Thus the exported uniqueness read is exactly the finite window named in the statement. Any read requiring quotient streams, selected representatives, countable choice, or ambient completeness would require a carrier coordinate that U does not contain. □

Falsifiable prediction: Every public $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$ uniqueness read factors through dyadic arithmetic, two finite stream windows, regular rational readback, a displayed tail-comparison window, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming. A public read that exports quotient stream equality,

a selected representative, countable choice, or ambient completeness from this packet refutes the carrier boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic arithmetic, two inspected stream windows, regular Cauchy moduli, a uniqueness-window comparison, real-name sealing, transport, replay, provenance, and local naming while refusing quotient equality, selected representatives, choice, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7120.1, Definition 7120.2, and Definition 7120.3 seed the finite uniqueness-window theorem surface over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected canonical representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic arithmetic admission, stream-window exposure, regular Cauchy readback, tail-comparison exactness, real-name sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyUniquenessWindowUp.

Constructive story: A $\mathsf{RegularCauchyUniquenessWindow}^{\uparrow}$ packet is generated from dyadic arithmetic rows, two stream-name windows, regular rational readbacks, a uniqueness-window comparison row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7121

A Concrete Naming Certificate for HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$

The HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$ packet realizes the Poincare disk geodesic-midpoint reading of chapter 9463 as finite phase, metric, boundary-transport, and midpoint rows. It sits after the disk metric of chapter 6209, the hyperbolic metric row of chapter 3474, the boundary-transport surface of chapter 6267, and the geodesic-flow packet of chapter 3856. The packet names a finite midpoint certificate for phase transport along one displayed geodesic chord; it does not select a completed geodesic space, identify physical observer motion, or export a host Riemannian midpoint theorem.

Definition 7121.1 (Hyperbolic phase geodesic-midpoint carrier)**.** *A* HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, M, B, F, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the Poincare disk row, storing the two displayed interior endpoints and the inspected disk coordinate window.*
2. *M is the hyperbolic metric row, exposing only the finite metric comparisons used to certify the midpoint read.*
3. *B is the Poincare disk boundary-transport row, recording the boundary endpoints that determine the displayed chord without selecting an ideal-boundary representative outside the packet.*
4. *F is the hyperbolic geodesic-flow row, storing the finite chord parameter window and the reversible transport read along that row.*
5. *Q is the midpoint row, recording the displayed midpoint candidate, the two equal-distance checks, and the dyadic tolerance used by the comparison.*
6. *T is the phase-transport row, preserving the phase label attached to the chord before and after the midpoint read.*
7. *H records componentwise* hsame *transport for $D, M, B, F, Q, T, C, P, N$.*
8. *C records displayed* Cont *replay from a geodesic-midpoint request through*

$$D, M, B, F \longmapsto Q, T, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseGeodesicMidpoint}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseGeodesicMidpoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, B, F, Q, T, H, C, P, N$. It has no coordinate for completed hyperbolic geometry, selected boundary representatives, global geodesic existence, physical observer trajectories, or host midpoint uniqueness.

Theorem 7121.2 (Hyperbolic phase geodesic-midpoint NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseGeodesicMidpoint}^{\uparrow}$ *carrier $G = (D, M, B, F, Q, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhas}}$ *surface consists exactly of disk-coordinate admission through D, hyperbolic metric readback through M, boundary-transport exposure through B, geodesic-flow windowing through F, midpoint comparison through Q, phase-transport preservation through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows $D, M, B, F, Q, T, H, C, P, N$ are the entire public inventory of the packet.

The disk and metric rows are read before any midpoint claim is visible. The rows D and M expose only displayed disk coordinates and finite hyperbolic metric comparisons.

The boundary and geodesic data are then routed through B and F. These rows determine the inspected chord and its finite transport window without selecting an ideal-boundary representative outside the packet.

The midpoint row Q stores the candidate and the two equal-distance checks, while T preserves the phase label attached to the chord. The rows H, C, P, N transport, replay, source, and name that same finite route.

Since none of the carrier rows contains completed hyperbolic geometry, global geodesic existence, physical observer motion, or host midpoint uniqueness, the displayed rows exhaust the local NameCert obligations. □

Theorem 7121.3 (Hyperbolic phase geodesic-midpoint route)**.** *Every phase-geodesic consumer that reads an accepted* $\mathsf{HyperbolicPhaseGeodesicMidpoint}^{\uparrow}$ *packet must factor its midpoint request through*

$$\mathsf{PoincareDiskMetric}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{PoincareDiskBoundaryTransport}^{\uparrow},\ \mathsf{HyperbolicGeodesicFlow}^{\uparrow} \longmapsto Q, T, H, C,$$

The consumer receives displayed disk coordinates, finite hyperbolic metric comparisons, boundary transport, a geodesic-flow window, midpoint checks, phase transport, componentwise transport, replay, provenance, and local naming. It receives no completed geodesic space, no selected boundary representative, no physical observer trajectory, and no host midpoint theorem.

Proof. Begin with a phase-geodesic midpoint request. The disk row D and metric row M provide the only coordinate and distance reads available to the request.

Use the boundary and flow rows B, F to expose the displayed chord. This determines the finite transport window but not a completed geodesic space or a selected ideal-boundary object.

Read the midpoint and phase rows Q, T. The candidate midpoint is accepted only through the recorded equal-distance checks, and the phase label is preserved through the same finite chord route.

Finally H, C, P, N transport, replay, source, and name the route. Thus the exported midpoint surface is the finite packet named in the statement, with no additional host geometry or physical-observer content. □

Falsifiable prediction: Every accepted HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$ midpoint read factors through displayed Poincare disk coordinates, hyperbolic metric comparisons, boundary transport, a geodesic-flow window, a midpoint row, phase transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming. A public read that exports a midpoint without one of those rows refutes the carrier boundary.

Independence witness: hyperbolic-metric, poincare-disk-boundary-transport, hyperbolic-geodesic-flow, real, metric: HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk coordinates, metric readback, boundary transport, geodesic-flow windowing, midpoint equal-distance checks, phase transport, replay, provenance, and local naming.

The Lean TasteGate surface for this packet must provide explicit Nontrivial HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$ and FieldFaithful HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$ instances before a checked carrier-alignment theorem can witness the public route.

Closure status for NameCert$_{\text{HyperbolicPhaseGeodesicMidpoint}^{\uparrow}}$.

Constructive story: A HyperbolicPhaseGeodesicMidpoint$^{\uparrow}$ packet is generated from Poincare disk coordinates, hyperbolic metric comparisons, boundary transport, geodesic-flow windows, midpoint equal-distance checks, phase transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicPhaseGeodesicMidpoint}^{\uparrow}}$, seed)

Scope closed: Definition 7121.1, Definition 7121.2, and Definition 7121.3 seed the finite phase-geodesic midpoint packet over disk, metric, boundary-transport, geodesic-flow, midpoint, phase, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicPhaseGeodesicMidpoint}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic geometry, selected ideal-boundary representatives, global geodesic existence, physical observer motion, host midpoint uniqueness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk admission, metric readback, boundary-transport exposure, geodesic-flow windowing, midpoint exactness, phase preservation, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseGeodesicMidpointUp.

Chapter 7122

A Concrete Naming Certificate for $\mathsf{BishopModulusCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopModulusCompletion}^{\uparrow}$ packet records the finite BEDC surface by which a modulus-controlled regular sequence enters the constructive completion route and reaches the terminal real-name seal. It sits after the finite observation schedule of chapter 126, the regular rational source of chapter 301, the dyadic tolerance ledger of chapter 291, the completion admission criterion of chapter 1476, and the terminal Real packet of chapter 38. The packet names a modulus-governed handoff as finite NameCert data; it does not select a quotient limit, compare host real equality, invoke countable choice, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7122.1 (Bishop modulus completion carrier)**.** *A* $\mathsf{BishopModulusCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, M, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window ledger naming the observations inspected by the completion request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational values are read only through the displayed stream windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same requests, carrying the dyadic scales used by the modulus schedule.*
4. *M is the modulus schedule row, assigning each requested tolerance to a displayed tail bound over S, R, D.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, exposed only after the schedule has met the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *admission surface.*
6. *H records componentwise* hsame *transport for the window, source, tolerance, modulus, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a dyadic tolerance request through the same rows.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopModulusCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopModulusCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, R, D, M, L, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, arbitrary Cauchy completion, or ambient completeness of the Real carrier.

Theorem 7122.2 (Bishop modulus completion NameCert obligations)**.** *For every accepted* BishopModulusCompleti *carrier $K = (S, R, D, M, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopModulusCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the StreamName windows, RegSeqRat source, DyadicRatCore tolerances, modulus schedule, Real seal handoff, classifier transport, displayed replay, provenance, and local naming; modulus coverage requiring every tolerance request to read M after S, R, D; regular-tail compatibility requiring the scheduled tail to preserve the same RegSeqRat readback; Real seal handoff through the completion criterion; componentwise transport and replay through H, C; provenance through P; and nonescape excluding quotient limits, host real equality, countable choice, arbitrary completion, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7122.1. The rows $S, R, D, M, L, H, C, P, N$ are exactly the visible StreamName, RegSeqRat, DyadicRatCore, modulus, Real seal, transport, replay, provenance, and naming coordinates.

The modulus coverage is read from M only after the window, source, and tolerance rows are displayed. Thus each tolerance request is tied to the same $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ source, and $\mathsf{DyadicRatCore}^{\uparrow}$ scale.

The regular-tail compatibility and Real seal handoff are local to the displayed route. The scheduled tail preserves the source readback, and the seal L is exposed only through the $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ admission surface.

Finally H, C, P, N transport, replay, package, and name the same finite rows. Since the carrier has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, arbitrary completion, or ambient completeness, the listed obligations exhaust the NameCert surface. □

Theorem 7122.3 (Bishop modulus completion Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopModulusCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyCompletionCriterion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The modulus row M binds the displayed windows, regular rational source, and dyadic tolerances before the Real seal L can be read.

Proof. Start with an accepted carrier $K = (S, R, D, M, L, H, C, P, N)$. The consumer first reads the displayed window row S, the regular rational source row R, and the dyadic tolerance row D.

Next the modulus row M supplies the tail bound for the requested tolerance over those same rows. This prevents the read from replacing the displayed regular source by a host sequence or by a quotient representative.

The seal row L is downstream of the criterion-facing admission surface, and H, C, P, N preserve the same finite data during transport, replay, provenance, and naming. Therefore the Real-facing consumer receives only the displayed modulus-controlled completion handoff. □

Falsifiable prediction: Every accepted $\mathsf{BishopModulusCompletion}^{\uparrow}$ consumer reaches the Real seal only through displayed StreamName windows, a RegSeqRat source, DyadicRatCore tolerances, a modulus schedule, completion-criterion admission, componentwise transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, regseqrat, dyadicratcore, cauchycompletioncriterion, real: none is bijective with $\mathsf{BishopModulusCompletion}^{\uparrow}$ because this packet alone binds finite windows, regular rational source data, dyadic tolerances, and a modulus schedule before exposing the Real seal handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopModulusCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopModulusCompletion}^{\uparrow}$ packet is generated from StreamName windows, a RegSeqRat source, DyadicRatCore tolerance rows, a modulus schedule, RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopModulusCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7122.1, Definition 7122.2, and Definition 7122.3 seed the modulus-controlled completion handoff over StreamName, RegSeqRat, DyadicRatCore, CauchyCompletionCriterion, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopModulusCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, countable choice, arbitrary completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus coverage, regular-tail compatibility, Real seal handoff, classifier transport, replay, provenance, and nonescape for BEDC.Derived.BishopModulusCompletionUp.

Chapter 7123

A Concrete Naming Certificate for BishopDyadicLocatedReal$^{\uparrow}$

Following Bishop and Bridges constructive analysis, located real data are read through explicit rational approximations, apartness tests, and finite tolerance responses rather than through quotient reals, selected limits, countable choice, or an ambient completeness theorem. The BishopDyadicLocatedReal$^{\uparrow}$ packet records the dyadic located-real route as finite NameCert data over the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the rational interval locator of chapter 4202, the locatedness surface of **??**, the terminal seal of chapter 38, and the threshold selector of chapter 6642.

Definition 7123.1 (Bishop dyadic located-real carrier)**.** *A* BishopDyadicLocatedReal$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, Q, I, L, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row naming the positive dyadic radius and comparison budget requested by the located read;*
2. *W is the* StreamName$^{\uparrow}$ *finite-window row opened for that tolerance;*
3. *Q is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed windows;*
4. *I is the* RationalIntervalLocator$^{\uparrow}$ *row exposing lower and upper rational brackets for the same dyadic request;*
5. *L is the* LocatedReal$^{\uparrow}$ *row deciding the displayed overlap or separation test between the readback and the rational interval at the named tolerance;*
6. *E is the* Real$^{\uparrow}$ *seal row exposed only after D, W, Q, I, L have been displayed;*
7. *H records componentwise* hsame *transport for the dyadic tolerance, stream-window, readback, interval-locator, locatedness, Real seal, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay from dyadic tolerance through finite windows, regular rational readback, rational interval location, locatedness, Real seal, and the structural rows;*
9. *P is the* Pkg *provenance over* BishopDyadicLocatedReal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RationalIntervalLocator$^{\uparrow}$, LocatedReal$^{\uparrow}$, Real$^{\uparrow}$, LocatedCauchyModulusSelector$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedReal}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for quotient real equality, a selected host limit, countable choice, an unlocated Cauchy witness, an ambient completeness theorem, or a Real seal read that bypasses the dyadic locatedness data.

Theorem 7123.2 (Bishop dyadic located-real NameCert obligations)**.** *For every accepted* BishopDyadicLocatedReal *carrier*

$$B = (D, W, Q, I, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance, finite stream-window, regular rational readback, rational interval locator, locatedness, Real seal, transport, replay, provenance, and local naming rows; dyadic tolerance exactness; window and readback compatibility; rational bracket exposure; locatedness exactness at the displayed tolerance; Real-seal nonescape; componentwise* hsame *transport; displayed* Cont *replay;* Pkg *provenance; and local naming for the same finite packet.*

Proof. Carrier admission is projection from Definition 7123.1. The accepted packet exposes exactly the rows $D, W, Q, I, L, E, H, C, P, N$.

The analytic route is finite. The dyadic tolerance row D opens the stream window W, the readback row Q records the regular rational data read from that window, and the locator row I supplies the rational bracket for the same request.

Locatedness is then local to the displayed tolerance. The row L decides the overlap or separation test after D, W, Q, I are visible, and the Real seal E is downstream of that locatedness row.

