schedule, RealOscillation window, LowerSemicontinuous epigraph handoff, LocatedReal and Real seal row, local point-continuity row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireOnePointContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7062.1, Definition 7062.2, Definition 7062.3, Definition 7062.4, and Definition 7062.5 seed the finite local point-continuity route from Baire-one pointwise data through dense-open, oscillation, lower-semicontinuous, located-real, and real seal rows.

Formal verification: FormalStatus(NameCert$_{\text{BaireOnePointContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a global Baire-one continuity theorem, point selection outside the displayed seal, quotient real equality, countable choice, open-cover compactness, semantic liminf data, ambient Real completeness, Lean theorem checking, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, dense-open exposure, oscillation-window exposure, lower-semicontinuous handoff, local point seal, transport, replay, provenance, and nonescape for BEDC.Derived.BaireOnePointContinuityU

Chapter 7063

A Concrete Naming Certificate for $\mathsf{DyadicDifferentiationBasis}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis and the classical dyadic basis used in differentiation theory, the $\mathsf{DyadicDifferentiationBasis}^{\uparrow}$ packet records the finite interval basis read before an L10 Real or Completion consumer asks for a local refinement. It sits over the dyadic arithmetic surface of chapter 291, the rational interval locator of chapter 4202, the dyadic interval cover of chapter 1428, and the terminal real-name seal of chapter 38. The packet names only finite dyadic interval packets, rational locator rows, finite cover refinement rows, and Real seal handoffs; it is not a measure-theoretic differentiation theorem, a Vitali selection principle, quotient real equality, or ambient completeness.

Definition 7063.1 (Dyadic differentiation basis carrier)**.** *A* $\mathsf{DyadicDifferentiationBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, L, I, C, R, E, F, H, K, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, recording the admitted dyadic center, dyadic radius, positive tolerance, and endpoint comparisons for the requested interval.*
2. *L is the* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *row, locating the same request inside a rational interval window before any Real-facing read occurs.*
3. *I is the finite dyadic interval packet: a displayed lower endpoint, upper endpoint, radius, center, and containment witness over D and L.*
4. *C is the* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *row that stores the finite family of dyadic intervals covering the inspected rational window.*
5. *R is the refinement ledger, recording finite subinterval choices, containment checks, radius shrinkage, and common-refinement comparisons inside the cover row C.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is opened only after D, L, I, C, R have displayed the dyadic interval packet and its finite refinement route.*
7. *F is the consumer handoff row for L10 Real and Completion routes; it records that local basis reads pass through the displayed interval packet before any dense, cover, or completion-facing consumer sees a basis element.*

8. *H records componentwise* hsame *transport for dyadic endpoints, rational locator rows, interval packets, cover rows, refinement rows, Real seals, consumer handoffs, provenance, and local naming.*
9. *K records displayed* Cont *replay from a local Real request through D, L, I, C, R and then to E, F.*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicDifferentiationBasis}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalIntervalLocator}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicDifferentiationBasis}^{\uparrow}}$ *row.*

The classifier compares accepted basis packets only through these rows. It has no coordinate for a Vitali selector, an ambient sigma-algebra, a measure derivative, quotient real equality, countable choice, or Real completeness.

Lean4 ✓ `BEDC.Derived.DyadicDifferentiationBasisUp.DyadicDifferentiationBasisTasteGate single carrier alignment`

Theorem 7063.2 (Dyadic differentiation basis NameCert obligations)**.** *For every accepted* DyadicDifferentiationBas *carrier*

$$B = (D, L, I, C, R, E, F, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicDifferentiationBasis}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic endpoint and radius admission, rational interval location, finite dyadic interval packet formation, finite cover admission, refinement exactness, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, L10 consumer handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The analytic rows are exactly the dyadic ledger D, rational locator L, interval packet I, finite cover C, refinement ledger R, terminal Real seal E, and consumer handoff F.

The dyadic endpoint and radius data are read first. The row D fixes the scale and endpoint comparisons, while L locates the request inside a rational interval window before any basis element can be exported.

The interval and cover rows then provide the basis surface. The packet row I gives a displayed dyadic interval, and C records the finite cover family in which refinements are searched.

The refinement ledger R is the only row that may shrink or compare basis intervals. It records finite subinterval choices and common-refinement checks before the terminal seal E and L10 handoff F are public.

Finally H, K, P, N transport, replay, source, and name the same route. Since the carrier has no row for Vitali selection, measure derivatives, quotient equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7063.3 (Dyadic differentiation basis finite refinement)**.** *Every accepted* $\mathsf{DyadicDifferentiationBasis}^{\uparrow}$ *read that refines a local Real or Completion request factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RationalIntervalLocator}^{\uparrow} \longmapsto \mathsf{DyadicIntervalCover}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

For a carrier $B = (D, L, I, C, R, E, F, H, K, P, N)$, the consumer first reads the dyadic endpoint and radius ledger D, then the rational locator L, then the interval packet I, then the finite cover and refinement rows C, R, and only then the terminal Real seal E and L10 handoff F.

Proof. Begin with the carrier projection of Definition 7063.1. The request has no public basis element before D, L, I, C, R are displayed.

Read the dyadic and rational rows first. The dyadic ledger D fixes the scale of the endpoint and radius comparisons, and the rational locator L places the same request in a displayed rational interval window.

Next open the finite cover. The interval packet I is one displayed dyadic interval over the locator row, and the cover row C is the finite family from which refinements are selected.

Use the refinement ledger R for shrinkage and common-refinement comparisons. Because R records only finite subinterval choices inside C, the route remains a finite dyadic basis route rather than a Vitali or measure-theoretic selection.

The terminal Real seal E and handoff F are therefore downstream of the finite basis packet. The structural rows H, K, P, N preserve that order and add no quotient real equality, countable choice, ambient completeness, or measure derivative coordinate. □

Falsifiable prediction: Every accepted $\mathsf{DyadicDifferentiationBasis}^{\uparrow}$ L10 Real or Completion read exposes a DyadicRatCore endpoint-radius ledger, a RationalIntervalLocator row, a finite dyadic interval packet, a DyadicIntervalCover row, a refinement ledger, a RealUp seal, a consumer handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any basis element is public.

Independence witness: dyadicratcore, rationalintervallocator, dyadicintervalcover, real: DyadicDifferentiationBas is not bijective to any listed sibling because it jointly carries endpoint-radius ledgers, locator rows, finite interval packets, finite cover rows, refinement ledgers, Real seal handoff, L10 consumer routing, transport, replay, provenance, and local naming as one finite basis certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicDifferentiationBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicDifferentiationBasis}^{\uparrow}$ packet is generated from DyadicRatCore endpoint and radius rows, a RationalIntervalLocator row, a finite dyadic interval packet, a DyadicIntervalCover row, finite refinement rows, a Real seal, an L10 consumer handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicDifferentiationBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7063.1, Definition 7063.2, and Definition 7063.3 seed the finite dyadic basis route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalIntervalLocator}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicDifferentiationBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic differentiation, Vitali selection, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint-radius exactness, rational locator compatibility, finite cover refinement, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicDifferentiationBasisUp.

Chapter 7064

A Concrete Naming Certificate for $\mathsf{DyadicDenominatorClearance}^{\uparrow}$

Following Bishop and Bridges on constructive real-number calculation and the Hardy–Wright denominator-clearing discipline for rational arithmetic, the $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ packet records the finite common-scale step used before regular Cauchy consumers compare dyadic approximants. It sits after the rational and dyadic source rows of chapter 291, the signed normal-form rows of chapter 1865, the valuation ledger of chapter 2106, the finite stream interface of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name boundary of chapter 38. The packet names common-denominator clearing as a displayed finite route; it does not import quotient rational equality, host integer normalization, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7064.1 (Dyadic denominator clearance carrier)**.** *A* $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, V, M, E, T, S, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational and dyadic source row, read through* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*, exposing only the finitely presented numerator and dyadic-scale cells admitted by the source certificate.*
2. *V is the* $\mathsf{DyadicValuation}^{\uparrow}$ *row that records the visible dyadic exponents and the divisibility checks used to compare source scales.*
3. *M is the signed mantissa row, read through* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$*, carrying sign, finite mantissa, and zero-status data for each displayed source cell.*
4. *E is the common exponent row, generated from the displayed V cells and naming the shared dyadic scale to which the visible source cells are lifted.*
5. *T is the dyadic tolerance row, recording that the common exponent is fine enough for the current local tolerance request.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that lists exactly the finite source windows whose entries have been lifted to the common exponent.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that consumes the common-scale windows without receiving a quotient rational object or a host sequence function.*

8. *H records componentwise* hsame *transport for source, valuation, mantissa, exponent, tolerance, stream-window, regular handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a tolerance request through $Q, V, M, E, T, S, R, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicDenominatorClearance}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicValuation}^{\uparrow}$, $\mathsf{SignedDyadicNormalForm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicDenominatorClearance}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, V, M, E, T, S, R, H, C, P, N$. It has no coordinate for quotient rational equality, host integer normalization, trichotomy, selected representatives, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7064.2 (Dyadic denominator clearance NameCert obligations)**.** *For every accepted* $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ *carrier $D = (Q, V, M, E, T, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicDenominatorClearan}}$ *surface consists exactly of rational and dyadic source exposure, valuation exposure, signed mantissa exposure, common exponent admission, dyadic tolerance admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted carrier. The only arithmetic source rows are Q, V, M, E, T, so every denominator-clearing read starts with finitely displayed rational and dyadic cells, their visible valuations, their signed mantissas, a named common exponent, and the tolerance row that licenses that exponent.

The stream and regular rows are downstream of that arithmetic surface. Row S records the finite windows lifted to the common scale, and row R is available only after those windows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since quotient rational equality, host integer normalization, trichotomy, selected representatives, countable choice, and ambient Real completeness are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7064.3 (Dyadic denominator clearance scale locality)**.** *Every common-scale comparison exposed by an accepted* $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ *packet factors through the finite route*

$$Q, V, M \longmapsto E, T \longmapsto S, R.$$

The common exponent row E is determined only from displayed valuation and mantissa rows, and the resulting comparison exports no quotient rational equality, no host normalization algorithm, no trichotomy, and no selected representative.

Proof. Read Q, V, M first. These rows expose the source cells, the dyadic exponents visible for the current comparison, and the signed mantissas attached to those cells.

The common exponent row E is then admitted as a finite row over the displayed valuation data, and T checks that this exponent is fine enough for the local tolerance. No unlisted normalization routine is consulted.

Finally S and R consume only the lifted finite windows. Because the refused objects are not carrier rows, the scale-clearing comparison remains local to the displayed BEDC data. □

Theorem 7064.4 (Dyadic denominator clearance regular handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ *packet receives regular rational data only through displayed common-scale* $\mathsf{StreamName}^{\uparrow}$ *windows and the structural rows* H, C, P, N*. The handoff cannot be read as a proof of quotient rational equality, a host integer normal form, a trichotomy decision, a selected representative, a countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from Definition 7064.3. It places every common-scale comparison downstream of the finite source, valuation, mantissa, exponent, and tolerance rows.

The $\mathsf{StreamName}^{\uparrow}$ row S records exactly the finite windows produced by that route. A $\mathsf{RegSeqRat}^{\uparrow}$ consumer therefore reaches R only after the common-scale windows have been displayed.

Transport, replay, provenance, and local naming keep the handoff attached to the same carrier. Since the excluded principles are not rows of D, the regular handoff has no route by which to export them. □

Falsifiable prediction: Every $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ regular-rational read factors through rational and dyadic source rows, DyadicValuation rows, SignedDyadicNormalForm mantissas, a common exponent row, dyadic tolerance, StreamName windows, RegSeqRat handoff, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, signed-dyadic-normal-form, dyadic-valuation, streamname, regseqrat, real: $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source dyadic cells, visible valuations, signed mantissas, common exponent clearance, tolerance admission, finite stream windows, and regular rational handoff as one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicDenominatorClearance}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicDenominatorClearance}^{\uparrow}$ packet is generated from rational and dyadic source rows, DyadicValuation rows, SignedDyadicNormalForm mantissas, a common exponent row, dyadic tolerance, StreamName windows, RegSeqRat handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicDenominatorClearance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7064.1, Definition 7064.2, Definition 7064.3, and Definition 7064.4 seed the finite denominator-clearing route from DyadicRatCore valuation data and signed normal forms to StreamName windows and RegSeqRat consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicDenominatorClearance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient rational equality, host integer normalization, trichotomy, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source exposure, valuation exposure, signed mantissa exposure, common exponent admission, dyadic tolerance exactness, StreamName window exposure, RegSeqRat handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicDenominatorClearanceUp.

Chapter 7065

A Concrete Naming Certificate for $\mathsf{FiniteDifferenceTable}^{\uparrow}$

Following Newton's finite-difference calculus and Bishop–Bridges constructive analysis, the $\mathsf{FiniteDifferenceTable}^{\uparrow}$ packet records a finite triangular table of successive differences as displayed BEDC rows. It sits over the finite window interface of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the finite-difference surface of chapter 5135, the terminal real-name seal of chapter 38, and the completion-facing boundary of chapter 95. The packet supplies calculus, Real, and completion consumers with a finite table surface; it does not import a host derivative operator, quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7065.1 (Finite difference table carrier)**.** *A* $\mathsf{FiniteDifferenceTable}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, W, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row listing the finite source-name windows whose values seed the first table row.*
2. *W is the window ledger recording the finite index interval, row height, mesh step, and endpoint reuse schedule for the displayed table.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every source value and every derived table entry.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for adjacent subtraction, row-to-row error budgeting, and terminal seal precision.*
5. *L is the table ledger, listing the displayed rows*

   $$L_0, L_1, \ldots, L_k$$

   where L_0 is the read source row and each L_{i+1} is obtained from adjacent finite differences in L_i under the same dyadic budget.
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the table entries and the completion-facing readback endpoints.*
7. *H records componentwise* hsame *transport for source windows, regular rational readbacks, dyadic tolerance rows, table rows, Real seals, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a table request through*

$$S, W \longmapsto R \longmapsto D \longmapsto L \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FiniteDifferenceTable}^{\uparrow}$, $\mathsf{FiniteDifference}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDifferenceTable}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source windows, regular readbacks, dyadic budgets, table rows, Real seals, transport, replay, provenance, and local naming rows. It has no coordinate for a host derivative operator, quotient stream equality, selected limiting process, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteDifferenceTableUp.FiniteDifferenceTableTasteGate single carrier alignment`

Theorem 7065.2 (Finite difference table NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDifferenceTable}^{\uparrow}$ *carrier*

$$T = (S, W, R, D, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDifferenceTable}^{\uparrow}}$ *surface consists exactly of source-window admission, table-window admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for every displayed entry,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness for adjacent differences, table-ledger exactness for $L_0, \ldots, L_k$, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, completion-facing endpoint exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.FiniteDifferenceTableUp.FiniteDifferenceTableCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 7065.1. The rows S and W are the only source of inspected names, finite windows, mesh requests, row height, and endpoint reuse.

Proceed by finite induction on the displayed table rows. The base row L_0 is read from S through R under the dyadic budget D. In the induction step, L_{i+1} is obtained only from adjacent entries of L_i, again through R and D, so no host derivative operator or selected limiting process is introduced.

The terminal rows E, H, C, P, N seal, transport, replay, source, and name the same finite table route. Since the carrier has no coordinate for quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local certificate surface. □

Theorem 7065.3 (Finite difference table RegSeqRat handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{FiniteDifferenceTable}^{\uparrow}$ *packet receives the table only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R has read each displayed source entry and each displayed adjacent-difference entry under the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget D. The handoff reaches* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *only through the finite route*

$$S, W \longmapsto R \longmapsto D \longmapsto L \longmapsto E,$$

not through derivative semantics, quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 7065.2. They force every accepted table read to expose the source windows, table-window ledger, regular rational readback, dyadic tolerance row, table ledger, and Real seal before a downstream consumer can use the result.

Use finite induction on the displayed table rows. The base row is a finite $\mathsf{RegSeqRat}^{\uparrow}$ readback of the source windows. Each successor row is a finite adjacent-difference pass through the same readback and dyadic tolerance rows, so the table never becomes an infinite stream quotient or a selected limit.

Finally read the handoff rows. The $\mathsf{Real}^{\uparrow}$ seal and the $\mathsf{Completion}^{\uparrow}$ endpoint exposure are downstream of L and preserve the same finite route through H, C, P, N. Thus a Real or completion consumer receives only the displayed table data and not a host derivative, countable-choice schedule, quotient equality, selected limiting process, or ambient completeness claim. □

Theorem 7065.4 (Finite difference table calculus and completion route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{Completion}^{\uparrow}$ *consumer citing an accepted* $\mathsf{FiniteDifferenceTable}^{\uparrow}$ *packet must first read the source windows* S*, the table-window ledger* W*, the regular rational readback row* R*, the dyadic tolerance row* D*, and the full table ledger* $L_0, \ldots, L_k$*. Only then may it consume the terminal seal* E *with transport, replay, provenance, and local naming rows still visible.*

Proof. Project the table carrier. The route to any calculus, Real, or completion consumer is displayed as $S, W, R, D, L, E, H, C, P, N$.

Apply the RegSeqRat handoff. It places every source entry and adjacent-difference entry behind R and D before the terminal seal can be read.

The finite induction on $L_0, \ldots, L_k$ accounts for the whole table ledger. The structural rows then transport and replay the same finite object, so the downstream route cannot add derivative operators, quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDifferenceTable}^{\uparrow}$ read factors through source StreamName windows, RegSeqRat readbacks, DyadicRatCore adjacent-difference budgets, displayed table rows, a RealUp seal, completion-facing endpoint exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: finite-difference, streamname, regseqrat, dyadicratcore, real, completion: $\mathsf{FiniteDifferenceTable}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source windows, finite table ledger, rowwise adjacent-difference route, rational readback, dyadic budgets, Real seal, completion endpoint exposure, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDifferenceTable}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteDifferenceTable}^{\uparrow}$ packet is generated from finite StreamName source windows, RegSeqRat readbacks, DyadicRatCore adjacent-difference budgets, a displayed table ledger, a RealUp seal, completion-facing endpoint exposure, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteDifferenceTable}^{\uparrow}}$, seed)

Scope closed: Definition 7065.1, Definition 7065.2, Definition 7065.3, and Definition 7065.4 seed the finite table carrier, certificate surface, rational readback handoff, and calculus/Real/completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteDifferenceTable}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host derivative operators, quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-window admission, rowwise difference induction, RegSeqRat readback exactness, DyadicRatCore tolerance exactness, Real sealing, completion endpoint exposure, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDifferenceTableUp.

Chapter 7066

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$ packet records the finite window-selection surface used when a regular Cauchy name is inspected at a displayed dyadic tolerance. It sits between the finite $\mathsf{StreamName}^{\uparrow}$ window route of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the tail selector of chapter 6941. The packet selects one finite inspection window already justified by the displayed regular-Cauchy data; it is not a quotient stream equality, a selected limit, a host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7066.1 (Regular Cauchy window selector carrier)**.** *A* $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, S, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the finite precision demand.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window row inspected for that demand.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to S.*
4. *T is the* $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ *tail-window row certifying that S is admitted by the displayed regular-Cauchy route.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R, T have been displayed.*
6. *H records componentwise* hsame *transport for the tolerance, window, readback, tail-selector, and seal rows.*
7. *C records displayed* Cont *replay of the same finite selection route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, T, E, H, C, P, N$. It contains no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7066.2 (Regular Cauchy window selector NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$ *carrier* $W = (D, S, R, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowSelector}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission, finite stream-window exposure, regular rational readback, tail-window selection, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7066.1. The rows $D, S, R, T, E, H, C, P, N$ are the whole selector packet, so the local naming surface is finite and displayed.

The selection route is read in order. The dyadic row fixes the demanded tolerance, the stream row exposes the inspected finite window, and the regular rational row reads the associated rational data.

The tail-window row T then records that this finite window is admitted by the existing $\mathsf{RegularCauchyTailWindowSelector}^{\uparrow}$ route. The rows E, H, C, P, N seal, transport, replay, source, and name the same finite route, leaving no separate coordinate for a choice schedule or hidden limit. □

Theorem 7066.3 (Regular Cauchy window selector Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$ *packet reads the seal row* E *only after the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{RegularCauchyTailWindowSelector}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

has exposed the rows $D, S, R, T, E, H, C, P, N$*. The seal is a finite BEDC-native window-selection certificate for downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *arguments; it does not claim quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7066.2. They place the dyadic tolerance, stream window, regular rational readback, and tail-window selector before any Real-facing row can be consumed.

Read the tail selector through chapter 6941. That sibling supplies the finite tail admission used by T, while the present packet binds the admitted window to the single Real seal row E.

The carrier is exhausted by $D, S, R, T, E, H, C, P, N$. Since no row names a quotient stream, selected limit, host real equality, countable-choice enumeration, trichotomy proof, or ambient completeness theorem, the seal remains a finite window-selection certificate. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$ consumer is refuted if it reaches a Real-facing seal before displaying the dyadic tolerance, StreamName window, RegSeqRat readback, RegularCauchyTailWindowSelector row, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, dyadicratcore, regseqrat, real, regular-cauchy-tail-window-selector: $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$ is not bijective to any listed sibling because it binds a precision demand, one finite stream window, regular rational readback, tail-window admission, Real sealing, componentwise hsame, displayed Cont, Pkg, and local NameCert into one accepted window-selection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowSelector}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyWindowSelector}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a RegularCauchyTailWindowSelector row, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyWindowSelector}\uparrow}$, seed)

Scope closed: Definition 7066.1, Definition 7066.2, and Definition 7066.3 seed the finite window-selection route for regular Cauchy names.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyWindowSelector}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exposure, dyadic tolerance coverage, RegSeqRat readback, tail-window admission, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyWindowSelectorUp.

Chapter 7067

A Concrete Naming Certificate for $\mathsf{F\Sigma Set}^{\uparrow}$

Following descriptive set theory and classical topology, the $\mathsf{F\Sigma Set}^{\uparrow}$ packet records the traditional countable-union-of-closed-sets interface as finite BEDC NameCert data. It sits after the generated-set boundary of chapter 3384, the zero-locus surface of chapter 1858, the dual open-schedule route of chapter 3547, and the indexed open and closed-row discipline of chapter 88. The packet names the finite surface that Borel hierarchy consumers need before they read a displayed closed-row schedule; it does not import host subsets, quotient set equality, a selected countable enumeration, ambient countable choice, or a classical descriptive-set theorem.

Definition 7067.1 (F-sigma set carrier)**.** *An* $\mathsf{F\Sigma Set}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, B, Z, G, S, W, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the named open and closed-row vocabulary visible to the current consumer.*
2. *B is the* $\mathsf{BorelSet}^{\uparrow}$ *generated-set row that receives the handoff after the displayed closed schedule has been inspected.*
3. *Z is the* $\mathsf{ZeroSet}^{\uparrow}$ *closed-locus row used when a closed component is supplied as the zero set of a displayed continuous* $\mathsf{Real}^{\uparrow}$*-valued map.*
4. *G is the* $\mathsf{GDeltaSet}^{\uparrow}$ *sibling row used only as a dual-route comparison for open schedules and Borel handoff discipline.*
5. *S is the countable closed-row schedule. Each visible prefix names the closed components, the schedule position, and the topology row over which that component is read.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row recording exactly the schedule positions, component indices, and finite membership queries visible before the Borel handoff.*
7. *H records componentwise* hsame *transport for the topology source, Borel row, zero-set row, GDeltaSet sibling row, schedule, windows, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a topology or Borel query through T, S, W before the generated-set row B is consumed.*

9. *P is the* Pkg *provenance over* $\mathsf{F\Sigma Set}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{ZeroSet}^{\uparrow}$, $\mathsf{GDeltaSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{F\Sigma Set}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, Z, G, S, W, H, C, P, N$. It has no coordinate for host powersets, quotient equality of subsets, selected countable enumerations, countable choice, or ambient Borel hierarchy completeness.

Lean4 (statement) `BEDC.Derived.FSigmaSetUp`

Theorem 7067.2 (F-sigma set NameCert obligations)**.** *For every accepted* $\mathsf{F\Sigma Set}^{\uparrow}$ *carrier* $F = (T, B, Z, G, S, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{F\Sigma Set}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, Borel row, zero-set row, GDeltaSet sibling row, closed-row schedule, finite windows, transport, replay, provenance, and local naming;*
2. *closed-schedule exposure, requiring every inspected union stage to appear as a displayed finite prefix of S before it reaches B;*
3. *finite-window stability, requiring each schedule position, component index, and membership query to be read through W;*
4. *closed-component readback, requiring every scheduled component to pass through the topology source T and, when supplied by a zero-locus presentation, through the* $\mathsf{ZeroSet}^{\uparrow}$ *row Z;*
5. *Borel handoff, requiring the generated-set row B to consume only the displayed route through T, S, W and the closed-component readback;*
6. *sibling compatibility, requiring the* $\mathsf{GDeltaSet}^{\uparrow}$ *row G to serve only as the dual open-schedule comparison surface and not as a complement-selection principle;*
7. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N;*
8. *ledger refusal, excluding host powersets, selected enumerations, countable choice, quotient set equality, classical complement selection, and ambient descriptive-set theorems.*

No $\mathsf{F\Sigma Set}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.FSigmaSetUp.FSigmaSetCarrier namecert obligations`

Proof. Project the carrier of Definition 7067.1. The tuple displays exactly the topology source, Borel row, zero-set row, GDeltaSet sibling row, countable closed-row schedule, finite windows, transport, replay, provenance, and local naming.

The schedule and window obligations are read through S and W. A consumer sees only a finite prefix of the countable closed schedule, and every component index and membership query is inspected through the same displayed finite window.

Closed-component readback is forced by T and Z. The topology source supplies the closed-row vocabulary, and the zero-set row supplies the zero-locus presentation when the component is offered in that form.

Finally H, C, P, N transport, replay, source, and name the same route. Since no listed row stores a host powerset, selected enumeration, countable-choice selector, quotient set equality, classical complement selector, or ambient descriptive-set theorem, the enumerated obligations exhaust the local NameCert surface. □

Theorem 7067.3 (F-sigma set Borel handoff)**.** *Every Borel consumer of an accepted* $\mathsf{F\Sigma Set}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{ZeroSet}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{BorelSet}^{\uparrow}.$$

More precisely, the consumer first reads the topology source row T*, then the closed-row schedule and finite windows* S, W*, then the zero-set row* Z *when a scheduled component is presented as a zero locus, and only then the generated-set row* B*. The exported object is a finite NameCert packet for the displayed countable closed-row route; it is not a host subset, a chosen enumeration, a complement-selected* $\mathsf{GDeltaSet}^{\uparrow}$ *packet, an ambient descriptive-set theorem, or a quotient set equality.*

Proof. Begin with a Borel consumer of the accepted packet. Carrier admission exposes the topology source row T, but the generated-set row B is not available until the closed schedule and finite windows have been displayed.

Replay the continuation row C. The read moves through S and W, so every countable-union stage is consumed only as a finite visible prefix with finite component and query observations.

When a closed component is presented by a zero locus, the read passes through Z and therefore through the zero-set discipline of chapter 1858. The sibling $\mathsf{GDeltaSet}^{\uparrow}$ row G supplies only a comparison route for the dual schedule shape; it does not choose complements.

The remaining rows H, P, N preserve, source, and name the same route. Therefore every Borel consumer factors through the displayed topology, zero-set, schedule, and window route, with no host subset, selected enumeration, complement-selected GDeltaSet packet, ambient descriptive-set theorem, or quotient set equality exported by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{F\Sigma Set}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{F\Sigma Set}^{\uparrow}}$, seed)

Scope closed: Definition 7067.1, Definition 7067.2, and Definition 7067.3 seed the finite F-sigma route over topology, zero-set, GDeltaSet, StreamName, Borel, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{F\Sigma Set}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close host powersets, selected countable enumerations, countable choice, quotient set equality, classical complement selection, ambient descriptive-set theorems, checked NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-schedule exposure, finite-window stability, closed-component readback, Borel handoff, sibling compatibility, transport, replay, provenance, local naming, and ledger-refusal proofs for BEDC.Derived.FSigmaSetUp.

Constructive story: An $\mathsf{F\Sigma Set}^{\uparrow}$ packet is generated from a $\mathsf{Topology}^{\uparrow}$ source row, a $\mathsf{BorelSet}^{\uparrow}$ row, a $\mathsf{ZeroSet}^{\uparrow}$ component row, a $\mathsf{GDeltaSet}^{\uparrow}$ sibling row, a countable closed-row schedule, finite StreamName windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7068

A Concrete Naming Certificate for $\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}$

Following Birkhoff and James on normed-space orthogonality, the $\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}$ packet records the finite norm-variation surface by which one displayed vector is orthogonal to another in the Birkhoff–James sense. It sits after the normed and Hilbert source rows of chapter 89 and chapter 91, the metric and projection rows of chapter 57 and chapter 2356, and the scalar readback rows of chapter 38. The packet names only a finite norm-comparison ledger for scalar perturbations; it does not import a host inner-product characterization, a selected projection map, quotient equality of vectors, trichotomy, or ambient completeness.

Definition 7068.1 (BirkhoffJamesOrthogonality carrier)**.** *A* $\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, H, x, y, \Lambda, L, R, M, Q, T, C, P, N)$$

with the following displayed rows:

1. *X is the normed-source row, exposing the carrier, addition, scalar action, zero vector, and norm read through* $\mathsf{Norm}^{\uparrow}$*.*
2. *H is the optional Hilbert-source comparison row, present only when an inner-product route is being compared with the norm-variation route.*
3. *x and y are the two displayed vector rows whose relation is being named.*
4. *Λ is the scalar perturbation window, listing the finite scalar samples and tolerance requests used to test $x + \lambda y$.*
5. *L is the norm-comparison ledger, recording the displayed inequalities $\|x\| \leq \|x + \lambda y\|$ for the perturbation window and its stated tolerance refinements.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for the norm values and comparison outcomes in L.*
7. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row induced by the norm source, keeping every distance read tied to the same displayed norm ledger.*
8. *Q is the projection-facing handoff row, recording what a* $\mathsf{MetricProjection}^{\uparrow}$ *consumer may read from the orthogonality ledger before adding its own endpoint evidence.*
9. *T records componentwise* hsame *transport for source, Hilbert comparison, vector, scalar-window, norm-ledger, Real readback, metric, projection-handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from an orthogonality request through* $X, H, x, y, \Lambda, L, R, M, Q, T, P, N$.
11. *P is the* Pkg *provenance over* BirkhoffJamesOrthogonality$^{\uparrow}$, Norm$^{\uparrow}$, Hilbert$^{\uparrow}$, MetricProjection$^{\uparrow}$, Real$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* NameCert$_{\text{BirkhoffJamesOrthogonality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host orthogonality predicate, an inner-product theorem, a selected best approximation, quotient vector equality, trichotomy of scalar comparisons, countable choice over perturbations, or ambient completion.

Theorem 7068.2 (BirkhoffJamesOrthogonality NameCert obligations)**.** *For every accepted* BirkhoffJamesOrthogon *carrier $O = (X, H, x, y, \Lambda, L, R, M, Q, T, C, P, N)$, the local* NameCert$_{\text{BirkhoffJamesOrthogonality}^{\uparrow}}$ *surface consists exactly of normed-source exposure, optional Hilbert comparison exposure, two-vector exposure, scalar perturbation-window exposure, norm-comparison ledger exactness, Real readback, induced metric readback, projection-facing handoff, componentwise transport, displayed replay, provenance, and local naming. A Birkhoff–James orthogonality read is admitted only after x, y, Λ, L, and R are visible in the same packet.*

Proof. Project the carrier of Definition 7068.1. The source norm, optional Hilbert comparison, and two vector rows are exactly X, H, x, y.

The scalar-variation data are supplied by Λ and L. The ledger L is the only row that records the comparison between $\|x\|$ and $\|x + \lambda y\|$, and R is the only row that exports these comparisons as Real-facing reads.

The metric and projection-facing rows M, Q remain downstream of the same norm ledger. They may expose distance and projection-consumer data, but they do not add a nearest-point selector or replace the norm-variation test by a host projection theorem.

Transport through T preserves the displayed coordinates, while C, P, N replay, source, and name the same packet. Since the refused objects are not carrier rows, the listed fields exhaust the local NameCert obligations. □

Theorem 7068.3 (BirkhoffJamesOrthogonality norm-variation handoff)**.** *Every projection-facing, Hilbert-facing, metric-facing, or Real-facing consumer of an accepted* BirkhoffJamesOrthogonality$^{\uparrow}$ *packet factors through the finite norm-variation route*

$$X, x, y, \Lambda, L, R \longmapsto M, Q.$$

The consumer receives a displayed scalar perturbation window, norm-comparison ledger, Real readback, induced metric row, and projection-facing handoff. It receives no host inner-product characterization, selected projection endpoint, quotient vector equality, trichotomy branch, countable-choice perturbation family, or ambient completeness theorem.

Proof. Start with an accepted consumer read. By the obligation surface, the read must first expose the normed source X, the two vectors x, y, the perturbation window Λ, the comparison ledger L, and the Real readback R.

The Hilbert row H can only compare an existing Hilbert presentation with that same norm-variation ledger. It is not a replacement for the ledger and does not export the inner-product characterization as a separate host theorem.

The metric and projection stages are M and Q. They read the norm ledger as distance data and hand it to projection-facing consumers, but endpoint selection belongs to the downstream MetricProjection$^{\uparrow}$ packet.

Thus every public handoff remains inside the displayed route and cannot project any of the refused host principles from the $\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}$ carrier. □

Falsifiable prediction: Every accepted $\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}$ read displays a normed source, optional Hilbert comparison row, two vector rows, a scalar perturbation window, a norm-comparison ledger, Real readback, induced Metric row, projection-facing handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert row before it is consumed.

Independence witness: norm, hilbert, metricprojection, real, metric: $\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two vectors, scalar perturbation windows, norm-comparison ledgers, Real readback, metric readback, projection-facing handoff, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}}$.

Constructive story: A $\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}$ packet is generated from a Norm source, optional Hilbert comparison row, two vector rows, scalar perturbation windows, norm-comparison ledgers, Real readback, induced Metric rows, MetricProjection-facing handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7068.1, Definition 7068.2, and Definition 7068.3 seed the finite Birkhoff–James norm-variation packet through displayed normed-source, two-vector, scalar-window, comparison-ledger, Real, Metric, and projection-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffJamesOrthogonality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host inner-product characterization, selected projection endpoint, quotient vector equality, trichotomy, countable choice over scalar perturbations, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scalar-window exposure, norm-comparison ledger exactness, Real readback, Metric readback, projection-facing handoff, transport, replay, provenance, and local NameCert registration for BEDC.Derived.BirkhoffJamesOrthogonalityUp.

Chapter 7069

A Concrete Naming Certificate for $\mathsf{Arc}^{\uparrow}$

Following Munkres and Bishop–Bridges, an arc is read as a certified image of a closed interval under a displayed continuous map. The $\mathsf{Arc}^{\uparrow}$ packet is anchored by the closed interval source of chapter 1591, the map graph and modulus rows of chapter 130, the compact-metric source of chapter 129, the connected-space boundary of chapter 2353, and the terminal real-name seal of chapter 38. It records the interval-image route through finite BEDC rows; it is not a host subset of a topological space, a quotient path image, or a selected point-set equality.

Definition 7069.1 (Arc carrier)**.** *An* $\mathsf{Arc}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, M, K, C, R, H, T, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, naming the endpoint interval, order witnesses, and endpoint real seals inspected by the packet.*
2. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, recording the displayed map from I into the target metric carrier together with the finite continuity or modulus ledger used for image reads.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *target-source row through which finite nets, distance tests, and compact image windows are exposed.*
4. *C is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *image-continuity row, recording the connected interval-image boundary visible to continuum-facing consumers.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for endpoints, radii, modulus budgets, and target-distance seals.*
6. *H records componentwise* hsame *transport for the interval, map, compact-metric, connectedness, real-readback, provenance, and naming rows.*
7. *T records displayed* Cont *replay from interval requests through map evaluation, compact-metric windows, connected-image reads, and real seals.*
8. *P is the* Pkg *provenance over* $\mathsf{Arc}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{Arc}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, K, C, R, H, T, P, N$. It has no coordinate for host subset equality, quotient path images, arbitrary open-cover compactness, selected representatives, or ambient real completeness.

Theorem 7069.2 (Arc NameCert obligations)**.** *For every accepted $\mathsf{Arc}^{\uparrow}$ carrier $A = (I, M, K, C, R, H, T, P, N)$, the local $\mathsf{NameCert}_{\mathsf{Arc}^{\uparrow}}$ surface consists exactly of closed-interval source admission through I, displayed continuous-map admission through M, compact-metric image-window admission through K, connected-image exposure through C, real endpoint and tolerance readback through R, componentwise transport through H, displayed replay through T, provenance through P, and local naming through N.*

Every arc-facing consumer must read these rows before it may treat the packet as interval-image data. No obligation is discharged by a host point-set topology theorem, quotient equality of images, selected image representatives, arbitrary open covers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Proof. Project the carrier of Definition 7069.1. The closed interval row I and the continuous-map row M are the only source rows through which an interval image can be read.

The compact and connected image faces are then finite rows of the same packet. The row K supplies compact-metric windows and distance tests for the target image, while C records the connected-image boundary consumed by continuum-facing readers. The row R supplies the endpoint and tolerance seals needed by both faces.

Transport and replay remain componentwise. The rows H and T move and expose exactly the interval, map, compact-metric, connectedness, and real-readback rows, while P and N record provenance and local naming.

Since the carrier has no coordinate for host subset equality, quotient image equality, arbitrary open-cover compactness, selected representatives, countable choice, or ambient real completeness, the NameCert obligations are exhausted by the displayed rows. □

Theorem 7069.3 (Arc interval image nonescape)**.** *Every public interval-image read of an accepted $\mathsf{Arc}^{\uparrow}$ packet factors through the displayed route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ConnectedSpace}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside the rows $I, M, K, C, R, H, T, P, N$. The route exposes a closed interval, a displayed continuous map, compact-metric image windows, connected-image data, and real tolerance seals; it exports no host image subset, quotient path-image equality, selected representative, open-cover compactness theorem, or ambient real-completeness witness.

Proof. Start from the carrier and read I before M. The packet names an interval-image object only after the closed interval and displayed continuous map are both visible.

Next read K, C, R. Compact-metric image windows, connected-image data, and real tolerance seals are downstream of the same map row, so a consumer cannot replace them by a detached host subset or by a quotient image object.

Finally use H, T, P, N. These rows transport, replay, source, and name the finite interval-image route without adding another image coordinate. Therefore every public interval-image read remains inside the displayed BEDC rows. □

Falsifiable prediction: Every accepted $\mathsf{Arc}^{\uparrow}$ read exposes a closed interval source, a displayed continuous-map row, compact-metric image windows, connected-image data, real endpoint and

tolerance seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before an arc-facing consumer can inspect the packet.

Independence witness: closedboundedinterval, continuousmap, compactmetric, connected-space, real: $\mathsf{Arc}^{\uparrow}$ is not bijective to any listed sibling because it binds interval-source rows, map rows, compact image windows, connected-image exposure, real readback, transport, replay, provenance, and local naming in one interval-image carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{Arc}^{\uparrow}}$**.**

Constructive story: An $\mathsf{Arc}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a ContinuousMapUp display row, CompactMetricUp image windows, a ConnectedSpaceUp image boundary, RealUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Arc}^{\uparrow}}$, seed)

Scope closed: Definition 7069.1, Definition 7069.2, and Definition 7069.3 seed the finite interval-image boundary over closed intervals, displayed continuous maps, compact-metric windows, connected-image rows, real readback, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Arc}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host subset equality, quotient image equality, arbitrary open-cover compactness, selected representatives, countable choice, Lean-checked obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, continuous-map admission, compact image-window admission, connected-image exposure, real readback, transport, replay, provenance, and local naming for BEDC.Derived.ArcUp.

Chapter 7070

A Concrete Naming Certificate for $\mathsf{RationalCauchyTailBound}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RationalCauchyTailBound}^{\uparrow}$ packet records the finite rational tail-bound ledger used before a regular Cauchy read is handed to a Real or Completion consumer. It sits after the interval localization of chapter 4202, the dyadic tolerance core of chapter 291, the finite stream-window route of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name boundary of chapter 38. The packet names only the displayed tail-bound evidence; it is not quotient equality of rational streams, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7070.1 (Rational Cauchy tail-bound carrier)**.** *A* $\mathsf{RationalCauchyTailBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *source row, exposing the rational center, interval endpoints, and the finite index threshold at which the tail read begins.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the displayed dyadic radius, slack row, and comparison budget used to test late rational observations.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by L and budgeted by D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational tail estimate obtained from the displayed windows and dyadic budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after L, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the locator, dyadic tolerance ledger, finite windows, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a requested precision threshold through L, D, W, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RationalCauchyTailBound}^{\uparrow}$, $\mathsf{RationalIntervalLocator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCauchyTailBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, D, W, R, E, H, C, P, N$. It has no coordinate for quotient equality of rational streams, a selected real limit, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7070.2 (Rational Cauchy tail-bound NameCert obligations)**.** *For every accepted* RationalCauchyTailBour *carrier*

$$T = (L, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCauchyTailBound}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the rational locator row, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *locator exactness, requiring L to display the rational center, interval endpoints, and finite tail threshold that the bound is allowed to inspect;*
3. *dyadic tolerance exactness, requiring D to store the radius, slack, and comparison budget used for late observations;*
4. *window compatibility, requiring W to expose only the StreamName observations opened by L and budgeted by D;*
5. *regular readback exactness, requiring R to consume L, D, W before any Real seal is visible;*
6. *Real-seal nonescape, requiring E to be terminal with respect to the route L, D, W, R and to export no quotient stream equality, selected limit, countable-choice schedule, host real equality, trichotomy, ambient completeness theorem, Lean verification, or bridge data;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No rational Cauchy tail-bound obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7070.1. The accepted packet displays exactly the rational locator, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows.