Finally H, C, P, N transport, replay, source, and name the same data. Since the carrier contains no quotient equality, selected host limit, choice schedule, unlocated witness, ambient completion theorem, or bypass seal coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 7123.3 (Bishop dyadic located-real Real handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{BishopDyadicLocatedReal}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RationalIntervalLocator}^{\uparrow} \longmapsto \mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

For a carrier $B = (D, W, Q, I, L, E, H, C, P, N)$, the consumer receives the dyadic tolerance request, finite window, regular rational readback, rational interval locator, locatedness row, Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. It receives no quotient real, selected limit, countable-choice schedule, unlocated Cauchy witness, or ambient completion datum.*

Proof. Start with the NameCert obligations of Definition 7123.2. They force any Real-facing read to stay on the displayed carrier rows.

Read the finite analytic rows in order. The dyadic request D opens W, the regular readback Q is obtained from the window, and the rational interval locator I brackets the same request.

The locatedness row L is then read before the seal. By the carrier definition, E is exposed only after D, W, Q, I, L have been displayed, and the structural rows H, C, P, N preserve that route for downstream consumers.

Thus the Real handoff is a dyadic located-real certificate, not a quotient real construction, a selected host limit, a countable-choice route, an unlocated Cauchy witness, or an ambient completion theorem. □

Falsifiable prediction: Every accepted $\mathsf{BishopDyadicLocatedReal}^{\uparrow}$ Real-facing read exposes one DyadicRatCore tolerance row, one StreamName finite-window row, one RegSeqRat readback row, one RationalIntervalLocator bracket row, one LocatedReal locatedness row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the Real seal is public.

Independence witness: dyadicratcore, streamname, regseqrat, rational-interval-locator, locatedreal, real, located-cauchy-modulus-selector: $\mathsf{BishopDyadicLocatedReal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic tolerance data, finite stream windows, regular rational readback, rational brackets, locatedness at the displayed tolerance, Real seal handoff, transport, replay, provenance, and local naming as one finite located-real certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedReal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopDyadicLocatedReal}^{\uparrow}$ packet is generated from dyadic tolerance requests, finite stream windows, regular rational readback, rational interval locator rows, locatedness rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7123.1, Definition 7123.2, and Definition 7123.3 seed the finite Bishop dyadic located-real route over DyadicRatCore, StreamName, RegSeqRat, RationalIntervalLocator, LocatedReal, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient reals, selected host limits, countable choice, unlocated Cauchy witnesses, ambient completion, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.BishopDyadicLocatedReal

Chapter 7124

A Concrete Naming Certificate for $\mathsf{CauchyBicategory}^{\uparrow}$

Following Lawvere on enriched metric completion and Street on bicategorical completion, the $\mathsf{CauchyBicategory}^{\uparrow}$ packet records the finite BEDC bookkeeping by which Cauchy-completion routes compose without turning into quotient representatives or chosen limits. It sits over the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the metric-completion carrier of chapter 1506. Its role is to name the identity, composition, and 2-cell rows used by L10 completion consumers, not to export a completed object in a host category.

Definition 7124.1 (Cauchy bicategory carrier)**.** *A* $\mathsf{CauchyBicategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, M, I, O, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by every displayed Cauchy comparison.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row serving the inspected prefixes.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion-request row read only after D, S, R are visible.*
5. *I is the identity-route ledger for an object row and its finite Cauchy window.*
6. *O is the composition-route ledger for two composable completion arrows.*
7. *T is the 2-cell ledger comparing two displayed completion routes through the same tolerance, window, and readback rows.*
8. *H records componentwise* hsame *transport for all displayed rows.*
9. *C records displayed* Cont *replay from a completion-composition request through the same rows.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyBicategory}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBicategory}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, M, I, O, T, H, C, P, N$. It has no coordinate for quotient completion equality, selected limit representatives, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host category equivalence, or a global choice of Cauchy representatives.*

Theorem 7124.2 (Cauchy bicategory NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBicategory}^{\uparrow}$ *carrier* $K = (D, S, R, M, I, O, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyBicategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, finite stream windows, regular rational readback, metric-completion request, identity ledger, composition ledger, 2-cell comparison ledger, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7124.1. The rows $D, S, R, M, I, O, T, H, C, P, N$ are exactly the visible identity, composition, and comparison surface.

The completion-facing rows are finite. The dyadic tolerance row D, stream windows S, and regular rational readback R must be displayed before the metric-completion request M can be consumed, so no quotient representative or selected limit is introduced at the entrance.

The identity row I, composition row O, and 2-cell row T are themselves finite BHist routes. They name the identity, composite, and comparison ledgers by replaying the same tolerance-window-readback surface, rather than by appealing to an ambient bicategory of completed objects.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient completion equality, selected limits, host category equivalence, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7124.3 (Cauchy bicategory completion-composition handoff)**.** *Every completion-composition consumer of an accepted* $\mathsf{CauchyBicategory}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow},\ I,\ O,\ T,\ H,\ C,\ P,\ N.$$

The exported handoff is the displayed identity, composition, and 2-cell BHist *ledger. It exports no quotient representative, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, host bicategorical equivalence, or choice-selected Cauchy object.*

Proof. Start with the NameCert obligations of Definition 7124.2. They force every accepted consumer to read the dyadic tolerance, stream-window, regular rational, metric-completion, identity, composition, and 2-cell rows before the structural rows are consulted.

The identity ledger I is tied to the same finite Cauchy window surface as the source object. The composition ledger O is tied to two displayed completion-arrow routes, and the 2-cell ledger T compares only those displayed routes.

The structural rows H, C, P, N preserve that route under componentwise transport, replay, provenance, and local naming. They do not add a host completed category, choose representatives, quotient streams, or import ambient completeness.

Therefore the completion-composition handoff is exactly the finite BHist route shown above. □

Falsifiable prediction: An accepted $\mathsf{CauchyBicategory}^{\uparrow}$ consumer is refuted if it reaches an identity, composition, or 2-cell completion route without displaying the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and $\mathsf{MetricCompletion}^{\uparrow}$ request row.

Independence witness: dyadicratcore, streamname, regseqrat, real, metriccompletion: no listed sibling is bijective to $\mathsf{CauchyBicategory}^{\uparrow}$ because this packet jointly binds identity ledgers, composition ledgers, 2-cell comparison ledgers, tolerance rows, finite windows, regular readback, completion requests, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBicategory}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyBicategory}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a MetricCompletion request, identity ledgers, composition ledgers, 2-cell comparison ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyBicategory}^{\uparrow}}$, seed)

Scope closed: Definition 7124.1, Definition 7124.2, and Definition 7124.3 seed the finite Cauchy-bicategory bookkeeping surface over displayed tolerance, window, readback, completion, identity, composition, 2-cell, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyBicategory}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.CauchyBicategoryUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limit representatives, ambient Real$^{\uparrow}$ completeness, host bicategorical equivalence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, identity-route exactness, composition-route exactness, 2-cell comparison stability, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyBicategoryUp

Chapter 7125

A Concrete Naming Certificate for $\mathsf{CantorNormalForm}^{\uparrow}$

Following Cantor on ordinal normal forms and Bishop–Bridges constructive ordinal scheduling, this packet records finite descending normal-form rows used by Real and Completion proof schedules. It sits beside the dyadic tolerance core of chapter 291, the finite stream-window service of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the Cauchy schedule surfaces of chapter 292, chapter 1968, chapter 2096, and chapter 7122. The packet names a finite descent schedule only; it does not import quotient ordinals, transfinite choice, ordinal comparison as a host primitive, or a completed Real construction.

Definition 7125.1 (Cantor normal form carrier)**.** *A* $\mathsf{CantorNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (E, K, D, W, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the exponent-descent row, listing a finite strictly descending sequence of ordinal-style exponent tags used only as schedule indices.*
2. *K is the finite coefficient-window row, attaching a positive finite coefficient budget to each exponent tag.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row consumed by Real and Completion estimates at each displayed descent stage.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing the finite stream observations opened by the same descent and coefficient windows.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to D and W.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular-rational readback has been displayed.*
7. *S is the schedule handoff row for* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RealCauchyModulusRefinement}^{\uparrow}$, *and* $\mathsf{BishopModulusCompletio}$ *consumers.*
8. *H records componentwise* hsame *transport for descent, coefficient, dyadic-budget, stream-window, regular-readback, real-seal, schedule, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay for Real-facing and Completion-facing schedule consumers.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorNormalForm}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RealCauchyModulusRefinement}^{\uparrow}$, $\mathsf{BishopModulusCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, K, D, W, Q, R, S, H, C, P, N$. It contains no coordinate for quotient ordinal equality, infinite ordinal induction, selected limit ordinals, trichotomy over all ordinals, or a host completion operator.

Theorem 7125.2 (Cantor normal form obligation surface)**.** *For every accepted* $\mathsf{CantorNormalForm}^{\uparrow}$ *carrier*

$$O = (E, K, D, W, Q, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorNormalForm}^{\uparrow}}$ *surface consists exactly of exponent-descent exposure through E, coefficient-window exposure through K, dyadic tolerance exposure through D, stream-window exposure through W, regular rational readback through Q, terminal Real sealing through R, schedule handoff through S, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 7125.1. The rows $E, K, D, W, Q, R, S, H, C, P, N$ are exactly the displayed schedule inventory.

Read the descent rows first. The exponent tags in E and coefficient windows in K are finite schedule data, so each later budget request is attached to a named position in the normal-form row.

Next read the analytic rows. The dyadic tolerance ledger D and stream windows W feed the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and only then can the terminal $\mathsf{Real}^{\uparrow}$ seal R be consumed by a Real or Completion schedule.

Finally use S, H, C, P, N to transport, replay, source, and name the same packet. Since the carrier has no quotient ordinal, infinite induction, selected-limit, trichotomy, or host-completion coordinate, the listed rows exhaust the obligation surface. □

Theorem 7125.3 (Cantor normal form Real completion route)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{CantorNormalForm}^{\uparrow}$ *packet must factor through the finite route*

$$E, K \longmapsto D, W \longmapsto Q \longmapsto R \longmapsto S, H, C, P, N.$$

The route provides ordinal-style descent as displayed schedule data for Real and Completion proofs; it does not provide quotient ordinal equality, transfinite choice, a selected limit ordinal, or an ambient completion theorem.

Proof. Begin with the finite normal-form prefix. Rows E and K expose the descending exponent tags and coefficient windows before any tolerance or stream request can be opened.

The dyadic and stream rows then determine the analytic read. A consumer reads D and W together, obtains the regular rational readback Q, and reaches the Real seal R only after that readback is visible.

The schedule handoff S is therefore downstream of the finite descent and analytic rows. Its Completion-facing use may cite the Cauchy-modulus siblings named in the provenance row, but only through the same displayed packet.

Transport, replay, provenance, and local naming preserve the route. The exclusions follow from carrier inspection: no coordinate names quotient ordinals, transfinite choice, selected limit ordinals, or host completion. □

Falsifiable prediction: Every accepted $\mathsf{CantorNormalForm}^{\uparrow}$ schedule read displays finite exponent descent, coefficient windows, dyadic tolerance budgets, StreamName windows, RegSeqRat readback, and the Real seal before any Completion-facing handoff is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchymodulus, bishop-modulus-completion: none is bijective to $\mathsf{CantorNormalForm}^{\uparrow}$ because this packet jointly binds finite normal-form descent to dyadic budgets, stream windows, regular readback, Real sealing, schedule handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorNormalForm}^{\uparrow}$ packet is generated from finite exponent-descent rows, coefficient windows, dyadic tolerance budgets, StreamName windows, RegSeqRat readback, Real sealing, schedule handoff rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7125.1, Definition 7125.2, and Definition 7125.3 seed the finite normal-form descent route consumed by Real and Completion schedules.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient ordinal equality, infinite ordinal induction, transfinite choice, selected limit ordinals, host completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, descent and coefficient exposure, dyadic and stream readback exactness, Real seal nonescape, schedule handoff, transport, replay, provenance, and local naming for BEDC.Derived.CantorNormalFormUp.

Chapter 7126

A Concrete Naming Certificate for $\mathsf{DistinctionCertificate}^{\uparrow}$

The $\mathsf{DistinctionCertificate}^{\uparrow}$ packet realizes the distinction-to-NameCert certification layer as a finite boundary object: a candidate distinction is accepted only when source, pattern, classifier, stability, ledger, transport, replay, provenance, and local naming rows are displayed together. It sits beside the primitive mark distinction ledger of chapter 1244, the observer distinction trace of chapter 882, the halting distinction trace of chapter 492, the certified event-flow packet of chapter 7098, and the supply taxonomy of chapter 7078. Those siblings supply concrete distinction sources or audit routes; this packet certifies the boundary at which a distinction becomes a NameCert object.

Definition 7126.1 (DistinctionCertificate carrier)**.** *A* $\mathsf{DistinctionCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, P_0, K, \Sigma, L, H, C, R, N)$$

with the following displayed rows:

1. *S is the source row naming the generated marks, histories, traces, event flows, or supply records whose distinction is being inspected.*
2. *P_0 is the pattern row, recording the finite feature, trace, boundary, or certificate pattern proposed as evidence for the distinction.*
3. *K is the candidate classifier row that compares source records through the displayed pattern.*
4. *Σ is the stability row, recording transport of the classifier under the admitted* hsame *movements.*
5. *L is the ledger row, naming hidden material, refusal cases, and not-claimed readings.*
6. *H records componentwise* hsame *transport for source, pattern, classifier, stability, ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for distinction-certification consumers.*
8. *R is the* Pkg *provenance over* $\mathsf{DistinctionCertificate}^{\uparrow}$, $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$, $\mathsf{ObserverDistinctionTrace}^{\uparrow}$, $\mathsf{HaltingDistinctionTrace}^{\uparrow}$, $\mathsf{CertifiedEventFlow}^{\uparrow}$, $\mathsf{SupplyTaxonomy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DistinctionCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for raw distinction objecthood, uncertified semantic assignment, hidden classifier shift, global explanation, or verifier acceptance detached from the five displayed certificate rows.

Theorem 7126.2 (DistinctionCertificate NameCert boundary)**.** *Every accepted* $\mathsf{DistinctionCertificate}^{\uparrow}$ *packet certifies a candidate distinction as a NameCert boundary only through*

$$S, P_0, K, \Sigma, L, H, C, R, N.$$

The source, pattern, classifier, stability, and ledger rows must all be present before the local naming row can be consumed.

Proof. Project the carrier of Definition 7126.1. Rows S, P_0, K, Σ, L are the five certificate rows, and H, C, R, N only transport, replay, source, and name that same surface.

The candidate classifier row K is not read by itself. It is tied to the source row S and pattern row P_0, then stabilized through Σ and audited through L.

Only after those rows are visible can the local $\mathsf{NameCert}$ row N be consumed. Thus the accepted packet is a certificate boundary, not a raw distinction or a bare classifier. □

Theorem 7126.3 (DistinctionCertificate sibling separation)**.** *The* $\mathsf{DistinctionCertificate}^{\uparrow}$ *packet is not bijective to* $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$*,* $\mathsf{ObserverDistinctionTrace}^{\uparrow}$*,* $\mathsf{HaltingDistinctionTrace}^{\uparrow}$*,* $\mathsf{CertifiedEventFlow}^{\uparrow}$*, or* $\mathsf{SupplyTaxonomy}^{\uparrow}$*. Each listed sibling supplies a distinction source, trace, event-flow, or audit route, while* $\mathsf{DistinctionCertificate}^{\uparrow}$ *additionally binds the candidate classifier to the five-field NameCert boundary* S, P_0, K, Σ, L *with transport, replay, provenance, and local naming.*

Proof. Compare the displayed rows. Primitive distinction, observer trace, halting trace, certified event flow, and supply taxonomy each provide a concrete source surface or audit path for distinctions.

The present packet has a different role. It requires the source row, pattern row, classifier row, stability row, and ledger row to be visible together before certification is licensed.

Therefore none of the listed siblings can replace $\mathsf{DistinctionCertificate}^{\uparrow}$ while preserving all fields of Definition 7126.1. A consumer that needs certification must read the full packet. □

Theorem 7126.4 (DistinctionCertificate TasteGate requirements)**.** *The Lean TasteGate surface for* $\mathsf{DistinctionCertificate}^{\uparrow}$ *must provide explicit* $\mathsf{Nontrivial\ DistinctionCertificate}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ DistinctionCertificat}$ *instances. The nontriviality witness must separate a certified classifier packet from a bare candidate distinction, and the field-faithfulness witness must keep* $S, P_0, K, \Sigma, L, H, C, R, N$ *as distinct rows under transport and replay.*

Proof. Nontriviality follows from the intended separation between raw distinction material and a certified NameCert boundary. A bare candidate distinction lacks at least one of S, P_0, K, Σ, L and therefore cannot be the same accepted packet as the full carrier.

Field faithfulness is the preservation requirement for the displayed coordinates. If source, pattern, classifier, stability, ledger, transport, replay, provenance, or naming were collapsed, the packet would no longer expose the certificate boundary of Definition 7126.2.

Thus the TasteGate must preserve both the distinction between bare and certified objects and the componentwise rows of the accepted packet. □

Falsifiable prediction: A consumer that reads $\mathsf{DistinctionCertificate}^{\uparrow}$ without displaying source, pattern, classifier, stability, and ledger rows is reading a bare candidate distinction rather than a certified NameCert boundary.

Independence witness: primitive-distinction-ledger, observerdistinctiontrace, haltingdistinctiontrace, certified-event-flow, supply-taxonomy: none is bijective to $\mathsf{DistinctionCertificate}^{\uparrow}$ because this packet binds candidate classifier certification through source, pattern, classifier, stability, ledger, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DistinctionCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{DistinctionCertificate}^{\uparrow}$ packet is generated from source rows, pattern rows, candidate classifier rows, stability rows, ledger rows, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistinctionCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7126.1, Definition 7126.2, Definition 7126.3, and Definition 7126.4 seed the finite NameCert boundary for certified distinctions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistinctionCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close raw distinction objecthood, uncertified semantic assignment, hidden classifier shift, global explanation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, five-field certificate exposure, sibling separation, Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.DistinctionCertificateUp.

Chapter 7127

A Concrete Naming Certificate for $\mathsf{TaoMetastableCauchy}^{\uparrow}$

Following Tao's metastability/no-counterexample interpretation of Cauchy convergence, the $\mathsf{TaoMetastableCauchy}^{\uparrow}$ packet records a finite control-window answer for a Cauchy read before any completed limit, quotient stream, or countable-choice selector is available. It sits on the dyadic tolerance ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the completion-facing boundary of chapter 1639. The point of the packet is not to prove ambient $\mathsf{Real}^{\uparrow}$ completeness; it is to make the finite Cauchy window demanded by a control function into named BEDC data.

Definition 7127.1 (Tao metastable Cauchy carrier)**.** *A* $\mathsf{TaoMetastableCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (q, F, W, D, S, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *q is the dyadic precision request, read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*
2. *F is the finite control row, naming the inspected control-function values only through displayed requests.*
3. *W is the metastable window row, displaying a bound n and the finite interval from n to $F(n)$.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger used by every comparison inside the window.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row opened for the named stream positions in W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row for the observed values.*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after q, F, W, D, S, R have been displayed.*
8. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary row, recording that the window is completion-facing without selecting a completed limit.*
9. *H records componentwise* hsame *transport for all displayed rows.*
10. *C records displayed* Cont *replay from the precision request and control row through the finite window, dyadic ledger, stream observations, rational readback, terminal seal, and completion boundary.*
11. *P records* Pkg *provenance over* $\mathsf{TaoMetastableCauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{TaoMetastableCauchy}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only by $q, F, W, D, S, R, E, B, H, C, P, N$. It has no coordinate for countable choice, quotient stream equality, selected limits, host real equality, trichotomy, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.TaoMetastableCauchyUp.TaoMetastableCauchyTasteGate single carrier alignment`

Theorem 7127.2 (Tao metastable Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{TaoMetastableCauchy}^{\uparrow}$ *carrier*

$$T = (q, F, W, D, S, R, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TaoMetastableCauchy}^{\uparrow}}$ *surface consists exactly of finite carrier admission, precision request exposure, finite control-row exposure, metastable window extraction, dyadic tolerance accounting, StreamName observation, RegSeqRat readback, Real seal boundary, Bishop regular Cauchy completion boundary, componentwise transport, displayed replay, provenance, and local naming. Every public read factors through those rows before it can cite a metastable Cauchy answer.*

Lean4 ✓ `BEDC.Derived.TaoMetastableCauchyUp.TaoMetastableCauchyCarrier namecert obligations`

Proof. Project the carrier of Definition 7127.1. The accepted packet exposes exactly $q, F, W, D, S, R, E, B, H, C, P, N$ so no hidden limit selector or quotient stream coordinate is available.

The request, control, and window rows supply the finite no-counterexample data. The row q fixes the tolerance, F fixes the displayed control values, and W names the finite interval in which all comparisons are inspected.

The analytic rows remain on the same route. The dyadic ledger D, StreamName row S, and RegSeqRat row R provide the only comparison data before the terminal $\mathsf{Real}^{\uparrow}$ seal E and the $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ boundary row B are read.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no row for countable choice, quotient stream equality, selected limits, host real equality, trichotomy, or ambient completeness, the displayed rows exhaust the NameCert obligations. □

Theorem 7127.3 (Tao metastable Cauchy window extraction)**.** *Every accepted* $\mathsf{TaoMetastableCauchy}^{\uparrow}$ *public read extracts a finite window before any real-facing or completion-facing output is consumed: the precision request q and control row F determine the displayed window W, every comparison in W is read through the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the inspected values are read through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows S, R, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal E and* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary row B remain after that finite route. The read exports no countable choice, quotient stream equality, selected limit, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.TaoMetastableCauchyUp.TaoMetastableCauchyWindowExtraction`

Proof. Use Definition 7127.2. A public read must open q, F, W before it can reach the analytic rows, so the control request is answered by a displayed finite interval rather than by an infinite selection principle.

The comparison data are then forced through D, S, R. The dyadic ledger records the tolerance, StreamName supplies the finite observations named by the window, and RegSeqRat supplies the rational readbacks actually compared.

The endpoint rows are downstream only. The $\mathsf{Real}^{\uparrow}$ seal E and $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ boundary row B can be cited only after the finite window route has been displayed, while H, C, P, N preserve the same route as transport, replay, provenance, and local naming.

Therefore the extracted object is a finite metastable Cauchy window. Since no carrier row stores a selected limit, quotient equality, countable-choice witness, host equality, trichotomy, or ambient completeness principle, none of those objects is exported by the read. □

Closure status for $\mathsf{NameCert}_{\mathsf{TaoMetastableCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{TaoMetastableCauchy}^{\uparrow}$ packet is generated from a dyadic precision request, finite control row, metastable window row, dyadic tolerance ledger, StreamName observations, RegSeqRat readback, Real seal boundary, Bishop regular Cauchy completion boundary, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaoMetastableCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7127.1, Definition 7127.2, and Definition 7127.3 seed the choice-free metastable Cauchy window route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TaoMetastableCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient stream equality, selected limits, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite control-window extraction, dyadic tolerance accounting, StreamName observation, RegSeqRat readback, Real seal boundary, Bishop regular Cauchy completion boundary, transport, replay, provenance, and local naming for BEDC.Derived.TaoMetastableCauchyUp.

Chapter 7128

A Concrete Naming Certificate for GaugeIntegralCriterion$^{\uparrow}$

Following Henstock, Kurzweil, and Bishop–Bridges on constructive integration, the GaugeIntegralCriterion$^{\uparrow}$ packet records the finite gauge-test surface used to read an integral claim through displayed gauges, tagged sums, dyadic tolerances, regular rational witnesses, and a terminal Real seal. It sits between the gauge integral route of chapter 1999, the tagged-sum surface of RiemannSumGauge$^{\uparrow}$, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal Real row of chapter 38. The packet is a finite BEDC criterion; it is not Lebesgue measure, a selected partition principle, open-cover compactness, countable choice, or ambient Real completeness.

Definition 7128.1 (Gauge integral criterion carrier)**.** *A* GaugeIntegralCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, S, W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* GaugeIntegral$^{\uparrow}$ *row naming the displayed integrand, interval, and gauge-integral claim.*
2. *S is the* RiemannSumGauge$^{\uparrow}$ *row exposing tagged Riemann sums for the same displayed claim.*
3. *W is the finite gauge-window row recording the inspected tagged subintervals and their local gauge bounds.*
4. *T is the tolerance row naming the positive request against which the sums are compared.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *row encoding the dyadic comparison budget for T and W.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row recording the regular rational sum comparisons visible inside the window.*
7. *E is the* Real$^{\uparrow}$ *seal row available only after I, S, W, T, D, R have been displayed.*
8. *H records componentwise* hsame *transport for the gauge-integral, tagged-sum, window, tolerance, dyadic, readback, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the gauge-integral row through tagged sums, gauge windows, tolerance comparison, dyadic readback, Real seal, and the structural rows.*
10. *P is the* Pkg *provenance over* GaugeIntegralCriterion$^{\uparrow}$, GaugeIntegral$^{\uparrow}$, RiemannSumGauge$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GaugeIntegralCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for Lebesgue measure completion, a selected partition, open-cover compactness, countable choice, quotient Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7128.2 (Gauge integral criterion NameCert obligations)**.** *For every accepted* $\mathsf{GaugeIntegralCriterion}^{\uparrow}$ *carrier*

$$G = (I, S, W, T, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GaugeIntegralCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the gauge-integral, tagged-sum, gauge-window, tolerance, dyadic-budget, regular-rational readback, Real-seal, transport, replay, provenance, and local naming rows; gauge-window exposure; tolerance exactness; tagged-sum comparison through the displayed dyadic and regular rational rows; Real-seal nonescape; componentwise* hsame *transport; displayed* Cont *replay;* Pkg *provenance; and local naming for the same finite packet.*

Proof. Carrier admission is projection from Definition 7128.1. The accepted packet exposes exactly the rows $I, S, W, T, D, R, E, H, C, P, N$.

The analytic route is finite. The row I names the gauge-integral claim, S exposes the tagged sums, W records the inspected gauge window, and T fixes the tolerance request against which those sums are read.

The comparison rows are also displayed. The dyadic budget D and regular rational readback R are the only numerical comparison rows before the Real seal E is available. Thus a consumer cannot replace the criterion with Lebesgue measure completion, a selected partition, open-cover compactness, countable choice, quotient Real equality, or ambient Real completeness.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no further coordinate exists in the carrier, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{GaugeIntegralCriterion}^{\uparrow}$ read exposes one GaugeIntegral row, one RiemannSumGauge row, one finite gauge-window row, one tolerance row, one DyadicRatCore comparison row, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the criterion is consumed.

Independence witness: gauge-integral, riemann-sum-gauge, dyadicratcore, regseqrat, real: GaugeIntegralCriterio is not bijective to any listed sibling because it jointly carries gauge claims, tagged sums, finite windows, tolerance budgets, dyadic comparison, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{GaugeIntegralCriterion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GaugeIntegralCriterion}^{\uparrow}$ packet is generated from a GaugeIntegral row, a RiemannSumGauge row, finite gauge windows, tolerance requests, DyadicRatCore comparison budgets, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GaugeIntegralCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 7128.1 and Definition 7128.2 seed the finite gauge criterion over GaugeIntegral, RiemannSumGauge, gauge-window, tolerance, DyadicRatCore, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GaugeIntegralCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lebesgue measure completion, selected partitions, open-cover compactness, countable choice, quotient Real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gauge-window exposure, tolerance exactness, tagged-sum comparison, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.GaugeIntegralCriterionUp.

Chapter 7129

Bishop interval modulus NameCert construction

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopIntervalModulus}^{\uparrow}$ packet records the finite modulus data by which a rational interval window controls a regular rational name and its Real-facing readback. It sits after the rational refinement surface of chapter 1432, the dyadic tolerance core of chapter 291, the stream-name windows of chapter 126, the regular rational source of chapter 301, and the terminal Real packet of chapter 38. The packet names interval-local modulus control as finite NameCert data; it does not choose an infinite refinement branch, select a completed real point, import a host interval subset, or claim ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7129.1 (BishopIntervalModulus carrier)**.** *A* $\mathsf{BishopIntervalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, r, W, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *row naming the parent-child rational interval containment and retained interval window.*
2. *r is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used as the requested interval radius or endpoint precision.*
3. *W is the modulus-window row assigning the tolerance r to a displayed retained rational interval window inside I.*
4. *S is the shared source row reading the relevant* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *handoff data through the same finite window.*
5. *H records componentwise* hsame *transport for the interval-refinement row, dyadic tolerance, modulus window, source handoff, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a tolerance request through I, r, W, S, H, P, N without changing the retained window.*
7. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalModulus}^{\uparrow}$*,* $\mathsf{RationalIntervalRefinement}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalModulus}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through I, r, W, S, H, C, P, N. It has no coordinate for an infinite interval tree, completed point selection, host subset relation, quotient real equality, countable choice, or standard bridge.

Theorem 7129.2 (BishopIntervalModulus window stability)**.** *Let $M = (I, r, W, S, H, C, P, N)$ be an accepted* $\mathsf{BishopIntervalModulus}^{\uparrow}$ *carrier. Replacing I, r, W, S by componentwise* hsame *rows and replaying the same tolerance request through C preserves the accepted modulus window: the consumer still reads the retained rational interval from W after the refinement row I and dyadic tolerance row r, and the stream, regular-rational, and Real-facing source data remain the row S.*

Proof. Project the carrier of Definition 7129.1. The only interval-refinement coordinate is I, the only dyadic tolerance coordinate is r, the only modulus-window coordinate is W, and the only source handoff coordinate is S.

The componentwise transport row H preserves those coordinates without adding a second window source. The displayed replay row C rereads the same tolerance request through I, r, W, S, H, P, N, so the retained rational interval window remains the one named by W.