The analytic clauses are forced by the route. The row L is the only coordinate that carries the rational center, interval endpoints, and finite tail threshold, while D is the only coordinate that carries the dyadic radius, slack, and comparison budget.

The window and readback clauses are downstream. The row W reads only the observations opened by L and budgeted by D, and R is the first row that repacks those finite observations as regular rational tail evidence.

Finally, E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient completeness, Lean verification, and bridge data are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7070.3 (Rational Cauchy tail-bound regular Real handoff)**.** *Every accepted rational tail-bound read that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer must factor through the finite route*

$$L \longmapsto D \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives the rational locator row, dyadic tolerance ledger, finite StreamName windows, regular rational readback, terminal Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The consumer receives no quotient equality of rational streams, selected limit, countable-choice schedule, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

Proof. Project the accepted carrier $T = (L, D, W, R, E, H, C, P, N)$. The tail-bound data starts in L, and the only tolerance data available to the read is the dyadic ledger D.

The observation route is finite. The StreamName row W exposes the bounded windows licensed by L and D, and the RegSeqRat row R is the first point where those windows are repacked as regular rational tail evidence.

The Real-facing consumer reaches the terminal seal only through E and then through the structural rows H, C, P, N. These rows preserve and replay the same route; they do not add quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Falsifiable prediction: Every $\mathsf{RationalCauchyTailBound}^{\uparrow}$ read into RegSeqRat, Real, or Completion factors through one RationalIntervalLocator row, one DyadicRatCore tolerance ledger, one StreamName finite-window row, one RegSeqRat readback row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: rational-interval-locator, dyadicratcore, streamname, regseqrat, real: $\mathsf{RationalCauchyTailBound}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a rational interval locator, finite tail threshold, dyadic tolerance ledger, finite stream windows, regular rational readback, and the terminal RealUp seal that witnesses a bounded tail route rather than a completed quotient object.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCauchyTailBound}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalCauchyTailBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7070.1, Definition 7070.2, and Definition 7070.3 seed the finite rational tail-bound route through RationalIntervalLocator source data, DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalCauchyTailBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of rational streams, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, locator exactness, dyadic tolerance exactness, window compatibility, regular readback exactness, Real-seal nonescape, transport, replay, provenance, and handoff factorization for BEDC.Derived.RationalCauchyTailBoundUp.

Constructive story: A $\mathsf{RationalCauchyTailBound}^{\uparrow}$ packet is generated from one RationalIntervalLocator row, one DyadicRatCore tolerance ledger, one StreamName finite-window row, one RegSeqRat readback row, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7071

A Concrete Naming Certificate for $\mathsf{FinitePrefixBar}^{\uparrow}$

Following Brouwer, Troelstra–van Dalen, and Bishop–Bridges on spreads, bars, and finite choice-sequence observation, the $\mathsf{FinitePrefixBar}^{\uparrow}$ packet records the constructive L10 interface by which a finite bar over admitted spread prefixes is named before any countable-name or real-facing consumer can read it. It sits after the spread-prefix carrier of chapter 1677, the spread-bar route of chapter 5976, and the finite fan packet of chapter 400. The packet is a finite certificate surface, not a completed branch, countable choice principle, quotient stream equality, fan compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness row.

Definition 7071.1 (Finite prefix bar carrier)**.** *A* $\mathsf{FinitePrefixBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, B, A, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the accepted* $\mathsf{BrouwerSpread}^{\uparrow}$ *row, including the decidable prefix tree, StreamName schedule, and admitted finite-prefix window.*
2. *B is the* $\mathsf{BrouwerSpreadBar}^{\uparrow}$ *row restricted to the prefixes visible in S, with decidable bar decisions and monotone prefix-extension checks.*
3. *A is the* $\mathsf{FanTheorem}^{\uparrow}$ *comparison row, used only as a finite bounded-bar witness when the displayed spread is binary or finitely branching.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *read window through which countable-name consumers request the displayed prefixes.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to every analytic observation generated from the finite prefix window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed to real-facing consumers after the prefix, bar, stream-name, and regular-rational rows have already been displayed.*
7. *H records componentwise* hsame *transport for spread prefixes, bar decisions, fan comparison, stream windows, regular-rational readback, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a finite prefix-bar request through*

$$S, B, A \longmapsto W \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FinitePrefixBar}^{\uparrow}$, $\mathsf{BrouwerSpread}^{\uparrow}$, $\mathsf{BrouwerSpreadBar}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePrefixBar}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, A, W, R, E, H, C, P, N$. It has no coordinate for a completed branch, a selector over all bars, quotient stream equality, fan compactness as an ambient theorem, selected limits, or Real completeness.

Theorem 7071.2 (Finite prefix bar NameCert obligations)**.** *For every accepted* $\mathsf{FinitePrefixBar}^{\uparrow}$ *carrier*

$$F = (S, B, A, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FinitePrefixBar}^{\uparrow}}$ *surface consists exactly of carrier admission for the Brouwer spread prefix row, restricted spread-bar row, finite fan comparison row, StreamName window, RegSeqRat readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; classifier agreement on the same rows; and nonescape requiring every public read to factor through $S, B, A, W, R, E, H, C, P, N$.*

Proof. Project the carrier of Definition 7071.1. The tuple exposes the spread prefix row S, the restricted bar row B, the finite fan comparison row A, the stream-name window W, the regular-rational readback R, and the terminal Real seal E before the structural rows are considered.

Classifier agreement is rowwise agreement over that same tuple. The spread component is read through chapter 1677, the finite bar component through chapter 5976, and the finite fan comparison through chapter 400.

The structural rows close the certificate surface. The transport row H compares only displayed coordinates, the continuation row C replays only the finite route, and P, N source and name the same packet. Since no extra coordinate exists, the listed rows exhaust the local NameCert obligations. □

Theorem 7071.3 (Finite prefix bar nonescape)**.** *Every countable-name, completion-facing, or real-facing read of an accepted* $\mathsf{FinitePrefixBar}^{\uparrow}$ *packet must first pass through the finite route*

$$S, B, A \longmapsto W \longmapsto R \longmapsto E, H, C, P, N.$$

The read receives only admitted spread prefixes, restricted bar decisions, finite fan comparison data, StreamName windows, RegSeqRat readbacks, a terminal Real seal, transport, replay, provenance, and local naming. It does not obtain a completed branch, countable choice, quotient stream equality, fan compactness as a global theorem, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a public read of the packet. The only route to the analytic rows passes through the displayed prefix and bar rows S, B and, when available, the finite fan comparison row A.

Replay the continuation row C. It opens the StreamName window W, then reads the regular-rational row R, and only after those rows have been displayed does it expose the terminal Real seal E.

Finally attach transport, provenance, and naming through H, P, N. The packet has no field for a branch selector, quotient stream equality, an external compactness theorem, selected limits, or Real completeness. Therefore every downstream read remains inside the stated finite route. □

Falsifiable prediction: Every accepted $\mathsf{FinitePrefixBar}^{\uparrow}$ public StreamName, RegSeqRat, Real, or Completion-facing read factors through a Brouwer spread prefix row, restricted Brouwer spread-bar row, finite FanTheorem comparison row, StreamName window, RegSeqRat readback, RealUp

seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: brouwer-spread, brouwer-spread-bar, fan-theorem, streamname, regseqrat, real: $\mathsf{FinitePrefixBar}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite spread-prefix admission, restricted bar decisions, bounded fan comparison, stream-name windows, regular-rational readback, terminal Real sealing, transport, replay, provenance, and local naming while refusing completed branches, countable choice, quotient streams, ambient compactness, selected limits, and Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePrefixBar}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitePrefixBar}^{\uparrow}$ packet is generated from Brouwer spread prefixes, restricted Brouwer spread-bar decisions, finite FanTheorem comparison data, StreamName windows, RegSeqRat readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePrefixBar}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7071.1, Definition 7071.2, and Definition 7071.3 seed the constructive L10 finite-bar interface for countable-name and real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePrefixBar}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed branches, countable choice, quotient stream equality, fan compactness, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier agreement, finite-bar route exactness, StreamName and RegSeqRat handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.FinitePrefixBarUp.

Chapter 7072

A Concrete Naming Certificate for $\mathsf{AxisCarryCriticalPair}^{\uparrow}$

Following Newman-style local confluence analysis for finite rewrite systems, the $\mathsf{AxisCarryCriticalPair}^{\uparrow}$ packet records the displayed critical pair formed by two overlapping Zeckendorf carry windows. It sits between the carry classifier of chapter 544, the carry-normalization handoff of chapter 608, the normal-word boundary of chapter 278, the route-separation surface of chapter 1049, the diamond-route packet of chapter 1118, and the confluence packet of chapter 713. The packet names a finite local overlap only; it is not a kernel rewrite, a quotient by history sameness, a global normalizer, or an unbounded confluence theorem.

Definition 7072.1 (Axis carry critical-pair carrier)**.** *An* $\mathsf{AxisCarryCriticalPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (s, \ell, r, j, n, V, B, H, C, P, N)$$

with the following displayed rows:

1. *s is the overlapping Zeckendorf source-window row containing two visible carry redexes.*
2. *ℓ is the left-first carry target row reached by applying the left window through* $\mathsf{ZCarry}^{\uparrow}$*.*
3. *r is the right-first carry target row reached by applying the right window through* $\mathsf{ZCarry}^{\uparrow}$*.*
4. *j is the shared join row obtained by normalizing the remaining visible carry window from both ℓ and r.*
5. *n is the terminal* $\mathsf{ZNormal}^{\uparrow}$ *row reached from j by the local carry-normalization handoff.*
6. *V is the Fibonacci value ledger, recording that s, ℓ, r, j, n display the same finite value sum.*
7. *B is the boundary row recording the non-*hsame *status of the two carry edges and the fact that the join is a route comparison rather than a history identification.*
8. *H records componentwise* hsame *transport for s, ℓ, r, j, n, V, B and the structural rows.*
9. *C records displayed* Cont *replay through the source window, the two one-step branches, the shared join, the normal target, the value ledger, the boundary row, provenance, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{AxisCarryCriticalPair}^{\uparrow}$*,* $\mathsf{ZCarry}^{\uparrow}$*,* $\mathsf{ZeckendorfCarryNormalization}^{\uparrow}$*,* $\mathsf{ZNormal}^{\uparrow}$*,* $\mathsf{AxisCarryRouteSeparation}^{\uparrow}$*,* $\mathsf{AxisCarryDiamondRoute}^{\uparrow}$*,* $\mathsf{AxisCarryConfluence}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AxisCarryCriticalPair}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $s, \ell, r, j, n, V, B, H, C, P, N$. It has no coordinate for source-target history sameness, quotient normal forms, host arithmetic equality, unbounded critical-pair search, global confluence, Lean verification, or bridge checking.

Theorem 7072.2 (Axis carry critical-pair NameCert obligations)**.** *For every accepted* $\mathsf{AxisCarryCriticalPair}^{\uparrow}$ *carrier*

$$K = (s, \ell, r, j, n, V, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AxisCarryCriticalPair}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the overlapping source window, two one-step carry branches, shared join, terminal normal row, value ledger, non-*hsame *boundary, transport, replay, provenance, and local naming;*
2. *left-branch exactness, requiring ℓ to be read only through the displayed left carry window of s;*
3. *right-branch exactness, requiring r to be read only through the displayed right carry window of s;*
4. *join exactness, requiring j to be reached by normalizing the remaining visible carry window from both ℓ and r;*
5. *value-ledger exactness, requiring V to record the same finite Fibonacci value for s, ℓ, r, j, n;*
6. *boundary nonescape, requiring B to keep both carry edges outside* hsame *and to export no quotient normal form, host arithmetic equality, unbounded search, global confluence, Lean verification, or bridge data;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same displayed rows through H, C, P, N.*

No local critical-pair obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7072.1. The accepted packet displays exactly the overlapping source window, the two one-step carry targets, the shared join, the terminal normal row, the value ledger, the boundary row, transport, replay, provenance, and local naming.

The two branch clauses are forced by the route. The row ℓ is reachable only from the left carry window of s, while r is reachable only from the right carry window of s.

The join and value clauses are downstream. The row j is the common target of the remaining visible carry window from both branches, and V records the finite Fibonacci value read through all displayed windows.

Finally, B, H, C, P, N keep the comparison local. Since history-sameness collapse, quotient normal forms, host arithmetic equality, unbounded critical-pair search, global confluence, Lean verification, and bridge data are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7072.3 (Axis carry critical-pair local diamond)**.** *Every accepted* $\mathsf{AxisCarryCriticalPair}^{\uparrow}$ *packet exposes the local diamond route*

$$s \longmapsto \ell \longmapsto j \qquad \text{and} \qquad s \longmapsto r \longmapsto j$$

before any $\mathsf{AxisCarryConfluence}^{\uparrow}$ *consumer may read the overlap as confluence evidence. The shared target j is accompanied by the terminal normal row n, the value ledger V, the non-*hsame *boundary B, and the structural rows H, C, P, N; the handoff exports no source-target history sameness, quotient normal form, global normalizer, unbounded critical-pair search, or host arithmetic equality.*

Proof. Start from the NameCert obligations of Definition 7072.2. They force any accepted read to expose $s, \ell, r, j, n, V, B, H, C, P, N$ as one finite packet.

The two branches are visible before the join. The left route reads s then ℓ then j, while the right route reads s then r then j; both routes are replayed through the same continuation row C and transported through H.

The confluence-facing handoff is therefore the displayed diamond plus the value and boundary rows. Since B keeps the carry edges outside hsame and no omitted endpoint is a carrier row, an $\mathsf{AxisCarryConfluence}^{\uparrow}$ consumer receives only the finite local critical-pair packet stated above. □

Falsifiable prediction: Every $\mathsf{AxisCarryCriticalPair}^{\uparrow}$ overlap read exposes one source window, two one-step carry branches, one shared join, one terminal normal row, one Fibonacci value ledger, one non-hsame boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any confluence-facing handoff is visible.

Independence witness: zcarry, zeckendorf-carry-normalization, zeckendorf-normal, axis-carry-route-separation, axis-carry-diamond-route, axis-carry-confluence: $\mathsf{AxisCarryCriticalPair}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the overlapping source, both one-step carry branches, the shared join, the terminal normal row, the value ledger, the non-hsame boundary, and the local confluence-facing handoff as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{AxisCarryCriticalPair}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AxisCarryCriticalPair}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7072.1, Definition 7072.2, and Definition 7072.3 seed the finite local critical-pair route for overlapping Zeckendorf carry windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AxisCarryCriticalPair}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close source-target history sameness, quotient normal forms, host arithmetic equality, unbounded critical-pair search, global confluence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch exactness, join exactness, value-ledger exactness, boundary nonescape, transport, replay, provenance, and local-diamond handoff for BEDC.Derived.AxisCarryCriticalPairUp.

Constructive story: An $\mathsf{AxisCarryCriticalPair}^{\uparrow}$ packet is generated from one overlapping Zeckendorf source window, two one-step carry branches, one shared join, one terminal normal row, one Fibonacci value ledger, one non-hsame boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7073

A Concrete Naming Certificate for $\mathsf{DualityMapping}^{\uparrow}$

Following Browder and Cioranescu, the $\mathsf{DualityMapping}^{\uparrow}$ packet records the normalized duality mapping of a displayed normed or Hilbert-facing carrier as finite NameCert data. It sits over the Banach carrier of **??**, the dual-row interface of chapter 2265, the norm readback surface of chapter 89, the Hilbert specialization of chapter 91, and convex admissible domains named by chapter 208. The packet names the pairing and norm-equality obligations without importing a Hahn–Banach selector or a host dual-space theorem.

Definition 7073.1 (Duality mapping carrier)**.** *A* $\mathsf{DualityMapping}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, X^*, N, J, E, Q, H, C, P, L)$$

with the following displayed rows:

1. *X is the* $\mathsf{BanachSpace}^{\uparrow}$ *source row, or the* $\mathsf{Hilbert}^{\uparrow}$ *source row when the normalized duality map is read through the Hilbert inner-product specialization.*
2. *X^* is the* $\mathsf{BanachDual}^{\uparrow}$ *row naming the admitted dual observations available to the packet.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row for source and dual norms, including the Real-valued norm endpoints used by the normalized condition.*
4. *J is the graph row of the normalized duality mapping, relating each displayed source point to the admitted dual row that witnesses the mapping read.*
5. *E is the norm-pairing exactness row, recording the displayed equalities between the pairing, the source norm square, and the dual norm product.*
6. *Q is the admissible-domain row, read through* $\mathsf{ConvexSet}^{\uparrow}$ *when the mapping is consumed by monotonicity, variational-inequality, or convex-analysis packets.*
7. *H records componentwise* hsame *transport for source, dual, norm, graph, exactness, admissible-domain, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the source and dual rows through the normalized graph and exactness checks.*
9. *P is the* Pkg *provenance over* $\mathsf{DualityMapping}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. L is the local $\mathsf{NameCert}_{\mathsf{DualityMapping}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice-selected norming functional, a global Hahn–Banach extension, quotient dual equality, weak-star compactness, or an ambient Banach-dual existence theorem.

Theorem 7073.2 (Duality mapping NameCert obligations)**.** *For every accepted* $\mathsf{DualityMapping}^{\uparrow}$ *carrier* $D = (X, X^*, N, J, E, Q, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{DualityMapping}^{\uparrow}}$ *surface consists exactly of carrier admission, dual-row admission, norm-pairing exactness, transport, replay, provenance, and non-escape of Hahn–Banach choice.*

Proof. Carrier admission projects the source row X and the norm row N. The packet may be consumed through $\mathsf{BanachSpace}^{\uparrow}$ or through the $\mathsf{Hilbert}^{\uparrow}$ specialization, but the source endpoint and norm readback remain displayed rows of the same finite carrier.

Dual-row admission projects X^* and the graph row J. A consumer reads only the dual observations already named in the $\mathsf{BanachDual}^{\uparrow}$ row, and the normalized mapping graph records which admitted dual row is paired with the displayed source point.

Norm-pairing exactness is the role of E. The pairing value, source norm, and dual norm are all read through N and sealed as displayed Real-valued data, so exactness is a packet row rather than a host dual-space equality.

Transport, replay, and provenance are carried by H, C, P, L. They preserve the same source, dual, norm, graph, exactness, and admissible-domain rows when a $\mathsf{ConvexSet}^{\uparrow}$ or Hilbert-facing consumer reuses the mapping.

Finally, Hahn–Banach choice is outside the carrier. Since no row of D stores a selected norming functional, an extension selector, quotient dual equality, weak-star compactness, or an ambient Banach-dual existence theorem, the local NameCert surface cannot export any of those objects. □

Falsifiable prediction: Every accepted $\mathsf{DualityMapping}^{\uparrow}$ read must expose the $\mathsf{BanachSpace}^{\uparrow}$ or $\mathsf{Hilbert}^{\uparrow}$ source row, the $\mathsf{BanachDual}^{\uparrow}$ dual row, the $\mathsf{Norm}^{\uparrow}$ exactness row, the graph row, the $\mathsf{ConvexSet}^{\uparrow}$ admissible-domain row when used, BHist transport, hsame, Cont, Pkg, and local NameCert rows before any normalized duality-mapping conclusion is public.

Independence witness: banachspace, banachdual, norm, hilbert, convexset: $\mathsf{DualityMapping}^{\uparrow}$ is not bijective to any listed sibling because it jointly records source admission, dual-row admission, normalized norm-pairing exactness, graph replay, convex-domain handoff, transport, provenance, and local naming while refusing choice-selected norming functionals and Hahn–Banach extension data.

Closure status for $\mathsf{NameCert}_{\mathsf{DualityMapping}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DualityMapping}^{\uparrow}$ packet is generated from a displayed BanachSpaceUp or HilbertUp source row, a BanachDualUp row, NormUp source and dual norm readbacks, a normalized graph row, a norm-pairing exactness row, an optional ConvexSetUp admissible-domain row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DualityMapping}^{\uparrow}}$, seed)

Scope closed: Definition 7073.1 and Definition 7073.2 seed the finite normalized duality-mapping packet over displayed Banach, dual, norm, Hilbert, and convex-domain rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DualityMapping}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close maximal monotonicity, smoothness of Banach spaces, strict convexity, reflexivity, weak-star compactness, Hahn–Banach extension, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dual-row admission, norm-pairing exactness, convex-domain handoff, transport, replay, provenance, and Hahn–Banach non-escape for BEDC.Derived.DualityMappingUp.

Chapter 7074

A Concrete Naming Certificate for $\mathsf{HadamardMatrix}^{\uparrow}$

Following Hadamard and the finite orthogonal-design tradition, the $\mathsf{HadamardMatrix}^{\uparrow}$ packet records a finite square matrix whose entries are displayed signs and whose distinct rows have zero inner product. It consumes the matrix carrier of chapter 49, the finite endpoint discipline of $\mathsf{Bool}^{\uparrow}$ in chapter 32, the size and row-index ledger of $\mathsf{Nat}^{\uparrow}$ in chapter 28, the vector carrier of $\mathsf{VecSpace}^{\uparrow}$ in chapter 47, and the inner-product rows of $\mathsf{InnerProduct}^{\uparrow}$ in chapter 86. The packet names only this finite sign-matrix certificate; it is not an infinite design theorem, a classification of all Hadamard orders, a selected normalization, a quotient matrix equality, or an ambient orthogonal-array construction.

Definition 7074.1 (Hadamard matrix carrier)**.** *A* $\mathsf{HadamardMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (N, M, S, R, O, V, I, T, C, P, L)$$

with the following displayed rows:

1. N *is the* $\mathsf{Nat}^{\uparrow}$ *size row, naming the common row and column index boundary.*
2. M *is the* $\mathsf{Mat}^{\uparrow}$ *row, exposing the finite square table and its row-column readback.*
3. S *is the sign ledger, recording for each displayed entry a Boolean endpoint whose decoded value is* $+1$ *or* -1*.*
4. R *is the row-vector ledger, reading every matrix row as a finite* $\mathsf{VecSpace}^{\uparrow}$ *vector over the same index boundary.*
5. O *is the orthogonality ledger, recording that the inner product of any two distinct displayed rows is zero.*
6. V *is the* $\mathsf{VecSpace}^{\uparrow}$ *source row for the row vectors and finite sign combinations.*
7. I *is the* $\mathsf{InnerProduct}^{\uparrow}$ *source row used by the pairwise orthogonality checks.*
8. T *records componentwise* hsame *transport for* N, M, S, R, O, V, I *and the local naming row.*
9. C *records displayed* Cont *replay from the matrix and sign rows through row-vector readback, inner-product checks, provenance, and local naming.*
10. P *is the* Pkg *provenance over* $\mathsf{HadamardMatrix}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

11. L is the local $\mathsf{NameCert}_{\mathsf{HadamardMatrix}^\uparrow}$ *row.*

The classifier compares accepted packets only through $N, M, S, R, O, V, I, T, C, P, L$. It has no coordinate for a host classification theorem, quotient matrix equality, selected equivalence normalization, infinite orthogonal design, or ambient completion.

Theorem 7074.2 (Hadamard matrix NameCert obligations)**.** *For every accepted* $\mathsf{HadamardMatrix}^\uparrow$ *carrier $H = (N, M, S, R, O, V, I, T, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{HadamardMatrix}^\uparrow}$ *surface consists exactly of size exposure through N, finite square-table exposure through M, sign-entry exposure through S, row-vector readback through R, V, pairwise orthogonality exposure through O, I, componentwise transport through T, displayed replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 7074.1. The rows $N, M, S, R, O, V, I, T, C, P, L$ are the only displayed rows available to a local $\mathsf{NameCert}_{\mathsf{HadamardMatrix}^\uparrow}$ read.

The size and table rows are read first. The size row N fixes the finite index boundary, while M exposes the square matrix entries and row-column readback.

The sign ledger S then restricts every entry to a displayed Boolean endpoint decoded as $+1$ or -1. The row-vector ledger R reads those entries through the $\mathsf{VecSpace}^\uparrow$ source row V before any orthogonality check is available.

Finally the orthogonality ledger O reads pairwise row products through the $\mathsf{InnerProduct}^\uparrow$ row I, and the structural rows T, C, P, L transport, replay, source, and name the same finite packet. Since no classification, normalization selector, quotient matrix equality, infinite design, or ambient completion coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7074.3 (Hadamard matrix orthogonality handoff)**.** *Every* $\mathsf{Mat}^\uparrow$, $\mathsf{VecSpace}^\uparrow$, *or* $\mathsf{InnerProduct}^\uparrow$ *consumer that reads orthogonality from an accepted* $\mathsf{HadamardMatrix}^\uparrow$ *carrier must first pass through*

$$N, M, S \longmapsto R, V \longmapsto O, I \longmapsto T, C, P, L.$$

Thus the exported orthogonality datum is a finite sign-row handoff, not a host matrix classification theorem, selected equivalence normalization, quotient equality, or ambient orthogonal-design principle.

Proof. Start with a consumer request for row orthogonality. By Definition 7074.1, the request first sees the finite size row N, the square table row M, and the sign ledger S.

The row-vector readback is next. Each row is exposed through R and the vector source V, so a consumer cannot inspect an inner-product row before the finite sign rows have been translated into displayed vector rows.

Only then does the orthogonality ledger O read the $\mathsf{InnerProduct}^\uparrow$ source row I. The structural rows T, C, P, L keep the same matrix, vector, and inner-product data attached to the local name.

Therefore the handoff exports exactly finite sign-row orthogonality. It does not provide a classification theorem, a selected normalized representative, quotient matrix equality, an infinite design, or an ambient orthogonal-array construction. □

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardMatrix}^\uparrow}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HadamardMatrix}^\uparrow}$, seed)

Scope closed: Definition 7074.1, Definition 7074.2, and Definition 7074.3 seed the finite sign-matrix route over Matrix, Bool, Nat, VecSpace, InnerProduct, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HadamardMatrix}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Hadamard-order existence, classification, selected normalization, quotient matrix equality, orthogonal-array construction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign-entry exposure, row-vector readback, pairwise orthogonality exposure, transport, replay, provenance, and local naming for BEDC.Derived.HadamardMatrixUp.

Constructive story: A HadamardMatrix$^{\uparrow}$ packet is generated from a Nat size row, Matrix square-table row, Bool sign ledger, VecSpace row-vector ledger, InnerProduct orthogonality checks, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7075

A Concrete Naming Certificate for $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ packet records total boundedness through displayed finite epsilon-net data rather than through open-cover compactness or a selected choice principle. It sits over the metric and total-bounded sources of chapter 127, the finite epsilon-net carrier of chapter 1767, the compact-metric consumer surface of chapter 129, and the terminal real-name seal of chapter 38.

Definition 7075.1 (Finite total bounded net carrier)**.** *A* $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, T, E, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point classifier, distance classifier, and metric-distance ledger read by the net.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *source row, exposing the total-bounded request at the displayed tolerance.*
3. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *witness row, naming the finite center bundle, center-admission ledger, and coverage-distance ledger.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row used when compact-metric or uniform-continuity consumers inspect the net through finite source schedules.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the positive dyadic tolerance and comparison cells used by the coverage ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational coverage values and tolerance comparisons.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for downstream real-valued distance reads.*
8. *H records componentwise* hsame *transport for the metric source, total-bounded source, finite-net witness, stream windows, dyadic tolerance, regular-rational readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a total-bounded coverage request through $M, T, E, W, D, R, S, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteTotalBoundedNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, E, W, D, R, S, H, C, P, N$. It has no coordinate for an ambient finite subset, an open cover, a selected compactness proof, countable choice, quotient metric equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7075.2 (Finite total bounded net NameCert obligations)**.** *For every accepted* $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ *carrier $F = (M, T, E, W, D, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteTotalBoundedNet}^{\uparrow}}$ *surface consists exactly of metric-source admission, total-bounded request exposure, finite epsilon-net witness exposure, finite stream-window inspection, dyadic tolerance comparison, regular-rational readback, Real seal handoff, componentwise transport, displayed replay, provenance, and local naming for the same finite packet.*

Proof. Project the carrier of Definition 7075.1. The analytic source rows are the metric source M, the total-bounded request T, and the finite epsilon-net witness E.

The tolerance and readback route is finite. The stream windows W restrict the inspected source schedules, the dyadic row D supplies the positive tolerance comparisons, and the regular-rational row R records the coverage readback before the Real seal S is offered.

The structural rows H, C, P, N then transport, replay, source, and name the same packet. Since no additional coordinate is present, the local NameCert obligations are exhausted by the listed rows and cannot import an open cover, a selected compactness proof, countable choice, quotient metric equality, or ambient Real completeness. □

Theorem 7075.3 (Finite total bounded net Real handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *or real-valued uniform-continuity consumer of an accepted* $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through*

$$M, T, E, W, D, R \longmapsto S.$$

Thus each Real-facing distance or tolerance read factors through the displayed metric source, total-bounded source, finite epsilon-net witness, stream window, dyadic tolerance row, and regular-rational readback before any sealed Real output is public.

Proof. Start from the obligation surface of Definition 7075.2. It places M, T, E before any coverage consumer can read a total-bounded net.

Use the finite epsilon-net route of chapter 1767. The row E supplies center admission and coverage-distance data, while W restricts the inspection to displayed finite source schedules.

The tolerance rows are then forced by D and R. Dyadic comparisons are read before regular-rational coverage values, and the Real seal S receives only that already displayed readback.

Therefore a compact-metric or uniform-continuity consumer reaches $\mathsf{Real}^{\uparrow}$ through the finite route shown above. The carrier has no coordinate from which it could export open-cover compactness, countable choice, quotient equality, or ambient completeness. □

Theorem 7075.4 (Finite total bounded net sibling dependency)**.** *The* $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ *packet is consumed only as a sibling route tying* $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows together. Dropping any one of M, T, E, W, D, R, S leaves the read before the finite total-bounded net boundary and cannot be retyped as a* $\mathsf{CompactMetric}^{\uparrow}$ *coverage witness.*

Proof. Read the carrier rows in Definition 7075.1. The packet has separate coordinates for the metric source, total-bounded source, finite epsilon-net witness, stream windows, dyadic tolerance, regular-rational readback, and Real seal.

Apply Definition 7075.2. Each coordinate is a local NameCert obligation, so none can be inferred from a different sibling row after the packet has been accepted.

Use Definition 7075.3. Compact-metric and Real-facing consumers read the route through M, T, E, W, D, R, S in order. If any one of these rows is absent, the consumer has not reached the finite total-bounded net handoff and receives no compact-metric coverage witness. □

Falsifiable prediction: Every accepted $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ consumer exposes metric, total-bounded, finite epsilon-net, stream-window, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows before reading a compact-metric or uniform-continuity coverage route.

Independence witness: totallybounded, compactmetric, finite-epsilon-net, real: $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ is not bijective to any listed sibling because it binds total-bounded requests to finite epsilon-net data, finite source windows, dyadic tolerances, regular rational readbacks, Real seals, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTotalBoundedNet}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteTotalBoundedNet}^{\uparrow}$ packet is generated from Metric, TotallyBounded, FiniteEpsilonNet, StreamName, DyadicRatCore, RegSeqRat, and Real rows, plus componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteTotalBoundedNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7075.1, Definition 7075.2, Definition 7075.3, and Definition 7075.4 seed the finite total-bounded net packet over displayed metric, total-bounded, finite epsilon-net, stream-window, dyadic tolerance, regular-rational readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteTotalBoundedNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, quotient metric equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite epsilon-net exposure, tolerance readback, Real seal nonescape, sibling dependency, transport, replay, provenance, and local naming for BEDC.Derived.FiniteTotalBoundedNetUp.

Chapter 7076

A Concrete Naming Certificate for $\mathsf{RealInverseModulus}^{\uparrow}$

The $\mathsf{RealInverseModulus}^{\uparrow}$ packet realizes the guarded reciprocal-modulus route of the Real and Completion vision as finite BEDC data. It sits after the reciprocal-window budget of chapter 703, the regular Cauchy reciprocal surface of chapter 1471, the real reciprocal handoff of chapter 6251, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet records a reciprocal modulus for guarded reads; it is not a total inverse on $\mathsf{Real}^{\uparrow}$ and not a completeness theorem.

Definition 7076.1 (Real inverse-modulus carrier)**.** *A* $\mathsf{RealInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, A, B, Q, R, G, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted* $\mathsf{Real}^{\uparrow}$ *source row whose guarded reciprocal modulus is being read.*
2. *A is the displayed apartness or lower-bound row that keeps the source away from the zero boundary.*
3. *B is the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row selecting the finite inverse-window budget before any reciprocal readback is public.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by that finite budget.*
5. *R is the* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *sibling route, retaining the regular-source, apartness, window, dyadic, budget, readback, and seal rows.*
6. *G is the* $\mathsf{RealReciprocal}^{\uparrow}$ *guarded reciprocal handoff row.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the reciprocal-modulus candidate.*
8. *H records componentwise* hsame *transport for the Real source, apartness row, inverse budget, regular readback, regular-Cauchy reciprocal route, Real reciprocal handoff, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a reciprocal-modulus request through $X, A, B, Q, R, G, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RealInverseModulus}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}$ $\mathsf{RealReciprocal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{RealInverseModulus}^\uparrow}$ *row.*
The classifier compares accepted packets only through $X, A, B, Q, R, G, E, H, C, P, N$. It has no coordinate for total inversion, trichotomy, quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 7076.2 (Real inverse-modulus NameCert obligations)**.** *For every accepted* $\mathsf{RealInverseModulus}^\uparrow$ *carrier $I = (X, A, B, Q, R, G, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealInverseModulus}^\uparrow}$ *surface consists exactly of source Real admission, apartness exposure, finite Cauchy inverse budget selection,* $\mathsf{RegSeqRat}^\uparrow$ *reciprocal-modulus readback,* $\mathsf{RegularCauchyReciprocal}^\uparrow$ *sibling routing,* $\mathsf{RealReciprocal}^\uparrow$ *guarded handoff, terminal* $\mathsf{Real}^\uparrow$ *sealing, componentwise transport, displayed replay, provenance, and local naming for the same finite packet.*

Proof. Project the carrier of Definition 7076.1. The source and domain rows are X and A, and the first reciprocal-facing row is the finite inverse budget B.

The readback route is ordered. The budget B produces the regular rational row Q, the sibling route R retains the regular-Cauchy reciprocal window, and the guarded Real reciprocal handoff G precedes the terminal Real seal E.

The rows H, C, P, N transport, replay, source, and name the same packet. Since no further coordinate is present, the listed rows exhaust the local NameCert obligations and exclude total inversion, trichotomy, quotient equality, selected representatives, countable choice, and ambient Real completeness. □

Theorem 7076.3 (Real inverse-modulus Cauchy inverse budget handoff)**.** *Every accepted* $\mathsf{RealInverseModulus}^\uparrow$ *read factors through*

$$X, A \longmapsto B \longmapsto Q \longmapsto R, G \longmapsto E.$$

In particular, the $\mathsf{CauchyInverseBudget}^\uparrow$ *row is consumed before any* $\mathsf{RealReciprocal}^\uparrow$ *seal is public, and the reciprocal-modulus route remains guarded by the displayed apartness row.*

Proof. Apply Definition 7076.2. It exposes the source and apartness rows before any inverse budget or reciprocal readback can be consumed.

Use the budget route from chapter 703. The row B is the finite window selector for the guarded source, and Q is read only after that budget is present.

Next use the sibling reciprocal surfaces of chapter 1471 and chapter 6251. They keep the reciprocal route downstream of the budgeted regular readback and refuse a total inverse on arbitrary Real names.

The terminal seal E therefore receives only the guarded route displayed above. Because the carrier has no coordinate for a total inverse, trichotomy, quotient equality, selected representative, or completeness principle, none of those endpoints is exported. □

Falsifiable prediction: Every accepted $\mathsf{RealInverseModulus}^\uparrow$ read factors through $\mathsf{CauchyInverseBudget}^\uparrow$ before any $\mathsf{RealReciprocal}^\uparrow$ seal is public.

Independence witness: cauchyinversebudget, regular-cauchy-reciprocal, real-reciprocal, regseqrat, real: $\mathsf{RealInverseModulus}^\uparrow$ carries the guarded modulus route tying these siblings together, while none of them alone records the full inverse-modulus packet.

The Lean TasteGate file for this packet must supply $\mathsf{Nontrivial}$ and $\mathsf{FieldFaithful}$ instances by exhibiting accepted guarded reciprocal-modulus packets and refused boundary packets over $X, A, B, Q, R, G, E, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{RealInverseModulus}^\uparrow}$.

Constructive story: A RealInverseModulus$^{\uparrow}$ packet is generated from a Real source, apartness row, CauchyInverse-Budget row, RegSeqRat readback, RegularCauchyReciprocal route, RealReciprocal handoff, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RealInverseModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7076.1, Definition 7076.2, and Definition 7076.3 seed the guarded reciprocal-modulus packet over finite inverse budgets, regular rational readbacks, reciprocal sibling routes, and Real sealing.

Formal verification: FormalStatus(NameCert$_{\text{RealInverseModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a total inverse on Real$^{\uparrow}$, trichotomy, quotient real equality, selected representatives, countable choice, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, budget-first readback, guarded reciprocal handoff, Real seal nonescape, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.RealInverseModulusUp.

Chapter 7077

A Concrete Naming Certificate for $\mathsf{RegulatedSequence}^{\uparrow}$

Following Bishop and Bridges on regulated and Cauchy sequence moduli, the $\mathsf{RegulatedSequence}^{\uparrow}$ packet records the finite window discipline that turns a displayed stream name into regular rational readback data before the terminal real-name seal is read. It sits between the finite $\mathsf{StreamName}^{\uparrow}$ window route of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ admission surface of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite means object for the L10 corridor; it is not a quotient stream representative, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7077.1 (Regulated sequence carrier)**.** *A* $\mathsf{RegulatedSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing the inspected sequence indices and the visible window schedule.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, naming the dyadic precision demand attached to that window.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readiness row, recording that the displayed window and tolerance data are acceptable for regular rational readback.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-refusal row, available only after S, D, Q have been displayed and refusing use as ambient completeness.*
5. *H records componentwise* hsame *transport for the stream, tolerance, readiness, and seal rows.*
6. *C records displayed* Cont *replay from stream windows through dyadic tolerance rows to regular readback and Real sealing.*
7. *P is the* Pkg *provenance over* $\mathsf{RegulatedSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, D, Q, E, H, C, P, N. It has no coordinate for quotient stream equality, selected limits, countable-choice schedules, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.RegulatedSequenceUp`

Theorem 7077.2 (Regulated sequence window obligations)**.** *For every accepted* $\mathsf{RegulatedSequence}^{\uparrow}$ *carrier* $G = (S, D, Q, E, H, C, P, N)$*, any consumer that asks for regulated-sequence data must expose the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readiness row* Q *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal-refusal row* E *is available.*

Proof. Project the carrier of Definition 7077.1. The rows S, D, Q, E, H, C, P, N are the whole accepted packet, so no consumer has a route to E outside the displayed finite rows.

Read the dependency order in the carrier. The stream row supplies the inspected finite window, the dyadic row supplies the precision demand, and the readiness row records that the pair can be consumed by the regular rational readback surface.

The structural rows preserve the same route. Transport, replay, provenance, and local naming do not add a hidden limit, quotient representative, choice schedule, trichotomy proof, or ambient Real-completeness coordinate. □

Theorem 7077.3 (Regulated sequence shift stability)**.** *If two accepted* $\mathsf{RegulatedSequence}^{\uparrow}$ *packets have componentwise* hsame *stream-window, dyadic-tolerance, readiness, and Real-seal rows, then every shifted finite-window read admitted by the first packet is transported to the corresponding shifted finite-window read of the second packet through the displayed* H *and replayed through* C*. The transported read remains a* $\mathsf{RegulatedSequence}^{\uparrow}$ *read and does not become quotient stream equality or a selected limit.*

Proof. Start with the componentwise transport row H. It identifies the displayed stream-window, tolerance, readiness, and seal rows under hsame, so the shifted window read is transported only along rows already present in the two carriers.

Next use the replay row C. The same finite route from S through D and Q to E is replayed after the shift, preserving the order in which the tolerance and readiness data are exposed.