Finally P and N only source and name the same finite packet. No row is available for an infinite branch, completed point, host subset, quotient equality, or choice schedule, so the accepted modulus window is stable under the displayed transport and replay. □

Theorem 7129.3 (BishopIntervalModulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalModulus}^{\uparrow}$ *carrier $M = (I, r, W, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the rational interval refinement, dyadic tolerance, modulus window, streamname, regular-rational, and Real-facing source rows; classifier transport through H; displayed continuation replay through C; provenance through P; local naming through N; and nonescape from infinite interval trees, completed point selection, host interval subsets, quotient real equality, countable choice, and standard bridges.*

Proof. Carrier admission is projection from $M = (I, r, W, S, H, C, P, N)$ in Definition 7129.1. These are precisely the rows exposed to a local consumer.

The interval and tolerance obligations are finite because I is read from the $\mathsf{RationalIntervalRefinement}^{\uparrow}$ surface and r is read from the $\mathsf{DyadicRatCore}^{\uparrow}$ surface. The modulus obligation is exactly the retained window row W, with S tying the same request to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback data.

The remaining rows transport, replay, source, and name the same displayed packet. Since the carrier has no additional coordinate, the listed obligations exhaust the local NameCert surface and exclude the named nonlocal objects. □

Falsifiable prediction: Any accepted $\mathsf{BishopIntervalModulus}^{\uparrow}$ consumer that reads interval-local modulus control must display the rational refinement row, dyadic tolerance row, retained window row, source handoff row, componentwise transport, replay, provenance, and local NameCert row.

Independence witness: rationalintervalrefinement, dyadicratcore, streamname, regseqrat, real: none is bijective with $\mathsf{BishopIntervalModulus}^{\uparrow}$ because this packet alone binds a dyadic tolerance request to a retained rational interval window and the corresponding finite regular-name readback.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalModulus}^{\uparrow}$ packet is generated from a RationalIntervalRefinement row, a DyadicRatCore tolerance, a modulus-window row, StreamName, RegSeqRat, and Real-facing source data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopIntervalModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7129.1, Definition 7129.2, and Definition 7129.3 seed the finite interval-local modulus packet over RationalIntervalRefinement, DyadicRatCore, StreamName, RegSeqRat, and RealUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopIntervalModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite interval trees, completed real point selection, host interval subsets, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window stability, NameCert obligation coverage, source handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BishopIntervalModulusUp.

Chapter 7130

A Concrete Naming Certificate for $\mathsf{RegularCauchyPairModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ packet records finite shared-window modulus evidence for a pair of regular Cauchy rational names before either name is read by a completion-facing consumer. It sits over the stream windows of chapter 126, the regular rational rows of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the rate readback of chapter 2085. The packet supplies a finite paired-modulus boundary for equality, null-difference, separability, and completion arguments without turning shared precision evidence into quotient equality or a host-selected limit.

Definition 7130.1 (Regular Cauchy pair modulus carrier)**.** *A* $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (R_0, R_1, W, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *R_0 and R_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose rational observations are compared only through finite precision requests.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row exposing one finite stage at which both source rows are observed.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the shared window, including the two endpoint observations, the requested radius, and the slack cells needed for a paired read.*
4. *M is the paired modulus row assigning each requested joint precision to the displayed shared window and dyadic tolerance data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for any completion-facing read that consumes the paired modulus.*
6. *H records componentwise* hsame *transport for the two regular sources, the shared window, the dyadic ledger, the paired modulus row, the Real seal, provenance, and local naming.*
7. *C records displayed* Cont *replay for the finite route*

$$R_0, R_1 \longmapsto W \longmapsto D \longmapsto M \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyPairModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyRateExtraction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyPairModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R_0, R_1, W, D, M, E, H, C, P, N$. It has no coordinate for quotient equality of regular names, selected limits, trichotomy, countable choice, hidden independent moduli, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7130.2 (Regular Cauchy pair modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ *carrier*

$$X = (R_0, R_1, W, D, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyPairModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, paired modulus row,* $\mathsf{Real}^{\uparrow}$ *seal, transport row, replay row, provenance row, and local naming row;*
2. *shared-window exactness, requiring both source reads to use the same displayed W before any paired modulus entry is consumed;*
3. *dyadic-budget exactness, requiring D to expose the requested radius, endpoint observations, and slack rows used by the paired read;*
4. *paired-modulus exactness, requiring M to send each joint precision request only to the displayed W, D data and not to a detached selector or countable-choice schedule;*
5. *Real-seal nonescape, requiring E to be downstream of R_0, R_1, W, D, M and to export no quotient equality, selected limit, trichotomy, or ambient completeness claim;*
6. *structural stability, requiring H, C, P, N to transport, replay, source, and name the same finite shared-window route.*

Proof. Carrier admission is projection from Definition 7130.1. The accepted packet displays exactly two regular rational rows, one shared window row, one dyadic ledger, one paired modulus row, one Real seal, and the structural rows H, C, P, N.

Shared-window exactness is read from R_0, R_1, W. Both source rows must be observed at the same displayed finite stage before the packet can answer a joint precision request.

Dyadic-budget exactness is the role of D. The ledger stores the requested radius, endpoint observations, and slack cells for the same shared window, so the paired read cannot appeal to an independent tolerance source.

The paired modulus row M then assigns the joint precision request to the displayed W, D data. Since M is the only modulus coordinate in the carrier, no selected limit, quotient equality, trichotomy, or countable-choice schedule is available.

Finally, E, H, C, P, N close the route. The Real seal is downstream of the paired modulus, while transport, replay, provenance, and naming preserve only the displayed finite packet; hence the listed obligations exhaust the local NameCert surface. □

Theorem 7130.3 (Regular Cauchy pair modulus shared-window handoff)**.** *Every equality, null-difference, separability, or completion-route consumer of an accepted* $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ *carrier receives paired regular-Cauchy precision evidence only through*

$$R_0, R_1 \longmapsto W \longmapsto D \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

The handoff preserves the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the paired modulus row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data. It exports no quotient equality, selected limit, trichotomy, countable choice, hidden independent modulus, or ambient Real completeness theorem.*

Proof. Begin with a consumer read of an accepted packet. By Definition 7130.2, the read starts from the displayed rows $R_0, R_1, W, D, M, E, H, C, P, N$.

For equality or null-difference uses, the consumer first reaches the two regular rational source rows through the same shared window W. The dyadic ledger D then supplies the radius and slack data at that window, so no quotient equality or detached comparison coordinate is present.

For separability or completion-route uses, the consumer must still pass through M before the terminal Real seal E is visible. Thus the precision evidence is the paired modulus row itself rather than a selected limit or ambient completeness principle.

The structural rows H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Therefore every downstream handoff factors through the shared-window packet and receives none of the excluded escape objects. □

Falsifiable prediction: Every $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ read factors through two RegSeqRat source rows, one shared StreamName window row, one DyadicRatCore tolerance ledger, a paired modulus row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, regular-cauchy-rate-extraction, real: $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular rational source rows, one shared finite window, dyadic paired-tolerance data, a paired modulus row, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyPairModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one shared StreamName window, a DyadicRatCore tolerance ledger, a paired modulus row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyPairModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7130.1, Definition 7130.2, and Definition 7130.3 seed the finite shared-window modulus route for paired regular Cauchy reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyPairModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of regular names, selected limits, trichotomy, countable choice, hidden independent moduli, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window exactness, dyadic-budget exactness, paired-modulus exactness, Real-seal nonescape, and structural stability for BEDC.Derived.RegularCauchyPairModulusUp.

Chapter 7131

A Concrete Naming Certificate for $\mathsf{DyadicCofinalGrid}^{\uparrow}$

Following Bishop and Bridges constructive analysis, finite dyadic approximation work is read through explicit meshes and tolerances rather than through an ambient dense-subset theorem. The $\mathsf{DyadicCofinalGrid}^{\uparrow}$ packet records the finite cofinal grid surface used when rational sources are approximated by dyadic windows before reaching regular rational sequences and real-name seals. It sits after the rational source of chapter 37, the dyadic ledger of chapter 291, the finite request windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite grid carrier only; it does not assert quotient real equality, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7131.1 (Dyadic cofinal grid carrier)**.** *A* $\mathsf{DyadicCofinalGrid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (Q, D, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source row whose finite rational samples are the only inputs inspected by the grid.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row recording dyadic denominators, endpoint comparisons, and tolerance budgets.*
3. *M is the cofinal mesh row: for each displayed tolerance in D, it lists a finite dyadic grid whose spacing refines that tolerance on the displayed rational window.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records which precision requests and grid cells are opened.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the rational source, dyadic scale, cofinal mesh, and stream window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after Q, D, M, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the rational source, dyadic scale, mesh, windows, readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a grid request through $Q, D, M, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicCofinalGrid}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCofinalGrid}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, D, M, W, R, E, H, C, P, N$. It has no coordinate for arbitrary real-density completion, quotient equality of real names, countable choice, selected limiting grids, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7131.2 (Dyadic cofinal grid NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCofinalGrid}^{\uparrow}$ *carrier*

$$G = (Q, D, M, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCofinalGrid}^{\uparrow}}$ *surface consists exactly of rational source exposure, dyadic scale exposure, cofinal mesh admission, StreamName window exposure, RegSeqRat readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation may be discharged by an ambient density theorem, quotient real equality, countable choice, a selected limiting grid, or ambient real completeness.*

Proof. Project the carrier of Definition 7131.1. The displayed analytic rows are exactly Q, D, M, W, R, E, and the structural rows are exactly H, C, P, N.

Read the approximation data in dependency order. The rational samples enter through Q, the dyadic denominators and tolerances enter through D, and the cofinal mesh row M records only finite dyadic grids attached to those displayed tolerances.

The window and readback rows are downstream. The row W opens only the requested precision cells, and R reads those cells as a regular rational sequence before the terminal real seal E is visible.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no additional coordinate exists, the excluded density, quotient, choice, selected-limit, and completeness principles are not part of the local NameCert surface. □

Theorem 7131.3 (Dyadic cofinal grid real readback route)**.** *Let $G = (Q, D, M, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{DyadicCofinalGrid}^{\uparrow}$ *carrier. Every Real-facing consumer of the grid must read the rational source row Q, dyadic scale row D, cofinal mesh row M, StreamName window row W, and RegSeqRat readback row R before it reaches the Real seal row E. The route supplies finite dyadic approximation data for displayed tolerances; it does not supply real completeness, quotient equality of real names, a selected limit, or countable choice.*

Proof. Begin with an accepted consumer read of G. Carrier admission exposes the tuple $Q, D, M, W, R, E, H, C, P, N$ and no other analytic row.

The Real-facing route is ordered by the displayed rows. The source row Q supplies finite rational samples, D supplies dyadic scales, M supplies the cofinal finite grids for those scales, and W records the finite precision requests being opened.

Only after those rows are visible can R be read as a regular rational handoff. The terminal seal E is downstream of that handoff, so a consumer cannot reach $\mathsf{Real}^{\uparrow}$ through a hidden density or limit principle.

The transport, replay, provenance, and local naming rows preserve the same route. Therefore every Real-facing read factors through the displayed finite grid surface and leaves real completeness, quotient equality, selected limits, and countable choice outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCofinalGrid}^{\uparrow}$ read factors through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, cofinal mesh data, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCofinalGrid}^{\uparrow}}$.

Constructive story: A DyadicCofinalGrid$^{\uparrow}$ packet is generated from RatUp source rows, DyadicRatCoreUp scale rows, finite cofinal mesh rows, StreamNameUp windows, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicCofinalGrid}^{\uparrow}}$, seed)

Scope closed: Definition 7131.1, Definition 7131.2, and Definition 7131.3 seed the finite dyadic-grid route over RatUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicCofinalGrid}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, real completeness, quotient equality of real names, countable choice, selected limiting grids, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exactness, cofinal mesh admission, StreamName window replay, RegSeqRat readback exactness, RealUp seal nonescape, transport stability, and TasteGate field faithfulness for BEDC.Derived.DyadicCofinalGridUp.

Chapter 7132

A Concrete Naming Certificate for $\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}$ packet records a shared-window synchronization certificate for paired regular Cauchy reads before the pair is handed to equality, completion, or Real-facing consumers. It refines the paired-source route of chapter 7130 by naming the synchronization obligation as its own finite carrier surface over the regular rational rows of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet synchronizes two displayed reads at one shared window; it does not identify quotient names, select limits, invoke trichotomy, use countable choice, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7132.1 (Regular Cauchy synchronization modulus carrier)**.** *A* $\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R_0, R_1, W, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations are to be synchronized.*
2. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row at which both reads are inspected for the same requested precision.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested dyadic radius, the two displayed observations, and the slack cells used to compare them inside* W*.*
4. M *is the synchronization modulus row assigning each paired precision request to the displayed window and tolerance data.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available to downstream equality, completion, or Real-facing consumers only after* R_0, R_1, W, D, M *have been read.*
6. H *records componentwise* hsame *transport for the two sources, the shared window, the tolerance ledger, the synchronization modulus, the Real seal, provenance, and local naming.*
7. C *records displayed* Cont *replay for the route*

$$R_0, R_1 \longmapsto W \longmapsto D \longmapsto M \longmapsto E.$$

8. *P is the* Pkg *provenance over* RegularCauchySynchronizationModulus$^{\uparrow}$, RegularCauchyPairModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{RegularCauchySynchronizationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R_0, R_1, W, D, M, E, H, C, P, N$. It has no coordinate for quotient equality of regular Cauchy names, a selected limit, host real equality, trichotomy, countable choice, hidden independent windows, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7132.2 (Regular Cauchy synchronization modulus NameCert obligations)**.** *For every accepted* RegularCauchySynchronizationModulus$^{\uparrow}$ *carrier*

$$S = (R_0, R_1, W, D, M, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchySynchronizationModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* RegSeqRat$^{\uparrow}$ *source rows, shared* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *tolerance ledger, synchronization modulus row,* Real$^{\uparrow}$ *seal, transport row, replay row, provenance row, and local naming row;*
2. *shared-window synchronization, requiring both source reads to use the same displayed W before a paired precision answer is accepted;*
3. *dyadic-budget synchronization, requiring D to expose the requested radius, both endpoint observations, and the slack rows used by the synchronized read;*
4. *modulus exactness, requiring M to route each paired precision request through the displayed W, D data rather than through a detached selector, a second independent window, or a countable-choice schedule;*
5. *Real-seal handoff, requiring E to be downstream of R_0, R_1, W, D, M and to export no quotient equality, selected limit, trichotomy, or ambient completeness claim;*
6. *structural stability, requiring H, C, P, N to transport, replay, source, and name the same finite synchronization route.*

Proof. Carrier admission is projection from Definition 7132.1. The accepted packet displays exactly two regular rational sources, one shared window, one dyadic ledger, one synchronization modulus row, one Real seal, and the structural rows H, C, P, N.

Shared-window synchronization is read from R_0, R_1, W. Both source rows are inspected at the same finite window before any paired precision answer is accepted, so the packet cannot replace the displayed window by two unrelated observation schedules.

Dyadic-budget synchronization is the role of D. The ledger stores the requested radius, the two endpoint observations, and the slack cells for the same shared window, which prevents the synchronized read from appealing to an independent tolerance source.

The modulus exactness clause is supplied by M. Since M is the only synchronization-modulus coordinate in the carrier, every paired precision request is routed through W, D and not through quotient equality, selected limits, trichotomy, or countable choice.

Finally E, H, C, P, N close the route. The Real seal is downstream of the synchronized finite packet, while transport, replay, provenance, and local naming preserve only that packet; hence the listed obligations exhaust the local NameCert surface. □

Theorem 7132.3 (Regular Cauchy synchronization shared-window handoff)**.** *Every equality, completion, null-difference, or Real-facing consumer of an accepted* $\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}$ *carrier receives synchronized paired-source evidence only through*

$$R_0, R_1 \longmapsto W \longmapsto D \longmapsto M \longmapsto E \longmapsto H, C, P, N.$$

The handoff preserves the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the synchronization modulus row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data. It exports no quotient equality, selected limit, trichotomy, countable choice, hidden independent window, or ambient Real completeness theorem.*

Proof. Begin with a consumer read of an accepted packet. By Definition 7132.2, the read starts from the displayed rows $R_0, R_1, W, D, M, E, H, C, P, N$.

For equality or null-difference uses, the consumer first reaches the two regular rational source rows through the same shared window W. The dyadic ledger D supplies the requested radius and slack data at that window, so no quotient equality or detached comparison coordinate is present.

For completion or Real-facing uses, the consumer must still pass through the synchronization modulus row M before the terminal Real seal E is visible. Thus the precision evidence is the displayed synchronization certificate rather than a selected limit or ambient completeness principle.

The structural rows H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Therefore every downstream handoff factors through the shared-window packet and receives none of the excluded escape objects. □

Falsifiable prediction: Every $\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}$ read factors through two RegSeqRat source rows, one shared StreamName window row, one DyadicRatCore tolerance ledger, a synchronization modulus row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regular-cauchy-pair-modulus, regseqrat, streamname, dyadicratcore, real: $\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}$ is not bijective to any listed sibling because it isolates the shared-window synchronization certificate for paired regular Cauchy reads as its own finite NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one shared StreamName window, a DyadicRatCore tolerance ledger, a synchronization modulus row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7132.1, Definition 7132.2, and Definition 7132.3 seed the shared-window synchronization route for paired regular Cauchy reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySynchronizationModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality of regular Cauchy names, selected limits, host real equality, trichotomy, countable choice, hidden independent windows, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window synchronization, dyadic-budget synchronization, modulus exactness, Real-seal handoff, and structural stability for BEDC.Derived.RegularCauchySynchronizationModulusUp.

Chapter 7133

A Concrete Naming Certificate for $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$ packet records the finite BEDC route by which a continuous real-valued map on a closed bounded interval is read as Riemann integrable. It sits after the interval carrier of chapter 1591, the map surface of chapter 130, the uniform-modulus row of chapter 369, the Riemann-sum gauge surface of chapter 4115, the gauge-integral packet of chapter 1999, the stream-name interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the compact-continuity theorem surface as finite NameCert data; it does not assert a host integration theorem, selected partitions, quotient functions, or ambient completeness.

Definition 7133.1 (Continuous compact Riemann-integrability carrier)**.** *A* $\mathsf{ContinuousCompactRiemannIntegrabilit}$ *carrier is a finite* BHist *packet*

$$I = (J, F, U, G, A, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *row, exposing the compact interval endpoints and admitted interval classifier.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, storing the real-valued map read only through its displayed continuity data.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row, recording the finite modulus schedule used on the compact interval.*
4. *G is the* $\mathsf{RiemannSumGauge}^{\uparrow}$ *row, exposing tagged partition, mesh, and gauge-admission data.*
5. *A is the* $\mathsf{GaugeIntegral}^{\uparrow}$ *row, recording the finite gauge-integral acceptance surface.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for finite partition and modulus probes.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row for rational readback of sums, tolerances, and endpoint windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value and comparison tolerances.*
9. *H records componentwise* hsame *transport for $J, F, U, G, A, S, R, E, C, P, N$.*
10. *C records displayed* Cont *replay from a compact-continuity integrability request through*

$$J, F, U \longmapsto G, A, S, R, E, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $J, F, U, G, A, S, R, E, H, C, P, N$. It has no coordinate for a host Riemann integral, selected partition family, quotient function equality, countable choice, or ambient completeness.

Theorem 7133.2 (Continuous compact Riemann-integrability obligations)**.** *For every accepted* $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$ *carrier $I = (J, F, U, G, A, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of compact interval admission through J, continuous-map readback through F, uniform-modulus exposure through U, Riemann-sum gauge data through G, gauge-integral acceptance through A, finite stream probes through S, regular rational readback through R, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows $J, F, U, G, A, S, R, E, H, C, P, N$ are the entire inventory visible to a compact-integrability consumer.

The source side is finite. The interval row J supplies only displayed closed-bounded endpoints, the map row F supplies only the continuity readback, and the modulus row U supplies the compact uniformity schedule.

The integration side is also finite. The gauge row G exposes tagged-partition and mesh data, while A records the gauge-integral acceptance surface. The stream row S and regular rational row R give the inspected finite probes and rational tolerances before the terminal real seal E is read.

Finally H, C, P, N transport, replay, source, and name the same route. Since no row contains a host integral, selected partition family, quotient function equality, countable choice, or ambient completeness, the listed rows exhaust the local obligations. □

Theorem 7133.3 (Continuous compact Riemann-integrability gauge route)**.** *Every accepted* ContinuousCompactRi *packet factors a compact-continuity integrability request through*

$$\mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{RiemannSumGauge}^{\uparrow},\ \mathsf{GaugeIntegral}^{\uparrow},\ \mathsf{StreamName}$$

The consumer receives a displayed compact interval, continuous-map data, a uniform modulus, gauge-controlled Riemann sums, gauge-integral acceptance, finite probes, rational readback, a terminal real seal, transport, replay, provenance, and local naming. It receives no host integral theorem and no selected family of partitions.

Proof. Begin with a compact-continuity read. The interval and map rows are J and F, and compact uniformity is available only through the displayed modulus row U.

Use the Riemann-sum gauge row G to route each inspected partition and tolerance request. The gauge-integral row A records acceptance only after that finite gauge route has been displayed.

Read finite probes through S, rational bounds through R, and the terminal real value through E. The transport and replay rows H, C preserve the same route, and P, N source and name it locally.

Thus the exported integrability surface is exactly the gauge route named in the statement. A stronger read would require a carrier coordinate that I does not contain. □

Theorem 7133.4 (Continuous compact Riemann-integrability L10 non-escape)**.** *An accepted* $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$ *packet remains an L10/L11 finite NameCert route. Downstream Real or GaugeIntegral consumers may inspect* $J, F, U, G, A, S, R, E, H, C, P, N$*, but they cannot replace those rows by host compactness, host uniform continuity, a selected refining partition sequence, quotient-function equality, countable choice, or an ambient completeness theorem.*

Proof. Read the carrier inventory from Definition 7133.1. The only compactness-facing row is J, the only continuity-facing row is F, and the only compact-uniformity row is U.

Apply Definition 7133.3. The integrability read reaches G, A, S, R, E only after the displayed compact-continuity source has been exposed.

The remaining rows H, C, P, N preserve, replay, source, and name the same finite packet. None of them adds a selected refining sequence, host compactness theorem, quotient-function equality, countable-choice selector, or ambient completeness row.

Therefore the packet is a finite L10/L11 dependency route rather than a host theorem about all continuous functions on compact intervals. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$ packet is generated from closed bounded interval data, continuous-map readback, uniform-modulus scheduling, Riemann-sum gauge rows, gauge-integral acceptance, stream probes, regular rational readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7133.1, Definition 7133.2, Definition 7133.3, and Definition 7133.4 seed the finite compact-continuity Riemann-integrability surface over interval, map, modulus, gauge, integral, stream, rational, Real, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, host uniform continuity, selected partition families, quotient-function equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval admission, continuous-map readback, uniform-modulus exposure, Riemann-sum gauge exactness, gauge-integral acceptance, stream probes, rational readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousCompactRiemannIntegrabilityUp.

Chapter 7134

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$

The $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$ packet realizes the phase-transport budget surface of chapter 9463 as finite metric, phase, energy, and curvature-budget rows. It sits after the disk metric of chapter 6209, the hyperbolic metric row of chapter 3474, the phase-transport carrier of chapter 6146, and the finite ledger of chapter 6481. The packet names the local transport budget for one accepted observer-phase route; it does not assert a completed hyperbolic manifold, a physical energy law, global phase holonomy, or a host curvature theorem.

Definition 7134.1 (Hyperbolic phase-transport budget carrier)**.** *A* $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, M, G, E, K, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *row, exposing the inspected disk coordinate and disk-distance window.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, recording the finite hyperbolic metric comparison used by the transport budget.*
3. *G is the* $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ *row, storing the source phase, target phase, inverse route, and compositional boundary for the displayed transport.*
4. *E is the* $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$ *row, recording the finite energy debit, credit, and conservation check associated with the route.*
5. *K is the curvature-budget row, recording the local curvature allowance consumed by the displayed disk and phase transport.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for metric, energy, and curvature tolerances.*
7. *H records componentwise* hsame *transport for $D, M, G, E, K, R, C, P, N$.*
8. *C records displayed* Cont *replay from a phase-transport budget request through*

$$D, M, G, E \longmapsto K, R, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$, $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, M, G, E, K, R, H, C, P, N$. It has no coordinate for completed hyperbolic geometry, physical energy conservation, global holonomy, selected observer trajectories, or host curvature integration.

Theorem 7134.2 (Hyperbolic phase-transport budget obligations)**.** *For every accepted* HyperbolicPhaseTransportB *carrier $B = (D, M, G, E, K, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}}$ *surface consists exactly of disk-metric admission through D, hyperbolic metric readback through M, phase groupoid transport through G, energy-ledger exposure through E, curvature-budget recording through K, terminal Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows $D, M, G, E, K, R, H, C, P, N$ are the entire public inventory of the budget packet.

The metric source is displayed before any phase budget is read. The disk row D supplies the inspected coordinate window, and the hyperbolic metric row M supplies the finite comparison used by the budget.

The phase and ledger rows are then read through G and E. The curvature row K records the local allowance consumed by that route, while R seals the metric, energy, and curvature tolerances as Real-facing data.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row contains completed hyperbolic geometry, physical energy conservation, global holonomy, selected observer trajectories, or host curvature integration, the listed rows exhaust the local obligations. □

Theorem 7134.3 (Hyperbolic phase-transport budget vision route)**.** *Every accepted* HyperbolicPhaseTransportBud *packet factors the vision-level phase-budget request through*

$$\mathsf{PoincareDiskMetric}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{ObserverPhaseGroupoid}^{\uparrow},\ \mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow} \longmapsto K, \mathsf{Real}^{\uparrow}, H, C$$

The consumer receives disk metric data, hyperbolic metric comparison, phase groupoid transport, an energy ledger, a curvature-budget row, a Real seal, componentwise transport, replay, provenance, and local naming. It receives no global phase geometry, no physical observer trajectory, and no host curvature theorem.

Proof. Begin with the disk and hyperbolic metric rows. The route can inspect D and M, but it cannot introduce a completed hyperbolic metric space outside the packet.

Read phase transport through G and the energy ledger through E. These rows supply the local groupoid and ledger data named by the source vision.

The curvature budget is the finite row K, and the Real-facing tolerances are sealed by R. Transport and replay preserve the same row order through H and C, while P, N source and name the route.

Thus the vision-level request is concretized only as the finite packet displayed in the statement. Any stronger geometric or physical reading would require a coordinate absent from B. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$ packet exposes disk metric, hyperbolic metric, phase groupoid transport, energy ledger, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows. A public phase-budget read that omits any of those rows, or that exports global phase geometry, physical observer motion, or host curvature integration, refutes the carrier boundary.

Independence witness: poincare-disk-metric, hyperbolic-metric, observer-phase-groupoid, hyperbolic-phase-energy-ledger, hyperbolic-phase-curvature-budget: $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk metric data, hyperbolic metric comparison, phase groupoid transport, energy ledger, curvature-budget recording, Real sealing, transport, replay, provenance, and local naming while refusing completed geometry, physical energy laws, global holonomy, selected trajectories, and host curvature theorems.

The Lean TasteGate surface for this packet must provide explicit $\mathsf{Nontrivial\ HyperbolicPhaseTransportBudget}^{\uparrow}$ and $\mathsf{FieldFaithful\ HyperbolicPhaseTransportBudget}^{\uparrow}$ instances before a checked carrier-alignment theorem can witness the public route.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$ packet is generated from Poincare disk metric data, hyperbolic metric comparison, observer phase groupoid transport, hyperbolic phase energy ledger rows, a curvature-budget row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7134.1, Definition 7134.2, and Definition 7134.3 seed the finite phase-transport budget packet over disk, metric, phase groupoid, energy ledger, curvature budget, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic geometry, physical energy conservation, global holonomy, selected observer trajectories, host curvature integration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk admission, metric readback, phase groupoid transport, energy-ledger exactness, curvature-budget recording, Real sealing, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseTransportBudgetUp.

Chapter 7135

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$ packet records the finite extraction surface by which a regular Cauchy rational name answers a bounded precision request through displayed windows. It sits after the finite stream rows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the choice-free completion route of chapter 4237. The packet is a finite interface for Real and Completion consumers; it is not quotient completion, representative selection, countable choice, host equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7135.1 (Regular-Cauchy window extraction carrier)**.** *A* $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (R, W, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row carrying the regular rational name, its modulus surface, and the readback rows available to a completion-facing consumer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *inspected-window row listing the finite windows and indices opened for the requested precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic bound, comparison rows, and arithmetic checks attached to the inspected windows.*
4. *Q is the finite query/request row that binds the consumer request to the displayed source, window, and tolerance rows.*
5. *H records componentwise* hsame *transport for R, W, D, Q, C, P, N.*
6. *C records the displayed* Cont *replay route from the query row through the regular source, inspected windows, dyadic tolerance checks, transport, provenance, and local naming rows.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through R, W, D, Q, H, C, P, N. It has no coordinate for quotient streams, selected limits, countable-choice schedules, host equality of completed objects, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7135.2 (Regular-Cauchy window extraction NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$ *carrier*

$$X = (R, W, D, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowExtraction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, classifier transport through H, finite-window extraction of the inspected* $\mathsf{StreamName}^{\uparrow}$ *rows, dyadic tolerance exactness through D, regular-rational readback stability through R, displayed replay through C, provenance through P, and local naming through N. Every completion-facing read is routed through the finite query row Q before it can consume a downstream* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the carrier of Definition 7135.1. The rows R, W, D, Q, H, C, P, N are exactly the displayed inventory exposed by an accepted packet.