Since the carrier has no row for quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the shifted read remains a regulated finite-window certificate. □

Theorem 7077.4 (Regulated sequence Real source route)**.** *Every Real-facing source read of an accepted* $\mathsf{RegulatedSequence}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The $\mathsf{Real}^{\uparrow}$ *seal is downstream of finite stream windows, dyadic tolerance rows, and RegSeqRat readiness rows, and it exports no quotient real equality, selected limit, countable-choice schedule, trichotomy, or ambient completeness.*

Proof. Use Definition 7077.2 to expose the rows S, D, Q, E. This places the stream window and dyadic tolerance before the regular rational readiness row and before the Real seal.

The route is grounded in the existing L10 chapters: $\mathsf{StreamName}^{\uparrow}$ supplies finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies tolerance rows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular rational admission surface, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal boundary.

Finally project H, C, P, N. These rows transport, replay, source, and name the same route, so a Real-facing read cannot bypass the finite sequence corridor or obtain any of the refused host principles. □

Falsifiable prediction: An accepted $\mathsf{RegulatedSequence}^{\uparrow}$ read is refuted if it reaches a Real-facing seal before displaying the StreamName window, DyadicRatCore tolerance, RegSeqRat readiness, Real seal-refusal, transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, dyadicratcore, regseqrat, real: $\mathsf{RegulatedSequence}^{\uparrow}$ is not bijective to any listed sibling because it binds finite stream windows, dyadic tolerance demands, RegSeqRat-readiness rows, terminal Real seal refusal, componentwise hsame, displayed Cont, Pkg, and local NameCert into one L10 intermediate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedSequence}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance rows, RegSeqRat-readiness rows, Real seal refusal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegulatedSequence}^{\uparrow}}$, seed)

Scope closed: Definition 7077.1, Definition 7077.2, Definition 7077.3, and Definition 7077.4 seed the finite regulated-sequence route between stream windows and regular rational readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegulatedSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, ambient Real completeness, checked obligation coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window obligations, shift stability, Real source routing, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedSequenceUp.

Chapter 7078

A Concrete Naming Certificate for $\mathsf{SupplyTaxonomy}^{\uparrow}$

The $\mathsf{SupplyTaxonomy}^{\uparrow}$ packet realizes the source, audit, and refusal surface of chapter 9394 as finite NameCert data. It sits beside the wider socket-kind classifier of chapter 523, the socket ledger of chapter 528, the audit route of chapter 1107, and the legitimate-claim ledger of chapter 5122. Those siblings classify socket kinds, record socket use, audit external routes, or police claim status; this packet binds the source taxonomy row that a classifier must inspect before it decides whether a supplied item is internal, external, auditable, or refused.

Definition 7078.1 (Supply taxonomy carrier)**.** *A* $\mathsf{SupplyTaxonomy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, E, A, R, K, H, C, P, N)$$

with the following displayed rows:

1. *I is the internal-source row, naming the displayed constructor, definition, setup field, certificate row, or generated carrier that supplies the item.*
2. *E is the external-supply row, naming the socket, boundary, corpus, observer, or apophatic source position from which a non-internal item is requested.*
3. *A is the audit-gate row, recording the local gate that decides whether I is sufficient, whether E is only named, and which refusal is active.*
4. *R is the refusal row, recording the exact missing witness, unrestricted induction step, quotient equality, empirical persistence, inter-history recognition, inscription source, or self-reference closure that is not supplied.*
5. *K is the classifier-decision row, read only after I, E, A, R have been exposed.*
6. *H records componentwise* hsame *transport for source, external supply, audit gate, refusal, and classifier rows.*
7. *C records displayed* Cont *replay of the same finite source-audit-refusal route.*
8. *P is the* Pkg *provenance over* $\mathsf{SupplyTaxonomy}^{\uparrow}$, $\mathsf{TranscendentalSupplyTaxonomy}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{ExternalSupplyAuditRoute}^{\uparrow}$, $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SupplyTaxonomy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, E, A, R, K, H, C, P, N$. It has no coordinate for hidden theorem supply, unledgered external import, global truth validation, quotient collapse, or a silent conversion from named supply to internal evidence.

Theorem 7078.2 (Supply taxonomy decision obligations)**.** *Every accepted* $\mathsf{SupplyTaxonomy}^{\uparrow}$ *classifier decision must expose the internal-source row I, external-supply row E, audit-gate row A, and refusal row R before the decision row K is read. A decision that sees only a socket kind, only a claim marker, or only a boundary name is not an accepted supply-taxonomy read.*

Proof. Project the carrier of Definition 7078.1. The rows $I, E, A, R, K, H, C, P, N$ are the entire accepted packet, so the classifier decision K has no route outside the displayed source, audit, and refusal rows.

The source split is visible before the decision. The internal row I records what is supplied by a displayed substrate route, while the external row E records the requested non-internal position without consuming it.

The audit and refusal rows then govern the decision. Row A names the local gate and row R names the missing or refused content; only after those rows are present may K classify the read.

Transport, replay, provenance, and local naming preserve the same finite route. They cannot turn a socket kind, marker, or boundary name into supplied content. □

Theorem 7078.3 (Supply taxonomy audit refusal nonescape)**.** *For an accepted* $\mathsf{SupplyTaxonomy}^{\uparrow}$ *packet $S = (I, E, A, R, K, H, C, P, N)$, any downstream consumer that reads K must retain the audit gate A and refusal row R in the same carrier. Thus an external supply request can be classified, transported, replayed, and named, but it cannot escape as internal evidence unless a separate displayed internal-source row is present.*

Proof. Start from the decision obligations of Definition 7078.2. They require I, E, A, R before K, so the decision is never detached from the audit gate or refusal row.

If the item is internal, the row I names the substrate route that supplies it. If the item is external, the row E names the supply position and R records the content that remains refused.

The structural rows do not change that split. Componentwise hsame transport and displayed Cont replay preserve the rows already present, while provenance and local naming record the same packet for later consumers. □

Theorem 7078.4 (Supply taxonomy sibling separation)**.** *The* $\mathsf{SupplyTaxonomy}^{\uparrow}$ *packet is not reducible to* $\mathsf{TranscendentalSupplyTaxonomy}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{ExternalSupplyAuditRoute}^{\uparrow}$, *or* $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$. *It jointly carries internal source, external supply, audit gate, refusal, classifier decision, transport, replay, provenance, and local naming rows, whereas each listed sibling omits at least one of the internal-source or classifier-decision coordinates required by Definition 7078.1.*

Proof. Compare the carrier rows. The wider transcendental taxonomy classifies socket kinds, and the socket ledger records socket use, but neither one by itself binds the internal-source row I to a classifier decision K.

The external-supply audit route records an audit path for a boundary request, while the legitimate-claim audit ledger records claim status. Those siblings supply important gates, but they do not jointly carry I, E, A, R, K as one source/audit/refusal classifier surface.

Therefore no listed sibling can be a bijective replacement for the present packet. A consumer that needs the supply decision must read the full $\mathsf{SupplyTaxonomy}^{\uparrow}$ carrier. □

The Lean follow-up for $\mathsf{SupplyTaxonomy}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ SupplyTaxonomy}^{\uparrow}$ and $\mathsf{FieldFaithful\ SupplyTaxonomy}^{\uparrow}$ instances. The field-faithfulness witness must keep $I, E, A, R, K, H, C, P, N$ as distinct rows so internal source, external supply, audit gate, refusal, and classifier decision cannot collapse.

Falsifiable prediction: Every accepted $\mathsf{SupplyTaxonomy}^{\uparrow}$ read exposes internal source, external supply, audit gate, and refusal rows before a classifier decision.

Independence witness: theorem-dna-complexity-scoring, trigger-blocker-duality, legitimate-claim-audit-ledger, external-supply-boundary: $\mathsf{SupplyTaxonomy}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries internal source, external supply, audit gate, refusal, classifier decision, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SupplyTaxonomy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SupplyTaxonomy}^{\uparrow}$ packet is generated from internal-source rows, external-supply rows, audit gates, refusal rows, classifier decisions, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SupplyTaxonomy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7078.1, Definition 7078.2, Definition 7078.3, and Definition 7078.4 seed the finite source/audit/refusal classifier surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SupplyTaxonomy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, hidden theorem supply, unledgered external import, global truth validation, quotient collapse, or apophatic discharge.

Upgrade path: Obligation closure requires checked carrier admission, decision obligations, audit-refusal retention, sibling separation, Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.SupplyTaxonomyUp.

Chapter 7079

A Concrete Naming Certificate for $\mathsf{HadamardDeterminantInequality}^{\uparrow}$

Following Hadamard and classical finite-dimensional matrix theory, the $\mathsf{HadamardDeterminantInequality}^{\uparrow}$ packet records the finite row-norm surface behind the determinant bound as BEDC NameCert data. It consumes the matrix carrier of chapter 49, the determinant boundary of chapter 84, the norm rows of chapter 89, the inner-product surface of chapter 86, the vector-space rows of chapter 47, the terminal scalar seal of chapter 38, and the Gram determinant packet of chapter 5127. The packet names a finite determinant-estimate route; it does not import host spectral theory, selected orthonormal bases, quotient matrix equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7079.1 (Hadamard determinant inequality carrier)**.** *A* $\mathsf{HadamardDeterminantInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (V, M, D, I, N, G, R, B, E, T, C, P, L)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row carrying the finite row-vector source.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *row carrying the displayed square matrix and its finite row ledger.*
3. *D is the* $\mathsf{Determinant}^{\uparrow}$ *row naming the determinant read for the same displayed matrix.*
4. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row used to read row inner products and orthogonality comparisons when they are displayed.*
5. *N is the* $\mathsf{Norm}^{\uparrow}$ *row listing the finite row-norm reads and their* $\mathsf{Real}^{\uparrow}$ *scalar seals.*
6. *G is the* $\mathsf{GramDeterminant}^{\uparrow}$ *handoff row, recording the Gram matrix and determinant surface obtained from the displayed row vectors.*
7. *R is the row-product budget, the finite product of the displayed row-norm bounds in N.*
8. *B is the determinant-bound ledger, relating the determinant row D to the Gram determinant handoff G and then to the product budget R.*
9. *E is the equality-case exposure row: it records only displayed orthogonality or zero-row data already present in I, N, G, not an ambient spectral argument.*
10. *T records componentwise* hsame *transport for the vector, matrix, determinant, inner-product, norm, Gram, budget, bound, and equality-case rows.*

11. *C records displayed* Cont *replay from matrix rows to determinant rows, row-norm rows, Gram determinant rows, and the final bound ledger.*
12. *P is the* Pkg *provenance over* $\mathsf{HadamardDeterminantInequality}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{GramDeterminant}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *L is the local* $\mathsf{NameCert}_{\mathsf{HadamardDeterminantInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host spectral theory, selected orthonormal bases, quotient matrix equality, hidden row operations, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7079.2 (Hadamard determinant inequality NameCert obligations)**.** *For every accepted* $\mathsf{HadamardDeterminantInequality}^{\uparrow}$ *carrier*

$$H = (V, M, D, I, N, G, R, B, E, T, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{HadamardDeterminantInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the vector-space, matrix, determinant, inner-product, norm, Gram determinant, row-product, bound, equality-case, transport, replay, provenance, and local naming rows; row-norm exposure through N and* $\mathsf{Real}^{\uparrow}$*; determinant exposure through M, D; Gram handoff through I, G; row-product budget exposure through R; determinant-bound exactness through B; equality-case exposure through E; and non-escape from host spectral theory, selected orthonormal bases, quotient matrix equality, hidden row operations, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7079.1. The displayed matrix row M is read together with the vector-space row V, and the determinant row D is attached to that same square matrix.

The row-norm data are then read through N and sealed through $\mathsf{Real}^{\uparrow}$. The inner-product row I supplies only displayed scalar products, while the Gram handoff G packages those reads as a finite Gram determinant surface.

The bound ledger B is downstream of D, G, R. It can compare the displayed determinant read with the Gram determinant route and the finite row-product budget, but it cannot add spectral data or a selected orthonormal basis.

Finally, T, C, P, L transport, replay, source, and name the same finite packet. Since no remaining coordinate stores quotient matrix equality, hidden row operations, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7079.3 (Hadamard row-norm determinant-bound route)**.** *Every determinant-estimate consumer of an accepted* $\mathsf{HadamardDeterminantInequality}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Mat}^{\uparrow} \longmapsto \mathsf{Determinant}^{\uparrow} \longmapsto (\mathsf{InnerProduct}^{\uparrow}, \mathsf{Norm}^{\uparrow}) \longmapsto \mathsf{GramDeterminant}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $V, M, D, I, N, G, R, B, E, T, C, P, L$. The consumer receives the row-norm determinant bound only after the matrix row, determinant row, row-norm ledger, Gram determinant handoff, row-product budget, bound ledger, transport, replay, provenance, and local naming row have all been displayed. No accepted route exports host spectral theory, selected orthonormal bases, quotient matrix equality, hidden row operations, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a determinant-estimate consumer. Carrier projection exposes the matrix row M and determinant row D before any bound can be read.

Next read the row geometry. The inner-product row I and norm row N expose only the finite scalar products, row norms, and real scalar seals attached to the displayed rows of M.

The Gram determinant row G is then the only bridge from row geometry to a determinant comparison. The product budget R and bound ledger B record the finite row-norm product and the displayed comparison with the determinant row.

The equality-case row E remains internal to displayed zero-row or orthogonality evidence. It does not select a basis or invoke a spectral decomposition. Transport, replay, provenance, and local naming through T, C, P, L preserve this route, so the consumer receives exactly the finite row-norm determinant-bound surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardDeterminantInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{HadamardDeterminantInequality}^{\uparrow}$ packet is generated from displayed VecSpaceUp, MatrixUp, DeterminantUp, InnerProductUp, NormUp, RealUp, GramDeterminantUp, row-product, determinant-bound, equality-case, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HadamardDeterminantInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7079.1, Definition 7079.2, and Definition 7079.3 seed the finite row-norm determinant-bound surface over displayed matrix, determinant, norm, inner-product, vector-space, real, and Gram determinant rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HadamardDeterminantInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host spectral theory, selected orthonormal bases, quotient matrix equality, hidden row operations, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, determinant exposure, row-norm exposure, Gram determinant handoff, row-product budget exactness, bound-ledger non-escape, transport, replay, provenance, and local naming for BEDC.Derived.HadamardDeterminantInequalityUp.

Chapter 7080

A Concrete Naming Certificate for $\mathsf{HalfOpenRealInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{HalfOpenRealInterval}^{\uparrow}$ packet records a half-open real interval $[a, b)$ as finite endpoint, containment, and boundary data rather than as a host subset of the classical real line. It sits between the dyadic endpoint ledger of chapter 291, the located endpoint surface of chapter 1709, the closed interval boundary of chapter 1591, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the traditional interval shape with an included left boundary and an excluded right boundary, while keeping topology, quotient real equality, selected endpoint representatives, trichotomy, and ambient real completeness outside the carrier.

Definition 7080.1 (HalfOpenRealInterval carrier)**.** *A* $\mathsf{HalfOpenRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, O, D, W, R, E, A, B, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint* $\mathsf{Real}^{\uparrow}$ *seal rows.*
2. *O is the endpoint-order row, recording the displayed route from L to U through finite comparison data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *boundary ledger, carrying dyadic lower cells, upper-cut cells, positive-radius rows, and one-sided comparison budgets.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect endpoint and candidate observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff for candidate membership reads.*
7. *A is the left-admission row, saying that the lower endpoint is included by the displayed boundary route.*
8. *B is the right-refusal row, saying that the upper endpoint is excluded unless a stricter displayed left-of-upper witness is present.*
9. *H records componentwise* hsame *transports for endpoint seals, order, dyadic boundary data, finite windows, readback, seal handoff, one-sided boundary rows, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a membership request through $L, U, O, D, W, R, E, A, B, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{HalfOpenRealInterval}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HalfOpenRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed rows. It has no coordinate for a host topology, quotient real equality, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7080.2 (HalfOpenRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{HalfOpenRealInterval}^{\uparrow}$ *carrier*

$$I = (L, U, O, D, W, R, E, A, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HalfOpenRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the two endpoint* $\mathsf{Real}^{\uparrow}$ *seals, endpoint-order row, dyadic boundary ledger, finite windows, regular rational readback, terminal seal handoff, one-sided boundary rows, transport, replay, provenance, and local naming;*
2. *located endpoint exactness, requiring endpoint and containment reads to pass through the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *and* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *sibling surfaces before the half-open boundary is consumed;*
3. *dyadic boundary exactness, requiring the left-inclusion and right-exclusion reads to use the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D;*
4. *regular readback exactness, requiring every membership observation to pass through the finite window row W and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before reaching the* $\mathsf{Real}^{\uparrow}$ *seal handoff E;*
5. *left-boundary admission, requiring A to display that L belongs to the interval boundary;*
6. *right-boundary refusal, requiring B to display that U is not admitted as a member unless a stricter below-U witness is supplied;*
7. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the displayed rows above.*

No obligation is stored in a host subset predicate, quotient real equality proof, selected endpoint representative, trichotomy branch, choice functional, or ambient completeness theorem.

Proof. Project the accepted carrier. The projection exposes exactly the endpoint seals, endpoint-order row, dyadic boundary ledger, finite windows, regular readback, terminal seal handoff, one-sided boundary rows, and structural rows.

The located and closed-bounded sibling surfaces supply the endpoint discipline. They ensure that endpoint, order, and containment reads begin from displayed interval rows rather than from a host real-line subset.

The dyadic and regular-rational rows then determine the one-sided boundary. The ledger D supplies the lower cells, upper-cut cells, and positive comparison budgets, while W and R expose the finite observations used by the candidate and endpoint seals.

Finally A admits the left endpoint and B refuses the right endpoint as a member of the half-open boundary. The rows H, C, P, N preserve and name the same packet, so no host topology, quotient equality, selected representative, trichotomy branch, choice functional, or ambient completeness theorem can be read from the certificate. □

Lean4 ✓ `BEDC.Derived.HalfOpenRealIntervalUp.TasteGate.HalfOpenRealIntervalTasteGate single carrier alignment`

Theorem 7080.3 (HalfOpenRealInterval dyadic boundary induction)**.** *Let*

$$I = (L, U, O, D, W, R, E, A, B, H, C, P, N)$$

be an accepted $\mathsf{HalfOpenRealInterval}^{\uparrow}$ *carrier. Any finite extension of the dyadic boundary ledger* D *by one displayed comparison row preserves the half-open membership route: left-boundary reads still factor through* A*, right-boundary reads still factor through* B*, and every* $\mathsf{Real}^{\uparrow}$*-facing membership consumer still reads through* W, R, E, H, C, P, N *after the extended dyadic ledger is displayed.*

Proof. Proceed by finite induction on the displayed dyadic comparison extension. The base route is the carrier route of Definition 7080.1: membership reads pass from endpoint seals and endpoint order through $D, W, R, E, A, B, H, C, P, N$.

For the successor step, add one comparison row to the same dyadic ledger. Since the row is displayed inside D, it can refine the finite boundary budget but cannot introduce a second endpoint, a second membership classifier, or a host order predicate.

The left and right boundary rows are preserved separately. The left-admission row A continues to identify the included lower endpoint, while the right-refusal row B continues to require a stricter below-U witness before a point is admitted on the upper side.

The regular readback and Real seal rows are unchanged by the extension. Thus every Real-facing consumer still reaches the membership route through W, R, E, H, C, P, N, and no quotient real equality, selected endpoint representative, trichotomy branch, or ambient completeness coordinate is exported. □

Theorem 7080.4 (HalfOpenRealInterval sibling route)**.** *Every accepted* $\mathsf{HalfOpenRealInterval}^{\uparrow}$ *membership read factors through the finite sibling route*

$$\mathsf{LocatedRealInterval}^{\uparrow},\ \mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route first reads located and closed-bounded endpoint data, then the dyadic one-sided boundary ledger, then finite stream windows and regular rational readback, and only then the terminal real-name seal and local $\mathsf{NameCert}_{\mathsf{HalfOpenRealInterval}^{\uparrow}}$ *rows.*

Proof. Start with the endpoint rows L, U, O. Their interval meaning is inherited from the located and closed-bounded sibling surfaces cited above, so endpoint order and containment are visible before the half-open boundary rows are consumed.

Next read the dyadic ledger D. It records the one-sided lower inclusion and upper exclusion budget that distinguishes $[a, b)$ from an open or closed interval over the same endpoints.

Finally pass through W, R, E, H, C, P, N. The finite windows and regular rational readback precede the terminal $\mathsf{Real}^{\uparrow}$ seal, and the structural rows transport, replay, source, and name only that displayed route. Hence the sibling route supplies the whole membership surface without importing host topology, quotient real equality, selected representatives, trichotomy, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted HalfOpenRealIntervalUp membership read passes through located endpoint rows, a closed-bounded endpoint boundary, a DyadicRatCoreUp one-sided comparison ledger, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any half-open membership result is visible.

Independence witness: dyadicratcore, locatedrealinterval, closedboundedinterval, regseqrat, real: $\mathsf{HalfOpenRealInterval}^{\uparrow}$ is not bijective to any listed sibling because it binds left endpoint admission, right endpoint refusal, dyadic one-sided comparison rows, finite readback, terminal seal handoff, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HalfOpenRealInterval}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{HalfOpenRealInterval}^{\uparrow}$ packet is generated from lower and upper RealUp endpoint seals, an endpoint-order row, a DyadicRatCore one-sided boundary ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal handoff, left-admission and right-refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HalfOpenRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7080.1, Definition 7080.2, Definition 7080.3, and Definition 7080.4 seed the half-open interval boundary over located endpoint, closed-bounded interval, dyadic, regular-rational, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HalfOpenRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host topology, quotient real equality, selected endpoint representatives, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.HalfOpenRealIntervalUp covering carrier admission, dyadic boundary exactness, one-sided boundary stability, regular readback, Real seal nonescape, transport, replay, provenance, and local naming.

Chapter 7081

A Concrete Naming Certificate for $\mathsf{StreamReindexing}^{\uparrow}$

Following Bishop and Bridges on constructive sequence names, the $\mathsf{StreamReindexing}^{\uparrow}$ packet records the finite schedule operation that reads one displayed $\mathsf{StreamName}^{\uparrow}$ observation plan through another. It sits before the regular-rational and real-facing reindexing routes of chapter 301, chapter 38, chapter 1568, and chapter 6960, and it uses the dyadic tolerance core of chapter 291 only after the reindexed stream windows have been displayed. The packet names a finite schedule certificate; it does not quotient streams, choose a tail representative, import countable choice, identify host stream equality, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7081.1 (Stream reindexing carrier)**.** *A* $\mathsf{StreamReindexing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, I, J, W, D, R, E, H, C, P, N)$$

with the following rows:

1. *X is the source* $\mathsf{StreamName}^{\uparrow}$ *row whose finite observations are being reread;*
2. *I is the displayed input schedule window listing the source indices available to the request;*
3. *J is the displayed reindexing schedule, assigning each requested output window to a finite input-window read;*
4. *W is the synchronized finite window ledger certifying that every output request has a displayed source read;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached only to the observed window requests;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after X, I, J, W, D have been displayed;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available to real-facing consumers of the reindexed name;*
8. *H records componentwise* hsame *transport for the stream row, schedules, windows, dyadic tolerance row, readback, and seal;*
9. *C records displayed* Cont *replay of the same finite reindexing route;*
10. *P is the* Pkg *provenance over* $\mathsf{StreamReindexing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{RegularCauchyReindexing}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamReindexing}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected tails, unbounded schedule choice, host stream equality, countable choice, or ambient Real completeness.

Theorem 7081.2 (Stream reindexing NameCert obligations)**.** *For an accepted* $\mathsf{StreamReindexing}^{\uparrow}$ *carrier* $S = (X, I, J, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StreamReindexing}^{\uparrow}}$ *surface consists exactly of source-stream admission through* X*, input-window admission through* I*, reindexing-schedule admission through* J*, synchronized finite-window coverage through* W*, dyadic tolerance compatibility through* D*, regular-rational readback through* R*, terminal real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7081.1. The source stream, input schedule, reindexing schedule, synchronized windows, dyadic tolerance ledger, readback row, and terminal seal are all displayed coordinates.

Carrier admission reads only those coordinates. The synchronized window row W accounts for every output request by a finite source-window read, so the local certificate has no detached schedule object to compare.

Transport and replay are then the structural rows H and C, with provenance and local naming supplied by P and N. Since no excluded object is a carrier coordinate, the obligation surface cannot export quotient stream equality, selected tails, countable choice, host stream equality, or ambient completeness. □

Theorem 7081.3 (Stream reindexing window stability)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyReindexing}^{\uparrow}$*, or* $\mathsf{RegularCauchyReindexing}^{\uparrow}$ *consumer of an accepted* $\mathsf{StreamReindexing}^{\uparrow}$ *packet must first read the displayed rows*

$$X, I, J, W, D, R, E, H, C, P, N.$$

In particular, the consumer receives the reindexed stream only through finite $\mathsf{StreamName}^{\uparrow}$ *windows, the synchronized schedule ledger, the dyadic tolerance row, the regular-rational readback, and the terminal real seal. It receives no quotient stream, selected tail, countable-choice schedule, host stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 7081.2. They place the source stream row X, schedule rows I, J, synchronized window row W, and dyadic tolerance row D before any readback row can be consumed.

Next read the regular-rational and real-facing rows. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff R is downstream of the finite schedule window, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of that handoff.

Finally apply componentwise transport and displayed replay through H and C. The provenance and local naming rows keep the same finite packet attached to the downstream $\mathsf{CauchyReindexing}^{\uparrow}$ route and its $\mathsf{RegularCauchyReindexing}^{\uparrow}$ specialization, so no hidden quotient, selected tail, countable-choice schedule, host equality, or ambient completeness coordinate is available. □

Falsifiable prediction: Every consumer of a $\mathsf{StreamReindexing}^{\uparrow}$ packet must expose the source $\mathsf{StreamName}^{\uparrow}$ row, finite input schedule, reindexing schedule, synchronized window ledger, dyadic tolerance row, regular-rational readback, and Real seal before it can use the reindexed stream.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy-reindexing: $\mathsf{StreamReindexing}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source stream row, input schedule, reindexing schedule, synchronized finite windows, dyadic tolerance ledger, regular-rational handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamReindexing}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamReindexing}^{\uparrow}$ packet is generated from a source StreamName row, finite input schedule, reindexing schedule, synchronized window ledger, dyadic tolerance row, RegSeqRat handoff, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StreamReindexing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7081.1, Definition 7081.2, and Definition 7081.3 seed the finite schedule-reindexing surface used by regular-rational, real, and Cauchy reindexing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StreamReindexing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected tails, countable-choice schedules, host stream equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized window coverage, dyadic tolerance compatibility, regular-rational handoff, Real seal nonescape, and local NameCert registration for BEDC.Derived.StreamReindexingUp.

Chapter 7082

A Concrete Naming Certificate for $\mathsf{DedekindCompleteOrderedField}^{\uparrow}$

Following Bourbaki and Kelley-style ordered-field completeness, and Bishop–Bridges constructive located-supremum discipline, the $\mathsf{DedekindCompleteOrderedField}^{\uparrow}$ packet records Dedekind completeness only as a finite NameCert boundary for displayed located, bounded field-family windows. It sits after the complete ordered-field interface of chapter 6012, the located upper-and-lower witness surface of chapter 1427, the terminal real-name seal of chapter 38, the algebraic order carrier of chapter 766, and the rowwise comparison boundary of chapter 3754. The packet is an L10 completion-boundary object; it does not construct $\mathsf{Real}^{\uparrow}$ by Dedekind cuts, quotient real names, choose suprema, import classical trichotomy, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7082.1 (Dedekind-complete ordered-field carrier)**.** *A* $\mathsf{DedekindCompleteOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, A, L, R, U, G, W, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CompleteOrderedField}^{\uparrow}$ *source row naming the ordered-field operations and completion-facing service only through finite BEDC data;*
2. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row exposing addition, multiplication, positivity, and order comparison as displayed algebraic-order evidence;*
3. *L is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row for located inhabited bounded family windows over the displayed field carrier;*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the ordered-field, algebraic-order, and located-supremum rows have been exposed;*
5. *U is the* $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ *comparison row, used when a consumer compares this boundary with a Cauchy-complete ordered-field presentation;*
6. *G is the Dedekind-boundary ledger listing the inspected lower-family rows, upper-bound rows, locatedness requests, and lower-approximation witnesses currently in scope;*
7. *W is the finite precision window controlling which field-family observations may be read through L and G;*
8. *H records componentwise* hsame *transport for $F, A, L, R, U, G, W, C, P, N$;*

9. *C records displayed* Cont *replay for the ordered-field, algebraic-order, located-supremum, Real-seal, comparison, boundary-ledger, and precision-window rows;*
10. *P is the* Pkg *provenance over* $\mathsf{DedekindCompleteOrderedField}^{\uparrow}$, $\mathsf{CompleteOrderedField}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCompleteOrderedField}^{\uparrow}}$ *row.*

The accepted packet compares only $F, A, L, R, U, G, W, H, C, P, N$. It has no coordinate for a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$*, quotient equality of real names, classical trichotomy, selected suprema, countable choice, host field equality, or ambient Real completeness.*

Theorem 7082.2 (Dedekind-complete ordered-field NameCert obligations)**.** *For an accepted packet $D = (F, A, L, R, U, G, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DedekindCompleteOrderedField}^{\uparrow}}$ *obligations consist exactly of carrier admission for those rows, algebraic-order compatibility through A, ordered-field source exposure through F, located-supremum witnessing through L, terminal Real sealing through R, comparison routing through U, boundary-ledger exactness through G, finite precision control through W, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows F, A, L, R, U, G, W are the only mathematical coordinates, and H, C, P, N are the structural certificate rows.

Ordered-field and algebraic-order reads are forced through F and A. Located upper-bound and lower-approximation reads are forced through L and the finite window W, with the inspected lower-family and upper-bound rows recorded in G before the terminal Real seal R is available.

When a consumer compares the packet with a Cauchy-complete ordered-field presentation, the only available comparison surface is U. Transport and replay preserve the same rows componentwise.

Since the carrier contains no Dedekind-cut constructor for $\mathsf{Real}^{\uparrow}$, no quotient-real equality row, no trichotomy oracle, no selected-supremum coordinate, no countable-choice schedule, no host field equality, and no ambient Real-completeness coordinate, none of those objects can be a local NameCert obligation. □

Theorem 7082.3 (Dedekind-complete ordered-field L10 boundary)**.** *Every L10 consumer of an accepted* $\mathsf{DedekindCompleteOrderedField}^{\uparrow}$ *packet must pass through the sibling route*

$$\mathsf{CompleteOrderedField}^{\uparrow} \longmapsto \mathsf{RealAlgOrder}^{\uparrow} \longmapsto \mathsf{LocatedSupremum}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and, for comparison with Cauchy-complete presentations, through $\mathsf{CauchyCompleteOrderedFieldUniqueness}^{\uparrow}$ *before reading Dedekind-complete ordered-field service. The exported service is only the finite boundary ledger G over the precision window W together with structural transport, replay, provenance, and local naming; it exports no Dedekind-cut construction of* $\mathsf{Real}^{\uparrow}$*, quotient equality, classical trichotomy, selected supremum, countable choice, host field equality, or ambient Real completeness.*

Proof. Start with the source row F. It exposes complete ordered-field service through chapter 6012, not through a host complete ordered field.

Next read the algebraic order and located-supremum rows. The row A supplies only displayed $\mathsf{RealAlgOrder}^{\uparrow}$ operations and comparisons, while L supplies the upper-bound and lower-approximation faces already licensed by chapter 1427.

The terminal real-facing observation is then R, which is downstream of F, A, L, G, W. If the consumer compares this boundary with a Cauchy-complete presentation, it must additionally read U through chapter 3754.

The structural rows H, C, P, N preserve and name exactly that route. Because the excluded objects are not carrier coordinates, the L10 boundary cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCompleteOrderedField}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCompleteOrderedField}^{\uparrow}$ packet is generated from a CompleteOrderedField source, a RealAlgOrder row, a LocatedSupremum handoff, a terminal Real seal, a CauchyCompleteOrderedFieldUniqueness comparison row, a Dedekind-boundary ledger, a finite precision window, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCompleteOrderedField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7082.1, Definition 7082.2, and Definition 7082.3 seed the L10 Dedekind-complete ordered-field boundary over displayed ordered-field, algebraic-order, located-supremum, Real-seal, and comparison rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCompleteOrderedField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a Dedekind-cut construction of RealUp, quotient equality, classical trichotomy, selected suprema, countable choice, host field equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal work can encode carrier admission, NameCert obligations, and the L10 boundary route for BEDC.Derived.DedekindCompleteOrderedFieldUp.

Chapter 7083

A Concrete Naming Certificate for $\mathsf{RegularRealLineAtlas}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{RegularRealLineAtlas}^{\uparrow}$ packet is a finite atlas of dyadic chart rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and $\mathsf{Real}^{\uparrow}$ seals. It sits after the dyadic tolerance carrier of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the modulus schedule of chapter 292. The packet names finite real-line chart reads without importing a host real line, quotient stream equality, selected limits, countable choice, or open-cover compactness.

Definition 7083.1 (Regular real-line atlas carrier)**.** *A* $\mathsf{RegularRealLineAtlas}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, S, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *chart ledger, carrying the dyadic center, radius, overlap tolerance, and one-step refinement budget for each displayed chart row.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only the finite stream entries inspected by the chart read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window and dyadic tolerance data.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic chart row, finite window, and regular rational readback are visible.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *scheduling row that bounds the chart-window read by a finite precision request.*
6. *H records componentwise* hsame *transport for dyadic chart rows, stream windows, regular readback, Real seals, modulus schedules, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the finite atlas route*

$$D, S, M \longmapsto R \longmapsto E \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularRealLineAtlas}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularRealLineAtlas}^{\uparrow}}$ *row.*
The classifier compares accepted atlas packets only through $D, S, R, E, M, H, C, P, N$. It has no coordinate for a host real line, quotient stream equality, selected limit, countable-choice selector, global open cover, compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7083.2 (Regular real-line atlas NameCert obligations)**.** *For every accepted* $\mathsf{RegularRealLineAtlas}^{\uparrow}$ *carrier $A = (D, S, R, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularRealLineAtlas}^{\uparrow}}$ *surface consists exactly of dyadic chart admission through D, finite stream-window exposure through S, regular rational readback through R, Real seal handoff through E, finite modulus scheduling through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7083.1. The displayed rows are exactly $D, S, R, E, M, H, C, P, N$, so every chart read begins from finite dyadic and stream data.

The scheduling and readback rows determine the chart obligation surface. Row M bounds the requested precision, row S displays the inspected window, and row R supplies the regular rational readback attached to that same window.

The Real seal row E is downstream of those finite rows. Transport, replay, provenance, and local naming preserve the same route, so no host real line, quotient stream equality, selected limit, countable-choice selector, open-cover compactness, or ambient completeness theorem can be exported. □

Theorem 7083.3 (Regular real-line atlas window handoff)**.** *Every window read from an accepted* $\mathsf{RegularRealLineAtlas}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The atlas can therefore hand a chart window to a downstream real-facing consumer only after the dyadic chart ledger, finite stream window, modulus schedule, regular rational readback, and terminal seal are all displayed.

Proof. Start with the dyadic chart row D and the schedule row M. Together they name the finite tolerance and precision bound for the chart window.

Read the window row S next. Since S exposes only finitely many stream observations, the regular rational readback R is a finite handoff rather than a quotient stream.

Finally attach the Real seal row E and the structural rows H, C, P, N. The resulting route is exactly the displayed atlas route, and it contains no selected limit, global cover, countable-choice enumeration, host equality, or ambient completeness coordinate. □

Theorem 7083.4 (Regular real-line atlas Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{RegularRealLineAtlas}^{\uparrow}$ *packet must pass through the rows*

$$D, S, R, E, M, H, C, P, N.$$

The terminal seal certifies only the finite atlas route already displayed by $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{CauchyModulus}^{\uparrow}$ *rows; it cannot be read as Real completeness, quotient stream equality, host real equality, a selected limit, countable choice, or open-cover compactness.*

Proof. Use Definition 7083.3. It places every atlas window read downstream of dyadic chart data, finite stream observations, modulus scheduling, and regular rational readback.

The Real seal row E occurs only after that route in the carrier. A Real-facing consumer therefore receives a sealed finite chart read, not an external real-line object.

Rows H, C, P, N preserve and name the same packet. Since completeness, quotient equality, host equality, selected limits, countable choice, and open-cover compactness are absent from the carrier, the Real seal has no escape route beyond the displayed finite atlas. □

Falsifiable prediction: Every accepted $\mathsf{RegularRealLineAtlas}^{\uparrow}$ chart read displays a DyadicRatCoreUp chart ledger, StreamNameUp finite window, RegSeqRatUp readback, RealUp seal, CauchyModulusUp schedule, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before any Real-facing consumer can use the atlas.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchymodulus: $\mathsf{RegularRealLineAtlas}^{\uparrow}$ is not bijective to any listed sibling because it binds finite dyadic chart rows, stream windows, regular rational readbacks, Real seals, modulus schedules, transport, replay, provenance, and local naming into one atlas packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealLineAtlas}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularRealLineAtlas}^{\uparrow}$ packet is generated from DyadicRatCore chart rows, StreamName finite windows, RegSeqRat readback, RealUp seal rows, a CauchyModulus schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRealLineAtlas}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7083.1, Definition 7083.2, Definition 7083.3, and Definition 7083.4 seed the finite dyadic chart-window atlas route from displayed tolerances and windows to regular readback and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularRealLineAtlas}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, host real equality, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.RegularRealLineAtlasUp covering dyadic chart admission, finite window exposure, regular readback, Real seal nonescape, modulus scheduling, transport, replay, provenance, and local naming.

Chapter 7084

A Concrete Naming Certificate for $\mathsf{RealCompletionUnit}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the packet records the unit map from dyadic and rational data into the $\mathsf{Real}^{\uparrow}$ seal as finite BEDC data. It sits over the dyadic tolerance core of chapter 291, the finite stream-window row of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion boundary of chapter 95. The packet names the unit-map surface available to Real and Completion consumers without quotienting Cauchy names, selecting representatives, importing countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7084.1 (Real completion unit carrier)**.** *A* $\mathsf{RealCompletionUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, W, R, E, H, C, P, N)$$

with the following rows:

1. *D is the dyadic constant row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, that supplies the rational or dyadic source data for the unit map.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the finite observations by which the source data are presented to a regular-name consumer.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from D and W.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular readback has been displayed.*
5. *H records componentwise* hsame *transport for the dyadic row, stream-window row, regular readback, and Real seal.*
6. *C records displayed* Cont *replay of the same finite unit-map route.*
7. *P is the* Pkg *provenance over* $\mathsf{RealCompletionUnit}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionUnit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, selected Cauchy representatives, host real equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7084.2 (Real completion unit NameCert obligations)**.** *For an accepted* $\mathsf{RealCompletionUnit}^{\uparrow}$ *carrier $U = (D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionUnit}^{\uparrow}}$ *surface consists of five*

obligation rows: dyadic source admission through D, finite stream-window admission through W, regular rational readback through R, terminal Real sealing through E, and structural certification through H, C, P, N. Every Real or Completion consumer of the unit map must read those rows on the same finite BEDC surface.

Proof. Project the carrier of Definition 7084.1. The dyadic source row D, stream-window row W, regular readback row R, and terminal seal row E are displayed coordinates, and the structural rows H, C, P, N transport, replay, source, and name exactly that route.

The first four obligations are therefore the analytic face of the unit map: source admission, window admission, readback, and sealing. The fifth obligation is the structural face binding those reads into one local NameCert surface.

No excluded shortcut is a coordinate of the carrier. Hence a consumer receives the unit map only through the displayed rows and cannot replace the route by quotient completion, selected representatives, host equality, countable choice, open-cover compactness, or ambient completeness. □

Theorem 7084.3 (Real completion unit nonescape)**.** *Any* $\mathsf{Real}^{\uparrow}$ *endpoint consumer of an accepted* $\mathsf{RealCompletionUnit}^{\uparrow}$ *carrier* $U = (D, W, R, E, H, C, P, N)$ *that drops one of* D*,* W*,* R*,* E*,* H*,* C*,* P*, or* N *leaves the accepted unit-map surface. In particular, after dropping any one of those rows, the consumer cannot read the* $\mathsf{Real}^{\uparrow}$ *endpoint, cannot replace the finite route with quotient equality of completed names, cannot choose a representative Cauchy name, cannot import external real completeness, and cannot appeal to countable choice.*

Proof. Start with the carrier projection of Definition 7084.1. The endpoint row E is downstream of the dyadic source row D, the stream-window row W, and the regular readback row R.

Apply the obligation surface of Definition 7084.2. It binds the analytic rows D, W, R, E and the structural rows H, C, P, N into one local $\mathsf{NameCert}_{\mathsf{RealCompletionUnit}^{\uparrow}}$ surface, so a consumer that drops any row no longer has the displayed certificate route.

The excluded replacements are not rows of U. Thus dropping a coordinate cannot be repaired by quotient equality, a selected representative, external completeness, or countable choice; it simply removes the consumer from the accepted finite unit-map packet. □

Falsifiable prediction: Every consumer of a $\mathsf{RealCompletionUnit}^{\uparrow}$ packet must expose the dyadic source row, stream-window row, regular rational readback, Real seal, componentwise transport, replay, provenance, and local NameCert row before it can use the unit map into $\mathsf{Real}^{\uparrow}$.