Carrier admission and classifier transport are componentwise. The row H transports the source, inspected windows, dyadic tolerance ledger, query row, replay row, provenance, and local name without adding a second completion coordinate.

The extraction step is finite. The query row Q names the requested precision, W lists the inspected windows answering that request, and D records the dyadic tolerance comparisons used to certify the answer.

Readback stability is then the regular rational row R reread through the same windows and tolerances. Replay through C follows the displayed route, while P and N bind provenance and local naming.

Since the carrier contains no quotient stream equality, selected representative, countable-choice schedule, host equality, open-cover compactness datum, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle, none of those objects can replace the finite extraction surface. □

Theorem 7135.3 (Regular-Cauchy extraction nonescape)**.** *Every consumer-facing route out of an accepted* $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$ *packet factors through the finite rows R, W, D, Q, H, C, P, N. In particular, a completion consumer receives the RegSeqRat source, inspected StreamName windows, DyadicRatCore tolerance ledger, finite request row, componentwise transport, replay, provenance, and local NameCert rows, and receives no quotient stream equality, selected limit, countable-choice schedule, host equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use the obligation surface of Definition 7135.2. It identifies each admissible consumer read with the displayed carrier rows.

The source, window, tolerance, and request rows R, W, D, Q form the public extraction surface. The structural rows H, C, P, N preserve, replay, source, and name that same surface.

Any route exporting quotient streams, selected limits, countable choice, host equality, compactness, or ambient completeness would require an additional carrier coordinate. The carrier has none, so every consumer-facing route remains inside the finite extraction packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$ read exposes a RegSeqRat source row, StreamName inspected windows, a DyadicRatCore tolerance ledger, a finite query row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any completion-facing seal is consumed.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-choice-free-completion: $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a regular source, inspected windows, dyadic tolerances, finite precision requests, transport, replay, provenance, and local naming while refusing quotient completion, selected representatives, countable choice, host equality, compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowExtraction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7135.1, Definition 7135.2, and Definition 7135.3 seed the finite regular-Cauchy window-extraction surface over RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, finite-window extraction, tolerance exactness, readback stability, replay, provenance, local naming, and nonescape for BEDC.Derived.RegularCauchyWindowExtractionUp.

Constructive story: A $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName inspected windows, a DyadicRatCore tolerance ledger, a finite query row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7136

A Concrete Naming Certificate for $\mathsf{ChoiceSequenceBar}^{\uparrow}$

Following Brouwer on bars over choice sequences and the Bishop–Bridges use of finite prefix evidence, the $\mathsf{ChoiceSequenceBar}^{\uparrow}$ packet records a bar only as a finite BEDC surface over inspected choice-sequence prefixes. It sits beside the lawless-sequence surface of chapter 1495, the finite $\mathsf{StreamName}^{\uparrow}$ route of chapter 126, the $\mathsf{BaireSpace}^{\uparrow}$ prefix carrier of chapter 334, the $\mathsf{Bool}^{\uparrow}$ hit row of chapter 32, the $\mathsf{Nat}^{\uparrow}$ prefix ledger of chapter 28, and the finite fan/bar boundary of chapter 5863. The packet names prefix-bar coverage and monotone extension evidence; it is not a host infinite choice sequence, not countable choice, and not an arbitrary bar-induction principle.

Definition 7136.1 (Choice-sequence bar carrier)**.** *A* $\mathsf{ChoiceSequenceBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, B, I, M, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite prefix-window row over* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{BaireSpace}^{\uparrow}$*, listing exactly the inspected choice-sequence prefixes.*
2. *B is the* $\mathsf{Bool}^{\uparrow}$ *hit row, recording for each displayed prefix whether the bar has already been met.*
3. *I is the* $\mathsf{Nat}^{\uparrow}$ *prefix ledger, ordering the inspected prefix lengths and finite extension steps.*
4. *M is the monotone-extension evidence row: once a displayed prefix has a positive hit in B, every displayed extension of that prefix in W keeps the same hit.*
5. *H records componentwise* hsame *transport for prefix windows, Bool hit rows, prefix ledgers, monotone-extension evidence, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from a prefix-ledger request through the finite window W, the hit row B, and the monotone-extension row M.*
7. *P is the* Pkg *provenance over* $\mathsf{ChoiceSequenceBar}^{\uparrow}$*,* $\mathsf{LawlessSequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{FiniteFanTheorem}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoiceSequenceBar}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through W, B, I, M, H, C, P, N. It has no coordinate for a completed choice sequence, a branch selector, a countable-choice schedule, quotient equality of streams, or bar induction outside the displayed finite prefix surface.

Theorem 7136.2 (Choice-sequence bar NameCert obligations)**.** *For every accepted* $\mathsf{ChoiceSequenceBar}^{\uparrow}$ *carrier* $Q = (W, B, I, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ChoiceSequenceBar}^{\uparrow}}$ *surface consists exactly of carrier admission for the eight displayed rows, finite-prefix window coverage through* W*, Bool hit readback through* B*, Nat prefix-ledger ordering through* I*, monotone extension stability through* M*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. Every accepted bar-facing read remains inside the same finite prefix packet and cannot escape to a host infinite choice sequence or a countable-choice schedule.*

Proof. Project the carrier of Definition 7136.1. The only bar data visible to a consumer are the displayed prefix window W, the Bool hit row B, the prefix ledger I, and the monotone-extension evidence M.

Use finite induction over the $\mathsf{Nat}^{\uparrow}$ ledger I. The base read inspects the displayed empty or initial prefix when it is present in W; each step extends the current displayed prefix by one ledger move and then reads the corresponding hit value from B.

Apply the monotone-extension row M. If a displayed prefix has already hit the bar, every displayed extension keeps that hit, so prefix-bar coverage and extension stability are properties of the finite packet rather than of an unseen branch.

Finally replay through H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve exactly the same rows, and none of them contains a coordinate for a host infinite choice sequence, a branch selector, countable choice, quotient stream equality, or unrestricted bar induction. □

Falsifiable prediction: An accepted ChoiceSequenceBarUp packet that exports a bar hit without displaying the prefix window W, Bool hit row B, Nat prefix ledger I, monotone-extension row M, and structural H, C, P, N route refutes the carrier.

Independence witness: lawlesssequence, streamname, bairespace, bool, nat, finitefantheorem: $\mathsf{ChoiceSequenceBar}^{\uparrow}$ is not bijective to any listed sibling because it binds finite prefix windows, Bool bar hits, Nat prefix ledgers, monotone-extension evidence, transport, replay, provenance, and local NameCert into one prefix-bar packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceSequenceBar}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChoiceSequenceBar}^{\uparrow}$ packet is generated from finite StreamName and BaireSpace prefix windows, Bool bar-hit rows, Nat prefix ledgers, monotone-extension evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceSequenceBar}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7136.1 and Definition 7136.2 seed the finite prefix-bar surface over choice-sequence prefixes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceSequenceBar}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host infinite choice sequences, countable choice, quotient stream equality, selected branches, or arbitrary bar induction.

Upgrade path: Obligation closure requires checked carrier admission, prefix-window coverage, Bool hit readback, Nat ledger ordering, monotone extension stability, transport, replay, provenance, and local naming for BEDC.Derived.ChoiceSequenceBarUp.

Chapter 7137

A Concrete Naming Certificate for $\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}$

Following Arzela, Ascoli, Kelley, and Bishop–Bridges, the $\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}$ packet records the constructive compact-open Ascoli route where compact-open source probes, equicontinuity moduli, compact metric source data, complete metric target data, and finite-window diagonal extraction are exposed as NameCert rows. It sits over the compact-open topology certificate of chapter 4138, the equicontinuity-family certificate of chapter 413, and the Ascoli finite-window handoff of chapter 412. The packet is a finite constructive-analysis carrier; it does not assert open-cover compactness, select a subnet, quotient functions by host equality, or import ambient completeness outside the displayed rows.

Definition 7137.1 (Compact-open equicontinuous Ascoli carrier)**.** *A* $\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (O, E, X, Y, D, S, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *source-probe row, listing the compact test windows and finite function-observation requests admitted by the compact-open topology.*
2. *E is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *modulus row, recording the shared finite equicontinuity moduli used on the displayed compact windows.*
3. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, read only through finite compact-metric witnesses and finite net data.*
4. *Y is the* $\mathsf{CompleteMetric}^{\uparrow}$ *target row, exposing the completion-facing target metric data used by limit-window reads.*
5. *D is the* $\mathsf{ArzelaAscoli}^{\uparrow}$ *finite-window diagonal handoff row, binding compact source windows, equicontinuity moduli, and target completeness into one displayed extraction route.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the inspected family stages and diagonal prefixes.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tolerance observations attached to the selected finite windows.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for scalar tolerances, distances, and completion-facing readbacks.*

9. *L records local compact-open and equicontinuity compatibility of O, E, X, Y, D, S, Q, R.*
10. *H records componentwise* hsame *transport for every displayed row and the local naming row.*
11. *C records displayed* Cont *replay for the finite route*

$$O, E, X, Y \longmapsto D \longmapsto S \longmapsto Q \longmapsto R.$$

12. *P is the* Pkg *provenance over* $\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, EquicontinuityFamily ArzelaAscoli$^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, E, X, Y, D, S, Q, R, L, H, C, P, N$. It has no coordinate for a selected subnet, host function equality, open-cover compactness, quotient function space, countable choice, or ambient target completeness beyond the displayed $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Theorem 7137.2 (Compact-open equicontinuous Ascoli NameCert obligations)**.** *For every accepted* $\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}$ *carrier*

$$A = (O, E, X, Y, D, S, Q, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}}$ *surface consists exactly of compact-open source-probe exposure through O; equicontinuity-family modulus exposure through E; compact metric source exposure through X; complete metric target exposure through Y; Ascoli finite-window diagonal handoff through D; StreamName window exposure through S; RegSeqRat readback through Q; Real sealing through R; local compatibility through L; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the accepted carrier of Definition 7137.1. The rows $O, E, X, Y, D, S, Q, R, L, H, C, P, N$ are exactly the displayed compact-open, equicontinuity, compact-source, complete-target, diagonal, stream, rational-readback, Real-seal, compatibility, transport, replay, provenance, and naming coordinates.

The compact-open and equicontinuity inputs are read first. The row O supplies only finite compact-window probes, while E supplies the shared modulus data needed to compare a family on those windows. The compact source row X and complete target row Y are therefore visible before any diagonal extraction is consumed.

The finite-window exhaustion is the role of D, S, Q, R. The Ascoli handoff D names the displayed diagonal route, S records the inspected windows, Q records rational readbacks, and R seals the scalar tolerance and distance data for downstream completion-facing consumers.

Finally L, H, C, P, N bind the route locally. Compatibility, transport, replay, provenance, and naming preserve only the projected finite packet, so no selected subnet, quotient function equality, open-cover compactness, countable choice, or ambient completeness principle can be exported from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOpenEquicontinuousAscoli}^{\uparrow}$ packet is generated from compact-open source probes, equicontinuity-family moduli, a compact metric source row, a complete metric target row, an Ascoli finite-window diagonal handoff, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactOpenEquicontinuousAscoli}^{\uparrow}}$, seed)

Scope closed: Definition 7137.1 and Definition 7137.2 seed the finite compact-open equicontinuous Ascoli route over CompactOpenTopology$^{\uparrow}$, EquicontinuityFamily$^{\uparrow}$, ArzelaAscoli$^{\uparrow}$, CompactMetric$^{\uparrow}$, CompleteMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{CompactOpenEquicontinuousAscoli}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected subnets, quotient function equality, open-cover compactness, countable choice, ambient target completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-open probe exposure, equicontinuity modulus exposure, finite-window diagonal handoff, StreamName and RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactOpenEquicontinuousAscoliUp.

Chapter 7138

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$

The $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$ packet realizes the closed reversible phase-transport branch of chapter 9463 as finite disk, boundary, metric, holonomy, transport, provenance, and NameCert rows. It sits after the hyperbolic metric route of chapter 3474, the disk-automorphism route of chapter 6776, the reversible observer-transport route of chapter 6146, the closed phase-holonomy route of chapter 6385, and the scalar seal of chapter 38. The packet names torsion only as a finite obstruction row for closed phase transport; it is not a host cohomology class, not a global curvature theorem, and not a selected boundary fixed point.

Definition 7138.1 (Hyperbolic phase torsion carrier)**.** *A* $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, B, M, A, G, H, R, \tau, U, C, P, N)$$

with the following displayed rows:

1. *D is the Poincare-disk readout row, listing the finite disk points and disk-coordinate windows used by the torsion read.*
2. *B is the boundary-fixedness row, recording which displayed boundary directions remain attached to the closed transport route.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric row used for distance and displacement comparisons.*
4. *A is the* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ *reversible disk-automorphism row, including inverse and composition readbacks for the displayed loop.*
5. *G is the* $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ *row carrying source, target, inverse, and composition data for observer-facing phase transport.*
6. *H is the* $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ *closed holonomy row attached to the displayed loop.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for the phase residue, displacement budget, and tolerance comparisons.*
8. *τ is the local torsion row, recording the finite obstruction residue left after the closed reversible transport is replayed.*
9. *U records componentwise* hsame *transport for disk, boundary, metric, automorphism, groupoid, holonomy, Real, torsion, provenance, and local naming rows.*

10. *C records displayed* Cont *replay for the finite route*

$$D, B, M, A, G, H \longmapsto R \longmapsto \tau.$$

11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$, $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$, $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTorsion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, B, M, A, G, H, R, \tau, U, C, P, N$. It has no coordinate for host curvature, selected boundary points, quotient phase equality, global disk dynamics, hidden observer state, or a detached holonomy invariant outside the displayed loop.

Theorem 7138.2 (Hyperbolic phase torsion NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$ *carrier*

$$T = (D, B, M, A, G, H, R, \tau, U, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTorsion}^{\uparrow}}$ *surface consists exactly of disk-window exposure through D; boundary-fixedness exposure through B; metric comparison through M; reversible disk automorphism through A; observer-phase groupoid transport through G; closed phase holonomy through H; Real sealing through R; finite torsion residue through τ; componentwise transport through U; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the accepted carrier of Definition 7138.1. The rows $D, B, M, A, G, H, R, \tau, U, C, P, N$ are exactly the displayed disk, boundary, metric, automorphism, groupoid, holonomy, scalar, torsion, transport, replay, provenance, and naming coordinates.

The reversible route is read before the torsion residue. The disk windows D, boundary row B, metric row M, automorphism row A, groupoid row G, and holonomy row H determine the closed transport loop visible to the packet.

The scalar and residue rows are downstream. The Real seal R records the displayed phase and displacement budgets, and τ records only the finite obstruction residue left by the replayed loop.

Finally U, C, P, N preserve the same packet under transport, replay, provenance, and local naming. Since no other coordinate appears in the carrier, the NameCert surface exports no host curvature theorem, selected boundary fixed point, quotient phase equality, global disk dynamics, or hidden observer state. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$ read factors through displayed disk windows, boundary-fixedness rows, HyperbolicMetricUp comparisons, PoincareDiskAutomorphismUp reversible transport, ObserverPhaseGroupoidUp composition, HyperbolicPhaseHolonomyUp closed-loop readback, a RealUp scalar seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert naming. A public torsion read that bypasses these rows refutes the carrier.