Independence witness: dyadicratcore, streamname, regseqrat, real, completion: $\mathsf{RealCompletionUnit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the dyadic source row, finite stream-window row, regular readback, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionUnit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealCompletionUnit}^{\uparrow}$ packet is generated from a dyadic constant row, StreamName window row, RegSeqRat readback row, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7084.1, Definition 7084.2, and Definition 7084.3 seed the finite unit-map surface from dyadic and rational data into the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionUnit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected Cauchy representatives, host real equality, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic source admission, stream-window admission, regular readback, Real seal nonescape, and local NameCert registration for BEDC.Derived.RealCompletionUnitUp.

Chapter 7085

A Concrete Naming Certificate for $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$

Following Bishop–Bridges on Archimedean bounds and regular Cauchy real names, the RegularCauchyArchimedeanB packet records the finite threshold handoff from Archimedean evidence to regular rational and real-facing reads. It sits between chapter 430, chapter 1672, chapter 126, chapter 301, and chapter 38. The packet is a finite L10 bridge, not a supremum principle, trichotomy row, quotient stream, countable-choice schedule, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness object.

Definition 7085.1 (Regular Cauchy Archimedean bridge carrier)**.** *A* $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row, including the rational bound witness and public threshold surface.*
2. *D is the* $\mathsf{DyadicArchimedean}^{\uparrow}$ *scale row that turns the Archimedean bound into finite dyadic threshold data.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family used by threshold and regular-Cauchy consumers.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed Archimedean, dyadic, and stream-window rows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the regular rational readback row R has been displayed.*
6. *H records componentwise* hsame *transport for the Archimedean bound, dyadic scale, stream windows, regular readback, Real seal, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the finite route*

$$A, D, S \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{DyadicArchimedean}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, D, S, R, E, H, C, P, N$. It has no coordinate for a supremum, trichotomy, quotient stream equality, countable-choice schedule, selected completed limit, or ambient Real completeness.

Theorem 7085.2 (Regular Cauchy Archimedean bridge NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$ *carrier*

$$B = (A, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}}$ *surface consists exactly of Archimedean bound admission, dyadic scale admission, finite StreamName window admission, RegSeqRat readback, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public read of the packet factors through these rows and receives no supremum, trichotomy, quotient stream equality, countable-choice schedule, selected limit, or ambient completeness coordinate.*

Proof. Project the carrier of Definition 7085.1. The rows A, D, S, R, E expose the Archimedean bound, dyadic scale, finite stream windows, regular rational readback, and terminal Real seal.

The first three rows are source rows. The Archimedean part is read through chapter 430, the dyadic scale through chapter 1672, and the finite windows through chapter 126.

The readback rows close the bridge. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is downstream of A, D, S, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of R.

Finally the structural rows H, C, P, N transport, replay, source, and name only the displayed route. Since no excluded object is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7085.3 (Regular Cauchy Archimedean threshold handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{ArchimedeanReal}^{\uparrow},\ \mathsf{DyadicArchimedean}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the rows $A, D, S, R, E, H, C, P, N$. The handoff exports Archimedean threshold evidence to regular rational and real-facing consumers without importing a supremum, trichotomy, quotient stream equality, countable-choice schedule, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 7085.2. They place the Archimedean bound row A, dyadic scale row D, and finite stream-window row S before any readback endpoint is available.

Read the regular-Cauchy endpoint next. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is produced only from the displayed A, D, S threshold route, so no quotient stream or countable schedule can be substituted for the finite window family.

Only after that row is visible may the terminal $\mathsf{Real}^{\uparrow}$ seal E be inspected. Transport and replay through H, C preserve the same finite route, while P, N source and name it.

Thus every downstream regular-rational or Real-facing consumer receives the stated threshold handoff and no excluded host or completeness object. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$ RegSeqRat or Real-facing read factors through an ArchimedeanRealUp bound row, a DyadicArchimedeanUp scale row, finite StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: archimedeanreal, dyadic-archimedean, streamname, regseqrat, real: $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Archimedean bound evidence, dyadic threshold scale data, finite stream windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming while refusing supremum, trichotomy, quotient streams, selected limits, countable choice, and Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}$ packet is generated from ArchimedeanReal bound evidence, a DyadicArchimedean scale row, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7085.1, Definition 7085.2, and Definition 7085.3 seed the finite Archimedean-threshold bridge from bound rows to regular-Cauchy and Real-facing reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyArchimedeanBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close supremum existence, trichotomy, quotient stream equality, countable-choice schedules, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier agreement, dyadic threshold exactness, StreamName window coverage, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyArchimedeanBridgeUp.

Chapter 7086

A Concrete Naming Certificate for $\mathsf{AbelUniformConvergence}^{\uparrow}$

Following Abel, Hardy, and Bishop–Bridges constructive analysis, the $\mathsf{AbelUniformConvergence}^{\uparrow}$ packet records the finite interface by which Abel radial convergence is read uniformly over displayed radius windows. It sits after the Abel theorem route of chapter 1922, the uniform limit packet of chapter 463, the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter packages traditional Abel uniform convergence as finite BEDC rows; it does not assert ambient real completeness, countable choice, quotient stream equality, or selected infinite sums.

Definition 7086.1 (AbelUniformConvergence carrier)**.** *An* $\mathsf{AbelUniformConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, W, S, U, T, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the finite radius-window row listing the dyadic subradius cells and boundary-approach windows inspected by the Abel consumer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite coefficient and partial-sum prefixes requested by R.*
3. *S is the Abel partial-sum row whose observations are read through the same finite windows.*
4. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *ledger row, assigning one displayed tail threshold to every radius cell in R.*
5. *T is the* $\mathsf{AbelTheorem}^{\uparrow}$ *boundary row recording the radial handoff after R, W, S, U have been accepted.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the synchronized Abel windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the Abel boundary and regular rational readback have been displayed.*
8. *H records componentwise* hsame *transport for radius windows, stream windows, partial sums, uniform-tail data, Abel boundary data, readback, seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from each Abel uniform convergence request through R, W, S, U, T, Q, E.*

10. *P is the* Pkg *provenance over* $\mathsf{AbelUniformConvergence}^{\uparrow}$, $\mathsf{AbelTheorem}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelUniformConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, S, U, T, Q, E, H, C, P, N$. It has no coordinate for ambient real completeness, countable choice, quotient stream equality, selected infinite sums, or a Real seal detached from the displayed Abel uniform route.

Theorem 7086.2 (AbelUniformConvergence NameCert obligations)**.** *For every accepted* $\mathsf{AbelUniformConvergence}^{\uparrow}$ *carrier*

$$A = (R, W, S, U, T, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbelUniformConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, radius-window admission through R, finite prefix exposure through W, Abel partial-sum alignment through S, uniform tail exactness through U, Abel boundary handoff through T, regular rational readback and Real seal nonescape through Q and E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No obligation row supplies ambient real completeness, countable choice, quotient stream equality, selected infinite sums, host analytic equality, or an unbounded stream selector.*

Proof. Project the carrier of Definition 7086.1. Its mathematical rows are the radius-window row R, the stream window row W, the partial-sum row S, the uniform-tail ledger U, the Abel boundary row T, the regular rational readback Q, and the Real seal E.

The radius and stream rows fix the finite inspection surface. Every coefficient or partial-sum observation is read through W only after a displayed radius cell in R has been selected.

The uniform row supplies the common tail budget. Because U is a $\mathsf{UniformLimit}^{\uparrow}$ ledger over the same windows, the Abel boundary read in T cannot choose a different threshold for each point of the displayed radius window.

The readback and seal rows are downstream. The row Q repacks the synchronized Abel windows as regular rational data, and E exposes the terminal Real seal only after R, W, S, U, T, Q have been read.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for ambient real completeness, countable choice, quotient stream equality, selected infinite sums, host analytic equality, or an unbounded selector, the listed rows exhaust the local NameCert obligations. □

Theorem 7086.3 (AbelUniformConvergence Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{AbelUniformConvergence}^{\uparrow}$ *packet reads the endpoint only through the finite route*

$$\mathsf{AbelTheorem}^{\uparrow},\ \mathsf{UniformLimit}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer first receives displayed radius windows, finite stream prefixes, one uniform tail ledger, and the Abel boundary handoff; only then may it consume the regular rational readback and terminal Real seal. The route exports no ambient real completeness theorem, countable-choice schedule, quotient stream equality, selected infinite sum, or host equality of boundary values.

Proof. Start from the accepted packet and read the displayed radius and stream rows R, W. These rows expose only finite windows, so the consumer has no independent stream quotient or unbounded selector.

Apply the uniform-tail row U. It supplies one threshold discipline for the whole displayed radius window, and therefore binds the Abel boundary read to the same finite window surface.

Read the Abel boundary row T through the sibling theorem route. The row records the radial handoff only after R, W, S, U have fixed the finite convergence surface.

Finally pass through $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and terminal $\mathsf{Real}^{\uparrow}$ seal E, with H, C, P, N preserving the same route. The refused objects are absent from the carrier, so every Real-facing read remains inside the displayed finite package. □

Falsifiable prediction: Every accepted AbelUniformConvergenceUp read exposes a finite radius-window row, StreamNameUp prefix row, Abel partial-sum row, UniformLimitUp tail ledger, AbelTheoremUp boundary row, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before a Real-facing consumer can inspect the endpoint.

Independence witness: abel-theorem, uniformlimit, streamname, regseqrat, real: $\mathsf{AbelUniformConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries radius-window admission, finite prefix exposure, Abel partial-sum alignment, one uniform tail ledger, Abel boundary handoff, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelUniformConvergence}^{\uparrow}}$.

Constructive story: An $\mathsf{AbelUniformConvergence}^{\uparrow}$ packet is generated from radius-window rows, StreamName finite prefixes, Abel partial sums, a UniformLimit tail ledger, an AbelTheorem boundary row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelUniformConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7086.1, Definition 7086.2, and Definition 7086.3 seed the finite Abel uniform convergence route over AbelTheorem, UniformLimit, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelUniformConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient real completeness, countable choice, quotient stream equality, selected infinite sums, host analytic equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.AbelUniformConvergenceUp covering carrier admission, radius-window admission, finite prefix exposure, uniform-tail exactness, Abel boundary handoff, readback, Real seal nonescape, transport, replay, provenance, and local naming.

Chapter 7087

A Concrete Naming Certificate for $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy sequences and finite extraction from regular data, the $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$ packet records the finite subsequence route used by Real and Completion consumers. It reads the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite NameCert carrier for extracting and replaying a monotone subsequence window; it is not a quotient stream, a selected host limit, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7087.1 (Finite regular Cauchy subsequence carrier)**.** *A* $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, M, O, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite index-window row, naming the inspected source positions and the target subsequence positions visible to the packet.*
2. *M is the monotone index ledger, recording that the selected target positions are strictly ordered inside the displayed finite window.*
3. *O is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, exposing only the stream-name observations read at the displayed indices.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the observations in O and the monotone ledger M.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget used to compare the source window, selected positions, and regular rational readback.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after W, M, O, R, D have been displayed.*
7. *H records componentwise* hsame *transport for finite windows, monotone ledgers, StreamName observations, RegSeqRat readback, dyadic budgets, Real seals, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite extraction route*

$$W \longmapsto M \longmapsto O \longmapsto R \longmapsto D \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, M, O, R, D, E, H, C, P, N$. It has no coordinate for an infinite choice function, quotient stream equality, selected host limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FiniteRegularCauchySubsequenceUp.FiniteRegularCauchySubsequenceTasteGate`
`single carrier alignment`

Theorem 7087.2 (Finite regular Cauchy subsequence NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$ *carrier*

$$S = (W, M, O, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index window, monotone index ledger, StreamName observations, RegSeqRat readback, DyadicRatCore tolerance budget, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; monotone-window exactness for the selected indices; regular readback compatibility through O, R, D; Real-seal routing through E; and nonescape for every excluded ambient sequence or completeness object.*

Proof. Carrier admission is projection from Definition 7087.1. The visible packet is the tuple $W, M, O, R, D, E, H, C, P, N$, and every obligation row names one of those coordinates.

The monotone-window obligation is local. The row M is the only place where index order is recorded, and it is attached to the finite window W before any StreamName observation can be read.

Regular readback compatibility then follows the displayed route. The row O supplies the inspected stream observations, R reads them as regular rational data, and D provides the dyadic tolerance budget used by the same finite extraction.

The Real seal is terminal. The row E is exposed only after W, M, O, R, D have been displayed, while H, C, P, N transport, replay, source, and name that same route. Since no excluded ambient object is a coordinate of the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7087.3 (Finite regular Cauchy subsequence extraction route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$ *carrier*

$$S = (W, M, O, R, D, E, H, C, P, N)$$

must factor its subsequence read through the finite route

$$W \longmapsto M \longmapsto O \longmapsto R \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a finite index window, a monotone index ledger, StreamName observations, RegSeqRat readback, a DyadicRatCore tolerance budget, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It receives no infinite selector, quotient stream, selected host limit, countable choice, host-level sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier. Before any analytic read is available, the packet exposes only the finite window W and the monotone ledger M for the selected indices.

Replay the observation route through C. The StreamName row O can be inspected only at the displayed indices, the RegSeqRat row R is read from those observations, and the DyadicRatCore budget D compares only the same finite data.

The terminal seal is then read from E. This seal is attached to the route already displayed by W, M, O, R, D, so it is a Real-facing seal of the finite extraction rather than a selected host limit.

Finally, H, C, P, N transport, replay, source, and name the same packet. Because the carrier contains no infinite selector, quotient stream, countable-choice row, host equality service, or ambient completeness coordinate, every public subsequence read factors through the stated finite route. □

Falsifiable prediction: Every accepted $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$ Real or Completion-facing read factors through a finite index window, monotone index ledger, $\mathsf{StreamName}^{\uparrow}$ observation row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: streamname, regseqrat, dyadicratcore, real, bishop-completion-induction: $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite selected-index window, monotone ledger, observation row, regular readback, dyadic tolerance budget, terminal Real seal, transport, replay, provenance, and local naming while refusing infinite selectors, quotient streams, selected host limits, countable choice, and ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}$ packet is generated from a finite index window, monotone index ledger, StreamName observations, RegSeqRat readback, a DyadicRatCore tolerance budget, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7087.1, Definition 7087.2, and Definition 7087.3 seed the finite subsequence extraction route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRegularCauchySubsequence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FiniteRegularCauchySubsequenceUp.FiniteRegularCauchySubsequenceTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not close infinite subsequence selection, quotient stream equality, selected host limits, countable choice, host-level sequence equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window exactness, StreamName observation routing, RegSeqRat readback, DyadicRatCore tolerance budgeting, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteRegularCauchySubsequenceUp.

Chapter 7088

A Concrete Naming Certificate for MetaCICTypedResidualBudget$^{\uparrow}$

The MetaCICTypedResidualBudget$^{\uparrow}$ packet realizes the MetaCIC residual-checker frontier as finite typed residual-budget data. It sits beside the MetaCIC residual-substitution boundary, confluence residual-checker, confluence residual envelope, local diamond witness, and substitution-diamond packets, but its own carrier is the typed budget ledger that a bounded residual checker consumes before it may report a local join or retain an obstruction. The packet does not claim subject reduction, a full parallel diamond, arbitrary Church–Rosser, or unrestricted residual-substitution compatibility.

The dependency route is row-sensitive. The typed-window row T is read with the residual-substitution premise visible through chapter 2181; the residual-frontier row R is checked against the bounded redex and checker inventory of chapter 3827; the checker-route row Q consumes the residual envelope of chapter 3921; the local-join row J is compared with the finite peak geometry of chapter 7042; and the obstruction row O retains the substitution boundary of chapter 6419 together with the frontier budget of chapter 4238. Thus the carrier records the typed windows, bounded checker routes, local joins, and obstruction rows that those sibling packets must read before any residual-diamond handoff is visible to a downstream confluence consumer.

Definition 7088.1 (MetaCIC typed residual-budget carrier)**.** *A* MetaCICTypedResidualBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, R, Q, J, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, naming the finite source term, target type annotation, context fragment, and closedness boundary visible to the residual checker.*
2. *R is the residual-frontier row, listing the redex and residual pairs that the bounded checker is allowed to inspect inside T.*
3. *Q is the checker-route row, recording the finite fuel, residual scheduling order, and local substitution-boundary reads used by the checker.*
4. *J is the local-join row, storing each displayed join candidate accepted by the bounded checker for the inspected residual pairs.*
5. *O is the obstruction row, retaining the exact typed residual pair, substitution-boundary failure, or fuel boundary when the checker does not close a local join.*

6. *H records componentwise* hsame *transport for typed windows, residual frontiers, checker routes, local joins, obstruction rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a residual-checker request through*

$$T \longmapsto R \longmapsto Q \longmapsto J, O.$$

8. *P is the* Pkg *provenance over* $\mathsf{MetaCICTypedResidualBudget}^{\uparrow}$*, the surrounding MetaCIC confluence and substitution-boundary packets,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedResidualBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, Q, J, O, H, C, P, N$. It has no coordinate for a subject-reduction theorem, full parallel diamond, arbitrary Church–Rosser theorem, unrestricted substitution compatibility, Lean verification, or bridge checking.

Theorem 7088.2 (MetaCIC typed residual-budget NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICTypedResidualBudget}^{\uparrow}$ *carrier*

$$B = (T, R, Q, J, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICTypedResidualBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for the typed window, residual frontier, checker route, local join row, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; typed-window exactness for the source and type boundary; residual-frontier coverage for the inspected pairs; checker-route boundedness; local-join or obstruction retention for each inspected pair; and nonescape from the named residual-budget rows.*

Proof. Carrier admission is projection from Definition 7088.1. The accepted packet exposes exactly $T, R, Q, J, O, H, C, P, N$.

Typed-window exactness is read from T. The checker has no access to a larger context, unrecorded closedness proof, or hidden subject-reduction theorem.

Residual-frontier coverage and checker-route boundedness are local. The row R lists the residual pairs under inspection, and Q records the finite route and fuel used to inspect them.

Each inspected pair then lands in either J or O. A successful local check is stored as a displayed join candidate in J, while an unclosed pair, substitution-boundary failure, or fuel boundary remains visible in O.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the stronger confluence and substitution principles are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7088.3 (MetaCIC typed residual-budget residual-checker route)**.** *Every MetaCIC residual-checker consumer of an accepted* $\mathsf{MetaCICTypedResidualBudget}^{\uparrow}$ *carrier*

$$B = (T, R, Q, J, O, H, C, P, N)$$

must factor its read through the finite typed-budget route

$$T \longmapsto R \longmapsto Q \longmapsto J, O \longmapsto H, C, P, N.$$

The consumer may export the displayed typed window, inspected residual frontier, bounded checker route, local join rows, retained obstruction rows, componentwise transport, replay, provenance, and local naming. It may not export subject reduction, a full parallel diamond, arbitrary Church–Rosser, unrestricted residual-substitution compatibility, Lean verification, or bridge checking.

Proof. Start with a residual-checker consumer. The typed window T is the only source of term, type, context, and closedness-boundary data available to the packet.

The residual frontier is then fixed by R. The checker cannot inspect a pair outside that displayed frontier, and the route row Q records the finite schedule and fuel used for the inspected pairs.

For each inspected pair, the packet records the outcome locally. A successful bounded local join is placed in J, while a residual pair that is blocked by substitution, typing, or fuel remains visible in O.

The structural rows add transport and replay without adding a stronger theorem. Thus every consumer export remains inside $T, R, Q, J, O, H, C, P, N$, and the excluded MetaCIC endpoints are not obtained from the typed residual-budget packet. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICTypedResidualBudget}^{\uparrow}$ residual-checker read factors through a typed-window row, residual-frontier row, bounded checker-route row, local-join row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: metacic-residual-substitution-boundary, metacic-confluence-residual-checker, metacic-confluence-residual-envelope, metacic-parallel-diamond-witness, metacic-substitution-diamond: $\mathsf{MetaCICTypedResidualBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries typed-window data, residual-frontier data, checker-route budget, local joins, retained obstructions, transport, replay, provenance, and local naming while refusing subject reduction, full parallel diamond, arbitrary Church–Rosser, and unrestricted residual-substitution compatibility.

Later Lean TasteGate work for $\mathsf{MetaCICTypedResidualBudget}^{\uparrow}$ must include explicit Nontrivial and FieldFaithful instances for the typed-window, residual-frontier, checker-route, local-join, obstruction, transport, replay, provenance, and NameCert rows before any discovery or public closure claim is made.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedResidualBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICTypedResidualBudget}^{\uparrow}$ packet is generated from a typed-window row, residual-frontier row, bounded checker-route row, local-join row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTypedResidualBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7088.1, Definition 7088.2, and Definition 7088.3 seed the finite typed residual-budget surface for the MetaCIC residual-checker frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICTypedResidualBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, full parallel diamond, arbitrary Church–Rosser, unrestricted residual-substitution compatibility, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exactness, residual-frontier coverage, bounded checker-route exactness, local-join or obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICTypedResidualBudgetUp.

Chapter 7089

A Concrete Naming Certificate for $\mathsf{RademacherFiniteDifference}^{\uparrow}$

Following Rademacher's finite-difference preparation for Lipschitz maps, the $\mathsf{RademacherFiniteDifference}^{\uparrow}$ packet isolates the endpoint-radius, quotient-window, and Lipschitz-bound data consumed by the $\mathsf{Rademacher}^{\uparrow}$ route of chapter 5146. It sits over the Lipschitz carrier of chapter 3762, the Real seal of chapter 38, the dyadic ledger of chapter 291, and the metric carrier of chapter 57. The chapter names a finite substrate for difference quotients; it does not claim almost-everywhere differentiability, measurable exceptional sets, selected derivatives, quotient completion, or a completed derivative space.

Definition 7089.1 (Rademacher finite-difference carrier)**.** *A* $\mathsf{RademacherFiniteDifference}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, E, D, M, Q, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LipschitzFunction}^{\uparrow}$ *row whose source metric, target metric, graph ledger, and Lipschitz bound are read by the finite-difference packet.*
2. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for base points, endpoint values, quotient values, and finite window radii.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius ledger, recording dyadic offsets, halved-window refinements, and tolerance comparisons.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *neighborhood row used to test source and target distance requests for the displayed Lipschitz window.*
5. *Q is the finite difference-quotient row, pairing displayed endpoint values with the dyadic denominator and the Real seal row that receives the quotient window.*
6. *H records componentwise* hsame *transport for L, E, D, M, Q, C, P, N.*
7. *C records displayed* Cont *replay from a finite Rademacher-facing request through D, M, L, Q and into E.*
8. *P is the* Pkg *provenance over* $\mathsf{RademacherFiniteDifference}^{\uparrow}$, $\mathsf{Rademacher}^{\uparrow}$, $\mathsf{LipschitzFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RademacherFiniteDifference}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, E, D, M, Q, H, C, P, N$. It has no coordinate for Lebesgue almost-everywhere differentiability, measurable null sets, selected derivatives, quotient completion points, countable-choice schedules, ambient measure completion, or completed derivative carriers.

Theorem 7089.2 (Rademacher finite-difference NameCert obligations)**.** *For every accepted* RademacherFiniteDiffer *carrier*

$$R = (L, E, D, M, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RademacherFiniteDifference}^{\uparrow}}$ *surface consists exactly of carrier admission, Lipschitz-row exposure, Real seal routing, dyadic endpoint-radius accounting, metric-neighborhood inspection, finite difference-quotient exposure, componentwise transport, displayed replay, provenance, local naming, and non-escape from the displayed rows.*

Proof. Carrier admission is projection from Definition 7089.1. The analytic rows are L, E, D, M, Q, and the structural rows are H, C, P, N.

The finite-difference route is row-bounded. The dyadic row supplies endpoint radii and denominator tolerances, the metric row supplies the neighborhoods in which the distance comparisons are read, and the Lipschitz row supplies the graph and bound ledger for the same window.

The quotient row Q only repackages the displayed endpoint values into a Real-facing window. Transport, replay, provenance, and local naming preserve the same coordinates, so the NameCert surface exports none of the excluded measurable, derivative-selection, quotient-completion, choice, or ambient-completion data. □

Theorem 7089.3 (Rademacher finite-difference Lipschitz window route)**.** *Every Lipschitz-window read exported by an accepted* $\mathsf{RademacherFiniteDifference}^{\uparrow}$ *carrier factors through the finite route*

$$D, M, L, Q \longmapsto E$$

before the $\mathsf{Rademacher}^{\uparrow}$ *consumer reads a derivative-candidate window. The route displays endpoint radii, metric neighborhoods, Lipschitz distance bounds, finite quotient rows, and terminal Real seals, but it exports no selected derivative, null exceptional set, quotient completion point, arbitrary measurable representative, or completed derivative space.*

Proof. Start with an accepted carrier $R = (L, E, D, M, Q, H, C, P, N)$. By Definition 7089.2, the Real-facing row E is reached only after the dyadic, metric, Lipschitz, and quotient rows have been displayed.

The Lipschitz window needs both endpoint control and distance control. The rows D and M supply those finite tests, while L supplies the bound that makes the quotient row Q readable as a finite window rather than as a global derivative.

Finally H, C, P, N transport, replay, source, and name the same route. Thus the downstream $\mathsf{Rademacher}^{\uparrow}$ chapter may consume a named finite-difference substrate without receiving any almost-everywhere, quotient-completion, selection, or ambient measure principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RademacherFiniteDifference}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RademacherFiniteDifference}^{\uparrow}}$, seed)

Scope closed: Definition 7089.1, Definition 7089.2, and Definition 7089.3 seed the finite-difference substrate over Lipschitz, Real, dyadic endpoint-radius, metric, quotient-window, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RademacherFiniteDifference}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lebesgue almost-everywhere differentiability, measurable exceptional sets, selected derivatives, quotient completion points, countable choice, ambient measure completion, completed derivative spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Lipschitz-row exposure, Real seal routing, dyadic endpoint-radius accounting, metric-neighborhood inspection, finite quotient-window exposure, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.RademacherFiniteDifferenceUp.

Constructive story: A RademacherFiniteDifference$^{\uparrow}$ packet is generated from a LipschitzFunction row, RealUp seal row, DyadicRatCore endpoint-radius ledger, MetricSpace neighborhood row, finite difference-quotient row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7090

A Concrete Naming Certificate for $\mathsf{RademacherTheorem}^{\uparrow}$

Following Rademacher and standard constructive real analysis, the $\mathsf{RademacherTheorem}^{\uparrow}$ packet records the theorem-level boundary at which a Lipschitz map may expose a weak differentiability route only after the finite derivative-candidate rows of chapter 5146 and the finite quotient-window rows of chapter 7089 have been displayed. It sits over the Lipschitz carrier of chapter 3762, the weak-derivative row of chapter 2210, the measure row of chapter 92, and the terminal real-name seal of chapter 38. The packet names a finite NameCert boundary for the theorem route; it does not select a derivative, identify quotient representatives, complete an ambient measure algebra, or assert a host-level differentiability theorem outside the displayed rows.

Definition 7090.1 (Rademacher theorem carrier)**.** *A* $\mathsf{RademacherTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, R, F, W, M, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LipschitzFunction}^{\uparrow}$ *source row, exposing the graph ledger, source and target metric reads, and Lipschitz bound that the theorem-level packet may inspect.*
2. *R is the* $\mathsf{Rademacher}^{\uparrow}$ *derivative-candidate row, recording only the finite dyadic and metric windows already exposed by the candidate packet.*
3. *F is the* $\mathsf{RademacherFiniteDifference}^{\uparrow}$ *quotient-window row, recording endpoint radii, finite difference quotients, and Real-facing window seals.*
4. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *row, naming the weak-derivative consumer boundary reached by the theorem packet after R and F have been displayed.*
5. *M is the* $\mathsf{Measure}^{\uparrow}$ *row, recording the displayed finite measure-facing exceptional-set interface without installing an ambient completed measure algebra.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for base values, quotient windows, weak-derivative test values, and finite tolerance comparisons.*
7. *H records componentwise* hsame *transport for $L, R, F, W, M, E, C, P, N$.*
8. *C records displayed* Cont *replay from a theorem-level request through the Lipschitz row, finite candidate row, quotient-window row, weak-derivative row, measure row, and Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RademacherTheorem}^{\uparrow}$, $\mathsf{Rademacher}^{\uparrow}$, $\mathsf{RademacherFiniteDifference}^{\uparrow}$, $\mathsf{LipschitzFunction}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RademacherTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, F, W, M, E, H, C, P, N$. It has no coordinate for a selected pointwise derivative, quotient equality of representatives, completed measure spaces, arbitrary measurable representatives, countable-choice schedules, or host-level differentiability outside the displayed theorem boundary.

Theorem 7090.2 (Rademacher theorem NameCert obligations)**.** *For every accepted* $\mathsf{RademacherTheorem}^{\uparrow}$ *carrier*

$$T = (L, R, F, W, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RademacherTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission, Lipschitz-row exposure, finite derivative-candidate readback, finite difference-window readback, weak-derivative boundary routing, displayed measure-interface routing, Real seal routing, componentwise transport, displayed replay, provenance, local naming, and non-escape from the displayed rows.*

Proof. Carrier admission is projection from Definition 7090.1. The theorem-level analytic rows are L, R, F, W, M, E, and the support rows are H, C, P, N.

The Lipschitz source row L supplies only the displayed graph, metric, and bound ledger. The candidate row R and finite-difference row F then expose the dyadic windows, metric neighborhoods, endpoint radii, quotient windows, and Real seals already named by chapter 5146 and chapter 7089.

The weak-derivative row W is a downstream boundary row, not a chosen pointwise derivative. The measure row M records only the finite measure-facing interface needed to state where the weak route is read, not an ambient completed measure object.

The rows H and C transport and replay the same finite route, while P and N source and name it. Since no other coordinate occurs in the carrier, the certificate exports no selected derivative, quotient equality, arbitrary measurable representative, countable choice, completed measure algebra, or host differentiability theorem outside the displayed rows. □

Theorem 7090.3 (Rademacher Lipschitz weak-derivative route)**.** *Every weak-derivative-facing read exported by an accepted* $\mathsf{RademacherTheorem}^{\uparrow}$ *carrier factors through the finite route*

$$L \longmapsto R, F \longmapsto W, M, E \longmapsto H, C, P, N.$$

The route displays the Lipschitz source, finite derivative-candidate windows, finite quotient-window data, weak-derivative boundary, measure-facing interface, Real seal, transport, replay, provenance, and local naming rows before any analysis or PDE consumer may cite the theorem packet.

Proof. Start with an accepted carrier $T = (L, R, F, W, M, E, H, C, P, N)$. The carrier definition places the Lipschitz row first, so a consumer cannot ask for theorem-level weak differentiability before reading the source graph, metric, and bound data.

The next reads are R and F. They force the consumer through the existing Rademacher candidate packet and the finite-difference quotient-window packet, so the theorem route is downstream of displayed finite windows rather than a direct appeal to a host almost-everywhere theorem.

Only after those rows are present may the consumer read W, M, E. The weak-derivative boundary, measure-facing interface, and Real seal are therefore tied to the same finite route and do not install a selected derivative, quotient equality, arbitrary measurable representative, or completed measure algebra.

Finally H, C, P, N transport, replay, source, and name the route. Thus any downstream analysis or PDE chapter receives a theorem-level NameCert boundary, not data beyond the displayed Lipschitz, Rademacher, finite-difference, weak-derivative, measure, and Real rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{RademacherTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RademacherTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7090.1, Definition 7090.2, and Definition 7090.3 seed the theorem-level boundary over Lipschitz, Rademacher candidate, finite-difference, weak-derivative, measure, Real, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RademacherTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected pointwise derivatives, quotient equality, arbitrary measurable representatives, countable choice, ambient measure completion, completed derivative spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Lipschitz-row exposure, finite derivative-candidate readback, finite difference-window readback, weak-derivative routing, displayed measure-interface routing, Real seal routing, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.RademacherTheoremUp.

Constructive story: A $\mathsf{RademacherTheorem}^{\uparrow}$ packet is generated from a LipschitzFunction row, Rademacher finite candidate row, RademacherFiniteDifference quotient-window row, WeakDerivative boundary row, Measure interface row, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7091

A Concrete Naming Certificate for $\mathsf{CauchyRealAddition}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealAddition}^{\uparrow}$ packet records addition of Cauchy real names as a finite BEDC naming surface before any $\mathsf{Real}^{\uparrow}$ consumer is allowed to read a sum. It sits over the synchronized addition route of chapter 1695, the regular rational sequence surface of chapter 301, the finite window schedule of chapter 126, the dyadic tolerance arithmetic of chapter 291, and the terminal seal of chapter 38. The packet gives Real-facing algebra consumers a finite route from two Cauchy names to one sealed sum name; it does not assert quotient equality of real names, selected host limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a completed field operation.

Definition 7091.1 (Cauchy real addition carrier)**.** *A* $\mathsf{CauchyRealAddition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathsf{Real},+} = (A, R_0, R_1, W, D, S, E, Z, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *source certificate for the synchronized sum route.*
2. *R_0 and R_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *input-name rows read by the source certificate.*
3. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used by the addition request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint-addition row.*
5. *S is the summed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed by the synchronized route.*
6. *E is the finite tail ledger recording the two source tolerances, the dyadic addition tolerance, and the output tolerance.*
7. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, R_0, R_1, W, D, S, E are displayed.*
8. *H records componentwise* hsame *transport for the source certificate, input names, window schedule, dyadic row, summed readback, tail ledger, seal row, replay row, provenance row, and local naming row.*
9. *C records displayed* Cont *replay from every Real-facing addition request through $A, R_0, R_1, W, D, S, E, Z, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyRealAddition}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRealAddition}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, R_0, R_1, W, D, S, E, Z, H, C, P, N$. The carrier has no coordinate for quotient equality of Cauchy names, host real addition, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached completed-real algebra operation.*

Theorem 7091.2 (Cauchy real addition NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealAddition}^{\uparrow}$ *carrier*

$$A_{\mathsf{Real},+} = (A, R_0, R_1, W, D, S, E, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealAddition}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *source certificate A, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *input-name rows R_0, R_1, the paired* $\mathsf{StreamName}^{\uparrow}$ *window row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint row D, the summed readback row S, the tail ledger E, the* $\mathsf{Real}^{\uparrow}$ *seal row Z, and the structural rows H, C, P, N.*

Proof. Project the carrier of Definition 7091.1. Its analytic rows are $A, R_0, R_1, W, D, S, E, Z$, and its structural rows are H, C, P, N.

Read the source certificate first. The $\mathsf{RegularCauchyAddition}^{\uparrow}$ row A supplies the synchronized-window addition route, while R_0, R_1, W, D expose the two regular rational names, the paired window schedule, and the dyadic endpoint arithmetic used by that route.

The summed readback and seal rows are downstream. The ledger E records the finite tail accounting before S is consumed, and the $\mathsf{Real}^{\uparrow}$ row Z is exposed only after the summed regular rational name has been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no other coordinate appears in the carrier, the local certificate has no hidden quotient-equality, host-arithmetic, selected-limit, trichotomy, or ambient-completeness obligation. □

Theorem 7091.3 (Cauchy real addition tail stability)**.** *Let two accepted* $\mathsf{CauchyRealAddition}^{\uparrow}$ *packets have matching* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *source certificates, input-name rows, paired finite-window schedules, dyadic tolerance rows, summed readbacks, tail ledgers, and* $\mathsf{Real}^{\uparrow}$ *seal rows through their displayed* hsame *data. Then every Real-facing sum read of the first packet transports to the corresponding sum read of the second packet through the same finite route $A, R_0, R_1, W, D, S, E, Z, H, C, P, N$.*

Proof. Start with the componentwise transport row H. It matches the source addition certificate A, the two input rows R_0, R_1, the window row W, and the dyadic tolerance row D.

Use the synchronized route supplied by chapter 1695. The row A keeps the pointwise sum tied to the paired windows and dyadic tolerance arithmetic, so transport cannot replace the finite tail route by host real addition.

The tail ledger and readback rows are preserved next. The ledger E remains the only displayed place where source and output tolerances are combined before the summed readback row S and the seal row Z are consumed.

Replay through C and repack through P, N. Every accepted Real-facing sum read is one of these displayed routes, so no quotient equality, selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle can enter under transport. □

Theorem 7091.4 (Cauchy real addition Real seal handoff)**.** *Every accepted* $\mathsf{CauchyRealAddition}^{\uparrow}$ *packet hands a sum to a* $\mathsf{Real}^{\uparrow}$ *consumer only through the finite route*

$$A \longmapsto (R_0, R_1) \longmapsto W \longmapsto D \longmapsto E \longmapsto S \longmapsto Z.$$

Thus the consumer receives a $\mathsf{RegularCauchyAddition}^{\uparrow}$ *source certificate, two* $\mathsf{RegSeqRat}^{\uparrow}$ *input-name rows, a paired* $\mathsf{StreamName}^{\uparrow}$ *window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, a finite*

tail ledger, a summed regular rational readback, and a terminal $\mathsf{Real}^{\uparrow}$ *seal; it receives no quotient real equality, host addition, selected host limit, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Begin with the carrier projection. The Real-facing addition request has no source rows other than $A, R_0, R_1, W, D, E, S, Z$.

Apply the source route of Definition 1695.5. It already orders the regular Cauchy addition read from input rows and paired windows through dyadic endpoint addition and finite regularity accounting before a $\mathsf{Real}^{\uparrow}$ seal is exposed.

The present packet records that route as A and exposes the same rows as R_0, R_1, W, D, E, S, Z. The structural rows H, C, P, N preserve the order of the handoff for downstream Real algebra consumers.

Therefore the packet supplies a finite Cauchy-name addition seal and nothing stronger. Quotient equality, host arithmetic, selected limits, trichotomy, and ambient completeness remain outside the exported surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealAddition}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealAddition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7091.1, Definition 7091.2, Definition 7091.3, and Definition 7091.4 seed the finite Cauchy-real addition surface over a $\mathsf{RegularCauchyAddition}^{\uparrow}$ source certificate, two $\mathsf{RegSeqRat}^{\uparrow}$ names, paired $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance arithmetic, a summed readback row, and a terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealAddition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, host real addition, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-certificate exposure, tail-stability transport, Real seal handoff, replay, provenance, and local naming for BEDC.Derived.CauchyRealAdditionUp.

Constructive story: A $\mathsf{CauchyRealAddition}^{\uparrow}$ packet is generated from a $\mathsf{RegularCauchyAddition}^{\uparrow}$ source certificate, two $\mathsf{RegSeqRat}^{\uparrow}$ input rows, paired $\mathsf{StreamName}^{\uparrow}$ finite-window schedules, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance arithmetic, a tail ledger, a summed readback row, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7092

A Concrete Naming Certificate for $\mathsf{EulerianGraph}^{\uparrow}$

Following Euler and standard finite graph theory, the $\mathsf{EulerianGraph}^{\uparrow}$ packet names the finite parity and edge-traversal ledger behind Eulerian closed trails. It reads its graph carrier from chapter 118, tree-style finite support traversal from chapter 119, path and endpoint rows from chapter 236, spanning support bookkeeping from chapter 237, matching-style incidence pairing from chapter 234, and residual edge-consumption ledgers from chapter 233. The packet is finite: it records vertices, edges, incidence parity, non-isolated connected support, a closed edge-traversal schedule, structural transport, replay, provenance, and local naming, without importing an ambient infinite graph, a host theorem of Eulerianity, quotient equality of trails, or a selected external traversal.

Definition 7092.1 (EulerianGraph finite trail carrier)**.** *An* $\mathsf{EulerianGraph}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (G, I, P, S, T, M, H, C, Q, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Graph}^{\uparrow}$ *carrier row, including finite vertex rows, finite edge rows, endpoint readback, and componentwise graph classification.*
2. *I is the incidence ledger, listing for each vertex the incident edge occurrences and their endpoint orientation as finite rows.*
3. *P is the even-degree parity row, pairing the incident edge occurrences at every vertex and exposing the empty-pair branch for isolated vertices.*
4. *S is the connected non-isolated support row, recording finite reachability among all vertices incident to at least one edge.*
5. *T is the edge-traversal schedule, a finite ordered row of edge occurrences whose edge projection lists every edge exactly once.*
6. *M is the closed-trail endpoint-match row, recording that consecutive entries of T share the displayed vertex endpoint and that the final endpoint returns to the initial endpoint.*
7. *H is componentwise* hsame *transport for graph, incidence, parity, support, schedule, endpoint-match, replay, provenance, and local naming rows.*
8. *C is the displayed* Cont *replay row forcing every Eulerian read through G, I, P, S, T, M, H.*

9. *Q is the* Pkg *provenance over* $\mathsf{EulerianGraph}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, $\mathsf{ShortestPath}^{\uparrow}$, $\mathsf{SpanningTree}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EulerianGraph}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows and their displayed transports.

Theorem 7092.2 (EulerianGraph NameCert obligations)**.** *For every accepted* $\mathsf{EulerianGraph}^{\uparrow}$ *carrier* $E = (G, I, P, S, T, M, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EulerianGraph}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the graph carrier, incidence ledger, even-degree parity row, connected non-isolated support row, traversal schedule, endpoint-match row, transport, replay, provenance, and local name;*
2. *incidence exactness, requiring every edge occurrence in I to read its two displayed endpoints from the* $\mathsf{Graph}^{\uparrow}$ *row G;*
3. *parity exactness, requiring the incident edge occurrences at each vertex to be partitioned into displayed pairs by P;*
4. *support connectedness, requiring every non-isolated vertex read to factor through the finite support row S;*
5. *traversal coverage, requiring T to list every displayed edge exactly once and no unlisted edge;*
6. *closed endpoint matching, requiring M to match consecutive endpoint rows in T and to identify the final endpoint with the initial endpoint;*
7. *structural stability, requiring H, C, Q, N to transport, replay, source, and name only the rows already listed.*

No Eulerian trail obligation for this packet is stored outside those finite rows.

Proof. Project the carrier of Definition 7092.1. The certificate can inspect only $G, I, P, S, T, M, H, C, Q, N$.

The graph and incidence obligations read G and I. Each incidence entry is tied to a displayed edge and its two endpoint rows, so the certificate cannot consult a hidden adjacency relation.

The parity and support obligations read P and S. The row P pairs incident occurrences at each vertex, while S supplies finite connected support for the non-isolated vertices.

The traversal obligations read T and M. Coverage is a finite ledger comparison between the edge projection of T and the edge rows of G, and closedness is the displayed endpoint match along consecutive entries and the terminal return.

Finally H, C, Q, N only transport, replay, source, and name the same finite rows. Thus the local NameCert surface exports no host Euler theorem, hidden graph equality, quotient trail, selected external traversal, or infinite graph data. □

Theorem 7092.3 (EulerianGraph even-degree trail exhaustion)**.** *Let $E = (G, I, P, S, T, M, H, C, Q, N)$ be an accepted* $\mathsf{EulerianGraph}^{\uparrow}$ *carrier. Every edge-traversal read of E is exhausted by finite induction on the schedule row T: each step consumes one displayed edge occurrence from I, preserves the parity pairing recorded by P at the two touched endpoints, and leaves the remaining unread occurrences inside the same connected non-isolated support row S until the final endpoint-match row M closes the trail.*

Proof. Induct over the finite schedule row T. In the empty branch, traversal coverage says that no displayed edge remains unread, and the endpoint-match row supplies the degenerate closed endpoint read.

For the successor branch, read the head edge occurrence through I. Its two endpoints are displayed by G, and its incidence memberships are part of the paired local parity ledger P.

Remove the head occurrence from the unread traversal ledger. The remaining entries are still rows of T, and support connectedness keeps every non-isolated endpoint inside S; no external search over graph edges is available.

At the terminal branch, the endpoint-match row M identifies the last endpoint with the first. The induction has consumed each scheduled edge exactly once, and traversal coverage identifies the scheduled edge projection with the displayed edge ledger of G. □

Theorem 7092.4 (EulerianGraph sibling dependency route)**.** *Every downstream consumer of an accepted* $\mathsf{EulerianGraph}^{\uparrow}$ *packet factors through the finite sibling route*

$$\mathsf{Graph}^{\uparrow},\ \mathsf{Tree}^{\uparrow},\ \mathsf{ShortestPath}^{\uparrow},\ \mathsf{SpanningTree}^{\uparrow},\ \mathsf{Matching}^{\uparrow},\ \mathsf{NetworkFlow}^{\uparrow} \longmapsto \mathsf{EulerianGraph}^{\uparrow}.$$

The graph row supplies endpoints and incidence, the tree and spanning-tree rows supply finite support traversal, the shortest-path row supplies endpoint reachability windows, the matching row supplies local parity pairings, and the network-flow row supplies residual edge-consumption bookkeeping. The consumer receives no host Eulerian graph object, hidden connectedness proof, selected external tour, quotient trail equality, or ambient infinite graph.

Proof. Begin with a consumer read of the Eulerian schedule. By Definition 7092.2, the read first exposes $G, I, P, S, T, M, H, C, Q, N$.

The row G is the entry point for finite vertices, edges, and endpoints. The rows S and M then use tree, spanning-tree, and shortest-path style support data only as finite traversal and endpoint windows over that same graph carrier.

The row P is the matching-style parity ledger: incident edge occurrences are paired locally before the schedule is accepted. The row T is the residual-consumption ledger: each edge is consumed exactly once, in the same finite bookkeeping style used by the network-flow surface.

Since H, C, Q, N preserve only this displayed route, every downstream read factors through the named sibling surfaces and cannot obtain any of the excluded host-level data. □

Closure status for $\mathsf{NameCert}_{\mathsf{EulerianGraph}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EulerianGraph}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7092.1, Definition 7092.2, Definition 7092.3, and Definition 7092.4 seed the finite Eulerian graph certificate route over graph, incidence, parity, support, traversal, endpoint-match, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EulerianGraph}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, standard bridge checking, infinite graph theory, selected external tours, quotient trail equality, host Eulerianity, or ambient connectedness principles.

Upgrade path: Obligation closure requires checked carrier admission, incidence exactness, parity exactness, support connectedness, traversal coverage, closed endpoint matching, sibling dependency routing, transport, replay, provenance, and local naming for BEDC.Derived.EulerianGraphUp.

Constructive story: An $\mathsf{EulerianGraph}^{\uparrow}$ packet is generated from a displayed GraphUp carrier, incidence rows, even-degree parity pairs, connected non-isolated support, an edge-traversal schedule, closed endpoint matching, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7093

A Concrete Naming Certificate for $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$

Following Vitali and Bishop–Bridges constructive covering practice, the $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$ packet records the finite gauge-controlled Vitali selection surface used before a compactness, differentiation, or integration consumer reads a covering theorem. It sits after the gauge presentation of chapter 4302, the finite subcover ledger of chapter 6125, the finite stream windows of chapter 126, the regular rational readback rows of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite gauge requests, candidate cells, disjoint selected subfamilies, finite cover handoff rows, rational readback, real sealing, transport, replay, provenance, and local naming; it does not import countable choice, measure completion, host selection, an ambient Vitali theorem, quotient point equality, or a selected infinite subcover.

Definition 7093.1 (Vitali covering finite-gauge carrier)**.** *A* $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (X, G, W, D, A, S, L, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the point-history source row whose local neighborhoods are inspected.*
2. *G is the* $\mathsf{GaugeSpace}^{\uparrow}$ *row naming the finite gauge family and tolerance requests.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the displayed request schedule.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare gauge radii and window bounds.*
5. *A is the admissible candidate-cell row: each candidate carries its point, gauge row, positive radius, and membership witness.*
6. *S is the selected disjoint finite subfamily row, stored as a closed* $\mathsf{ProbeBundle}$ *over candidates from A.*
7. *L is the local coverage ledger, recording which displayed source windows are covered by the selected subfamily after the gauge comparison.*
8. *F is the* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ *handoff row for compact or finite-cover consumers.*
9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational radius and tolerance comparisons.*
10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for any real-valued radius or size read.*

11. *H records componentwise* hsame *transport for source, gauge, window, tolerance, candidate, selection, coverage, subcover, readback, seal, replay, provenance, and local naming rows.*
12. *C records displayed* Cont *replay from a finite Vitali request through the gauge and selected-subfamily rows into the finite-cover handoff.*
13. *P is the* Pkg *provenance over* $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$, $\mathsf{GaugeSpace}^{\uparrow}$, $\mathsf{FiniteSubcoverLedger}^{\uparrow}$, $\mathsf{VitaliCover}^{\uparrow}$, $\mathsf{FiniteVitaliCover}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for countable selections, measure completion, host-level Vitali choice, quotient point equality, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7093.2 (Vitali covering finite-gauge NameCert obligations)**.** *For every accepted* VitaliCoveringFiniteGaug *carrier*

$$V = (X, G, W, D, A, S, L, F, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}}$ *surface consists exactly of carrier admission for the point source, gauge row, finite stream windows, dyadic tolerance ledger, admissible candidate cells, selected disjoint finite subfamily, local coverage ledger, finite subcover handoff, regular-rational readback, real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is discharged by countable choice, measure completion, host selection, quotient point equality, selected representatives, or ambient real completeness.*

Proof. Project the carrier of Definition 7093.1. The source row X, gauge row G, finite windows W, and dyadic ledger D are the only inputs available before candidate cells can be admitted.

Read the candidate and selection rows. The row A lists displayed gauge-admissible cells, while S stores only a finite disjoint subfamily drawn from those cells. The local coverage ledger L records what the selected subfamily covers in the displayed finite windows.

The handoff rows F, R, E then expose finite subcover consumption, rational readback, and real sealing. The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains none of the excluded choice, measure-completion, host-selection, quotient, representative, or completeness coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 7093.3 (Vitali covering finite-gauge disjoint-selection handoff)**.** *Every* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$, $\mathsf{VitaliCover}^{\uparrow}$, *or* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *consumer of an accepted* $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{GaugeSpace}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before the selected disjoint subfamily row S and the coverage handoff row L are public. The consumer receives a displayed finite selection-and-coverage packet, not a countable-choice selector, measure completion, host Vitali theorem, quotient point equality, or ambient compactness principle.

Proof. Begin with a finite-cover consumer. By Definition 7093.2, the consumer must inspect the gauge, window, dyadic, readback, and real-seal rows before the selected subfamily and coverage ledger are available.

The Vitali-facing siblings enter only through provenance and handoff rows. $\mathsf{VitaliCover}^{\uparrow}$ supplies the disjoint-selection discipline, $\mathsf{FiniteVitaliCover}^{\uparrow}$ supplies the finite shadow-cover route, and $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ consumes the displayed finite coverage row. None of these siblings replaces the carrier rows G, W, D, A, S, L, R, E.

Thus the handoff is the finite route displayed above. Because the packet has no coordinate for a countable selector, measure completion, host theorem, quotient point equality, or ambient compactness, no consumer can read such data from the $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$ surface. □

Falsifiable prediction: Every accepted $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$ read displays one source row, one GaugeSpaceUp row, one StreamNameUp window route, one DyadicRatCoreUp tolerance ledger, one admissible candidate-cell row, one selected disjoint finite subfamily, one local coverage ledger, one FiniteSubcoverLedgerUp handoff, one RegSeqRatUp readback, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: gauge-space, finite-subcover-ledger, vitali-cover, finite-vitali-cover, stream-name, regseqrat, real: $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite gauge requests, candidate cells, disjoint selected subfamilies, finite coverage handoff, rational readback, real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}$ packet is generated from a point source, GaugeSpace row, StreamName finite windows, DyadicRatCore tolerance ledger, admissible candidate cells, selected disjoint finite subfamily, local coverage ledger, FiniteSubcoverLedger handoff, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7093.1, Definition 7093.2, and Definition 7093.3 seed the finite gauge-controlled Vitali covering packet over GaugeSpaceUp, FiniteSubcoverLedgerUp, VitaliCoverUp, FiniteVitaliCoverUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VitaliCoveringFiniteGauge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable Vitali selection, measure completion, host selection, quotient point equality, selected representatives, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gauge admissibility, finite-window routing, dyadic tolerance exactness, disjoint selected-subfamily exposure, coverage handoff, finite-subcover consumption, readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.VitaliCoveringFiniteGaugeUp.

Chapter 7094

A Concrete Naming Certificate for $\mathsf{BishopRealArithmetic}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRealArithmetic}^{\uparrow}$ packet records the constructive arithmetic interface for regular Cauchy real names as finite BEDC NameCert data. It sits after the dyadic rational ledger of chapter 291, the finite stream-window route of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, the regular-Cauchy addition route of chapter 1695, and the regular-Cauchy multiplication route of chapter 1702. The packet gives $\mathsf{RealAlgOrder}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ consumers one public arithmetic route over displayed regular Cauchy names, not separate host operations.

Definition 7094.1 (Bishop real arithmetic carrier)**.** *A* $\mathsf{BishopRealArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Y, S_X, S_Y, R_X, R_Y, D, +_A, \cdot_A, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two source* $\mathsf{Real}^{\uparrow}$ *name rows, each read only through a displayed regular Cauchy route.*
2. *S_X and S_Y are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows requested for the two source names.*
3. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and error ledger used by both arithmetic operations.*
5. *$+_A$ is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *row, available only after $X, Y, S_X, S_Y, R_X, R_Y, D$ have been displayed.*
6. *$\cdot_A$ is the* $\mathsf{RegularCauchyMultiplication}^{\uparrow}$ *row, available only after the same source rows and the displayed product-bound entries in D have been displayed.*
7. *E is the output* $\mathsf{Real}^{\uparrow}$ *seal for the requested arithmetic read.*
8. *H records componentwise* hsame *transport for the source names, windows, readbacks, dyadic ledger, addition row, multiplication row, output seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from an arithmetic request through the source rows, finite windows, readbacks, dyadic budget, operation row, output seal, transport, package provenance, and local name.*

10. *P is the* Pkg *provenance over* BishopRealArithmetic$^\uparrow$, DyadicRatCore$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, RegularCauchyAddition$^\uparrow$, RegularCauchyMultiplication$^\uparrow$, RealAlgOrder$^\uparrow$, Met$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BishopRealArithmetic}^\uparrow}$ *row.*

The carrier predicate asserts exactly that these rows form one regular Cauchy arithmetic packet. It has no coordinate for quotient real equality, selected limits, trichotomy, ambient Real$^\uparrow$ *completeness, host real addition, or host real multiplication.*

Theorem 7094.2 (Bishop real arithmetic NameCert obligations)**.** *For every accepted* BishopRealArithmetic$^\uparrow$ *carrier*

$$A = (X, Y, S_X, S_Y, R_X, R_Y, D, +_A, \cdot_A, E, H, C, P, N),$$

the local NameCert$_{\text{BishopRealArithmetic}^\uparrow}$ *surface consists exactly of carrier admission for the two displayed* Real$^\uparrow$ *source rows, finite* StreamName$^\uparrow$ *windows,* RegSeqRat$^\uparrow$ *readbacks, the* DyadicRatCore$^\uparrow$ *tolerance ledger, the* RegularCauchyAddition$^\uparrow$ *row, the* RegularCauchyMultiplication$^\uparrow$ *row, the output* Real$^\uparrow$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* RealAlgOrder$^\uparrow$ *or* Met$^\uparrow$ *consumer of arithmetic on regular Cauchy real names must read through these rows before it consumes an operation result.*

Proof. Project the accepted carrier of Definition 7094.1. The source data are the two real-name rows, their finite stream windows, their regular rational readbacks, and the shared dyadic tolerance ledger.

The addition and multiplication rows are downstream of those finite rows. The addition row cites the regular-Cauchy addition chapter, while the multiplication row also uses the displayed product-bound entries in the dyadic ledger before the output seal is available.

The output seal E is therefore reached only through the finite regular Cauchy arithmetic route. Componentwise transport, continuation replay, provenance, and local naming preserve the same displayed rows for downstream RealAlgOrder$^\uparrow$ and Met$^\uparrow$ consumers.

Since the carrier has no coordinate for quotient real equality, selected limits, trichotomy, ambient Real$^\uparrow$ completeness, host real addition, or host real multiplication, those objects cannot become local NameCert obligations. □

Theorem 7094.3 (Bishop real arithmetic downstream route)**.** *Every* RealAlgOrder$^\uparrow$ *or* Met$^\uparrow$ *consumer of an accepted* BishopRealArithmetic$^\uparrow$ *packet reads arithmetic data only through the finite route*

$$X, Y, S_X, S_Y, R_X, R_Y, D, +_A, \cdot_A, E, H, C, P, N.$$

The route supplies regular Cauchy addition and multiplication over displayed real-name rows, and exports no quotient real equality, selected limits, trichotomy, ambient Real$^\uparrow$ *completeness, or host arithmetic operation.*

Proof. Start with an arithmetic consumer. The consumer first sees the displayed real-name sources and their finite windows, not host representatives of completed real numbers.

The regular rational readbacks and dyadic tolerance ledger are read before either arithmetic row. Thus the addition and multiplication entries are finite regular Cauchy operation rows rather than detached operations on an ambient real carrier.

Finally the output seal and structural rows package the same finite route for RealAlgOrder$^\uparrow$ and Met$^\uparrow$. No carrier row supplies quotient equality, selected limits, trichotomy, ambient completeness, or host arithmetic. □

Falsifiable prediction: Every accepted $\mathsf{BishopRealArithmetic}^{\uparrow}$ arithmetic read displays two Real source rows, two finite StreamName windows, two RegSeqRat readbacks, one DyadicRatCore tolerance ledger, a RegularCauchyAddition row, a RegularCauchyMultiplication row, one output Real seal, and local transport, replay, provenance, and naming rows before a RealAlgOrder or MetricSpace consumer receives the result.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-addition, regular-cauchy-multiplication: $\mathsf{BishopRealArithmetic}^{\uparrow}$ is not bijective to any listed sibling because it binds both regular Cauchy operation rows to one displayed dyadic budget, output real seal, structural transport, continuation replay, package provenance, and local naming row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealArithmetic}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealArithmetic}^{\uparrow}$ packet is generated from two Real name rows, finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, RegularCauchyAddition and RegularCauchyMultiplication rows, an output Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealArithmetic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7094.1, Definition 7094.2, and Definition 7094.3 seed the public arithmetic interface over regular Cauchy real names for RealAlgOrder and MetricSpace consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealArithmetic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, trichotomy, ambient Real completeness, host arithmetic, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of the carrier and checked theorems for the finite arithmetic NameCert surface over BEDC.Derived.BishopRealArithmeticUp.

Chapter 7095

A Concrete Naming Certificate for $\mathsf{WeakStarFiniteWindow}^{\uparrow}$

Following Banach–Alaoglu and Kelley functional analysis, the $\mathsf{WeakStarFiniteWindow}^{\uparrow}$ packet records the finite observation surface that a weak-star compactness route may inspect before any full compactness theorem is invoked. It sits between the weak-star topology window of chapter 5192, the finite dual-ball handoff of chapter 3420, the locally convex source rows of chapter 3386, the compact metric consumer rows of chapter 129, and the scalar seal of chapter 38. The packet names only finite dual-ball probes, sampled weak-star coordinates, and tolerance windows; it does not assert full weak-star compactness, choose subnets, construct quotient dual spaces, or import ambient completeness.

Definition 7095.1 (Weak-star finite-window carrier)**.** *A* $\mathsf{WeakStarFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, S, E, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite dual-ball probe row, listing the displayed bounded functional probes and source points admitted from* $\mathsf{BanachAlaoglu}^{\uparrow}$ *and* $\mathsf{WeakStarTopology}^{\uparrow}$*.*
2. *S is the sampled weak-star coordinate row, recording only the scalar values read from the finite probes in D.*
3. *E is the* $\mathsf{Real}^{\uparrow}$ *tolerance-window row, containing the finite scalar radii and comparison bounds used by the observation.*
4. *T records componentwise* hsame *transport for the dual-ball probes, sampled coordinates, tolerance windows, replay, provenance, and local naming rows.*
5. *H records the displayed finite-window history, including the locally convex source and compact-metric consumer context visible to the packet.*
6. *C records displayed* Cont *replay from a weak-star observation request through*

$$D \longmapsto S \longmapsto E \longmapsto T, H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{WeakStarFiniteWindow}^{\uparrow}$*,* $\mathsf{BanachAlaoglu}^{\uparrow}$*,* $\mathsf{WeakStarTopology}^{\uparrow}$*,* $\mathsf{LocallyConvexSpace}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

8. N is the local $\mathsf{NameCert}_{\mathsf{WeakStarFiniteWindow}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through D, S, E, T, H, C, P, N. It has no coordinate for full weak-star compactness, choice-selected subnets, quotient dual spaces, or ambient completeness.

Theorem 7095.2 (Weak-star finite-window NameCert obligations)**.** *For every accepted* $\mathsf{WeakStarFiniteWindow}^{\uparrow}$ *carrier $W = (D, S, E, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakStarFiniteWindow}^{\uparrow}}$ *surface consists exactly of finite dual-ball probe admission through D, sampled weak-star coordinate admission through S,* $\mathsf{Real}^{\uparrow}$ *tolerance-window admission through E, componentwise transport through T, finite-window history exposure through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The finite rows D, S, E, T, H, C, P, N are the entire public inventory of the packet.

The dual-ball and topology data enter only through D. The sampled coordinates are then read through S, and every scalar comparison must pass through the $\mathsf{Real}^{\uparrow}$ tolerance row E.

The structural rows do not add compactness or selection data. Transport, history, replay, provenance, and naming preserve the same finite route, so the NameCert surface is exhausted by the listed rows. □

Theorem 7095.3 (Weak-star finite-window Banach–Alaoglu route)**.** *Every Banach–Alaoglu, weak-star topology, locally convex, compact metric, or Real-and-Completion consumer that reads an accepted* $\mathsf{WeakStarFiniteWindow}^{\uparrow}$ *carrier must factor its request through*

$$D \longmapsto S \longmapsto E \longmapsto T, H, C, P, N.$$

The consumer receives finite dual-ball probes, sampled weak-star coordinates, $\mathsf{Real}^{\uparrow}$ *tolerance windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It receives no full weak-star compactness theorem, no choice-selected subnet, no quotient dual space, and no ambient completeness principle.*

Proof. Start with a compactness-facing or duality-facing request. The finite probe row D must be exposed before any scalar coordinate is visible, so the consumer cannot read an unrestricted dual ball or a completed function space.

The sampled weak-star coordinate row S and the tolerance row E then determine the only scalar comparisons available to the request. These rows are finite and pass through the displayed $\mathsf{Real}^{\uparrow}$ seal.

Finally, T, H, C, P, N transport, replay, source, and name the same finite observation. Since none of the carrier rows is a subnet selector, quotient-dual construction, full weak-star compactness theorem, or ambient completeness principle, the route remains the finite Banach–Alaoglu window named in the statement. □

Falsifiable prediction: Every public $\mathsf{WeakStarFiniteWindow}^{\uparrow}$ read factors through finite dual-ball probes, sampled weak-star coordinates, a $\mathsf{Real}^{\uparrow}$ tolerance window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming. A public read that exports full weak-star compactness, a choice-selected subnet, quotient dual space data, or ambient completeness from this packet refutes the carrier boundary.

Independence witness: banach-alaoglu, weak-star-topology, locally-convex-space, compactmetric, real: $\mathsf{WeakStarFiniteWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries

finite dual-ball probes, sampled weak-star coordinates, tolerance windows, history, transport, replay, provenance, and local naming while refusing full compactness, subnet choice, quotient dual spaces, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakStarFiniteWindow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakStarFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7095.1, Definition 7095.2, and Definition 7095.3 seed the finite weak-star observation surface for dual-ball and compactness-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakStarFiniteWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full weak-star compactness, choice-selected subnets, quotient dual spaces, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite dual-ball probe admission, sampled coordinate exactness, Real tolerance-window routing, transport, replay, provenance, and local naming for BEDC.Derived.WeakStarFiniteWindowUp.

Constructive story: A $\mathsf{WeakStarFiniteWindow}^{\uparrow}$ packet is generated from finite dual-ball probes, sampled weak-star coordinates, Real tolerance windows, componentwise hsame transport, finite-window history, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7096

A Concrete Naming Certificate for BetaSubstitutionPreservationFrontier$^{\uparrow}$

Following the standard subject-reduction theorem pattern for typed lambda calculi, the BetaSubstitutionPreservatior packet records the finite frontier at which the beta-redex case must present substitution-preservation data to the MetaCIC subject-reduction interface. It refines the beta obligation of Definition 9377.1, reads the concrete beta-row packet of chapter 716, and sits beside the four-row discharge surfaces of chapter 718 and chapter 712. The packet names a frontier and handoff ledger; it does not prove host substitution semantics, unrestricted conversion, the other three discharge obligations, or closed subject reduction.

Definition 7096.1 (Beta-substitution preservation frontier carrier)**.** *A* BetaSubstitutionPreservationFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, A, R, C, L, D, H, K, P, N)$$

with the following displayed rows:

1. *B is the beta-redex source row, recording the lambda body, shifted-domain context, argument, and displayed beta site.*
2. *A is the accepted* BetaSubstitutionPreservation$^{\uparrow}$ *row, read only through the carrier and handoff theorems of chapter 716.*
3. *R is the substituted-body and substituted-codomain readback row exposed at the frontier.*
4. *C is the codomain-boundary row, keeping the pre-substitution and post-substitution codomain reads paired.*
5. *L is the frontier ledger tying B, A, R, C to the beta row of the parameterised subject-reduction discharge interface.*
6. *D is the discharge-slot row, recording that the frontier supplies only the beta slot of the four-obligation interface named in section 9377.3.*
7. *H records componentwise* hsame *transport for beta source, accepted beta packet, readback, codomain boundary, frontier ledger, discharge slot, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from a subject-reduction beta request through*

$$B \longmapsto A \longmapsto R, C \longmapsto L, D.$$

9. *P is the* Pkg *provenance over* BetaSubstitutionPreservationFrontier$^{\uparrow}$, BetaSubstitutionPreservation$^{\uparrow}$, SubjectReduction$^{\uparrow}$, SubjectReductionDischarge$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BetaSubstitutionPreservationFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, A, R, C, L, D, H, K, P, N$. It has no coordinate for application-argument stability, lambda-domain preservation, Pi-domain preservation, unrestricted conversion, host substitution semantics, or closed subject reduction.

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationFrontierUp.TasteGate.BetaSubstitutionPreservationFront`
`single carrier alignment`

Theorem 7096.2 (Beta-substitution preservation frontier NameCert obligations)**.** *For every accepted* BetaSubstitutionPreservationFrontier$^{\uparrow}$ *carrier $F = (B, A, R, C, L, D, H, K, P, N)$, the local* NameCert$_{\text{BetaSubstitutionPreservationFrontier}^{\uparrow}}$ *surface consists exactly of beta-redex source admission through B, accepted beta-packet admission through A, substituted readback exposure through R, codomain-boundary pairing through C, frontier-ledger exactness through L, beta discharge-slot exposure through D, componentwise transport through H, displayed replay through K, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The visible rows are precisely $B, A, R, C, L, D, H, K, P, N$.

The beta source row B supplies the redex boundary, while A must be read through the existing BetaSubstitutionPreservation$^{\uparrow}$ packet. The readback row R and codomain-boundary row C are therefore frontier projections of the accepted beta packet, not host substitution semantics.

The ledger L and discharge row D place this frontier in the beta slot of the four-obligation interface. Transport, replay, provenance, and naming preserve the same finite route. Since no row names the other three discharge obligations or closed subject reduction, the listed obligations exhaust the local NameCert surface. □

Theorem 7096.3 (Beta-substitution preservation subject-reduction frontier route)**.** *Every subject-reduction consumer that reads an accepted* BetaSubstitutionPreservationFrontier$^{\uparrow}$ *carrier must factor the beta-redex request through*

$$B \longmapsto A \longmapsto R, C \longmapsto L, D \longmapsto H, K, P, N.$$

The route supplies only the beta-substitution preservation frontier row of the MetaCIC four-obligation interface. It does not supply application-argument stability, lambda-domain subject reduction, Pi-domain subject reduction, unrestricted conversion, host substitution semantics, or the closed subject-reduction theorem blocked by chapter 9377.

Proof. Begin with a subject-reduction beta request. The request first exposes B, so the lambda body, shifted-domain context, argument, and beta site are displayed before any handoff is visible.

Next read A through chapter 716. The rows R and C are the substituted readback and codomain-boundary projections of that accepted beta packet.

The frontier ledger L and discharge-slot row D identify the supplied row as the beta row of the four-obligation interface. They do not contain the application-argument, lambda-domain, or Pi-domain rows.

Finally H, K, P, N transport, replay, source, and name this finite frontier. The absence of host substitution semantics, unrestricted conversion, and closed subject reduction from the carrier prevents any stronger read. □

Falsifiable prediction: Every public $\mathsf{BetaSubstitutionPreservationFrontier}^{\uparrow}$ read factors through a beta-redex source row, an accepted $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ row, substituted readback, codomain-boundary pairing, frontier ledger, beta discharge slot, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming. A public read that exports the other discharge rows, host substitution semantics, unrestricted conversion, or closed subject reduction from this packet refutes the frontier boundary.

Independence witness: betasubstitutionpreservation, subjectreductiondischarge, metacic-subject-reduction-obligation: $\mathsf{BetaSubstitutionPreservationFrontier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the beta-redex source, accepted beta packet, substituted readback, codomain-boundary pairing, frontier ledger, discharge-slot row, transport, replay, provenance, and local naming while refusing the other discharge obligations and closed subject reduction.

Closure status for $\mathsf{NameCert}_{\mathsf{BetaSubstitutionPreservationFrontier}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BetaSubstitutionPreservationFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7096.1, Definition 7096.2, and Definition 7096.3 seed the finite beta-redex frontier consumed by the MetaCIC subject-reduction discharge interface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BetaSubstitutionPreservationFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close application-argument stability, lambda-domain subject reduction, Pi-domain subject reduction, host substitution semantics, unrestricted conversion, closed subject reduction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, beta-packet admission, substituted readback exposure, codomain-boundary pairing, frontier-ledger exactness, beta discharge-slot routing, transport, replay, provenance, and local naming for BEDC.Derived.BetaSubstitutionPreservationFrontierUp.

Constructive story: A $\mathsf{BetaSubstitutionPreservationFrontier}^{\uparrow}$ packet is generated from a beta-redex source row, an accepted BetaSubstitutionPreservation row, substituted readback, codomain-boundary pairing, a frontier ledger, beta discharge-slot exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7097

A Concrete Naming Certificate for $\mathsf{MatroidDual}^{\uparrow}$

Following Whitney, the $\mathsf{MatroidDual}^{\uparrow}$ packet records matroid duality as finite complement-basis and rank-nullity NameCert data. It reads the independent-set and exchange rows of chapter 202, the meet/join dependency surface of chapter 55, and the finite algebraic transport discipline of chapter 41. The packet names a dual carrier over the same finite ground; it does not import a host duality theorem, quotient ground equality, selected bases outside the displayed finite rows, or an ambient rank oracle.

Definition 7097.1 (Matroid dual carrier)**.** *A* $\mathsf{MatroidDual}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (E, M, B, Q, R, U, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite ground row, read through the same* $\mathsf{FinSet}^{\uparrow}$ *ground discipline used by* $\mathsf{Matroid}^{\uparrow}$*.*
2. *M is the source* $\mathsf{Matroid}^{\uparrow}$ *row, including independent-set, hereditary, and exchange data.*
3. *B is the finite basis row for the source matroid, recording maximal independent subsets over the displayed ground.*
4. *Q is the complement-basis row, assigning to each displayed source basis its finite complement in E and reading that complement as a dual basis.*
5. *R is the rank/nullity ledger, recording the finite rank of source basis rows and the nullity read used by the dual packet.*
6. *U is the dual independence row, generated from finite subsets of complement-basis rows and transported through the source exchange route.*
7. *H records componentwise* hsame *transport for ground, source matroid, basis, complement-basis, rank/nullity, dual independence, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for every consumer that reads the dual packet.*
9. *P is the* Pkg *provenance over* $\mathsf{MatroidDual}^{\uparrow}$*,* $\mathsf{Matroid}^{\uparrow}$*,* $\mathsf{FinSet}^{\uparrow}$*,* $\mathsf{Lattice}^{\uparrow}$*,* $\mathsf{Group}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MatroidDual}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host dual matroid, a quotient ground set, a selected global basis family, an external rank function, or an ambient linear representation.

Theorem 7097.2 (Matroid dual NameCert obligations)**.** *For every accepted* $\mathsf{MatroidDual}^{\uparrow}$ *carrier*

$$D = (E, M, B, Q, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MatroidDual}^{\uparrow}}$ *surface consists exactly of carrier admission for* D*, finite ground exposure through* E*, source* $\mathsf{Matroid}^{\uparrow}$ *exposure through* M*, source-basis exposure through* B*, complement-basis exposure through* Q*, rank/nullity ledger exposure through* R*, dual independence exposure through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The rows E, M, B, Q, R, U are the complete finite duality inventory: ground, source matroid, source bases, complement bases, rank/nullity data, and dual independence.

Read the source matroid through chapter 202. The hereditary and exchange rows are available only as displayed $\mathsf{Matroid}^{\uparrow}$ certificate rows, while the ground and finite subset reads remain inside $\mathsf{FinSet}^{\uparrow}$ and $\mathsf{Lattice}^{\uparrow}$ dependency surfaces.

The complement-basis row Q is then checked against E and B. Each dual basis is the finite complement of a displayed source basis, and the rank/nullity row R records the finite handoff by which source rank and complement size determine the dual rank read.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no coordinate stores a host dual matroid, quotient ground set, selected global basis family, external rank oracle, or ambient representation, none of those objects can discharge a local $\mathsf{NameCert}_{\mathsf{MatroidDual}^{\uparrow}}$ obligation. □

Theorem 7097.3 (Matroid dual rank-nullity handoff)**.** *Every rank-facing consumer of an accepted* $\mathsf{MatroidDual}^{\uparrow}$ *packet must read the finite route*

$$E, M, B, Q, R \longmapsto U, H, C, P, N$$

before exporting a dual rank or independence claim. The source rank row is read from the displayed $\mathsf{Matroid}^{\uparrow}$ *basis data, the nullity row is read from finite complements inside* E*, and the dual independence row is admitted only after the complement-basis and rank/nullity rows have been displayed.*

Proof. Start with the source $\mathsf{Matroid}^{\uparrow}$ row. The basis row B is meaningful only after the finite ground E and the source independent-set certificate M have been displayed.

Next open the complement-basis row. The row Q compares each displayed basis with its finite complement in E, so the dual basis data is a BHist complement ledger rather than a selected basis outside the packet.

The rank/nullity row R is downstream of this complement read. It records the finite handoff from source rank to dual rank by counting displayed basis and complement rows, not by invoking an ambient rank theorem.

The dual independence row U and the structural rows H, C, P, N preserve exactly this route. Thus a rank-facing consumer cannot export a dual rank or independence claim before reading the source basis, complement basis, rank/nullity, transport, replay, provenance, and local NameCert rows. □

Falsifiable prediction: A consumer that decodes a $\mathsf{MatroidDual}^{\uparrow}$ packet without displaying the source basis row, complement-basis row, rank/nullity ledger, hsame, Cont, Pkg, and local NameCert rows is not reading the carrier.

Independence witness: matroid, lattice, group: $\mathsf{Matroid}^{\uparrow}$ supplies the source independence rows, $\mathsf{Lattice}^{\uparrow}$ supplies finite meet/join dependency discipline, and $\mathsf{Group}^{\uparrow}$ supplies algebraic transport neighbours, but none carries the complement-basis plus rank/nullity dual packet as a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{MatroidDual}^{\uparrow}}$.

Constructive story: A $\mathsf{MatroidDual}^{\uparrow}$ packet is generated from a finite ground row, source MatroidUp row, finite basis rows, complement-basis rows, rank/nullity ledgers, dual independence rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MatroidDual}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7097.1, Definition 7097.2, and Definition 7097.3 seed the finite complement-basis and rank-nullity packet for matroid duality.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MatroidDual}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host matroid duality, quotient ground equality, selected global bases, external rank oracles, ambient linear representation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complement-basis exactness, rank/nullity handoff, dual independence transport, replay, provenance, and local naming for BEDC.Derived.MatroidDualUp.

Chapter 7098

A Concrete Naming Certificate for $\mathsf{CertifiedEventFlow}^{\uparrow}$

The $\mathsf{CertifiedEventFlow}^{\uparrow}$ packet realizes the channel-termination boundary of chapter 9369 as finite source/channel endpoint data. It sits beside the local channel boundary of chapter 3996, the budget certificate of chapter 5967, the GroundCompiler event-flow audit of chapter 829, and the hendeca event-flow certificate of chapter 6332. The packet names source events, legal channel bodies, terminators, endpoints, transport, replay, provenance, and local naming; it does not assert global halting, compiler correctness, or a host stream parser.

Definition 7098.1 (CertifiedEventFlow carrier)**.** *A* $\mathsf{CertifiedEventFlow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, B, T, E, L, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-event row naming the finite event before channel encoding.*
2. *B is the legal channel body row, recording the finite encoded body and its body-safety classifier.*
3. *T is the terminator row, displaying the local channel endpoint token.*
4. *E is the endpoint row, recording the first legal endpoint read and the decoded source event.*
5. *L is the local termination row, separating channel-level endpoint detection from certificate-level halting.*
6. *A is the audit handoff row, exposing the event-flow packet to GroundCompiler audit and hendeca event-flow consumers only through displayed rows.*
7. *H records componentwise* hsame *transport for source event, channel body, terminator, endpoint, local termination, audit handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for endpoint-facing and audit-facing consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{CertifiedEventFlow}^{\uparrow}$, $\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}$, $\mathsf{ChannelTerminationBud}$ $\mathsf{GroundCompilerEventFlowAudit}^{\uparrow}$, $\mathsf{BHistHendecaEventFlowNameCert}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CertifiedEventFlow}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden source text, an unrestricted evaluator, a global halting oracle, compiler correctness, carried metadata, or a host channel parser.

Theorem 7098.2 (CertifiedEventFlow NameCert obligations)**.** *For every accepted* $\mathsf{CertifiedEventFlow}^{\uparrow}$ *carrier*

$$F = (S, B, T, E, L, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CertifiedEventFlow}^{\uparrow}}$ *surface consists exactly of carrier admission for* F*, source-event exposure through* S*, legal channel-body exposure through* B*, terminator exposure through* T*, endpoint exposure through* E*, local termination separation through* L*, audit handoff through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The data rows S, B, T, E, L, A are the complete source/channel endpoint inventory, and the structural rows H, C, P, N only transport, replay, source, and name those rows.

Read the source and channel side first. The source event S is separated from the legal channel body B, the terminator T, and the endpoint read E before a local termination row can be exported.

Next apply the channel-termination boundary and budget siblings. They keep the endpoint row local to the channel and prevent it from becoming a certificate-level halting classifier.

Finally read the audit handoff through the GroundCompiler event-flow audit and hendeca event-flow neighbours. The handoff row A exposes the packet as finite event-flow data, while no coordinate supplies hidden source text, unrestricted evaluation, global halting, compiler correctness, carried metadata, or a host parser. □

Theorem 7098.3 (CertifiedEventFlow channel-termination handoff)**.** *Every endpoint-facing consumer of an accepted* $\mathsf{CertifiedEventFlow}^{\uparrow}$ *carrier must read*

$$S, B, T, E \longmapsto L, A, H, C, P, N$$

before it treats the event as locally terminated. The row E *is certified only as the endpoint of the legal channel body* B *at terminator* T*, and the row* L *records that this local endpoint is not a global halting classifier for arbitrary certificate continuations.*

Proof. Begin with the source/channel separation. The source event S and legal body B are distinct rows, so a consumer cannot identify channel bytes with source identity before the endpoint has been decoded.

Open the terminator and endpoint rows. The terminator T marks the local channel endpoint, and E records the first legal endpoint read together with the decoded source event.

Now attach the local termination row L. It reads the endpoint as local channel termination while preserving the refusal boundary against certificate-level halting.

The audit, transport, replay, provenance, and naming rows A, H, C, P, N carry that same finite route to downstream consumers. Since the packet contains no global halting oracle or host parser, the handoff exports source/channel endpoint separation and nothing stronger. □

Falsifiable prediction: A consumer that decodes a $\mathsf{CertifiedEventFlow}^{\uparrow}$ endpoint without displaying the source event, legal channel body, terminator, and endpoint rows is not reading the carrier.

Independence witness: channel-termination-halting-boundary, channel-termination-budget-certificate, groundcompilereventflowaudit, b-hist-hendeca-event-flow-name-cert: none has the same source-event/channel-event/endpoint triad plus local NameCert row.

The later Lean `TasteGate.lean` development for $\mathsf{CertifiedEventFlow}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial}\ \mathsf{CertifiedEventFlow}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{CertifiedEventFlow}^{\uparrow}$ instances preserving source event,

legal channel body, terminator, endpoint, local termination, audit handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CertifiedEventFlow}^{\uparrow}}$.

Constructive story: A $\mathsf{CertifiedEventFlow}^{\uparrow}$ packet is generated from source-event rows, legal channel-body rows, terminator rows, endpoint rows, local termination rows, audit handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CertifiedEventFlow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7098.1, Definition 7098.2, and Definition 7098.3 seed the finite source/channel endpoint packet for certified event flows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CertifiedEventFlow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global halting, compiler correctness, hidden source recovery, host stream parsing, carried metadata evidence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, local termination separation, audit handoff, transport, replay, provenance, and local naming for BEDC.Derived.CertifiedEventFlowUp.