Independence witness: hyperbolic-metric, poincare-disk-automorphism, observer-phase-groupoid, hyperbolic-phase-holonomy, real: $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk, boundary, metric, reversible transport, groupoid composition, closed holonomy, Real sealing, a local torsion residue, transport, replay, provenance, and naming rows.

The proposed Lean TasteGate surface for $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$ asks for a Nontrivial witness that some accepted closed phase-transport packet exposes a nonzero displayed torsion residue, and a FieldFaithful witness that the Real-sealed residue is still read through $D, B, M, A, G, H, R, \tau, U, C, P, N$ rather than through a detached scalar field.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTorsion}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseTorsion}^{\uparrow}$ packet is generated from disk windows, boundary-fixedness rows, hyperbolic metric comparisons, reversible disk automorphisms, observer phase groupoid transport, closed phase holonomy, a RealUp scalar seal, a local torsion residue, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTorsion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7138.1 and Definition 7138.2 seed the finite reversible closed phase-transport torsion route over $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$, $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$, $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseTorsion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host curvature, global disk dynamics, selected boundary fixed points, quotient phase equality, hidden observer state, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-fixedness exposure, reversible transport replay, holonomy residue sealing, torsion nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseTo

Chapter 7139

A Concrete Naming Certificate for $\mathsf{MirskyTheorem}^{\uparrow}$

Following Mirsky's theorem for finite partially ordered sets, the $\mathsf{MirskyTheorem}^{\uparrow}$ packet records the height-dual certificate to chapter 6083: a finite $\mathsf{Poset}^{\uparrow}$ row, a chain-height ledger, an antichain-partition ledger, rank-layer witnesses, and local NameCert data are read as one finite certificate surface. The packet is also adjacent to the finite ordered rows of chapter 2003, the matching discipline of chapter 234, and the ordered witness spines of chapter 36. It exports only displayed finite rows, not a host poset, not quotient order equality, and not a selected partition outside the carrier.

Definition 7139.1 (Mirsky theorem carrier)**.** *A* $\mathsf{MirskyTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, H, A, R, K, S, T, C, P, N)$$

with the following displayed rows:

1. *O is the finite* $\mathsf{Poset}^{\uparrow}$ *order row, including the carried elements, comparison ledger, and classifier for repeated element reads.*
2. *H is the chain-height row, recording a displayed maximal-chain height witness and a finite ledger that bounds all displayed chains by that height.*
3. *A is the antichain-partition row, recording finitely many layers whose union covers the carried elements and whose internal pairs are incomparable according to O.*
4. *R is the rank-layer row, assigning each element to the first displayed height level at which it appears in the finite predecessor recursion.*
5. *K is the chain-antichain consistency row, checking that the height ledger H and partition ledger A meet at the same number of displayed layers.*
6. *S is the sibling route row to* $\mathsf{DilworthDecomposition}^{\uparrow}$*,* $\mathsf{SpernerLemma}^{\uparrow}$*,* $\mathsf{Matching}^{\uparrow}$*, and* $\mathsf{List}^{\uparrow}$*.*
7. *T is componentwise* hsame *transport for the order, height, partition, rank, consistency, sibling route, replay, provenance, and local naming rows.*
8. *C is the displayed* Cont *replay route from O, H, A, R, K, S through T to P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{MirskyTheorem}^{\uparrow}$*,* $\mathsf{Poset}^{\uparrow}$*,* $\mathsf{DilworthDecomposition}^{\uparrow}$*,* $\mathsf{SpernerLemma}^{\uparrow}$*,* $\mathsf{Matching}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MirskyTheorem}^{\uparrow}}$ *row.*
The carrier has no coordinate for an ambient host partial order, quotient order equality, unlisted antichain partition, selected rank function outside R, countable choice, or infinite-height theorem.

Lean4 (statement) `BEDC.Derived.MirskyTheoremUp`

Theorem 7139.2 (Mirsky theorem NameCert obligations)**.** *For an accepted* $\mathsf{MirskyTheorem}^{\uparrow}$ *carrier*

$$M = (O, H, A, R, K, S, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MirskyTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite order, chain-height, antichain-partition, rank-layer, consistency, sibling-route, transport, replay, provenance, and local naming rows; order exposure through O; height exposure through H; antichain-partition exposure through A; rank-layer compatibility through R; height-partition equality through K; and nonescape for host posets, quotient order equality, unlisted partitions, external rank selectors, choice, and infinite-order data.*

Proof. Project the carrier of Definition 7139.1. The finite order is O, the height witness is H, the antichain partition is A, the rank-layer assignment is R, and the equality check between height and layer count is K.

The order exposure obligation is rowwise. Every chain, layer, rank comparison, and sibling read uses the same displayed $\mathsf{Poset}^{\uparrow}$ comparison ledger, so a consumer cannot mix the height of one order with the partition of another.

The height and partition obligations are the two visible halves of Mirsky's finite theorem. Row H records the maximal-chain height boundary, while A records the layer partition into antichains.

The rank and consistency rows then bind those halves. Row R places elements into displayed layers using the finite predecessor recursion, and row K checks that the number of layers agrees with the height ledger.

Finally S, T, C, P, N preserve the sibling route, transport, replay, provenance, and local name. Since the listed rows exhaust the carrier, the excluded host order, quotient equality, unlisted partitions, external rank selectors, choice, and infinite-order principles have no place in the certificate. □

Theorem 7139.3 (Mirsky chain-antichain rank handoff)**.** *Let $M = (O, H, A, R, K, S, T, C, P, N)$ be an accepted* $\mathsf{MirskyTheorem}^{\uparrow}$ *carrier. Every chain-height or antichain-partition consumer exported by M factors through the displayed route*

$$\mathsf{Poset}^{\uparrow},\ \mathsf{DilworthDecomposition}^{\uparrow},\ \mathsf{SpernerLemma}^{\uparrow},\ \mathsf{Matching}^{\uparrow},\ \mathsf{List}^{\uparrow}$$

by reading $O, H, A, R, K, S, T, C, P, N$ in order. The handoff identifies height, rank layers, and antichain partition only through the displayed finite rows, and it exports no host cardinality theorem, quotient order equality, selected external partition, countable choice, or infinite poset theorem.

Proof. First read the finite order row. The $\mathsf{Poset}^{\uparrow}$ packet supplies the carried elements, comparison ledger, and classifier needed before chains, ranks, or antichain layers can be inspected.

Next read the height and partition rows. The chain-height row H records the displayed height witness, while the antichain-partition row A records the covering family of layers.

The rank handoff is supplied by R and K. The rank-layer row assigns elements to finite levels, and the consistency row checks that the layer count and chain-height ledger meet at the same displayed boundary.

Finally route the handoff through S, T, C, P, N. The sibling route may cite Dilworth, Sperner, Matching, and List packets as finite dependency surfaces, but the exported Mirsky read remains the listed BEDC packet rather than an ambient theorem over a host poset. □

Closure status for $\mathsf{NameCert}_{\mathsf{MirskyTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{MirskyTheorem}^{\uparrow}$ packet is generated from a finite Poset row, a chain-height ledger, an antichain-partition ledger, rank-layer witnesses, height-partition consistency, sibling route rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MirskyTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7139.1, Definition 7139.2, and Definition 7139.3 seed the finite chain-height and antichain-partition certificate over Poset, DilworthDecomposition, SpernerLemma, Matching, and List rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MirskyTheorem}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim host partial orders, quotient order equality, selected external partitions, countable choice, infinite posets, checked Lean obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, order exposure, height exposure, antichain-partition exposure, rank-layer compatibility, height-partition consistency, transport, replay, provenance, and local naming for BEDC.Derived.MirskyTheoremUp.

Chapter 7140

A Concrete Naming Certificate for $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$

Following Bishop and Bridges on constructive interval compactness, the $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$ packet records a finite dyadic endpoint grid over a displayed closed Real interval. It sits over the dyadic arithmetic core of chapter 291, the finite stream-name windows of chapter 126, the regular rational readback rows of chapter 301, the terminal Real seal of chapter 38, and the closed interval boundary of chapter 1591. The packet names a constructive finite grid object for Real and Completion consumers; it is not Heine–Borel compactness, not open-cover compactness, not a selected limit principle, not trichotomy, not quotient real equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7140.1 (CompactIntervalDyadicGrid carrier)**.** *A* $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, \delta, E, M, W, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row naming the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint seals, endpoint order data, and interval-containment boundary.*
2. *δ is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row used as the displayed grid precision.*
3. *E is the endpoint-containment row recording dyadic lower and upper endpoint brackets for I at mesh δ.*
4. *M is the finite mesh row listing the dyadic grid cells between the endpoint brackets.*
5. *W is the finite window row exposing the* $\mathsf{StreamName}^{\uparrow}$ *observations used to read the endpoint brackets and each grid cell.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row sealing the endpoint and cell reads as regular rational names and terminal Real-facing rows.*
7. *H records componentwise* hsame *transport for the interval source, dyadic mesh, endpoint containment, finite mesh, finite windows, regular handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an interval-and-mesh request through $I, \delta, E, M, W, R, H, P, N$ without adding an off-grid point.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactIntervalDyadicGrid}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $I, \delta, E, M, W, R, H, C, P, N$. It has no coordinate for an arbitrary open cover, a choice-selected finite subcover, a selected limit point, trichotomy for Real endpoints, quotient real equality, or ambient Real completeness.

Theorem 7140.2 (CompactIntervalDyadicGrid NameCert obligations)**.** *For every accepted* CompactIntervalDyadic *carrier $G = (I, \delta, E, M, W, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalDyadicGrid}^{\uparrow}}$ *surface consists exactly of carrier admission for the closed interval source, dyadic mesh, endpoint-containment, finite mesh, finite window, regular-rational handoff, and Real-facing seal rows; componentwise classifier transport through H; displayed continuation replay through C; provenance through P; local naming through N; and nonescape from arbitrary open covers, selected finite subcovers, selected limits, trichotomy, quotient real equality, and ambient Real completeness.*

Proof. Project the carrier of Definition 7140.1. The only interval source is I, the only mesh source is δ, the only endpoint-containment source is E, and the only finite grid source is M.

The finite observation and completion-facing reads are carried by W and R. Thus every endpoint bracket and cell row is consumed through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ after the dyadic mesh has already been displayed.

The transport row H preserves these rows componentwise, and C replays the same interval-and-mesh request without adding an off-grid point. The provenance and local naming rows only source and name the same finite packet, so the listed obligations exhaust the NameCert surface and exclude the nonlocal objects named in the statement. □

Theorem 7140.3 (CompactIntervalDyadicGrid Real handoff)**.** *Every accepted* $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$ *read is consumed through the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{ClosedBoundedInterval}^{\uparrow}.$$

In this route the dyadic mesh row δ and endpoint-containment row E are read before finite stream windows W, the regular-rational and Real handoff row R, and the closed interval source row I are consumed by a Real or Completion-facing client. The route exports a finite endpoint grid and nonescape certificate, not Heine–Borel compactness, open-cover compactness, selected limits, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the dyadic mesh row δ and endpoint-containment row E. They are the only rows that determine the grid precision and endpoint brackets, so the finite mesh row M can only be read after the $\mathsf{DyadicRatCore}^{\uparrow}$ source has been exposed.

Next read the finite observation row W. It binds the endpoint brackets and each grid cell to displayed $\mathsf{StreamName}^{\uparrow}$ windows rather than to an ambient subset of a host real line.

Finally pass through R and I. The row R gives the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff for the endpoint and cell reads, while I supplies the $\mathsf{ClosedBoundedInterval}^{\uparrow}$ boundary consumed by the downstream interval client.

No carrier coordinate remains for an open cover, selected subcover, selected limit, trichotomy, quotient equality, or ambient completeness theorem. The handoff is therefore the displayed finite L10 route and nothing stronger. □

Falsifiable prediction: Every $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$ consumer that reads a finite endpoint grid over a closed Real interval must display the closed interval source, dyadic mesh, endpoint-containment row, finite mesh row, finite stream windows, RegSeqRat/Real handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row.

Independence witness: closedboundedinterval, dyadicratcore, streamname, regseqrat, real: none is bijective with $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$ because this packet alone binds a displayed closed Real interval to a finite dyadic endpoint grid, finite observation windows, regular-rational handoff, nonescape replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalDyadicGrid}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalDyadicGrid}^{\uparrow}$ packet is generated from a closed bounded interval source, a DyadicRatCore mesh, endpoint-containment rows, finite mesh rows, StreamName observations, RegSeqRat and Real handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalDyadicGrid}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7140.1, Definition 7140.2, and Definition 7140.3 seed the finite dyadic endpoint-grid packet over ClosedBoundedInterval, DyadicRatCore, StreamName, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalDyadicGrid}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Heine–Borel compactness, open-cover compactness, selected limits, trichotomy, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh exactness, endpoint containment, RegSeqRat and Real handoff, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.CompactIntervalDyadicGridUp.

Chapter 7141

A Concrete Naming Certificate for $\mathsf{RadonPartition}^{\uparrow}$

Following Radon and standard finite-dimensional convex geometry, the $\mathsf{RadonPartition}^{\uparrow}$ packet records a finite affine-dependence split as BEDC naming data. It sits over the ambient affine carrier of chapter 206, the vector-space dependence rows of chapter 47, the convex membership surface of chapter 208, the finite face and witness rows of chapter 209, the finite support route of chapter 2347, and the finite-intersection route of chapter 2309. The packet names only the displayed support family, signed coefficient ledger, convex-hull intersection witness, transport, replay, provenance, and local naming; it does not assert a host separation theorem, a selected intersection point outside the packet, quotient convex-set equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7141.1 (Radon partition carrier)**.** *A* $\mathsf{RadonPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, V, F, C, P, I, H, T, Q, N)$$

with the following displayed rows:

1. *A is the finite-dimensional* $\mathsf{AffineSpace}^{\uparrow}$ *ambient row through which all point histories and affine combinations are read;*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *translation row that records the vector-dependence read underlying the affine relation;*
3. *F is the finite support family, listing the displayed point histories whose affine dependence is being split;*
4. *C is the signed coefficient ledger, recording positive-side and negative-side coefficient rows, zero-sum balance, and equal normalized total mass;*
5. *P is the partition row, assigning each displayed support history to the positive side, the negative side, or a zero-coefficient boundary row;*
6. *I is the convex-hull intersection witness, stored as finite replay data over the two convex combinations and read through* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Polytope}^{\uparrow}$*,* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$*, and* $\mathsf{HellyTheorem}^{\uparrow}$ *sibling routes;*
7. *H is the componentwise* hsame *transport for ambient, vector, support, coefficient, partition, and intersection rows;*

8. *T is the displayed* Cont *route that replays the affine-dependence split without adding host convexity data;*
9. *Q is the* Pkg *provenance over* $\mathsf{RadonPartition}^{\uparrow}$, $\mathsf{AffineSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{CaratheodoryConvexHull}^{\uparrow}$, $\mathsf{HellyTheorem}^{\uparrow}$, BHist, hsame, Cont, *and local* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RadonPartition}^{\uparrow}}$ *row.*

The carrier exposes no ambient theorem that every large finite point family admits such a split, no quotient equality of convex hulls, no selected host point, and no standard bridge row.