Chapter 7099

A Concrete Naming Certificate for $\mathsf{FareyMediantInterval}^{\uparrow}$

Following Hardy and Wright's treatment of Farey sequences and mediants, the $\mathsf{FareyMediantInterval}^{\uparrow}$ packet records the finite interval-refinement surface where two determinant-neighbor rational endpoints generate a displayed mediant and a dyadic subinterval before any Real or Completion consumer reads the result. It sits over the rational carrier of chapter 37, the dyadic arithmetic core of chapter 291, the terminal real-name surface of chapter 38, the Stern–Brocot branch row of chapter 1704, and the Farey adjacency ledger of chapter 1759. The packet is finite interval data for rational refinement; it is not a quotient-real equality theorem, a selected representative, a trichotomy principle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7099.1 (Farey mediant interval carrier)**.** *A* $\mathsf{FareyMediantInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, R, M, D, H, C, P, N)$$

with the following displayed rows:

1. *L is the left rational endpoint row, read through* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *numerator, denominator, sign, and scale data.*
2. *R is the right rational endpoint row, read through the same rational and dyadic arithmetic surface.*
3. *M is the mediant row. It records the rational*

$$\frac{p_L + p_R}{q_L + q_R}$$

   formed from the displayed endpoint numerators and denominators, together with the determinant-neighbor and Farey adjacency checks for L and R.
4. *D is the dyadic-refinement row. It records the chosen child interval, the finite dyadic tolerance budget, and the gap comparison used by downstream Real and Completion consumers.*
5. *H records componentwise* hsame *transport for endpoint, determinant-neighbor, Farey, mediant, dyadic-refinement, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the finite route*

$$L, R \longmapsto M \longmapsto D \longmapsto H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{FareyMediantInterval}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FareyMediantInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through L, R, M, D, H, C, P, N. It has no coordinate for quotient real equality, selected endpoint representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7099.2 (Farey mediant interval NameCert obligations)**.** *For every accepted* $\mathsf{FareyMediantInterval}^{\uparrow}$ *carrier*

$$I = (L, R, M, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FareyMediantInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two rational endpoint rows, determinant-neighbor evidence, Farey adjacency row, mediant row, dyadic-refinement row, transport, replay, provenance, and local naming;*
2. *endpoint exactness, requiring L and R to be displayed* $\mathsf{Rat}^{\uparrow}$ *rows with dyadic arithmetic support before a mediant is formed;*
3. *determinant-neighbor exactness, requiring the endpoint rows to expose the finite determinant-one check used by the Farey and Stern–Brocot sibling routes;*
4. *mediant exactness, requiring M to use only the displayed endpoint numerators and denominators;*
5. *dyadic-refinement exactness, requiring D to choose a displayed child interval and a finite dyadic tolerance budget downstream of M;*
6. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the displayed rows above.*

No obligation is stored in a quotient real equality proof, selected representative, host real order, countable-choice functional, or ambient completeness theorem.

Proof. Project the accepted carrier. The endpoint data are exactly L and R, and the arithmetic information available to the packet is the rational and dyadic data displayed in those rows.

The determinant-neighbor and Farey checks are finite rows attached to the endpoint pair. They identify the pair as an adjacent rational bracket for the sibling Stern–Brocot and Farey routes without adding a host order, trichotomy branch, or selected Real representative.

The mediant row is then forced by the endpoint numerators and denominators. Since M contains no other arithmetic coordinate, the inserted rational is read only from the displayed endpoint rows.

Finally D records the child interval and dyadic budget, while H, C, P, N preserve the same packet by componentwise transport, replay, provenance, and naming. These rows exhaust the local certificate surface. □

Theorem 7099.3 (Farey mediant dyadic refinement)**.** *Let*

$$I = (L, R, M, D, H, C, P, N)$$

be an accepted $\mathsf{FareyMediantInterval}^{\uparrow}$ *carrier. Every dyadic refinement read factors through the finite chain*

$$L, R \longmapsto M \longmapsto D.$$

Thus the child interval used by a Real or Completion consumer is selected only after the determinant-neighbor endpoint rows, the Farey mediant row, and the dyadic tolerance budget have been displayed.

Proof. Begin with the endpoint rows L and R. Their determinant-neighbor evidence gives the finite rational bracket that may be refined.

Read the mediant row M. The inserted rational is computed from the displayed endpoint numerators and denominators, so the refinement has no independent representative or host-order coordinate.

The dyadic row D then compares the resulting child interval with the finite tolerance budget. A downstream Real or Completion request can read only this displayed child interval, not a quotient real equality, a selected endpoint representative, or an ambient completeness witness. □

Theorem 7099.4 (Farey mediant interval Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{FareyMediantInterval}^{\uparrow}$ *carrier reads the displayed route*

$$\mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{SternBrocot}^{\uparrow},\ \mathsf{FareySequence}^{\uparrow} \longmapsto \mathsf{FareyMediantInterval}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes rational endpoint rows, determinant-neighbor and Farey rows, a mediant row, a dyadic-refinement row, componentwise transport, replay, provenance, and local naming before any Real-facing handoff is visible.

Proof. The rational and dyadic sources supply the two endpoint rows. The Stern–Brocot and Farey sibling rows then witness that the endpoints form the finite determinant-neighbor bracket consumed by this packet.

Apply Definition 7099.3. The mediant and dyadic rows are displayed before the child interval can be handed to a Real-facing consumer.

The structural rows H, C, P, N keep the handoff inside the same finite packet. Therefore the route exports finite rational interval refinement only, with no quotient real equality, selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FareyMediantInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{FareyMediantInterval}^{\uparrow}$ packet is generated from left and right rational endpoint rows, determinant-neighbor and Farey adjacency evidence, a mediant row, a dyadic-refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FareyMediantInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7099.1, Definition 7099.2, Definition 7099.3, and Definition 7099.4 seed the finite rational interval-refinement packet over Rat, DyadicRatCore, SternBrocot, FareySequence, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FareyMediantInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Real equality, selected rational or Real representatives, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, determinant-neighbor exactness, Farey route compatibility, mediant exactness, dyadic-refinement exactness, Real handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FareyMediantIntervalUp.

Chapter 7100

A Concrete Naming Certificate for $\mathsf{PorousSet}^{\uparrow}$

Following Zajicek and standard metric porosity theory, the $\mathsf{PorousSet}^{\uparrow}$ packet records a displayed hole schedule around a located subset of a metric space as finite BEDC NameCert data. It sits over the parent metric surface of chapter 57, the located-subset distance interface of chapter 1541, the terminal real-name seal of chapter 38, and the finite epsilon-net witness discipline of chapter 1767. The packet names the finite boundary where a consumer can read a center, a scale, and a displayed empty ball before using porous-set data; it does not assert measure-nullness, Baire meagreness, open-cover compactness, choice-selected holes, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7100.1 (Porous set carrier)**.** *A* $\mathsf{PorousSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, L, R, E, H, W, D, S, T, C, Q, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row, carrying the point classifier, distance classifier, and metric-distance ledger used by every hole request.*
2. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *row naming the admitted subset and its distance-to-set readback surface.*
3. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for distances, radii, and scale comparisons visible to the porous-set consumer.*
4. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *comparison row used only to expose finite center and tolerance windows around the inspected scale.*
5. *H is the hole-schedule row. Each visible entry records a base point, an outer scale, a candidate hole center, an inner radius, and the finite witness that the named inner ball is disjoint from the located subset at the inspected tolerance.*
6. *W is the finite window row for the base point, center point, outer-radius request, inner-radius request, and distance comparisons currently read by the consumer.*
7. *D records the dyadic or rational comparison cells that witness the positive scale relation between the outer request and the inner hole.*
8. *S records componentwise* hsame *transport for the metric source, located-set row, Real seal, finite-net comparison row, hole schedule, finite windows, comparison cells, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from a porous-set query through* $M, L, R, E, H, W, D, S, C, Q, N$.
10. *C is the* Pkg *provenance over* $\mathsf{PorousSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q is the local refusal ledger for measure, category, open-cover, selected-hole, and ambient-completion claims.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PorousSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, R, E, H, W, D, S, T, C, Q, N$. It has no coordinate for a measure-null theorem, Baire-category theorem, open-cover compactness proof, global hole selector, quotient subset equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.PorousSetUp.TasteGate.PorousSetTasteGate single carrier alignment`

Theorem 7100.2 (Porous set NameCert obligations)**.** *For every accepted* $\mathsf{PorousSet}^{\uparrow}$ *carrier* $P = (M, L, R, E, H, W, D, S, T, C, Q, N)$, *the local* $\mathsf{NameCert}_{\mathsf{PorousSet}^{\uparrow}}$ *surface consists exactly of ambient metric admission, located-set admission, Real distance seal handoff, finite epsilon-net comparison exposure, hole-schedule exposure, finite-window inspection, positive-scale comparison, componentwise transport, displayed replay, provenance, refusal-ledger recording, and local naming for the same finite packet.*

Proof. Project the carrier of Definition 7100.1. The analytic source rows are the ambient metric row M, the located-set row L, the Real seal R, and the finite epsilon-net comparison row E.

The hole data are finite. The schedule row H names only the currently inspected base point, scale, hole center, inner radius, and disjointness witness, while W restricts each read to the displayed finite window.

The comparison and structural rows then fix the same route. The row D records the positive relation between outer scale and inner hole, and S, T, C, N transport, replay, source, and name the packet.

Finally Q records the refused exits. Since no carrier coordinate stores measure-nullness, Baire meagreness, open-cover compactness, a global selector for holes, quotient subset equality, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7100.3 (Porous set metric hole route)**.** *Every metric or located-set consumer of an accepted* $\mathsf{PorousSet}^{\uparrow}$ *packet reads porous-set hole data through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{LocatedSet}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto H, W, D.$$

Thus the consumer must first read the ambient metric row, located-set distance surface, Real distance seal, and finite epsilon-net comparison row before it can inspect a displayed hole schedule, finite window, and positive-scale comparison.

Proof. Start from a porous-set query. The ambient metric row M supplies the point and distance observations, and the located-set row L supplies the admitted subset boundary through the distance interface of chapter 1541.

The query next reaches the Real and finite-net rows. The seal R carries the distance and radius readbacks, while E exposes only the finite center and tolerance windows relevant to the inspected scale.

Only after those rows are displayed can the hole schedule be read. The rows H, W, D name the base point, candidate center, inner radius, finite disjointness witness, finite observation window, and positive-scale comparison.

The structural rows S, T, C, Q, N preserve the same route and record the refused exits. Therefore the exported hole datum is a finite metric route, not a measure theorem, category theorem, open-cover compactness proof, choice-selected family of holes, or ambient completeness principle. □

Theorem 7100.4 (Porous set finite-hole dependency route)**.** *Every displayed hole read from an accepted* $\mathsf{PorousSet}^{\uparrow}$ *carrier factors through the finite dependency route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{LocatedSet}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto H, W, D.$$

The $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row is the sibling dependency that makes the packet non-orphan: it exposes the finite center and tolerance windows before the hole schedule* H*, finite window row* W*, and positive-scale comparison row* D *can be read.*

Proof. Project the carrier of Definition 7100.1. The rows M, L, R, E, H, W, D are the only analytic rows visible before transport, replay, provenance, refusal, and local naming.

Apply Definition 7100.3. It already forces the consumer to read the ambient metric row, located-set row, Real seal, and finite epsilon-net row before any displayed hole datum is exposed.

The refusal ledger Q closes the remaining exits. It records that the packet does not export measure-nullness, Baire meagreness, open-cover compactness, choice-selected holes, quotient subset equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the displayed hole remains finite dependency data over the named sibling route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PorousSet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PorousSet}^{\uparrow}$ packet is generated from a Metric source row, a LocatedSet distance row, a Real seal, a FiniteEpsilonNet comparison row, a displayed hole schedule, finite windows, positive-scale comparison cells, componentwise hsame transport, displayed Cont replay, Pkg provenance, a refusal ledger, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PorousSet}^{\uparrow}}$, seed)

Scope closed: Definition 7100.1, Definition 7100.2, Definition 7100.3, and Definition 7100.4 seed the finite porous-set packet over displayed metric, located-set, Real, finite epsilon-net, hole-schedule, window, comparison, transport, replay, provenance, refusal-ledger, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PorousSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure-nullness, Baire meagreness, open-cover compactness, choice-selected holes, quotient subset equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-set distance compatibility, Real seal handoff, finite epsilon-net exposure, hole-schedule exposure, finite-window inspection, positive-scale comparison, transport, replay, provenance, refusal-ledger, and local naming for BEDC.Derived.PorousSetUp.

Chapter 7101

A Concrete Naming Certificate for $\mathsf{BoundedRealLimsup}^{\uparrow}$

Following Bishop and Bridges on bounded real sequences and constructive upper envelopes, the $\mathsf{BoundedRealLimsup}^{\uparrow}$ packet records the finite surface by which a bounded real sequence exposes limsup data before any ambient supremum theorem is available. It sits over the bounded-sequence source of chapter 1415, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the general limsup boundary of chapter 768, and the dual liminf comparison of chapter 1553. The packet names the upper-envelope read for a displayed bounded sequence; it does not assert arbitrary set suprema, host order completeness, selected subsequences, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7101.1 (Bounded real limsup carrier)**.** *A* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, W, Q, U, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row, carrying the bounded real sequence and its visible bound ledger.*
2. *W is the finite upper-envelope window row, listing the inspected tail windows and rational upper estimates read from the bounded source.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tail estimates and tolerance requests visible inside W.*
4. *U is the* $\mathsf{Limsup}^{\uparrow}$ *upper-envelope row, storing the limsup request as a bounded tail-envelope handoff rather than as an arbitrary supremum.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, finite windows, rational readback, and upper-envelope handoff have been displayed.*
6. *H records componentwise* hsame *transport for the bounded source, windows, rational readback, upper envelope, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the same bounded-source, window, readback, upper-envelope, and seal route.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedRealLimsup}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Limsup}^{\uparrow}$, $\mathsf{Liminf}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BoundedRealLimsup}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, W, Q, U, E, H, C, P, N$. It has no coordinate for arbitrary subset suprema, Dedekind completeness, selected maximizing subsequences, open-cover compactness, quotient real equality, Lean verification, or bridge checking.

Theorem 7101.2 (Bounded real limsup NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *carrier*

$$L = (B, W, Q, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedRealLimsup}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded source, finite upper-envelope windows, regular rational readback, limsup handoff, real seal, componentwise transport, displayed replay, provenance, and local naming row; window coverage requiring every limsup read to inspect W before Q; upper-envelope exactness requiring U to consume only bounded tail data from B, W, Q; and nonescape from the named rows.*

Proof. Project the accepted carrier of Definition 7101.1. The rows B, W, Q, U, E are the only analytic rows available to a limsup consumer.

The bounded source is read first through B. Each tail-envelope request then enters the finite window row W, and the rational estimates visible in that window are read back through Q.

The upper-envelope handoff U is therefore sequence-local. It can compare displayed tail estimates and pass a limsup request onward, but it has no coordinate for an arbitrary subset supremum or a host completeness principle.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded endpoints are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7101.3 (Bounded real limsup Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *carrier*

$$L = (B, W, Q, U, E, H, C, P, N)$$

must factor its read through the finite upper-envelope route

$$B \longmapsto W \longmapsto Q \longmapsto U \longmapsto E \longmapsto H, C, P, N.$$

The consumer may export the bounded sequence source, inspected tail windows, regular rational readback, limsup handoff, real seal, transport, replay, provenance, and local naming. It may not export arbitrary real suprema, selected subsequences, open-cover compactness, quotient equality of real names, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Begin with a Real-facing consumer of the accepted carrier. The bounded real sequence is exposed through B, and every inspected tail request is restricted to the finite windows carried by W.

The rational observations are then read through Q. The $\mathsf{Limsup}^{\uparrow}$ row U can consume only those bounded tail-envelope observations, so the handoff is an upper-envelope route over a displayed bounded sequence rather than a general completeness theorem.

The terminal row E seals the resulting real-name request after B, W, Q, U have been exposed. The structural rows H, C, P, N preserve that route without adding a selected subsequence, host supremum, quotient equality, or ambient real completeness claim. □

Falsifiable prediction: Every accepted $\mathsf{BoundedRealLimsup}^{\uparrow}$ Real-facing read factors through a bounded real sequence row, finite upper-envelope windows, RegSeqRat readback, a Limsup handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: boundedrealsequence, regseqrat, real, limsup, liminf: $\mathsf{BoundedRealLimsup}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded-source data, tail-window data, rational readback, upper-envelope handoff, Real sealing, transport, replay, provenance, and local naming while refusing arbitrary supremum, selected subsequences, quotient real equality, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealLimsup}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRealLimsup}^{\uparrow}$ packet is generated from a bounded real sequence row, finite upper-envelope windows, RegSeqRat readback, a Limsup handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRealLimsup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7101.1, Definition 7101.2, and Definition 7101.3 seed the bounded sequence upper-envelope surface for Real and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRealLimsup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary subset suprema, Dedekind completeness, selected maximizing subsequences, open-cover compactness, quotient real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite upper-envelope window coverage, RegSeqRat readback, Limsup handoff exactness, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BoundedRealLimsup

Chapter 7102

A Concrete Naming Certificate for $\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}$

Following Heine–Cantor and Bishop compact metric practice, the $\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}$ packet records the finite route by which a uniform modulus over a compact metric source restricts to a displayed compact subspace. It concretizes the compact-uniform-continuity route of chapter 9237 and sits over the compact metric source of chapter 129, the continuous-map graph row of chapter 130, the uniform-modulus handoff of chapter 369, and the subspace admission boundary of chapter 1519. The packet exposes inherited modulus data only after compact-source, subspace, graph, and tolerance rows have been displayed; it does not assert host compactness, arbitrary subset continuity, selected finite covers, quotient subspace equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7102.1 (Compact subspace modulus-restriction carrier)**.** *A* $\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, S, F, M, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, carrying the compact metric finite-net and located-distance data available before restriction.*
2. *S is the* $\mathsf{MetricSubspace}^{\uparrow}$ *admission row, naming the displayed subspace predicate, inherited metric row, and inclusion route consumed by the packet.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, exposing the pointwise continuity data of the map before the restricted read reaches a modulus.*
4. *M is the subspace metric-comparison row, recording that source distances used by the restricted consumer are inherited from K through S.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row whose tolerance-to-precision ledger is read only after K, S, F, M have been displayed.*
6. *H records componentwise* hsame *transport for compact source, subspace admission, continuous graph, metric comparison, uniform modulus, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the same compact-subspace, graph, metric, and modulus route.*

8. *P is the* Pkg *provenance over* CompactSubspaceModulusRestriction$^{\uparrow}$, CompactMetric$^{\uparrow}$, MetricSubspace$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{CompactSubspaceModulusRestriction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, F, M, U, H, C, P, N$. It has no coordinate for an external compactness theorem, unrestricted subspace equality, selected cover refinement, host function extensionality, arbitrary Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CompactSubspaceModulusRestrictionUp.CompactSubspaceModulusRestrictionTasteGate`
`single carrier alignment`

Theorem 7102.2 (Compact subspace modulus-restriction NameCert obligations)**.** *For every accepted* CompactSubspaceModulusRestriction$^{\uparrow}$ *carrier*

$$R = (K, S, F, M, U, H, C, P, N),$$

the local NameCert$_{\text{CompactSubspaceModulusRestriction}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, metric subspace admission, continuous-map graph row, inherited metric-comparison row, uniform-modulus handoff, componentwise transport, displayed replay, provenance, and local naming row; restriction exactness requiring every subspace read to pass through S before M; modulus exactness requiring U to consume only the displayed graph and inherited metric rows; and nonescape from the named rows.*

Proof. Project the accepted carrier of Definition 7102.1. The compact source, subspace admission, graph, metric comparison, and modulus rows are the only analytic rows present.

The restricted consumer first reads the subspace admission row S against the compact source row K. Thus each source-distance comparison visible in the subspace route is inherited through M rather than supplied by a separate host metric.

The continuous-map row F then feeds the uniform-modulus row U. Since U is downstream from K, S, F, M, the packet restricts an already displayed modulus surface and does not choose a new compact cover or use arbitrary subspace equality.

Finally H, C, P, N transport, replay, source, and name the same finite route. The excluded compactness, equality, choice, and completeness endpoints have no carrier coordinate, so the listed rows exhaust the local NameCert obligations. □

Theorem 7102.3 (Compact subspace modulus-restriction uniform handoff)**.** *Every* UniformModulus$^{\uparrow}$ *consumer of an accepted* CompactSubspaceModulusRestriction$^{\uparrow}$ *carrier*

$$R = (K, S, F, M, U, H, C, P, N)$$

must factor its restricted read through the finite route

$$K \longmapsto S \longmapsto F, M \longmapsto U \longmapsto H, C, P, N.$$

The consumer may export the compact metric source, displayed subspace admission, continuous-map graph row, inherited metric comparison, uniform-modulus ledger, transport, replay, provenance, and local naming. It may not export host compactness, unrestricted subspace equality, selected finite covers, host function extensionality, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Start with a uniform-modulus consumer. The compact metric source K and subspace admission row S determine which source points and inherited distances may be inspected.

The graph and metric rows are then read together. The continuous-map row F supplies the displayed pointwise graph data, while M records that each restricted distance comparison is inherited from the parent compact metric source through S.

Only after those rows are visible may the consumer read U. The resulting modulus is therefore a restriction of the displayed compact-source modulus route, not a new external selector or cover-refinement theorem.

The structural rows H, C, P, N preserve the same route. Since no other coordinates are present, the packet exports exactly the compact-subspace uniform handoff named in the statement. □

Falsifiable prediction: Every accepted $\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}$ uniform-modulus read factors through a CompactMetric source row, MetricSubspace admission row, ContinuousMap graph row, inherited metric-comparison row, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: compactmetric, continuousmap, uniformmodulus, metric-subspace: CompactSubspaceM is not bijective to any listed sibling because it jointly carries compact-source data, subspace admission, graph data, inherited metric comparisons, a uniform-modulus handoff, transport, replay, provenance, and local naming while refusing host compactness, unrestricted subspace equality, selected cover refinement, and ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}$ packet is generated from a CompactMetric source row, MetricSubspace admission row, ContinuousMap graph row, inherited metric-comparison row, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7102.1, Definition 7102.2, and Definition 7102.3 seed the compact-subspace uniform-modulus restriction surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactSubspaceModulusRestriction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, unrestricted subspace equality, selected finite covers, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subspace admission exactness, inherited metric-comparison exactness, ContinuousMap graph exposure, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactSubspaceModulusRestrictionUp.

Chapter 7103

A Concrete Naming Certificate for $\mathsf{CauchyProductSequence}^{\uparrow}$

Following Bishop and Bridges on constructive real multiplication and the Mertens product discipline for Cauchy data, the $\mathsf{CauchyProductSequence}^{\uparrow}$ packet records the finite sequence-level product route before any completed-real multiplication theorem is available. It sits over the product source row of chapter 464, the finite stream windows of chapter 126, the dyadic product ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The sibling commutativity packet of chapter 2238 reads the same product surface after the two source windows are swapped; this chapter names the underlying product-sequence carrier itself.

Definition 7103.1 (Cauchy product sequence carrier)**.** *A* $\mathsf{CauchyProductSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, Y, W_X, W_Y, D, M, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *X and Y are the two accepted source rows whose product sequence is being read.*
2. *W_X and W_Y are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows exposing the source terms used by the product request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-observation ledger, containing the displayed dyadic products and tolerance comparisons for the retained windows.*
4. *M is the finite Cauchy-product budget row licensed by* $\mathsf{CauchyProduct}^{\uparrow}$*.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W_X, W_Y, D, M.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular readback is available.*
7. *H records componentwise* hsame *transport for source rows, windows, dyadic product observations, product budget, readback, seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from product-sequence requests through $X, Y, W_X, W_Y, D, M, R, E, H, Q, N$.*
9. *Q is the* Pkg *provenance over* $\mathsf{CauchyProductSequence}^{\uparrow}$*,* $\mathsf{CauchyProduct}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W_X, W_Y, D, M, R, E, H, C, Q, N$. It has no coordinate for host multiplication, quotient stream equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7103.2 (Cauchy product sequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductSequence}^{\uparrow}$ *carrier*

$$P = (X, Y, W_X, W_Y, D, M, R, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductSequence}^{\uparrow}}$ *surface consists exactly of source admission for X, Y, paired* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-observation exposure,* $\mathsf{CauchyProduct}^{\uparrow}$ *budget admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host multiplication, quotient streams, selected limits, trichotomy, countable choice, and ambient completeness.*

Proof. Project the carrier in Definition 7103.1. The only analytic rows are the two source rows, their finite stream windows, the dyadic product ledger, the product budget, the regular readback, and the Real-facing seal.

The product obligation is read through the displayed budget row M. It consumes the paired windows W_X, W_Y and the dyadic ledger D, so no product consumer can obtain a sequence product directly from host multiplication or from a quotient stream.

The rows R and E are downstream of that same finite route. Componentwise transport, replay, provenance, and local naming preserve exactly the displayed packet, so the listed obligations exhaust the local certificate surface. □

Theorem 7103.3 (Cauchy product sequence regular readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyProductSequence}^{\uparrow}$ *packet must first read*

$$\mathsf{CauchyProduct}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $M, D, W_X, W_Y, R, E, H, C, Q, N$. The readback may transport and replay the finite product-sequence route, but it cannot export host multiplication, quotient stream equality, a selected limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7103.2. They force the product request to expose the $\mathsf{CauchyProduct}^{\uparrow}$ budget row M, the dyadic ledger D, and the paired stream windows W_X, W_Y before the regular readback row R is consumed.

The Real-facing seal is later in the same carrier. Since E is downstream of R, any consumer reaching E has already passed through the product budget, dyadic observations, stream windows, and regular rational readback.

Finally inspect H, C, Q, N. These structural rows transport, replay, source, and name the same finite packet. None contains host multiplication, quotient stream equality, selected limits, trichotomy, countable choice, or ambient completeness, so the readback cannot export those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyProductSequence}^{\uparrow}$ packet is generated from two source rows, paired StreamName windows, a DyadicRatCore product ledger, a CauchyProduct budget row, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductSequence}^{\uparrow}}$, seed)

Scope closed: Definition 7103.1, Definition 7103.2, and Definition 7103.3 seed the finite product-sequence route for later Real multiplication and regular Cauchy arithmetic consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyProductSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host multiplication, quotient stream equality, selected limits, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, paired window exposure, dyadic product ledger exposure, CauchyProduct budget admission, regular readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductSequenceUp.

Chapter 7104

A Concrete Naming Certificate for $\mathsf{CauchyRealMultiplication}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyRealMultiplication}^{\uparrow}$ packet records multiplication of Cauchy real names as a finite BEDC naming surface before any $\mathsf{Real}^{\uparrow}$ consumer is allowed to read a product. It sits over the product route of chapter 464, the regular rational sequence surface of chapter 301, the finite window schedule of chapter 126, the dyadic tolerance arithmetic of chapter 291, the terminal seal of chapter 38, and the addition-facing neighbor of chapter 7091. The packet gives Real-facing algebra consumers a finite route from two Cauchy names to one sealed product name; it does not assert quotient equality of real names, selected host limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, host multiplication, or a completed field operation.

Definition 7104.1 (Cauchy real multiplication carrier)**.** *A* $\mathsf{CauchyRealMultiplication}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathsf{Real},\times} = (R_0, R_1, W_0, W_1, D_0, D_1, D_\times, C_\times, S, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *factor-name rows whose product is being read.*
2. W_0 *and* W_1 *are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedules used to inspect the two factors.*
3. D_0 *and* D_1 *are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *factor-tolerance ledgers for the two source windows.*
4. $D_\times$ *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-tolerance ledger, recording the dyadic product observation and the output tolerance budget.*
5. $C_\times$ *is the* $\mathsf{CauchyProduct}^{\uparrow}$ *product row that consumes* $R_0, R_1, W_0, W_1, D_0, D_1, D_\times$ *before any regular product readback is exposed.*
6. S *is the product* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplied by the displayed* $\mathsf{CauchyProduct}^{\uparrow}$ *route.*
7. E *is the* $\mathsf{Real}^{\uparrow}$ *multiplication seal row reached only after the factor rows, window rows, dyadic ledgers, product row, and product readback have been displayed.*
8. H *records componentwise* hsame *transport for the two factor rows, two window rows, dyadic ledgers, product row, readback row, seal row, replay row, provenance row, and local naming row.*
9. C *records displayed* Cont *replay from every Real-facing multiplication request through* $R_0, R_1, W_0, W_1, D_0, D_1, D_\times$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyRealMultiplication}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealAddition}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealMultiplication}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. The carrier has no coordinate for quotient equality of Cauchy names, host real multiplication, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached completed-real algebra operation.*

Theorem 7104.2 (Cauchy real multiplication NameCert obligations)**.** *For every accepted* CauchyRealMultiplication *carrier*

$$M_{\mathsf{Real},\times} = (R_0, R_1, W_0, W_1, D_0, D_1, D_\times, C_\times, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealMultiplication}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the two factor rows, paired windows, dyadic ledgers,* $\mathsf{CauchyProduct}^{\uparrow}$ *product row, product readback,* $\mathsf{Real}^{\uparrow}$ *seal, and structural rows;*
2. *factor classifier stability, requiring the two* $\mathsf{RegSeqRat}^{\uparrow}$ *factor rows and their* $\mathsf{StreamName}^{\uparrow}$ *windows to transport with the same displayed* hsame *data;*
3. $\mathsf{CauchyProduct}^{\uparrow}$ *regularity, requiring the product row to supply the product* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any Real-facing seal is visible;*
4. *Real-seal nonescape, requiring the multiplication seal E to be downstream of $C_\times$ and S;*
5. *ledger exactness, requiring $D_0, D_1, D_\times$ to account for every source tolerance, product observation, and output tolerance used by the read.*

Proof. Project the carrier of Definition 7104.1. Its analytic rows are the two factor rows, two window rows, dyadic ledgers, product row, readback row, and seal row; its structural rows are H, C, P, N.

The factor rows are read first. The $\mathsf{RegSeqRat}^{\uparrow}$ rows R_0, R_1 and $\mathsf{StreamName}^{\uparrow}$ rows W_0, W_1 fix the finite factor observations, while D_0, D_1 record the factor tolerance ledgers that travel with those observations.

The product route is downstream of that data. The row $C_\times$ is a $\mathsf{CauchyProduct}^{\uparrow}$ read through the displayed windows and dyadic product ledger $D_\times$, and it supplies the product $\mathsf{RegSeqRat}^{\uparrow}$ row S before the seal row E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no other coordinate appears in the carrier, the listed five obligations exhaust the local NameCert surface and exclude host multiplication, quotient equality, selected limits, trichotomy, and ambient completeness. □

Theorem 7104.3 (Cauchy real multiplication RegSeqRat handoff)**.** *Every Real-facing multiplication consumer of an accepted* $\mathsf{CauchyRealMultiplication}^{\uparrow}$ *carrier factors through the finite route*

$$(R_0, R_1) \longmapsto (W_0, W_1) \longmapsto (D_0, D_1, D_\times) \longmapsto C_\times \longmapsto S \longmapsto E.$$

Thus the consumer must read the $\mathsf{RegSeqRat}^{\uparrow}$ *factor rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and* $\mathsf{CauchyProduct}^{\uparrow}$ *product row before the product* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *multiplication seal are visible.*

Proof. Begin with carrier admission. The Real-facing multiplication request has no source rows other than $R_0, R_1, W_0, W_1, D_0, D_1, D_\times, C_\times, S, E$ and the structural rows H, C, P, N.

Apply the product route of Definition 464.33. It places the real-facing product read downstream of paired windows, dyadic product observations, a product ledger, and the $\mathsf{RegSeqRat}^{\uparrow}$ classifier row supplied by $\mathsf{CauchyProduct}^{\uparrow}$.

The present packet records those dependencies as $W_0, W_1, D_0, D_1, D_\times, C_\times, S$ and exposes the terminal seal as E. The structural rows preserve the same order for every multiplication consumer.

Therefore the multiplication handoff is a finite regular-rational route to a Real seal and nothing stronger. It exports no host multiplication primitive, quotient stream equality, selected product, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealMultiplication}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealMultiplication}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7104.1, Definition 7104.2, and Definition 7104.3 seed the finite Cauchy-real multiplication surface over two $\mathsf{RegSeqRat}^{\uparrow}$ names, paired $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, a $\mathsf{CauchyProduct}^{\uparrow}$ product row, product readback, and a terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealMultiplication}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, host real multiplication, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, factor classifier stability, CauchyProduct regularity, Real-seal nonescape, ledger exactness, replay, provenance, and local naming for BEDC.Derived.CauchyRealMultiplicationUp.

Constructive story: A $\mathsf{CauchyRealMultiplication}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ factor rows, paired $\mathsf{StreamName}^{\uparrow}$ finite-window schedules, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, a $\mathsf{CauchyProduct}^{\uparrow}$ product row, a product readback row, a $\mathsf{Real}^{\uparrow}$ multiplication seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7105

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real constructions and Mac Lane on functorial action, the $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$ packet records the finite BEDC route by which a uniformly continuous map on regular rational Cauchy sources induces a completion-map row through bounded windows. It sits after the regular rational source of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion-map route of chapter 1937. The packet names only the finite functoriality surface visible to completion consumers; it does not form quotient streams, choose limit representatives, assert host function equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7105.1 (Regular Cauchy completion-functoriality carrier)**.** *A* $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, B, W, D, F, M, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, exposing only the regular rational Cauchy data accepted by the source packet.*
2. *B is the target* $\mathsf{RegSeqRat}^{\uparrow}$ *row, exposing the regular rational Cauchy data produced after the source-map read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected source and target prefixes.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic bounds used to compare the displayed windows.*
5. *F is the uniformly continuous source-map row, carrying the finite modulus and graph evidence that transports the source window to the target window.*
6. *M is the induced completion-map row, read through* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *after A, B, W, D, F have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the endpoint readback produced by the regular Cauchy completion route.*
8. *H records componentwise* hsame *transport for the source row, target row, stream windows, tolerance ledger, source map, completion map, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a regular Cauchy map request through* $A, B, W, D, F, M, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W, D, F, M, E, H, C, P, N$. *It has no coordinate for quotient stream equality, selected representatives, countable choice, host function equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Theorem 7105.2 (Regular Cauchy completion-functoriality NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$ *carrier* $R = (A, B, W, D, F, M, E, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, uniformly continuous source-map row, induced* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ *completion-map row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7105.1. The accepted packet displays exactly the rows $A, B, W, D, F, M, E, H, C, P, N$.

The regular Cauchy source and target data are visible before any completion-map row is consumed. The stream-window row W restricts the read to finite prefixes, and D records the dyadic tolerance cells used to compare those prefixes.

The uniformly continuous source-map row F is then the only source-side map evidence. The induced completion-map row M is read through the existing $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ surface, and the endpoint is sealed by E as a finite $\mathsf{Real}^{\uparrow}$ readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no listed row stores quotient streams, selected representatives, countable choice, host function equality, or ambient Real completeness, the displayed rows exhaust the local NameCert obligations. □

Theorem 7105.3 (Regular Cauchy completion-map stability)**.** *Let* $R = (A, B, W, D, F, M, E, H, C, P, N)$ *and* $R' = (A', B', W', D', F', M', E', H', C', P', N')$ *be accepted* $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$ *carriers whose source regular-rational rows, finite windows, dyadic tolerance ledgers, and uniformly continuous source-map rows compare componentwise by* hsame. *Then the induced completion-map row and terminal* $\mathsf{Real}^{\uparrow}$ *seal compare by the same transported route. A completion consumer must read*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ F \longmapsto \mathsf{CauchyCompletionFunctoriality}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before it can consume the completed map.

Proof. Begin with the componentwise comparison of A, W, D, F against A', W', D', F'. The source regular-rational row, finite windows, tolerance ledger, and uniformly continuous map evidence are therefore the same visible route for both packets.

Project the completion-map rows M and M'. Each is generated only after the displayed regular source, stream-window, dyadic tolerance, and source-map data pass through the $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$ route.

Transport the resulting endpoint through H and H'. The terminal rows E and E' are finite $\mathsf{Real}^{\uparrow}$ seals attached to the same completion-map route, so the componentwise comparison of the source route determines the map-and-seal comparison.

The replay and provenance rows C, P, N and C', P', N' repack the same transported route. They add no quotient stream equality, selected representative, countable-choice schedule, host function equality, or ambient Real-completeness principle. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$ consumer is refuted if it reaches an induced completion-map row or terminal $\mathsf{Real}^{\uparrow}$ seal without displaying a $\mathsf{RegSeqRat}^{\uparrow}$ source, $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and a uniformly continuous source-map row.

Independence witness: regseqrat, streamname, dyadicratcore, real, cauchy-completion-functoriality: no listed sibling is bijective to $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$ because this packet jointly binds regular rational source and target rows, finite window inspection, dyadic tolerance accounting, source-map evidence, induced completion-map transport, Real sealing, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}$ packet is generated from RegSeqRat source and target rows, StreamName finite windows, a DyadicRatCore tolerance ledger, a uniformly continuous source-map row, an induced CauchyCompletionFunctoriality completion-map row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7105.1, Definition 7105.2, and Definition 7105.3 seed the finite regular Cauchy completion-map packet over displayed regular sources, finite windows, tolerance ledgers, source-map evidence, completion-map routing, Real sealing, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFunctoriality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host function equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target regular-rational visibility, stream-window routing, dyadic tolerance accounting, source-map exactness, completion-map stability, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionFunctorialityUp.

Chapter 7106

A Concrete Naming Certificate for $\mathsf{CompactUniformCauchyFamily}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the compact-metric finite-net presentation of uniform convergence, the $\mathsf{CompactUniformCauchyFamily}^{\uparrow}$ packet records the finite family certificate by which compact finite nets, shared modulus rows, uniform Cauchy family readbacks, and Real-seal handoff are made into NameCert data. It sits after the compact metric source of chapter 129, the finite epsilon-net row of chapter 1767, the shared family route of chapter 1555, the compact uniform Cauchy packet of chapter 6264, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. The packet gives compact-uniform-continuity consumers a finite family object; it does not select a completed limit, assert open-cover compactness, identify quotient streams, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7106.1 (Compact uniform Cauchy family carrier)**.** *A* $\mathsf{CompactUniformCauchyFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, N, F, \sigma, R, D, U, Q, E, H, C, P, L)$$

with the following displayed rows:

1. *X is the compact metric source row, read through finite compact-net data rather than through an open-cover choice principle.*
2. *N is the finite epsilon-net row whose cells cover the compact source for the inspected tolerance.*
3. *F is the displayed finite family row of regular Cauchy names over the compact source.*
4. *σ is the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule used by every family member over every displayed net cell.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *family readback row for the scheduled component windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the compact-net radius, family tail radius, and Real-seal tolerance rows.*
7. *U is the accepted* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *row using the same family, schedule, readback, and dyadic ledger.*
8. *Q is the compact-uniform Cauchy row that binds X, N, F, σ, R, D, U into one finite net-and-tail route.*

9. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after the compact finite-net row and shared family readback have been displayed.*
10. *H records componentwise* hsame *transport for compact source, net, family, schedule, readbacks, dyadic ledger, uniform-family row, compact-uniform row, seal, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from compact finite-net inspection through shared family readback, dyadic tolerance, uniform-Cauchy family routing, compact-uniform row, and Real-seal delivery.*
12. *P records* Pkg *provenance over* $\mathsf{CompactUniformCauchyFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{UniformCauchyFamily}^{\uparrow}$, $\mathsf{CompactUniformCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyFamily}^{\uparrow}}$ *row.*

The carrier contains no hidden coordinate for an open-cover choice, quotient stream, selected limit, host real equality, component-specific modulus, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 7106.2 (Compact uniform Cauchy family NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformCauchyFamily}^{\uparrow}$ *carrier*

$$K = (X, N, F, \sigma, R, D, U, Q, E, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact source, finite net, family row, shared schedule, regular readbacks, dyadic tolerance ledger, uniform-family row, compact-uniform row, Real seal, transport, replay, provenance, and local naming; compact-net exactness requiring N to remain attached to X; shared-modulus exactness requiring σ, D, U to be common to every displayed family member and net cell; Real-seal nonescape requiring E to be downstream of Q and U; and ledger exhaustion excluding open-cover choice, selected limits, quotient streams, component-specific moduli, countable choice, host real equality, and ambient completeness.*

Proof. Project the carrier of Definition 7106.1. The compact source, finite net, family row, shared schedule, regular readbacks, dyadic ledger, uniform-family row, compact-uniform row, and seal row are all explicit entries of the finite packet.

The compact-net and shared-modulus clauses are forced by the single rows N, σ, D, U. The net row remains attached to X, while the family route uses the same schedule and dyadic ledger for every displayed component and every displayed net cell.

The Real seal is downstream of this data. The row Q binds the compact-net and uniform-family routes, and E appears only after Q and U have been displayed.

Finally H, C, P, L transport, replay, source, and name the same rows. Since no additional coordinate appears in the carrier, the listed obligations exhaust the local NameCert surface and exclude the refused compactness, choice, quotient, and completeness routes. □

Theorem 7106.3 (Compact uniform Cauchy family vision route)**.** *Every compact-uniform-continuity consumer that reads an accepted* $\mathsf{CompactUniformCauchyFamily}^{\uparrow}$ *packet factors through the finite route*

$$X, N \longmapsto F, \sigma, R, D \longmapsto U \longmapsto Q \longmapsto E.$$

Thus the consumer receives compact metric finite-net data, a shared $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *family readbacks, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *row, a compact-uniform Cauchy row, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal before any compact-uniform output is visible.*

Proof. Begin with the compact finite-net side. The source row X and net row N are the only compactness coordinates in the carrier, so a consumer must read compact coverage as displayed finite data.

Next use the family route. The rows F, σ, R, D are the same finite family, schedule, regular readback, and dyadic tolerance rows consumed by $\mathsf{UniformCauchyFamily}^{\uparrow}$, so the shared modulus cannot split into component-specific hidden thresholds.

Apply the compact-uniform row Q. It binds the finite net route to the uniform-family route before the Real seal E is exposed, matching the compact finite-net and shared-modulus route described by chapter 9237.

Transport, replay, provenance, and local naming preserve the same finite route. Therefore no downstream consumer obtains open-cover choice, a selected limit, quotient-stream equality, countable choice, host real equality, or ambient completeness from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyFamily}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7106.1, Definition 7106.2, and Definition 7106.3 seed the finite compact-net and shared-modulus family route over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{UniformCauchyFamily}^{\uparrow}$, $\mathsf{CompactUniformCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient-stream completion, selected limits, component-specific hidden moduli, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exactness, shared-modulus exactness, Real-seal nonescape, ledger exhaustion, replay, provenance, and local naming for BEDC.Derived.CompactUniformCauchyFamilyUp.

Constructive story: A $\mathsf{CompactUniformCauchyFamily}^{\uparrow}$ packet is generated from compact metric finite-net data, a displayed finite family row, one shared $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{RegSeqRat}^{\uparrow}$ family readbacks, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{UniformCauchyFamily}^{\uparrow}$ row, a compact-uniform Cauchy row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise transport, displayed replay, provenance, and local naming.

Chapter 7107

A Concrete Naming Certificate for $\mathsf{OneOverNZeroLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{OneOverNZeroLimit}^{\uparrow}$ packet records the elementary convergence of the reciprocal natural-number row to zero as finite BEDC NameCert data. It sits beside the unary $\mathsf{Nat}^{\uparrow}$ index surface of chapter 28, the rational readback surface of chapter 37, the Archimedean tail-bound route of chapter 3372, the stream-window surface of chapter 126, the regular rational sequence surface of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes the displayed threshold route for the classical sequence $n \mapsto 1/(n+1)$ without importing host limits, quotient reals, trichotomy, countable choice, or ambient real completeness.

Definition 7107.1 (One-over-n zero-limit carrier)**.** *A* $\mathsf{OneOverNZeroLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (N, Q, A, W, R, E, H, C, P, L)$$

with the following displayed rows:

1. *N is the unary* $\mathsf{Nat}^{\uparrow}$ *index row, read as the finite index window for the reciprocal sequence.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *reciprocal row, displaying the rational value $1/(n+1)$ on the inspected index.*
3. *A is the* $\mathsf{RealArchimedeanProperty}^{\uparrow}$ *tail-bound row, assigning a displayed unary threshold to every positive tolerance read.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which finite requests for indices and tolerances are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational reciprocal sequence.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the Archimedean threshold and reciprocal readback rows are displayed as a zero-limit witness.*
7. *H records componentwise* hsame *transport for the index, reciprocal, threshold, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through A, W, R, Q, N and into the terminal seal E.*
9. *P is the* Pkg *provenance over* $\mathsf{OneOverNZeroLimit}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RealArchimedeanProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{OneOverNZeroLimit}^{\uparrow}}$ *row naming exactly this reciprocal zero-limit packet.*

The carrier admits no coordinate for a host limit operator, quotient real equality, trichotomy over reals, countable choice over tolerances, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7107.2 (One-over-n zero-limit NameCert obligations)**.** *For every accepted* $\mathsf{OneOverNZeroLimit}^{\uparrow}$ *carrier* $Z = (N, Q, A, W, R, E, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{OneOverNZeroLimit}^{\uparrow}}$ *surface consists of five obligation rows:*

1. *carrier admission for the displayed unary index row* N *and reciprocal rational row* Q*;*
2. *positive-tolerance routing through the* $\mathsf{RealArchimedeanProperty}^{\uparrow}$ *threshold row* A*;*
3. *finite-window and regular-rational readback exactness through* W *and* R*;*
4. *terminal zero-limit sealing through the* $\mathsf{Real}^{\uparrow}$ *row* E *only after* A, W, R, Q, N *are visible;*
5. *componentwise transport, replay, provenance, and local naming closure through* H, C, P, L*.*

Every accepted zero-limit read must display these rows before a consumer may use the reciprocal sequence as a real zero-limit witness.

Proof. Project the carrier of Definition 7107.1. The only index and value data are the unary natural row N and the rational reciprocal row Q, so carrier admission is finite.

The tolerance request is then routed through A. That row is an accepted $\mathsf{RealArchimedeanProperty}^{\uparrow}$ read, so it supplies a displayed unary threshold before any reciprocal tail claim can be consumed.

The window and readback rows W and R keep the sequence inspection finite. They expose the same reciprocal row Q on the inspected indices and do not add a selected infinite subsequence or a host limit.

Finally E seals the displayed tail witness as a $\mathsf{Real}^{\uparrow}$ zero-limit read, while H, C, P, L transport, replay, source, and name the same packet. Since no other coordinate is present, the five listed rows are the complete local NameCert surface. □

Theorem 7107.3 (One-over-n Archimedean tail)**.** *Every positive tolerance read accepted by a* $\mathsf{OneOverNZeroLimit}^{\uparrow}$ *packet receives a displayed unary threshold through* $\mathsf{RealArchimedeanProperty}^{\uparrow}$ *before the reciprocal row is sealed as a* $\mathsf{Real}^{\uparrow}$ *zero-limit witness. In particular, the consumer reads the route*

$$\mathsf{RealArchimedeanProperty}^{\uparrow},\ \mathsf{Nat}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as finite BEDC data, not as a host limit theorem.

Proof. Start with a positive tolerance request. The continuation row C sends that request to the Archimedean row A, where the tolerance receives a displayed unary threshold.

The threshold is read together with N and Q. Past that unary index, the inspected rational reciprocal values are routed through the finite window W and regular readback R.

Only after this route is visible does the seal row E present the zero-limit witness to a $\mathsf{Real}^{\uparrow}$ consumer. The carrier lacks host limits, quotient reals, trichotomy, countable choice, and ambient completeness, so the Archimedean tail is the only exported route. □

Closure status for $\mathsf{NameCert}_{\mathsf{OneOverNZeroLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{OneOverNZeroLimit}^{\uparrow}$ packet is generated from a unary Nat index row, a Rat reciprocal row, a RealArchimedeanProperty tail-bound row, a StreamName window row, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OneOverNZeroLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7107.1, Definition 7107.2, and Definition 7107.3 seed the finite reciprocal zero-limit route through Nat, Rat, RealArchimedeanProperty, StreamName, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{OneOverNZeroLimit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host limits, quotient reals, trichotomy, countable choice, RealUp completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-tolerance threshold routing, finite-window readback exactness, RealUp zero-limit sealing, and transport-replay-provenance naming for $N, Q, A, W, R, E, H, C, P, L$.

Chapter 7108

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$

The $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$ packet realizes the phase-space branch of chapter 9463 as finite reversible disk-phase transport, boundary refusal, and provenance rows. It sits after the disk carrier of chapter 377, the Poincare disk metric of chapter 6209, the hyperbolic metric row of chapter 3474, and the reversible transport route of chapter 3455. The packet names a finite phase-space carrier for observer-expansion reads; it does not complete the disk, select boundary representatives, identify a physical observer trajectory, or import a host symplectic phase space.

Definition 7108.1 (Hyperbolic phase-space carrier)**.** *A* $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, D, M, T, B, G, R, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *source row for the inspected disk observations.*
2. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *metric row over the same displayed disk points.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *readback row used to compare phase displacement through hyperbolic distance.*
4. *T is the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *reversible transport row.*
5. *B is the boundary-refusal row, recording that interior-center or selected-boundary exits are unavailable to the packet.*
6. *G is the observer-phase groupoid row: it records finite source, target, inverse, and composition windows for reversible phase moves without asserting a host groupoid of all disk paths.*
7. *R is the route-stability row, preserving U, D, M, T, B, G under the local classifier.*
8. *H records componentwise* hsame *transport for disk, metric, transport, refusal, groupoid, stability, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a phase-space request through $U, D, M, T, B, G, R, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$*,* $\mathsf{UnitDisk}^{\uparrow}$*,* $\mathsf{PoincareDiskMetric}^{\uparrow}$*,* $\mathsf{HyperbolicMetric}^{\uparrow}$*,* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, D, M, T, B, G, R, H, C, P, N$. It has no coordinate for completed disk geometry, selected ideal-boundary points, global geodesic flow, host symplectic form, physical cosmology, or observer substance.

Theorem 7108.2 (Hyperbolic phase-space NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$ *carrier* $S = (U, D, M, T, B, G, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseSpace}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, Poincare disk metric visibility, hyperbolic metric readback, reversible phase-transport routing, boundary-refusal recording, finite observer-phase groupoid windows, route stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7108.1. The accepted packet displays exactly $U, D, M, T, B, G, R, H, C, P, N$

The disk and metric rows are read first. The rows U, D, M keep the packet inside displayed disk observations and metric readbacks rather than a completed hyperbolic surface.

The reversible phase data are read next. The row T supplies the phase transport, B records the boundary refusal, and G exposes only finite source, target, inverse, and composition windows for observer-phase movement.

Finally R, H, C, P, N preserve, transport, replay, source, and name that same route. Since none of those rows contains completed disk geometry, selected ideal-boundary points, global geodesic flow, a host symplectic form, physical cosmology, or observer substance, the displayed rows exhaust the local NameCert obligations. □

Theorem 7108.3 (Hyperbolic phase-space boundary refusal stability)**.** *Every phase-space consumer of an accepted* $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$ *packet must pass through*

$$\mathsf{UnitDisk}^{\uparrow},\ \mathsf{PoincareDiskMetric}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{PoincareDiskPhaseTransport}^{\uparrow} \longmapsto B, G, R, H, C, P, N.$$

Thus reversible disk-phase transport and finite observer-phase groupoid windows remain available, while interior-center collapse, selected ideal-boundary representatives, completed disk geometry, and host phase-space structure remain outside the exported surface.

Proof. Begin with a phase-space read. The disk carrier U supplies the inspected disk observations, and the metric rows D, M provide the only distance readbacks available to the route.

Read the reversible phase row T. It transports the displayed phase data across the disk surface, but it does not create a selected boundary representative or a global path space.

Use the refusal and groupoid rows B, G. The refusal row blocks interior-center collapse and selected-boundary exits, while the groupoid row records only finite source, target, inverse, and composition windows.

The stability and structural rows R, H, C, P, N preserve the same finite route. They therefore export reversible disk-phase transport and provenance without adding completed disk geometry, host symplectic data, physical cosmology, or observer substance. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$ consumer is refuted if it obtains reversible phase transport, boundary refusal, or observer-phase composition without displaying UnitDisk observations, PoincareDiskMetric and HyperbolicMetric reads, PoincareDiskPhaseTransport routing, componentwise transport, replay, provenance, and local naming.

Independence witness: hyperbolic-metric, poincare-disk-metric, poincare-disk-phase-transport, observer-phase-groupoid: no listed sibling is bijective to $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$ because this packet jointly carries disk observations, two metric readback rows, reversible phase transport, boundary

refusal, finite groupoid windows, route stability, componentwise transport, replay, provenance, and local naming.

The proposed Lean TasteGate surface for this packet must include explicit Nontrivial HyperbolicPhaseSpace$^{\uparrow}$ and FieldFaithful HyperbolicPhaseSpace$^{\uparrow}$ instances. Those instances must keep $U, D, M, T, B, G, R, H, C, P, N$ as separate rows before any checked carrier-alignment theorem can serve as the public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseSpace}\uparrow}$.

Constructive story: A HyperbolicPhaseSpace$^{\uparrow}$ packet is generated from UnitDisk observations, PoincareDiskMetric and HyperbolicMetric readbacks, PoincareDiskPhaseTransport rows, a boundary-refusal ledger, finite observer-phase groupoid windows, route stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicPhaseSpace}\uparrow}$, seed)

Scope closed: Definition 7108.1, Definition 7108.2, and Definition 7108.3 seed the finite hyperbolic phase-space packet over disk observations, metric readbacks, reversible phase transport, boundary refusal, finite groupoid windows, route stability, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicPhaseSpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed disk geometry, selected ideal-boundary representatives, global geodesic flow, host symplectic structure, physical cosmology, observer-substance readings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk admission, Poincare and hyperbolic metric visibility, reversible phase routing, boundary-refusal exactness, finite observer-phase groupoid windows, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseSpaceUp.

Chapter 7109

A Concrete Naming Certificate for $\mathsf{UniformLocalConnectedness}^{\uparrow}$

Following Hausdorff, Bourbaki, and Bishop–Bridges metric topology, the $\mathsf{UniformLocalConnectedness}^{\uparrow}$ packet records a finite uniform local-connectedness certificate by which a metric source, local connected basis rows, epsilon-chain rows, compact finite-window compatibility, continuous-map consumers, and Real readbacks are made into NameCert data. It sits over the metric surface of chapter 57, the local basis row of chapter 5809, the chain-connected metric route of chapter 2050, the compact metric finite-window surface of chapter 129, the continuous-map consumer interface of chapter 130, the stream-name schedule of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet gives downstream metric-topology consumers a finite route from local connected neighborhoods to uniform chain windows; it does not assert arbitrary open-cover local connectedness, choose components, import path connectedness, select moduli by choice, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7109.1 (Uniform local connectedness carrier)**.** *A* $\mathsf{UniformLocalConnectedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, L, A, K, F, C, \sigma, R, Q, H, T, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point classifier, distance classifier, and metric-distance ledger used by every local window.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *local basis row, naming the displayed connected neighborhood family around each inspected point.*
3. *A is the* $\mathsf{ChainConnectedMetric}^{\uparrow}$ *epsilon-chain row, storing the finite chain witnesses available inside the displayed metric ball.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-window compatibility row, restricting compact reads to finite net cells and bounded metric windows.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer row, recording how a continuous-map request may read the local basis and chain rows without selecting a hidden modulus.*
6. *C is the compact local-window row binding the local basis row L, chain row A, and compact window row K to the same inspected metric scale.*
7. *σ is the* $\mathsf{StreamName}^{\uparrow}$ *schedule for visible local-window, chain, compact-window, and consumer reads.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for metric radii, chain tolerances, local-basis thresholds, and consumer moduli.*
9. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for distance and tolerance comparisons after the finite rows have been displayed.*
10. *H records componentwise* hsame *transport for metric source, local basis, chain row, compact window, continuous-map consumer, compact local-window row, stream schedule, regular readbacks, Real seal, replay, provenance, and local naming.*
11. *T records displayed* Cont *replay from a uniform local-connectedness query through $M, L, A, K, F, C, \sigma, R, Q, H, P,$*
12. *P records* Pkg *provenance over* $\mathsf{UniformLocalConnectedness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{ChainConnectedMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformLocalConnectedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, A, K, F, C, \sigma, R, Q, H, T, P, N$. It has no coordinate for arbitrary open-cover local connectedness, selected components, path connectedness, choice-selected moduli, quotient equality of neighborhoods, or ambient Real completeness.

Theorem 7109.2 (Uniform local connectedness NameCert obligations)**.** *For every accepted* $\mathsf{UniformLocalConnectedn}$ *carrier*

$$U = (M, L, A, K, F, C, \sigma, R, Q, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformLocalConnectedness}^{\uparrow}}$ *surface consists exactly of metric-source admission, local-basis admission, epsilon-chain admission, compact finite-window compatibility, continuous-map consumer compatibility, compact local-window binding, stream-schedule readback, regular rational comparison, Real seal handoff, componentwise transport, displayed replay, provenance, and local naming for the same finite packet. It also contains the refusal ledger excluding arbitrary open-cover local connectedness, selected components, path connectedness, choice-selected moduli, quotient neighborhood equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7109.1. The metric source, local basis, chain, compact-window, continuous-map consumer, and compact local-window rows are explicit entries of the finite packet.

The uniformity requirement is witnessed by shared rows. The same schedule σ, regular rational readback R, and Real seal Q are used for metric radii, local-basis thresholds, chain tolerances, compact windows, and consumer moduli.

The structural rows preserve the same route. The transport row H identifies corresponding displayed entries, T replays the route through Cont, and P, N record provenance and local naming.

Since no additional coordinate appears in the carrier, the listed rows exhaust the NameCert surface. The omitted open-cover, component-selection, path, choice-modulus, quotient, and ambient-completeness exits are therefore not available to a consumer. □

Theorem 7109.3 (Uniform local connectedness chain-modulus handoff)**.** *Every continuous-map or compact-metric consumer that reads an accepted* $\mathsf{UniformLocalConnectedness}^{\uparrow}$ *packet factors its local connectedness request through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{LocallyConnected}^{\uparrow} \longmapsto \mathsf{ChainConnectedMetric}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{C}$$

Thus the consumer sees a displayed local basis, an epsilon-chain witness, a compact finite-window compatibility row, a stream schedule, regular rational modulus readbacks, and a Real-facing comparison seal before it can export a uniform local-connectedness modulus.

Proof. Begin with the metric and local rows. The source row M supplies distances, while the local basis row L supplies the connected neighborhood family visible at the inspected point.

Next use the chain and compact rows. The epsilon-chain row A records finite chain witnesses inside the displayed metric ball, and the compact row K restricts the read to finite windows compatible with chapter 129.

The readback rows then bind the modulus. The schedule σ, regular rational row R, and Real seal Q expose only displayed thresholds and comparisons, matching the chain-connected handoff of chapter 2050.

Finally the consumer row F may replay the same data through $\mathsf{ContinuousMap}^{\uparrow}$. The rows H, T, P, N preserve transport, replay, provenance, and local naming, so the exported modulus is finite packet data rather than an open-cover, component-selection, path, choice, quotient, or ambient-completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLocalConnectedness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLocalConnectedness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7109.1, Definition 7109.2, and Definition 7109.3 seed the finite uniform local-connectedness route over $\mathsf{Met}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{ChainConnectedMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLocalConnectedness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover local connectedness, selected components, path connectedness, choice-selected moduli, quotient neighborhood equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-basis exactness, epsilon-chain exactness, compact finite-window compatibility, continuous-map consumer compatibility, Real-seal handoff, replay, provenance, and local naming for BEDC.Derived.UniformLocalConnectednessUp.

Constructive story: A $\mathsf{UniformLocalConnectedness}^{\uparrow}$ packet is generated from a Metric source row, a LocallyConnected local basis row, a ChainConnectedMetric epsilon-chain row, CompactMetric finite-window compatibility, a ContinuousMap consumer row, a compact local-window binding, StreamName scheduling, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7110

A Concrete Naming Certificate for $\mathsf{GelfandTransform}^{\uparrow}$

Following Gelfand's transform for commutative Banach algebras, the $\mathsf{GelfandTransform}^{\uparrow}$ packet records the finite NameCert surface that evaluates an algebra element against displayed character rows before any spectrum-level quotient or maximal-ideal selection is used. It sits after the algebraic normed source of chapter 2189, the involutive boundary of chapter 211, the duality-facing package of chapter 262, the compact character-window source of chapter 60, the topology carrier of chapter 88, and the scalar seal of chapter 38. The packet names the constructive evaluation route from a displayed element and displayed character row to a displayed scalar read; it does not choose maximal ideals, quotient functions, unrestricted spectra, or ambient completeness.

Definition 7110.1 (Gelfand transform carrier)**.** *A* $\mathsf{GelfandTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, X, T, K, E, V, H, C, P, N)$$

with the following displayed rows:

1. *A is the commutative* $\mathsf{BanachAlgebra}^{\uparrow}$ *source row, exposing the algebra operations, norm ledger, and displayed element under inspection.*
2. *X is the* $\mathsf{CStarAlg}^{\uparrow}$ *compatibility row when the source is read through an involutive normed boundary.*
3. *T is the* $\mathsf{GelfandDuality}^{\uparrow}$ *handoff row, keeping the transform on the same character-facing duality surface.*
4. *K is the compact character-window row read through* $\mathsf{Compact}^{\uparrow}$ *and* $\mathsf{Topology}^{\uparrow}$*, naming only the finite observation windows of displayed characters.*
5. *E is the element row, naming the algebra element whose transform is evaluated.*
6. *V is the scalar evaluation row, landing in the displayed* $\mathsf{Real}^{\uparrow}$ *scalar seal for the value of the character on E.*
7. *H records componentwise* hsame *transport for algebra, involution, duality, compact-window, topology, element, value, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a character-window request through $A, X, T, K, E, V, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{GelfandTransform}^{\uparrow}$, $\mathsf{BanachAlgebra}^{\uparrow}$, $\mathsf{CStarAlg}^{\uparrow}$, $\mathsf{GelfandDuality}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{GelfandTransform}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for an unrestricted spectrum, quotient function equality, selected maximal ideals, host algebra homomorphism equality, selected character spaces, or ambient completeness.

Theorem 7110.2 (Gelfand transform NameCert obligations)**.** *For every accepted* $\mathsf{GelfandTransform}^{\uparrow}$ *carrier $G = (A, X, T, K, E, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GelfandTransform}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for $A, X, T, K, E, V, H, C, P, N$;*
2. *Banach-algebra source exposure, requiring all operation, norm, and element reads to pass through the displayed* $\mathsf{BanachAlgebra}^{\uparrow}$ *row A;*
3. *involutive compatibility, requiring any* $\mathsf{CStarAlg}^{\uparrow}$ *read to remain a displayed boundary row X and not an ambient spectral theorem;*
4. *duality handoff, requiring the transform to use the same* $\mathsf{GelfandDuality}^{\uparrow}$ *character-facing row T;*
5. *compact-topology windowing, requiring character observations to pass through K as a finite* $\mathsf{Compact}^{\uparrow}$ *and* $\mathsf{Topology}^{\uparrow}$ *window;*
6. *character evaluation exactness, requiring the scalar value V to be read only as evaluation of the displayed element E by the displayed character row;*
7. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the rows already listed.*

No Gelfand-transform obligation for this packet is stored outside those rows.

Proof. Project the accepted carrier $G = (A, X, T, K, E, V, H, C, P, N)$. The algebraic source is A, with X available only as an involutive compatibility row and T as the existing Gelfand-duality handoff.

The character side is then forced through K. Its compact and topology rows expose finite character windows rather than a selected character space or unrestricted spectrum.

The element and value rows E, V record the actual evaluation. Since V is downstream of the displayed algebra element and displayed character window, it is a finite scalar read rather than quotient function equality.

Finally H, C, P, N preserve, replay, package, and name the same finite surface. The excluded spectrum, quotient, maximal-ideal, host-equality, selected-character, and completeness objects are absent from the carrier, so the listed rows exhaust the local NameCert obligations. □

Theorem 7110.3 (Gelfand transform character-evaluation route)**.** *Every character-evaluation consumer of an accepted* $\mathsf{GelfandTransform}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{BanachAlgebra}^{\uparrow},\ \mathsf{CStarAlg}^{\uparrow},\ \mathsf{GelfandDuality}^{\uparrow} \longmapsto \mathsf{Compact}^{\uparrow},\ \mathsf{Topology}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

For $G = (A, X, T, K, E, V, H, C, P, N)$, the consumer must expose the Banach-algebra source row, optional involutive boundary, Gelfand-duality handoff, compact character-window row, topology row, displayed element, scalar evaluation row, transport, replay, provenance, and local naming before reading the transform value. The route exports no unrestricted spectrum, quotient function equality, selected maximal ideal, selected character space, host homomorphism equality, or ambient completeness.

Proof. Start with a transform-value request. The only algebraic source available to the packet is A, with X and T recording the compatible involutive and Gelfand-duality rows when those surfaces are consumed.

Next expose the character window. The row K is read through the compact and topology sources, so the consumer sees finite character observations instead of a selected maximal ideal or unrestricted spectrum.

Now evaluate the displayed element. The rows E and V bind the scalar read to the element and character window already displayed.

The structural rows H, C, P, N keep the same route under transport, replay, provenance, and local naming. Since the carrier contains no quotient function equality, selected character space, host homomorphism equality, selected maximal ideal, or ambient completeness row, no consumer can obtain those objects from the $\mathsf{GelfandTransform}^{\uparrow}$ packet. □

Falsifiable prediction: An accepted $\mathsf{GelfandTransform}^{\uparrow}$ read is refuted if a character-evaluation consumer obtains a transform value without displaying the BanachAlgebra source, CStarAlgebra compatibility row when used, GelfandDuality handoff, Compact character-window row, Topology row, Real scalar seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: banachalgebra, cstaralgebra, gelfandduality, compact, topology, and real: none is bijective to $\mathsf{GelfandTransform}^{\uparrow}$ because only this packet jointly records displayed algebra-element evaluation, finite character windows, scalar readback, transport, replay, provenance, and local NameCert rows as one transform surface.

Closure status for $\mathsf{NameCert}_{\mathsf{GelfandTransform}^{\uparrow}}$.

Constructive story: A $\mathsf{GelfandTransform}^{\uparrow}$ packet is generated from a commutative BanachAlgebra source row, optional CStarAlg compatibility row, GelfandDuality handoff, Compact and Topology character-window rows, displayed algebra element, Real scalar evaluation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GelfandTransform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7110.1, Definition 7110.2, and Definition 7110.3 seed the finite character-evaluation route from BanachAlgebra and CStarAlgebra rows through GelfandDuality, Compact and Topology character windows, and Real scalar readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GelfandTransform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an unrestricted spectrum, quotient function equality, selected maximal ideals, selected character spaces, host homomorphism equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Banach-algebra exposure, involutive compatibility, duality handoff, compact-topology windowing, character-evaluation exactness, transport, replay, provenance, and local naming for BEDC.Derived.GelfandTransformUp.

Chapter 7111

A Concrete Naming Certificate for $\mathsf{UniformLipschitzModulus}^{\uparrow}$

Following Bishop–Bridges constructive metric analysis and Kelley-style uniform-space bookkeeping, the $\mathsf{UniformLipschitzModulus}^{\uparrow}$ packet records the textbook passage from a displayed Lipschitz bound to a uniform modulus as finite certificate data. It reads the Lipschitz modulus route of chapter 3724, the constant handoff of chapter 2328, and the surrounding metric, real, dyadic, uniform-modulus, and uniform-continuity rows. The chapter names the carrier that makes this handoff local to BEDC; it is not a host continuity theorem, a quotient-map equality, a hidden reciprocal selection, or an ambient completeness principle.

Definition 7111.1 (Uniform Lipschitz modulus carrier)**.** *A* $\mathsf{UniformLipschitzModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, F, K, L, E, D, U, W, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row and Y is the target* $\mathsf{Met}^{\uparrow}$ *row.*
2. *F is the* $\mathsf{LipschitzMap}^{\uparrow}$ *graph row whose source and target reads use X and Y.*
3. *K is the displayed* $\mathsf{LipschitzConstant}^{\uparrow}$ *row for the same source, target, and graph data.*
4. *L is the accepted* $\mathsf{LipschitzModulus}^{\uparrow}$ *row that turns the displayed bound into a tolerance route.*
5. *E is the positive target-tolerance row, read through* $\mathsf{Real}^{\uparrow}$ *before any source-tolerance request is exported.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *division and rounding ledger used by K, L, E.*
7. *U is the exported* $\mathsf{UniformModulus}^{\uparrow}$ *row.*
8. *W is the* $\mathsf{UniformContinuity}^{\uparrow}$ *consumer row that may read U only after X, Y, F, K, L, E, D have been displayed.*
9. *H records componentwise* hsame *transport for metric rows, graph rows, bound rows, modulus rows, tolerance rows, dyadic ledger rows, uniform-continuity consumers, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a target-tolerance request through E, K, L, D, U, W.*

11. *P is the* Pkg *provenance over* $\mathsf{UniformLipschitzModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{LipschitzConstant}^{\uparrow}$, $\mathsf{LipschitzModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformLipschitzModulus}^{\uparrow}}$ *row.*

The classifier accepts only packets with these rows. It has no coordinate for host continuity, quotient function equality, implicit reciprocal choice, selected limits, countable choice, or ambient metric or real completeness.

Theorem 7111.2 (Uniform Lipschitz modulus NameCert obligations)**.** *For every accepted* UniformLipschitzModulus *carrier $Q = (X, Y, F, K, L, E, D, U, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformLipschitzModulus}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the two metric rows, Lipschitz graph row, displayed constant row, Lipschitz modulus row, positive tolerance row, dyadic division and rounding ledger, exported uniform modulus, uniform-continuity consumer, transport, replay, provenance, and local naming;*
2. *source-target alignment, requiring F, K, L to read the same X and Y before any tolerance conversion is exported;*
3. *tolerance route exactness, requiring E to be displayed before D and requiring D to be the only division and rounding ledger used by U;*
4. *uniform-consumer handoff, requiring every* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{UniformContinuity}^{\uparrow}$ *read to pass through K, L, E, D, U in that order;*
5. *ledger non-escape, excluding host continuity, quotient map equality, hidden reciprocal choice, selected limits, countable choice, and ambient completeness.*

Proof. Carrier admission is projection from Definition 7111.1. The displayed packet exposes exactly the metric, graph, constant, Lipschitz-modulus, tolerance, dyadic, exported-modulus, consumer, transport, replay, provenance, and naming rows.

The source-target alignment obligation follows from the shared positions of X and Y in F, K, L. A consumer cannot read a bound or modulus row for a different metric pair because no such coordinate occurs in Q.

The tolerance and handoff obligations use the same finite route as chapter 3724 and the displayed constant handoff of chapter 2328. The positive tolerance E is read before the dyadic ledger D, and U is the only exported $\mathsf{UniformModulus}^{\uparrow}$ row available to W.

The refusal clause is an inventory check on the carrier. None of the displayed rows supplies host continuity, quotient equality, hidden reciprocal selection, selected limits, countable choice, or ambient completeness. □

Theorem 7111.3 (Uniform Lipschitz modulus consumer boundary)**.** *Let $Q = (X, Y, F, K, L, E, D, U, W, H, C, P, N$ be an accepted* $\mathsf{UniformLipschitzModulus}^{\uparrow}$ *carrier. Every downstream* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{UniformContinuity}^{\uparrow}$ *consumer receives the source-tolerance route only through the displayed Lipschitz constant K, the Lipschitz modulus row L, the positive target tolerance E, the dyadic ledger D, and the exported row U. The consumer boundary is therefore a finite BEDC handoff rather than a rereading of a host Lipschitz proof.*

Proof. Project the carrier. The only graph row is F, the only displayed constant row is K, and the only Lipschitz-modulus row is L; all three read the same source and target metric rows.

The target-tolerance request is E. It reaches a source-tolerance request only through the dyadic division and rounding ledger D, so no hidden reciprocal or selected real approximation can replace the finite arithmetic row.

The exported row U is then the sole $\mathsf{UniformModulus}^{\uparrow}$ coordinate available to W. Componentwise transport through H and replay through C preserve this order, while P and N record the same finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLipschitzModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLipschitzModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7111.1, Definition 7111.2, and Definition 7111.3 seed the finite route from displayed Lipschitz constant and Lipschitz modulus data to a uniform-modulus consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLipschitzModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host continuity, quotient map equality, hidden reciprocal choice, selected limits, countable choice, or ambient metric or real completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-target alignment, tolerance route exactness, uniform-consumer handoff, transport stability, and replay stability for BEDC.Derived.UniformLipschitzModulusUp.

Constructive story: A $\mathsf{UniformLipschitzModulus}^{\uparrow}$ packet is generated from source and target metric rows, a Lipschitz graph row, a displayed Lipschitz constant row, an accepted Lipschitz modulus row, a positive tolerance row, a DyadicRatCore division and rounding ledger, a UniformModulus export, a UniformContinuity consumer, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 7112

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverPhase}^{\uparrow}$

The $\mathsf{HyperbolicObserverPhase}^{\uparrow}$ packet realizes the observer phase route of chapter 9463 as a canonical finite carrier. It binds boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, provenance, hsame, Cont, Pkg, and local NameCert rows before any observer-expansion conclusion can be consumed. The packet is BEDC-native phase data: it is not a host hyperbolic manifold, not empirical cosmology, and not a hidden observer center.

The packet consumes the observer-expansion rows of chapter 4167 and the shell aggregation rows of chapter 5180 before its phase row is read. This is a finite boundary-shadow and observer-shell route: the phase carrier records how displayed boundary-facing data pass through shell aggregation, not a geometric primitive and not a host phase space.

Definition 7112.1 (Hyperbolic observer phase carrier)**.** *A* $\mathsf{HyperbolicObserverPhase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, V, D, T, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the boundary-shadow row read through* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*.*
2. *V is the visual-boundary row read through* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$*.*
3. *D is the phase-distance row read through* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$*.*
4. *T is the reversible-transport row read through* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*,* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$*, and the observer phase groupoid surface.*
5. *R is the refusal row blocking hidden interior centers, unlogged global geometry, empirical expansion laws, and private phase-distance oracles.*
6. *H records componentwise* hsame *transport for B, V, D, T, R.*
7. *C records displayed* Cont *replay from boundary-shadow reads through visual-boundary reads, phase-distance reads, reversible transport, refusal, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverPhase}^{\uparrow}$*,* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*,* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$*,* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$*,* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$*,* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$*,* $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhase}^{\uparrow}}$ *row.*

The classifier accepts only packets with these rows. It has no coordinate for an ambient hyperbolic space, a selected ideal boundary, a physical expansion law, a global geodesic completion, or an interior observer center.

Theorem 7112.2 (Hyperbolic observer phase NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicObserverPhase}$ *carrier* $Q = (B, V, D, T, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhase}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, transport, replay, provenance, and local naming rows;*
2. *boundary coverage, requiring* B *and* V *to be displayed before any phase-distance row is read;*
3. *phase-distance and transport exactness, requiring* D *and* T *to be the only comparison and reversible-transport rows exported by the carrier;*
4. *refusal coverage, requiring* R *to block hidden center, selected boundary, global-geometry, empirical-cosmology, and private-oracle interpretations;*
5. *ledger non-escape, requiring downstream consumers to pass through* H, C, P, N *rather than rereading the vision text as a proof surface.*

Proof. Carrier admission is projection from Definition 7112.1. The geometric rows are exactly B, V, D, T, R, and the structural rows are exactly H, C, P, N.

Boundary coverage follows because B and V are the only boundary-facing rows. A phase-distance read therefore has no route into the carrier until boundary-shadow and visual-boundary data have been displayed.

The exactness and refusal clauses are row-order checks. The phase-distance row D and transport row T provide the only comparison and reversible movement data, while R blocks hidden center, selected boundary, global geometry, empirical law, and private-oracle readings.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no further coordinate, every downstream observer-phase read is confined to the displayed BEDC route. □

Theorem 7112.3 (Hyperbolic observer phase downstream boundary)**.** *Every downstream read of an accepted* $\mathsf{HyperbolicObserverPhase}^{\uparrow}$ *packet factors through boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhase}^{\uparrow}}$ *row. It exports a finite observer-phase interface, not an ambient hyperbolic geometry or a total observer-expansion law.*

Proof. Apply Definition 7112.2. The accepted packet exposes only the nine rows $B, V, D, T, R, H, C, P, N$.

The boundary-shadow and visual-boundary rows keep the read boundary-facing. The phase-distance and reversible-transport rows provide only displayed comparisons and movement, and the refusal row prevents those readings from becoming global geometry or empirical cosmology.

Transport, replay, provenance, and naming preserve the same finite route. A downstream consumer therefore receives the observer-phase interface and no stronger object. □

The later Lean TasteGate for this packet must provide Nontrivial and FieldFaithful instances for the boundary-shadow, visual-boundary, phase-distance, reversible-transport, and refusal rows before any stronger classifier claim is recorded.

Falsifiable prediction: An accepted $\mathsf{HyperbolicObserverPhase}^{\uparrow}$ consumer that exports observer phase data without first displaying boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, hsame, Cont, Pkg, and local NameCert rows refutes this carrier.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-visual-boundary, phase-distance-observer-expansion, poincare-boundary-fixed-transport, observer-phase-groupoid: none is bijective to $\mathsf{HyperbolicObserverPhase}^{\uparrow}$ because this packet jointly carries boundary-facing reads, phase-distance comparison, reversible transport, refusal, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhase}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7112.1, Definition 7112.2, and Definition 7112.3 seed the finite observer-phase carrier over boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ambient hyperbolic geometry, empirical cosmology, selected ideal boundaries, global geodesic completion, or observer-center existence.

Upgrade path: Obligation closure requires checked carrier admission, boundary coverage, phase-distance exactness, reversible-transport exactness, refusal coverage, Nontrivial and FieldFaithful TasteGate instances, transport stability, and downstream nonescape for BEDC.Derived.HyperbolicObserverPhaseUp.

Constructive story: A $\mathsf{HyperbolicObserverPhase}^{\uparrow}$ packet is generated from boundary-shadow, visual-boundary, phase-distance, reversible-transport, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 7113

A Concrete Naming Certificate for $\mathsf{ClosedIntervalCauchyField}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ClosedIntervalCauchyField}^{\uparrow}$ packet records the interval-local regular Cauchy field rows available on a displayed closed bounded interval. It sits after the closed interval source of chapter 1591, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the local Cauchy-field corridor without claiming general $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, or an ambient field-completion principle.

Definition 7113.1 (Closed-interval Cauchy-field carrier)**.** *A* $\mathsf{ClosedIntervalCauchyField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed interval source row, exposing the accepted* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *lower endpoint, upper endpoint, endpoint-order, containment, finite-window, readback, and Real-seal boundary.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect only the displayed interval-local observations.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested precision, endpoint containment, and local comparison budget.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the same finite window and dyadic tolerance route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-facing value only after I, S, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the interval source, stream window, dyadic tolerance ledger, regular rational readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from interval-source admission through finite windows, tolerance checks, readback, and terminal sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalCauchyField}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyField}^{\uparrow}}$ *row.*
The local classifier compares accepted carriers only by $I, S, D, Q, E, H, C, P, N$. It has no coordinate for quotient streams, selected limit points, countable choice, host real-field completion, or an ambient proof that every Cauchy family on $\mathsf{Real}^{\uparrow}$ *converges.*

Theorem 7113.2 (Closed-interval Cauchy-field NameCert obligations)**.** *For every accepted* ClosedIntervalCauchyFi *carrier*

$$F = (I, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyField}^{\uparrow}}$ *surface consists exactly of closed interval source exposure, finite StreamName window admission, DyadicRatCore tolerance accounting, RegSeqRat readback, terminal RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local naming row. Every interval-local Cauchy-field read must pass through $I, S, D, Q, E, H, C, P, N$ before it can be consumed.*

Proof. Project the carrier of Definition 7113.1. The rows $I, S, D, Q, E, H, C, P, N$ are the whole accepted packet.

The source and analytic rows are exposed first. The closed interval source I fixes the endpoint and containment boundary, the window row S exposes the finite observations, the dyadic row D records the requested tolerance, and Q reads those observations as regular rational data.

The remaining rows preserve the route. The Real seal E is downstream of I, S, D, Q, while H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, quotient streams, selected limits, countable choice, and ambient completeness cannot be exported by the local NameCert. □

Theorem 7113.3 (Closed-interval Cauchy-field window readback)**.** *Every accepted* $\mathsf{ClosedIntervalCauchyField}^{\uparrow}$ *read that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal first displays the finite lattice*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The readback is interval-local and finite; it does not identify quotient streams, select a global limit, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let $F = (I, S, D, Q, E, H, C, P, N)$ be an accepted carrier. The source row I is the only interval entry point, so the read begins with the closed bounded interval boundary.

The finite window and tolerance rows then determine the local request. The row S exposes the inspected StreamName observations, D records the DyadicRatCore precision and containment budget, and Q replays the same data as RegSeqRat readback.

Only after this route is visible can the seal row E be read. Transport, replay, provenance, and naming do not add a hidden stream quotient or chosen limit; they preserve the displayed finite lattice. □

Theorem 7113.4 (Closed-interval Cauchy-field Real-seal nonescape)**.** *An accepted* $\mathsf{ClosedIntervalCauchyField}^{\uparrow}$ *carrier exports the terminal* $\mathsf{Real}^{\uparrow}$ *row only as the seal of the displayed closed-interval Cauchy-field route. No consumer may read that seal as a proof of general Real completeness, a selected completion point for an arbitrary Cauchy stream, a countable-choice family, or a host field-completion operator.*

Proof. Use Definition 7113.2. Every consumer reaches the local naming row through the closed interval source, finite window, dyadic tolerance ledger, regular readback, and terminal Real seal.

Apply Definition 7113.3. The exported Real row is tied to the finite interval-local lattice and has no coordinate for a quotient stream, arbitrary Cauchy family, selected limit, or countable-choice schedule.

Thus the seal is a terminal row of this packet, not a global completeness theorem. Any consumer that treats it as an ambient field-completion principle leaves the displayed carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyField}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedIntervalCauchyField}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7113.1, Definition 7113.2, Definition 7113.3, and Definition 7113.4 seed the interval-local Cauchy-field packet over finite readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCauchyField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, general Real completeness, quotient stream equality, selected limits, countable choice, or an ambient field-completion operator.

Upgrade path: Obligation closure requires checked carrier admission, window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ClosedIntervalCauchyFieldUp.

Chapter 7114

A Concrete Naming Certificate for ProofRelevantNormalJoin$^{\uparrow}$

The ProofRelevantNormalJoin$^{\uparrow}$ packet realizes the checked closed-normal and atom confluence fragments of chapter 9378 as finite NameCert data. It records the proof-relevant join witness available for closed normal sources, the atom handoff, and the beta-star route while keeping the residual-substitution compatibility boundary visible. The proof-relevant join witness consumes the confluence-audit rows of chapter 735, the closed-normal seal of chapter 741, the critical-path pressure rows of chapter 765, the audit-witness boundary of chapter 745, and the closed-normal join certificate of chapter 6833. These sibling routes supply the closed-normal and atom fragment rows while the packet retains the residual-substitution compatibility boundary and the conditional ledger for full confluence. The packet is not a full confluence theorem for arbitrary closed terms and does not discharge the conditional parallel-diamond premise.

Definition 7114.1 (Proof-relevant normal-join carrier)**.** *A* ProofRelevantNormalJoin$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, W, B, L, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the closed-normal source row, exposing the closed term, normal-source classifier, and atom cases admitted by the checked fragment.*
2. *W is the proof-relevant join witness row, recording the finite common reduct evidence for the closed-normal or atom branch.*
3. *B is the beta-star handoff row, carrying the transport from the parallel or atom join witness into the multi-step beta-star route.*
4. *L is the conditional-boundary ledger, recording that the full substitution-compatibility input and arbitrary closed-source confluence remain outside this packet.*
5. *T records componentwise* hsame *transport for source, witness, beta-star handoff, boundary ledger, replay, provenance, and local naming rows.*
6. *H records displayed* Cont *replay from closed-normal source admission through join witness construction, beta-star handoff, and boundary retention.*
7. *C is the* Pkg *provenance over* ProofRelevantNormalJoin$^{\uparrow}$*, MetaCIC closed-normal confluence, atom joins, beta-star transport,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

8. *P records the public readback route for the proof-relevant normal join, separated from the conditional full-confluence interface.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofRelevantNormalJoin}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only by $S, W, B, L, T, H, C, P, N$. It has no coordinate for unrestricted substitution compatibility, full parallel diamond, arbitrary closed Church–Rosser, subject reduction, host conversion equality, or an erased proof-irrelevant confluence oracle.

Theorem 7114.2 (Proof-relevant normal-join NameCert obligations)**.** *For every accepted* ProofRelevantNormalJoin *carrier*

$$J = (S, W, B, L, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ProofRelevantNormalJoin}^{\uparrow}}$ *surface consists exactly of closed-normal source exposure, proof-relevant join witness, beta-star handoff, conditional-boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, public readback, and local naming. Every public read factors through those rows before it can cite the closed-normal or atom confluence fragment.*

Proof. Project the carrier of Definition 7114.1. The rows $S, W, B, L, T, H, C, P, N$ are the whole packet.

The source and witness rows carry the positive fragment. The row S admits only the closed-normal and atom cases, W records the finite common-reduct witness, and B transports that witness into the beta-star route.

The boundary and structural rows preserve the refusal. The ledger L keeps the substitution-compatibility and arbitrary closed-source boundaries visible, while T, H, C, P, N transport, replay, source, read back, and name exactly the displayed rows. □

Theorem 7114.3 (Proof-relevant normal-join diamond fragment)**.** *Every accepted* $\mathsf{ProofRelevantNormalJoin}^{\uparrow}$ *public read exposes a closed-normal or atom source row, a proof-relevant common-reduct witness, and a beta-star handoff before it cites the checked confluence fragment. The read is a finite closed-fragment diamond packet and not a proof of full parallel diamond.*

Proof. Use Definition 7114.2. A public read must first pass through S, W, B before reaching transport, replay, provenance, readback, and local naming.

The witness row W is proof-relevant: it names the common reduct evidence for the admitted closed-normal or atom branch rather than merely asserting existence. The beta-star handoff B records the route by which that witness is consumed by the star relation.

Since the ledger L remains a required row, the read cannot be promoted into a full parallel diamond. It is exactly the displayed finite diamond fragment. □

Theorem 7114.4 (Proof-relevant normal-join full-confluence nonescape)**.** *An accepted* $\mathsf{ProofRelevantNormalJoin}^{\uparrow}$ *carrier cannot export unrestricted MetaCIC confluence. Any public consumer must retain the conditional-boundary ledger separating closed-normal and atom joins from arbitrary closed-source confluence, residual substitution compatibility, subject reduction, and host conversion equality.*

Proof. Start from the carrier rows of Definition 7114.1. The only positive confluence data are the closed-normal source, proof-relevant witness, and beta-star handoff rows.

Apply Definition 7114.3. The exported diamond fragment is available only for the admitted closed-normal and atom branches.

The boundary ledger L is part of every accepted read by Definition 7114.2. Therefore a consumer that drops residual-substitution compatibility, arbitrary closed-source confluence, subject reduction, or host conversion equality leaves the packet. □

Definition 7114.5 (MetaCIC proof-relevant candidate-diamond carrier)**.** *A MetaCIC proof-relevant candidate-diamond carrier is a finite* BHist *packet*

$$D = (R, L_1, L_2, Q, B, E, H, C, P, O, N)$$

with the following displayed rows:

1. *R is the candidate source row, naming the inspected MetaCIC expression, its closedness boundary, and the classifier row used by the confluence audit.*
2. *L_1 and L_2 are the left and right one-step rows from the same source row.*
3. *Q is the proof-relevant common-reduct witness row for the candidate pair.*
4. *B is the beta-star handoff from L_1, L_2, Q into the multi-step reduction route.*
5. *E is the residual-boundary ledger, recording the exact residual-substitution, subject-reduction, arbitrary closed-source confluence, and host-conversion boundaries still outside the carrier.*
6. *H records componentwise* hsame *transport for source, one-step, witness, beta-star, boundary, replay, provenance, public readback, and local naming rows.*
7. *C records displayed* Cont *replay from the candidate source request through the two one-step rows, witness row, beta-star handoff, and boundary ledger.*
8. *P is the* Pkg *provenance over* ProofRelevantNormalJoin$^{\uparrow}$*, MetaCIC one-step reduction, beta-star handoff, confluence-audit rows, residual-boundary rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *O is the public readback row, exposing the candidate-mediated local diamond only after the proof-relevant witness and the residual-boundary ledger are both visible.*
10. *N is the local* NameCert *row for the candidate-diamond packet.*

The classifier compares accepted candidate-diamond packets only by $R, L_1, L_2, Q, B, E, H, C, P, O, N$. It has no coordinate for arbitrary closed-source confluence, residual-substitution compatibility, subject reduction, host conversion equality, or a proof-erased diamond oracle.

Theorem 7114.6 (MetaCIC proof-relevant candidate-diamond NameCert obligations)**.** *For every accepted MetaCIC proof-relevant candidate-diamond carrier*

$$D = (R, L_1, L_2, Q, B, E, H, C, P, O, N),$$

the local NameCert *surface consists exactly of candidate source exposure, left and right one-step row exposure, proof-relevant common-reduct witness exposure, beta-star handoff, residual-boundary ledger exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, public readback, local naming, and nonescape from arbitrary closed-source confluence, residual-substitution compatibility, subject reduction, and host conversion equality.*

Proof. Project the carrier of Definition 7114.5. The source and two one-step rows are R, L_1, L_2, so any candidate pair is read through a single displayed source classifier and two displayed one-step reductions.

The proof-relevant join data are Q and B. The witness row Q names the common reduct for this candidate pair, and the beta-star handoff B records how the two one-step rows reach that common reduct in the multi-step route.

The boundary and structural rows are E, H, C, P, O, N. The ledger E keeps the residual-substitution, subject-reduction, arbitrary closed-source, and host-conversion boundaries visible, while H, C, P, O, N transport, replay, source, read back, and name only the displayed rows.

Because no further coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations and no proof-erased diamond oracle is exported. □

Theorem 7114.7 (MetaCIC proof-relevant candidate-diamond boundary)**.** *An accepted MetaCIC proof-relevant candidate-diamond packet exports a candidate-mediated local diamond only when the proof-relevant common-reduct witness Q and the residual-boundary ledger E are both public rows. The packet may hand the displayed candidate pair to the beta-star route through B and public readback row O, but it still refuses arbitrary closed-source confluence, residual-substitution compatibility, subject reduction, and host conversion equality.*

Proof. Use Definition 7114.6. A public candidate-diamond read must expose the source row, the two one-step rows, the proof-relevant witness, the beta-star handoff, and the residual-boundary ledger.

The local diamond is therefore candidate-mediated. It is witnessed by Q for the displayed pair L_1, L_2 and is transported into beta-star by B, then exposed by the readback row O.

The same read must retain E. Since E names the residual-substitution, subject-reduction, arbitrary closed-source, and host-conversion boundaries as still outside the packet, removing those boundaries would leave the accepted candidate-diamond carrier. □

Falsifiable prediction: Every public $\mathsf{ProofRelevantNormalJoin}^{\uparrow}$ read factors through closed-normal source, join witness, beta-star handoff, conditional-boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before any confluence-fragment output is visible.

Independence witness: metacic-confluence-audit-packet, closednormalconfluenceseal, metaciccriticalpath, metacicconfluenceauditwitness: $\mathsf{ProofRelevantNormalJoin}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a proof-relevant join witness, beta-star handoff, conditional-boundary ledger, transport, replay, provenance, public readback, and local naming while refusing arbitrary closed-source confluence and unrestricted substitution compatibility.

Later Lean TasteGate work for $\mathsf{ProofRelevantNormalJoin}^{\uparrow}$ must provide explicit Nontrivial ProofRelevantNormalJo and FieldFaithful $\mathsf{ProofRelevantNormalJoin}^{\uparrow}$ instances, preserving the source, witness, beta-star handoff, conditional-boundary ledger, transport, replay, provenance, readback, and NameCert rows as distinct fields.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofRelevantNormalJoin}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofRelevantNormalJoin}^{\uparrow}$ packet is generated from a closed-normal source row, proof-relevant join witness, beta-star handoff, conditional-boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, public readback, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProofRelevantNormalJoin}^{\uparrow}}$, seed)

Scope closed: Definition 7114.1, Definition 7114.2, Definition 7114.3, Definition 7114.4, and Definition 7114.7 seed the proof-relevant closed-normal, atom join, and candidate-diamond boundary packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProofRelevantNormalJoin}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, full parallel diamond, arbitrary closed Church–Rosser, residual substitution compatibility, subject reduction, or host conversion equality.

Upgrade path: Obligation closure requires checked carrier admission, proof-relevant witness readback, beta-star handoff, conditional-boundary nonescape, Nontrivial, FieldFaithful, transport, replay, provenance, and local naming for BEDC.Derived.ProofRelevantNormalJoinUp.

Chapter 7115

A Concrete Naming Certificate for McShaneExtensionReal$^{\uparrow}$

Following McShane and Bishop–Bridges constructive real analysis, the McShaneExtensionReal$^{\uparrow}$ packet records the finite BEDC surface for reading a real-valued Lipschitz map on a displayed subset of a displayed metric carrier as an ambient extension candidate. It sits after the metric source of chapter 57, the terminal real-name seal of chapter 38, the reusable Lipschitz extension interface of chapter 3650, the uniformly continuous extension handoff of chapter 769, and the dyadic tolerance core of chapter 291. The chapter isolates the Real-valued McShane handoff as a finite NameCert packet rather than a host supremum formula, quotient function, selected family of extrema, countable-choice construction, or ambient completeness theorem.

Definition 7115.1 (McShane real-valued extension carrier)**.** *A* McShaneExtensionReal$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, d, G, L, E, S, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the subset-source row, recording admitted source points, inclusion into the ambient metric carrier, and the finite membership evidence used by source-value reads.*
2. *d is the* Met$^{\uparrow}$ *distance row for the ambient carrier and the source subset, exposing only displayed distance observations.*
3. *G is the Real-valued source graph row, read through* Real$^{\uparrow}$ *seals and carrying the displayed source values without a host function object.*
4. *L is the Lipschitz-constant budget row, recording the finite bound ledger consumed by* LipschitzExtension$^{\uparrow}$ *and the dyadic tolerance requests mediated by* DyadicRatCore$^{\uparrow}$*.*
5. *E is the ambient extension graph row, recording the finite McShane envelope comparisons available at ambient inputs without selecting a supremum or infimum.*
6. *S is the subset-agreement row, requiring every source-admitted ambient read to return through the same A, d, G, L, E route before it can be identified with the source graph.*
7. *R is the Real seal row for source values, envelope comparisons, and ambient extension reads.*
8. *H records componentwise* hsame *transport for the subset source, metric distance, graph, budget, extension graph, agreement, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a precision request through $A, d, G, L, E, S, R, H, P, N$.*
10. *P is the* Pkg *provenance over* McShaneExtensionReal$^{\uparrow}$, Met$^{\uparrow}$, Real$^{\uparrow}$, LipschitzExtension$^{\uparrow}$, UniformContinuousExten DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{McShaneExtensionReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for host function equality, selected suprema, selected infima, quotient functions, countable choice, trichotomy, ambient Real$^{\uparrow}$ *completeness, or a public bridge credential.*

Theorem 7115.2 (McShane real-valued NameCert obligations)**.** *For every accepted* McShaneExtensionReal$^{\uparrow}$ *carrier*

$$M = (A, d, G, L, E, S, R, H, C, P, N),$$

the local NameCert$_{\text{McShaneExtensionReal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the subset source, metric distance, Real-valued graph, Lipschitz-constant budget, extension graph, subset agreement, Real seal, transport, replay, provenance, and local naming rows;*
2. *source-domain compatibility, requiring every source-value read to pass through A and d before it is compared with an ambient extension read;*
3. *Real graph admission, requiring G and R to be the only rows that expose source values and ambient extension values;*
4. *Lipschitz-budget transport, requiring L and* DyadicRatCore$^{\uparrow}$ *to mediate every tolerance transfer used by the extension graph row;*
5. *extension-graph exactness, requiring E to store only finite McShane comparison data and no selected supremum, selected infimum, quotient function, or host function object;*
6. *subset-agreement exactness, requiring S to identify the extension graph with the source graph only through the same displayed A, d, G, L, E, R route;*
7. *ledger non-escape, requiring H, C, P, N to preserve and replay the listed rows without adding host Real equality, selected extrema, quotient functions, countable choice, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7115.1. The accepted packet displays exactly the subset source, metric distance, Real-valued graph, Lipschitz budget, extension graph, subset agreement, Real seal, and structural rows.

Read the source-domain and graph clauses next. The row A admits source points, the distance row d supplies the metric observations, and G is the only Real-valued source graph row. Hence a source comparison cannot be formed before the packet has opened A, d, G, R.

The Lipschitz-budget clause is forced by L together with the dyadic tolerance core. The reusable interface of chapter 3650 and the dyadic route of chapter 291 keep every tolerance transfer finite and visible.

Project the extension and agreement rows E and S. The extension row stores finite McShane envelope comparisons, while the agreement row checks those comparisons on inputs admitted by A. Neither row selects an extremum, forms a quotient function, or imports a host equality of functions.

Finally inspect H, C, P, N. Transport is componentwise, replay follows the displayed request route, and provenance cites only the packet and its sibling dependencies, including chapter 769. Therefore the local NameCert obligations are exactly the listed finite rows. □

Theorem 7115.3 (McShane real-valued Lipschitz handoff)**.** *Let $M = (A, d, G, L, E, S, R, H, C, P, N)$ be an accepted* $\mathsf{McShaneExtensionReal}^{\uparrow}$ *carrier. Every* $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the ambient extension read must first traverse the finite route*

$$A, d \longmapsto G \longmapsto L \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto E \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

Along that route the displayed Lipschitz budget remains the only bound used for the Real-valued ambient extension graph. The handoff exports no host function equality, selected supremum, selected infimum, quotient function, countable-choice selector, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with an ambient extension read. The subset row A and distance row d provide the only source-domain and metric observations available to the consumer, while G supplies the source Real-valued graph.

Read the Lipschitz budget and dyadic tolerance rows. The row L records the displayed bound, and the $\mathsf{DyadicRatCore}^{\uparrow}$ route turns that bound into finite precision data before any ambient comparison is inspected.

The extension graph row E is then opened as finite McShane comparison data, and the subset-agreement row S checks that the same route restricts back to G on inputs admitted by A. The Real seal R is therefore reached only after the source graph, budget, extension graph, and agreement rows are visible.

Transport, replay, provenance, and local naming preserve the route through H, C, P, N. Since no listed row contains host function equality, selected extrema, quotient functions, countable choice, trichotomy, or ambient Real completeness, the $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoff cannot export any such object. □

Falsifiable prediction: An accepted $\mathsf{McShaneExtensionReal}^{\uparrow}$ consumer that reaches an ambient Real-valued extension read without first reading the subset source, metric distance, source graph, Lipschitz budget, dyadic tolerance, extension graph, subset agreement, and Real seal rows refutes the carrier surface.

Independence witness: metric, real, lipschitz-extension, uniform-continuous-extension, dyadicratcore: no listed sibling supplies the full eleven-row packet $M = (A, d, G, L, E, S, R, H, C, P, N)$, because each sibling contributes only a metric source, Real seal, reusable extension interface, continuity handoff, or dyadic tolerance route while this chapter binds the finite Real-valued McShane extension certificate into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{McShaneExtensionReal}^{\uparrow}}$.

Constructive story: A $\mathsf{McShaneExtensionReal}^{\uparrow}$ packet is generated from a subset-source row, a MetricUp distance row, a Real-valued graph row, a Lipschitz-constant budget, an ambient extension graph, a subset-agreement row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{McShaneExtensionReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7115.1, Definition 7115.2, and Definition 7115.3 seed the finite Real-valued McShane extension certificate over displayed subset, metric, Lipschitz-budget, dyadic-tolerance, and Real-seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{McShaneExtensionReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, selected suprema, selected infima, quotient functions, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-domain compatibility, Real graph admission, Lipschitz-budget transport, extension-graph exactness, subset-agreement exactness, non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.McShaneExtensionRealUp.

Chapter 7116

A Concrete Naming Certificate for $\mathsf{BanachSaks}^{\uparrow}$

Following Banach and Saks on Cesaro-convergent subsequences in Banach spaces, the $\mathsf{BanachSaks}^{\uparrow}$ packet records the finite NameCert surface by which a bounded Banach-space sequence, a weak-compactness handoff, a Cesaro block schedule, and normed real readback are exposed before any consumer treats the route as a Banach–Saks conclusion. It sits after the Banach carrier of chapter 90, the weak-compactness packet of chapter 6851, the bounded real sequence source of chapter 1415, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite Cesaro-subsequence certificate; it does not choose an infinite subsequence in the host, quotient sequence equality, countable choice, weak compactness itself, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7116.1 (Banach–Saks carrier)**.** *A* $\mathsf{BanachSaks}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, X, W, A, Q, R, T, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Banach}^{\uparrow}$ *source row, naming the normed complete carrier through the already displayed Banach packet.*
2. *X is the bounded Banach sequence source row, read through the bounded sequence frontier and not through a host sequence object.*
3. *W is the* $\mathsf{WeakCompactness}^{\uparrow}$ *handoff row, recording the weakly compact source surface that licenses a subsequence obligation without selecting a host subsequence.*
4. *A is the finite Cesaro block schedule, listing the inspected block indices and averaging windows.*
5. *Q is the norm and* $\mathsf{Real}^{\uparrow}$ *readback row for the displayed Cesaro averages.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *route by which the real-valued norm observations are read as regular rational windows.*
7. *T records transport from the bounded-source and weak-compactness rows to the Cesaro schedule and real readback rows.*
8. *H records componentwise* hsame *transport for B, X, W, A, Q, R, T and the local naming row.*
9. *C records displayed* Cont *replay through the bounded source, weak-compactness handoff, Cesaro schedule, norm readback, regular rational route, transport, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{BanachSaks}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{WeakCompactness}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachSaks}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, X, W, A, Q, R, T, H, C, P, N$. It has no coordinate for host subsequence choice, quotient sequence equality, countable choice, weak compactness as a theorem, completed Cesaro convergence outside the displayed windows, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7116.2 (Banach–Saks NameCert obligations)**.** *For every accepted* $\mathsf{BanachSaks}^{\uparrow}$ *carrier $S = (B, X, W, A, Q, R, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachSaks}^{\uparrow}}$ *surface consists exactly of Banach source exposure through B; bounded sequence exposure through X; weak-compactness handoff through W; finite Cesaro block scheduling through A; norm and* $\mathsf{Real}^{\uparrow}$ *readback through Q;* $\mathsf{RegSeqRat}^{\uparrow}$ *routing through R; transport through T and H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7116.1. The rows $B, X, W, A, Q, R, T, H, C, P, N$ are exactly the Banach source, bounded source, weak-compactness handoff, Cesaro schedule, readback, route, transport, replay, provenance, and naming coordinates.

The analytic content is split between the source rows and the schedule rows. The rows B, X, W expose the Banach, boundedness, and weak-compactness data, while A, Q, R expose only finite Cesaro averages and finite real readback.

Finally T, H, C, P, N preserve and name the same rows. Since no coordinate names a host subsequence selector, quotient sequence equality, countable-choice object, independent weak-compactness theorem, or ambient completeness principle, the displayed rows exhaust the local NameCert surface. □

Theorem 7116.3 (Banach–Saks Cesaro subsequence route)**.** *Every Cesaro-subsequence consumer of an accepted* $\mathsf{BanachSaks}^{\uparrow}$ *packet must read the route*

$$B, X, W, A, Q, R, T, H, C, P, N$$

in that order: the $\mathsf{Banach}^{\uparrow}$ *source row and bounded sequence row precede the* $\mathsf{WeakCompactness}^{\uparrow}$ *handoff, the handoff precedes the displayed Cesaro block schedule, and the schedule precedes normed* $\mathsf{Real}^{\uparrow}$ *readback and* $\mathsf{RegSeqRat}^{\uparrow}$ *routing. The route exports no host subsequence choice, quotient sequence equality, countable choice, weak-compactness theorem, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the source rows. The Banach carrier B and bounded sequence row X are the only sequence-source coordinates available to the packet.

Next read the weak-compactness handoff W and the finite schedule A. The handoff names the obligation surface, while A records only displayed block indices and averaging windows.

The readback rows Q and R then expose norm observations as finite real and regular-rational windows. Transport, replay, provenance, and local naming through T, H, C, P, N preserve the same route. Therefore the accepted packet supplies a finite Cesaro-subsequence route and none of the refused host principles. □

Falsifiable prediction: Every accepted $\mathsf{BanachSaks}^{\uparrow}$ consumer reaches Cesaro-subsequence data only through the displayed Banach source, bounded sequence source, weak-compactness handoff,

Cesaro block schedule, norm and Real readback, RegSeqRat route, transport, replay, provenance, and local NameCert rows.

Independence witness: banach, weakcompactness, boundedrealsequence, regseqrat, real: none is bijective with $\mathsf{BanachSaks}^{\uparrow}$ because this packet alone binds a bounded Banach sequence to a weak-compactness handoff and a finite Cesaro block schedule before the normed Real readback route is exposed.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachSaks}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachSaks}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7116.1, Definition 7116.2, and Definition 7116.3 seed the finite Cesaro-subsequence NameCert route over $\mathsf{Banach}^{\uparrow}$, $\mathsf{WeakCompactness}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachSaks}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host subsequence choice, quotient sequence equality, countable choice, weak compactness as a theorem, selected Cesaro limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source exactness, weak-compactness handoff, Cesaro schedule exactness, norm and Real readback, RegSeqRat routing, transport, replay, provenance, and local naming for BEDC.Derived.BanachSaksUp.

Constructive story: A $\mathsf{BanachSaks}^{\uparrow}$ packet is generated from a Banach source row, bounded sequence source, weak-compactness handoff, finite Cesaro block schedule, normed Real readback, RegSeqRat route, transport rows, displayed replay, provenance, and local naming.

Chapter 7117

A Concrete Naming Certificate for $\mathsf{CauchyNullModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyNullModulus}^{\uparrow}$ packet records the explicit modulus route by which a displayed regular-Cauchy difference is shown to be a null sequence before a $\mathsf{Real}^{\uparrow}$ equality seal is read. It sits between the zero-convergence classifier of chapter 380, the equality-facing difference route of chapter 1758, the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, the regular rational source of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies the explicit threshold row consumed by Real and Completion readers; it is not a quotient of streams, a selected limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7117.1 (Cauchy null-modulus carrier)**.** *A* $\mathsf{CauchyNullModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, T, W, B, Z, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{RegSeqRat}^{\uparrow}$ *difference row whose inspected observations are the rational difference stream being tested for zero convergence.*
2. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request row, including the positive dyadic budget requested by a downstream equality or completion-facing consumer.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window in which the difference row is inspected for the requested tolerance.*
4. *B is the explicit* $\mathsf{ZeroTailModulus}^{\uparrow}$ *threshold row, binding each tolerance request in T to a finite tail index and the corresponding window in W.*
5. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *row that consumes D, T, W, B as the displayed zero-tail witness.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *equality seal, readable only after Z has consumed the explicit threshold row.*
7. *H records componentwise* hsame *transport for difference rows, tolerance requests, windows, thresholds, null-sequence rows, equality seals, replay rows, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the consumer request to the tolerance row, from the tolerance row to the threshold and window rows, from those rows to the null-sequence classifier, and from the classifier to the equality seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyNullModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ZeroTailModulus}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNullModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, T, W, B, Z, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7117.2 (Cauchy null-modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNullModulus}^{\uparrow}$ *carrier $M = (D, T, W, B, Z, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyNullModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed difference, tolerance, window, threshold, NullSequence, Real seal, transport, replay, provenance, and naming rows; threshold exactness from each tolerance request in T to the finite row B; window compatibility between B and W; NullSequence consumption of D, T, W, B through Z; and Real-seal nonescape through E.*

Proof. Carrier admission is projection from Definition 7117.1. The accepted packet displays exactly the difference row, tolerance request, finite window, explicit threshold, null-sequence consumer, Real equality seal, transport, replay, provenance, and local naming rows.

Threshold exactness is the next obligation. The row T supplies the requested dyadic tolerance, while B is the only coordinate that can answer that request with a finite tail index. The window row W is then the finite observation surface attached to that threshold, so the route from tolerance to inspection is visible before zero-convergence is consumed.

Now apply the null-sequence row. The row Z receives the difference row D only together with the tolerance, window, and threshold rows T, W, B, and therefore records explicit zero-tail evidence rather than a host limit.

Finally inspect the carrier inventory. Since quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking are absent from M, none becomes a local NameCert obligation. □

Theorem 7117.3 (Cauchy null-modulus Real equality route)**.** *Let $M = (D, T, W, B, Z, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyNullModulus}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *equality read that uses the displayed regular-Cauchy difference must first expose the finite route*

$$D, T \longrightarrow B, W \longrightarrow Z \longrightarrow E$$

as replayed by H, C, P, N. The equality seal is therefore reached through an explicit null-modulus threshold and not through quotient stream equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the equality-facing consumer to the rows of M. The consumer tolerance is visible as the dyadic row T, and the difference stream under test is visible as the regular rational difference row D.

The explicit modulus route then supplies the threshold row B and finite window row W. These rows bind the requested tolerance to a displayed tail index and to the inspected finite stream window.

Only after that route is exposed can Z certify the displayed difference as a null sequence. The transport, replay, provenance, and local naming rows H, C, P, N preserve the same finite route when the terminal seal E is read.

The refused alternatives are absent from the carrier. Thus the $\mathsf{Real}^{\uparrow}$ equality seal is a consumer of the explicit null-modulus route, not a quotient equality, selected limit, trichotomy branch, countable-choice schedule, or ambient completeness theorem. □

Theorem 7117.4 (Cauchy null-modulus tail-budget scope)**.** *Every tail-budget read from an accepted* $\mathsf{CauchyNullModulus}^{\uparrow}$ *packet remains inside the rows*

$$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{ZeroTailModulus}^{\uparrow}, \mathsf{NullSequence}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The read may replay displayed difference observations, dyadic tolerances, finite windows, explicit thresholds, null-sequence consumption, Real equality seals, transport, provenance, and local naming, but it cannot import a quotient stream, a host limit, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a bridge certificate.*

Proof. Begin with the carrier inventory of Definition 7117.1. The only analytic source row is the displayed $\mathsf{RegSeqRat}^{\uparrow}$ difference row D, and the only tolerance source is the $\mathsf{DyadicRatCore}^{\uparrow}$ row T.

The tail budget is then exhausted by B and W. The row B gives the explicit threshold for the tolerance request, while W names the finite window in which the tail observation is inspected.

The downstream rows Z and E consume this evidence without adding a new source of analytic data. Transport, replay, provenance, and local naming rows preserve the same finite package.

Because no quotient stream, host limit, selected representative, countable-choice schedule, trichotomy row, ambient completeness theorem, or bridge certificate is present, every tail-budget read remains inside the stated scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNullModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNullModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7117.1, Definition 7117.2, Definition 7117.3, and Definition 7117.4 seed the explicit threshold route from a regular-Cauchy difference row through DyadicRatCore tolerance requests, StreamName windows, a ZeroTailModulus threshold, NullSequence consumption, and a terminal Real equality seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNullModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold exactness, window compatibility, NullSequence consumption, Real-seal nonescape, tail-budget scope, and TasteGate field faithfulness for BEDC.Derived.CauchyNullModulusUp.

Constructive story: A $\mathsf{CauchyNullModulus}^{\uparrow}$ packet is generated from one RegSeqRat difference row, one DyadicRatCore tolerance request row, one StreamName finite window, one explicit ZeroTailModulus threshold row, one NullSequence row, one Real equality seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7118

A Concrete Naming Certificate for $\mathsf{DyadicCauchyStream}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicCauchyStream}^{\uparrow}$ packet records a dyadic-valued Cauchy stream as finite $\mathsf{StreamName}^{\uparrow}$ observations with an explicit dyadic Cauchy modulus. It sits between the dyadic arithmetic core of chapter 291, the finite stream observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite Cauchy-stream handoff for the L10 Real and Completion spine; it does not quotient streams, select a limit, invoke countable choice, use trichotomy, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7118.1 (Dyadic Cauchy stream carrier)**.** *A* $\mathsf{DyadicCauchyStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, M, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the finite observation schedule for the stream.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic observation row recording the inspected values, arithmetic comparisons, and tolerance entries.*
3. *M is the dyadic Cauchy modulus row assigning each requested dyadic tolerance a displayed tail window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream observations, dyadic arithmetic rows, and modulus windows.*
5. *H records componentwise* hsame *transport for S, D, M, R and for the replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the route*

$$S, D, M \longmapsto R.$$

7. *P is the* Pkg *provenance over* $\mathsf{DyadicCauchyStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyStream}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed rows S, D, M, R, H, C, P, N. It has no coordinate for quotient stream equality, a selected limit, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7118.2 (Dyadic Cauchy stream NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyStream}^{\uparrow}$ *carrier*

$$K = (S, D, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCauchyStream}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, dyadic Cauchy modulus row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; classifier stability under those same displayed rows; exactness of every requested dyadic tail window through M and D; and ledger nonescape for quotient streams, selected limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7118.1. The projection exposes the stream schedule, dyadic observation row, Cauchy modulus row, regular rational readback, and structural rows as finite coordinates.

Classifier stability is componentwise on those displayed rows. Exactness is read by pairing a requested tolerance in M with the dyadic comparisons recorded in D and the finite observation window named by S.

The transport, replay, provenance, and naming rows preserve the same route. Since none of the excluded coordinates occurs in the carrier, the local NameCert obligations are precisely the displayed rows and their finite ledger checks. □

Theorem 7118.3 (Dyadic Cauchy stream regularity stability)**.** *Let $K = (S, D, M, R, H, C, P, N)$ be an accepted* $\mathsf{DyadicCauchyStream}^{\uparrow}$ *carrier. Any finite dyadic Cauchy modulus window displayed by M and checked against D transports through the componentwise* hsame *rows in H and replays through the displayed* Cont *row C as the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback window R. The transported window remains a finite dyadic observation route and does not become a quotient stream or selected limit.*

Proof. Read the modulus window from M together with the dyadic comparisons in D. The source of every inspected value is the finite schedule S, so the window is already a finite observation route.

The row H moves S, D, M, R componentwise. Thus the tolerance request, dyadic comparisons, and readback row keep the same roles after transport.

The continuation row C replays only the displayed route from stream observations and dyadic windows to regular rational readback. Therefore the replayed object is still the same finite $\mathsf{RegSeqRat}^{\uparrow}$ window, not a quotient stream, selected limit, or ambient completeness witness. □

Theorem 7118.4 (Dyadic Cauchy stream Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer admitted by an accepted* $\mathsf{DyadicCauchyStream}^{\uparrow}$ *packet receives only the displayed* $\mathsf{StreamName}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and terminal seal rows named by H, C, P, N. No consumer receives a quotient stream, selected limit, countable-choice schedule, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle from this packet.*

Proof. Apply Definition 7118.2. A Real-facing consumer can inspect the source schedule, dyadic observation row, modulus row, regular rational readback, transport, replay, provenance, and local naming rows, and no other coordinate.

The handoff to the Real boundary is therefore mediated by the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows together with the structural seal rows. The packet has no coordinate for quotienting streams or selecting a completed limit.

The excluded operations also cannot be produced by transport or replay: H is componentwise, and C replays only the displayed finite route. Hence the handoff is exactly the finite Real-and-Completion surface stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyStream}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyStream}^{\uparrow}$ packet is generated from a StreamName source row, DyadicRatCore observation rows, an explicit dyadic Cauchy modulus, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7118.1, Definition 7118.2, Definition 7118.3, and Definition 7118.4 seed the finite Cauchy-stream bridge through dyadic observations, stream windows, regular rational readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchyStream}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic modulus exactness, regularity stability, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicCauchyStreamUp.

Chapter 7119

A Concrete Naming Certificate for $\mathsf{TailWindowFilter}^{\uparrow}$

Following Bishop's filter language and the Real completeness route of chapter 9238, the $\mathsf{TailWindowFilter}^{\uparrow}$ packet records cofinal finite tail windows for completion-facing Cauchy data. It sits over the finite stream observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only a finite tail-filter carrier; it does not quotient filters, choose a limiting representative, invoke countable choice, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7119.1 (Tail-window filter carrier)**.** *A* $\mathsf{TailWindowFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite tail-index row naming the inspected lower bounds for the filter.*
2. *W is the cofinal finite-window row assigning each requested tail bound a displayed window beyond it.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the requested bounds and window estimates.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row consumed after the tail window has been displayed.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the observation schedule for the window.*
6. *H records componentwise* hsame *transport for T, W, D, R, S and for the replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*
$$T, W, D, S \longmapsto R.$$
8. *P is the* Pkg *provenance over* $\mathsf{TailWindowFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TailWindowFilter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by $T, W, D, R, S, H, C, P, N$. It has no coordinate for a completed filter quotient, selected limit, countable-choice schedule, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7119.2 (Tail-window filter NameCert obligations)**.** *For every accepted* $\mathsf{TailWindowFilter}^{\uparrow}$ *carrier*

$$F = (T, W, D, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TailWindowFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite tail-index row, cofinal finite-window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{StreamName}^{\uparrow}$ *source row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; classifier stability under those same rows; cofinality exactness for* W *over* T*; Real-completion handoff through* S, D, R*; and ledger nonescape for completed filter quotients, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7119.1. The finite tail-index, cofinal window, dyadic tolerance, regular rational readback, stream source, and structural rows are all displayed coordinates.

Classifier stability is componentwise on those coordinates. Cofinality exactness is read from W: each tail request named in T receives a displayed finite window beyond the request, with the dyadic ledger D recording the relevant comparison.

The handoff rows S, D, R, H, C, P, N preserve and replay the same finite route. Since no completed filter quotient, selected limit, choice schedule, or ambient completeness row occurs in the carrier, the NameCert surface has exactly the listed obligations. □

Theorem 7119.3 (Tail-window filter cofinality)**.** *Let* $F = (T, W, D, R, S, H, C, P, N)$ *be an accepted* $\mathsf{TailWindowFilter}^{\uparrow}$ *carrier. For every tail request displayed in* T*, the row* W *supplies a finite window beyond that request, and the dyadic ledger* D *records the comparison that makes the window cofinal. This cofinality is stable under the componentwise* hsame *transport row* H *and replay through the displayed* Cont *row* C*.*

Proof. Read a tail request from T. The cofinality row W is part of the carrier, so it supplies the finite window assigned to that request before any regular rational readback is opened.

The comparison that the window lies beyond the request is recorded in D. The stream source S names the finite observations used by that comparison, and R is read only after those rows have been displayed.

Transport through H moves the request, window, dyadic comparison, stream row, and readback row componentwise. Replay through C follows the same displayed route, so cofinality remains a finite tail-window property. □

Theorem 7119.4 (Tail-window filter Real completion handoff)**.** *Every Real-completion consumer admitted by an accepted* $\mathsf{TailWindowFilter}^{\uparrow}$ *packet receives only the displayed finite tail row* T*, cofinal window row* W*,* $\mathsf{StreamName}^{\uparrow}$ *source row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and seal rows* H, C, P, N*. It receives no completed filter quotient, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 7119.2. A completion-facing consumer can inspect exactly the carrier rows listed there, and those rows expose a finite tail request, a cofinal finite window, a stream schedule, a dyadic comparison ledger, and regular rational readback.

The transport and replay rows do not add analytic content. They preserve the same displayed route from tail request and window through stream and dyadic data to the regular rational readback.

Thus the Real-completion handoff is the finite row package $T, W, S, R, D, H, C, P, N$. The carrier inventory excludes completed filter quotients, selected limits, countable choice, and ambient real completeness, so none of them is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{TailWindowFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{TailWindowFilter}^{\uparrow}$ packet is generated from a finite tail-index row, a cofinal finite-window row, a DyadicRatCore tolerance row, RegSeqRat readback, a StreamName source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TailWindowFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7119.1, Definition 7119.2, Definition 7119.3, and Definition 7119.4 seed the finite cofinal tail-window route for Real completeness through StreamName, RegSeqRat, DyadicRatCore, and Real sealing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TailWindowFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed filter quotients, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, cofinality exactness, Real-completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.TailWindowFilterUp.

Chapter 7120

A Concrete Naming Certificate for $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$ packet records the finite-window theorem surface by which two regular Cauchy rational names are read as the same real only after a displayed modulus window has compared their rational tails. It sits after the dyadic arithmetic core of chapter 291, the stream-name interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite L10 uniqueness route for Real and Completion consumers; it is not quotient stream equality, a selected canonical representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7120.1 (Regular Cauchy uniqueness-window carrier)**.** *A* $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, S, R, W, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row, exposing dyadic addition, subtraction, absolute-value, and comparison data used inside the finite window.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, recording the two inspected rational streams and the finite indices requested by the consumer.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, exposing the displayed Cauchy moduli and rational readbacks for the two names.*
4. *W is the uniqueness-window row, listing the finite tail bound, the two tail indices, and the dyadic tolerance at which the names are compared.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording only the terminal real-name read permitted after the displayed comparison has passed through D, S, R, W.*
6. *H records componentwise* hsame *transport for D, S, R, W, E, C, P, N.*
7. *C records displayed* Cont *replay from a Real or Completion uniqueness request through*

$$D, S, R \longmapsto W \longmapsto E, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, R, W, E, H, C, P, N$. It has no coordinate for quotient streams, hidden representatives, unrestricted equality of host reals, countable choice, or ambient completeness.

Theorem 7120.2 (Regular Cauchy uniqueness-window NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$ *carrier $U = (D, S, R, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniquenessW}}$ *surface consists exactly of dyadic arithmetic admission through D, stream-name exposure through S, regular rational readback through R, uniqueness-window comparison through W, terminal real-name sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows $D, S, R, W, E, H, C, P, N$ are the entire inventory exposed to a Real or Completion consumer.

The arithmetic, stream, and regularity data are read before any equality-facing conclusion is available. The row D supplies the dyadic comparisons, S supplies the inspected stream windows, and R supplies the regular Cauchy moduli.

The uniqueness step is finite. The window row W records the tail indices and tolerance that allow the two regular names to be compared at the requested precision, and the real-name seal E is reached only after that row is displayed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of these rows contains quotient stream equality, a hidden canonical representative, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7120.3 (Regular Cauchy uniqueness-window route)**.** *Every Real or Completion consumer that reads an accepted* $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$ *packet must factor its uniqueness request through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto W \longmapsto \mathsf{Real}^{\uparrow}, H, C, P, N.$$

The consumer receives dyadic arithmetic, two finite stream windows, regular Cauchy readback, a displayed uniqueness window, a terminal real-name seal, componentwise transport, replay, provenance, and local naming. It receives no quotient stream equality, no selected representative, no countable-choice branch, and no ambient completeness principle.

Proof. Begin with a uniqueness-facing read of two regular Cauchy names. The source streams are visible only through S, and their rational arithmetic is visible only through D.

Use the regularity row R to obtain the displayed tail moduli. The packet then exposes W, which stores the finite tolerance and the two tail indices used by the comparison.

After this finite comparison, the route may pass to the real-name seal E. Transport, replay, provenance, and local naming preserve the same route through H, C, P, N.