Theorem 7141.2 (Radon partition NameCert obligations)**.** *For the carrier of Definition 7141.1, the local* $\mathsf{NameCert}_{\mathsf{RadonPartition}^{\uparrow}}$ *surface consists exactly of carrier admission for the affine ambient row, vector-dependence row, finite support family, signed coefficient ledger, partition row, convex-hull intersection witness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Classifier stability is tested only by replaying the same support family, coefficient balance, side assignment, and intersection witness through transported affine, vector, convex, polytope, Caratheodory, and Helly rows. Ledger exactness says that every accepted Radon-partition read exposes precisely $A, V, F, C, P, I, H, T, Q, N$ and no external convex-geometry datum.*

Theorem 7141.3 (Radon affine-dependence route)**.** *Every accepted* $\mathsf{RadonPartition}^{\uparrow}$ *packet routes a finite convex-geometry consumer through*

$$\mathsf{AffineSpace}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{Polytope}^{\uparrow},\ \mathsf{CaratheodoryConvexHull}^{\uparrow},\ \mathsf{HellyTheorem}^{\uparrow}.$$

The affine and vector rows fix the displayed dependence source, the finite support and signed coefficient rows record the zero-sum balance, the partition row separates the two convex sides, and the intersection witness is readable only after the convex-set, polytope, Caratheodory, and Helly sibling routes have been exposed. A consumer that omits any of those rows is outside the accepted $\mathsf{RadonPartition}^{\uparrow}$ *carrier.*

Closure status for $\mathsf{NameCert}_{\mathsf{RadonPartition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RadonPartition}^{\uparrow}$ packet is generated from finite-dimensional affine ambient data, vector-dependence data, a finite support family, signed coefficient and partition ledgers, a convex-hull intersection witness, componentwise transport, continuation replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RadonPartition}^{\uparrow}}$, seed)

Scope closed: Definition 7141.1, Definition 7141.2, and Definition 7141.3 seed the finite affine-dependence split, signed-coefficient, convex-hull intersection, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RadonPartition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host Radon theorem, host separation, selected intersection points, quotient convex-set equality, ambient Real completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, affine-dependence replay, signed-coefficient exactness, partition routing, convex-hull intersection witness, transport, provenance, and local naming for BEDC.Derived.RadonPartitionUp.

Chapter 7142

A Concrete Naming Certificate for $\mathsf{CompactIntervalChoiceSequence}^{\uparrow}$

Following Bishop and Bridges constructive interval analysis, the $\mathsf{CompactIntervalChoiceSequence}^{\uparrow}$ packet records the finite-window data needed to read a compact real interval through choice-sequence observations without importing open-cover compactness or ambient $\mathsf{Real}^{\uparrow}$ completeness. It sits between the located interval routes of chapter 1711 and chapter 6253, the dyadic tolerance core of chapter 1562, the stream-name surface of chapter 126, the regular rational readback of chapter 301, and the real-name boundary of chapter 38. The packet gives downstream L10 Real and Completion consumers a finite interval choice-sequence route over $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Definition 7142.1 (CompactIntervalChoiceSequence carrier)**.** *A* $\mathsf{CompactIntervalChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed real interval, its endpoint order, and its located membership tests;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the finite dyadic mesh budget used by the interval read;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing the finite choice-sequence prefix of sampled interval names;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational approximants visible in S;*
5. *E is the endpoint-and-enclosure ledger proving that every displayed sample remains inside the located interval named by I with tolerance budget D;*
6. *H records componentwise* hsame *transport for I, D, S, R, E;*
7. *C is the* Cont *replay row for the finite choice-sequence prefix and its dyadic tolerance window;*
8. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalChoiceSequence}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for open-cover compactness, selected infinite branches, quotient equality of streams, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CompactIntervalChoiceSequenceUp.CompactIntervalChoiceSequenceTasteGate single carrier alignment`

Theorem 7142.2 (CompactIntervalChoiceSequence NameCert obligations)**.** *For the carrier of Definition 7142.1, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceSequence}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *carrier exposure for* $K = (I, D, S, R, E, H, C, P, N)$*;*
2. *located interval admission through* I *and its endpoint order;*
3. *dyadic tolerance and regular rational readback through* D, S, R*;*
4. *endpoint and enclosure exactness through* E *and componentwise transport through* H*;*
5. *finite replay, provenance, and naming through* C, P, N*.*

Every accepted compact-interval choice-sequence consumer must read those rows before using the packet. No consumer may replace them by an arbitrary open-cover compactness theorem, a selected infinite branch, quotient stream equality, a hidden choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the displayed carrier. The rows $I, D, S, R, E, H, C, P, N$ are the complete local inventory, so the certificate cannot read an endpoint, tolerance, stream prefix, rational approximant, or enclosure fact outside that finite tuple.

The located interval admission is carried by I. The dyadic and rational data are then read through D, S, R, with S exposing only a finite choice-sequence prefix and R attaching regular rational readback to the observations already visible in that prefix.

Next inspect endpoint and enclosure exactness. The row E binds every displayed sample to the located interval named by I under the tolerance budget in D, and H transports exactly those rows componentwise.

Finally C, P, N replay, source, and name the same finite data. Since no carrier coordinate supplies an open cover, infinite branch selector, quotient stream witness, or completeness theorem for $\mathsf{Real}^{\uparrow}$, the five obligation rows exhaust the local NameCert surface. □

Theorem 7142.3 (CompactIntervalChoiceSequence L10 handoff)**.** *Every L10 Real and Completion consumer that reads a compact interval through* $\mathsf{CompactIntervalChoiceSequence}^{\uparrow}$ *factors through the finite chain*

$$\mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longrightarrow E, H, C, P, N \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff gives the consumer a located real interval, a dyadic tolerance budget, a finite choice-sequence prefix, regular rational readback, endpoint enclosure, componentwise transport, replay, provenance, and local naming. It gives no open-cover compactness theorem, selected infinite branch, quotient stream equality, countable-choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from the interval and tolerance rows. The L10 consumer receives the located interval only as the displayed row I, and its finite tolerance budget only through D.

The choice-sequence information is then finite. The row S displays the observed prefix, while R gives regular rational readback for the samples already exposed by that prefix.

Use the enclosure and structural rows next. The row E keeps the samples inside the located interval under the dyadic budget, and H, C, P, N transport, replay, source, and name the same finite packet.

Thus the route into $\mathsf{Real}^{\uparrow}$ is exhausted by the displayed chain. Because the carrier contains no open-cover row, branch selector, quotient stream witness, countable-choice coordinate, or completeness proof for $\mathsf{Real}^{\uparrow}$, the handoff cannot export any of those principles. □

Falsifiable prediction: Removing the stream-prefix row or the endpoint-and-enclosure ledger lets the consumer confuse finite interval observations with a selected infinite branch, so the L10 handoff no longer has a finite NameCert surface.

Independence witness: Nearest siblings: located-interval-bisection, located-interval-completion, dyadic-rat-core-arithmetic, stream-name, regseqrat, real. This packet combines a located interval row, dyadic tolerance budget, finite choice-sequence prefix, regular rational readback, and endpoint enclosure ledger as one carrier; each named sibling lacks at least one of those coordinates as a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalChoiceSequence}^{\uparrow}$ packet is generated from a located interval row, dyadic tolerance budget, finite choice-sequence prefix, regular rational readback, endpoint enclosure ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7142.1, Definition 7142.2, and Definition 7142.3 state the finite carrier, local NameCert surface, and L10 handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, quotient streams, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: The next step is a Lean carrier and NameCert obligation surface for the finite interval choice-sequence packet.

Chapter 7143

A Concrete Naming Certificate for $\mathsf{ClosedMetricGraph}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{ClosedMetricGraph}^{\uparrow}$ packet reconstructs sequential graph closure as finite BEDC NameCert data. It sits between the metric-graph source of chapter 6788, the closed-ball boundary of chapter 1451, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names one displayed graph row together with source and target convergence windows; it does not import the closed graph theorem, a Banach-space argument, quotient graph equality, or a choice-selected subsequence.

Definition 7143.1 (Closed metric graph carrier)**.** *A* $\mathsf{ClosedMetricGraph}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, F, S, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric carrier, read through the* $\mathsf{MetricGraph}^{\uparrow}$ *or sibling* $\mathsf{Met}^{\uparrow}$ *source surface.*
2. *Y is the target metric carrier whose endpoint comparisons are read through displayed* $\mathsf{MetricClosedBall}^{\uparrow}$ *rows.*
3. *F is the graph row, naming the finite membership relation between source rows of X and target rows of Y.*
4. *S is the source convergent-window ledger, recording the displayed source approximation windows before any limit packet is read.*
5. *T is the target convergent-window ledger, recording the displayed target approximation windows paired with S.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the target window ledger into regular rational comparison data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the target limit comparison exposed by R.*
8. *H records componentwise* hsame *transport for X, Y, F, S, T, R, E and the structural rows.*
9. *C records displayed* Cont *replay from paired graph rows through the source and target windows to the terminal seal.*
10. *P is the* Pkg *provenance over* $\mathsf{ClosedMetricGraph}^{\uparrow}$, $\mathsf{MetricGraph}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedMetricGraph}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient closed subset of a product, quotient equality of graph points, a selected subsequence, a Banach-space closed graph theorem, or a host completeness principle.

Theorem 7143.2 (Closed metric graph sequential closure)**.** *Let $G = (X, Y, F, S, T, R, E, H, C, P, N)$ be an accepted* $\mathsf{ClosedMetricGraph}^{\uparrow}$ *packet. If the displayed source graph rows converge through S and the displayed target graph rows converge through T, R, E, then the graph membership row F transports through H and replays through C to the limit packet named by the same local* NameCert *row N. The transport uses only the metric source rows, closed-ball target comparisons, regular rational readback, real seal, replay, provenance, and local naming rows already present in G; it does not use host quotient equality, external sequence choice, or ambient closed-subset semantics.*

Lean4 ✓ `BEDC.Derived.ClosedMetricGraphUp.ClosedMetricGraphCarrier sequential closure`

Proof. Project the carrier of Definition 7143.1. The only graph membership source is F, and the only convergence ledgers are the source window S and target window T.

Read the target limit route next. The regular rational readback R and terminal real seal E keep every target comparison inside the displayed $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ surfaces, while the closed-ball boundary keeps the comparison non-strict and packet-local.

Transport is then componentwise. The row H moves the source carrier, target carrier, graph row, source window, target window, readback row, and real seal together, and C replays the same route before the provenance row P and local name N expose the limit packet.

The exclusions follow from the finite inventory. No row of G stores a host product closed subset, a quotient equality test for graph points, a subsequence selector, a Banach-space theorem, or an ambient completeness principle, so the sequential closure read remains the displayed NameCert transport. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedMetricGraph}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedMetricGraph}^{\uparrow}$ packet is generated from source and target metric carriers, a graph membership row, source and target convergent windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosedMetricGraph}^{\uparrow}}$, seed)

Scope closed: Definition 7143.1 and Definition 7143.2 seed the finite graph-closure source packet over $\mathsf{MetricGraph}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosedMetricGraph}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.ClosedMetricGraphUp`

Bridge status: none

Not claimed: This chapter does not close the full closed graph theorem, any Banach-space theorem, quotient graph equality, choice-selected subsequences, ambient closed-subset semantics, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window convergence, target-window readback, Real seal transport, graph-membership replay, provenance, refusal, and local naming for BEDC.Derived.ClosedMetricGraphUp.

Chapter 7144

A Concrete Naming Certificate for $\mathsf{LocatedApartnessField}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedApartnessField}^{\uparrow}$ packet records the ordered-field-facing real interface whose comparisons are read through located apartness data rather than through a trichotomy principle. It consumes the constructive real-line surface of chapter 4041, the located real boundary of **??**, the located apartness boundary of chapter 1380, the positive-order handoff of chapter 1905, and the L10 source route through chapter 291, chapter 126, chapter 301, and chapter 38. The chapter names the finite field-facing packet; it does not claim quotient real equality, selected limits, trichotomy, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 7144.1 (Located apartness field carrier)**.** *A* $\mathsf{LocatedApartnessField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, E, L, A, O, M, I, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for radii, slack comparisons, and field-operation error bounds.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect each real-name input and each operation output.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected windows into regular rational approximants.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been displayed.*
5. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *interval-location row for the same readback surface.*
6. *A is the* $\mathsf{LocatedApartness}^{\uparrow}$ *positive-separation row used when a consumer requests apartness.*
7. *O records the finite addition, negation, multiplication, and unit rows whose outputs are again read through D, S, R, E.*
8. *M records the inverse row, available only with an A-witness separating the input from zero.*
9. *I is the* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *comparison handoff from positive apartness data to order-facing finite comparison cells.*
10. *H records componentwise* hsame *transport for $D, S, R, E, L, A, O, M, I, C, P, N$.*

11. *C records displayed* Cont *replay from a field-facing request to the finite tolerance, window, readback, seal, locatedness, apartness, operation, inverse, and order-handoff rows.*
12. *P is the* Pkg *provenance over* $\mathsf{LocatedApartnessField}^{\uparrow}$, $\mathsf{ConstructiveRealLine}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{RealApartnessOrderBridge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedApartnessField}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the rows $D, S, R, E, L, A, O, M, I, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7144.2 (Located apartness field NameCert obligations)**.** *For every accepted* $\mathsf{LocatedApartnessField}^{\uparrow}$ *carrier*

$$F = (D, S, R, E, L, A, O, M, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedApartnessField}^{\uparrow}}$ *surface consists exactly of carrier admission; L10 source admission through D, S, R, E; locatedness admission through L; apartness admission through A; operation admission through O; inverse admission through M only under displayed apartness from zero; order-handoff admission through I; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7144.1. The L10 source rows D, S, R, E are visible before any field-facing output can be read.

Read the located and apartness boundary rows next. The row L supplies interval-location data, while A supplies positive separation evidence for apartness-sensitive consumers.

The algebra rows are then forced to remain on the same route. The operation row O reads its inputs and outputs through D, S, R, E, and the inverse row M is available only after the zero-separation evidence is displayed through A.

Finally the order bridge I and the structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no further coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7144.3 (Located apartness field real nonescape)**.** *Every field-facing consumer exported by an accepted* $\mathsf{LocatedApartnessField}^{\uparrow}$ *carrier factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the displayed $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, *and* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *boundary rows. The consumer receives a finite located-apartness field interface, not trichotomy, quotient real equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the L10 source route D, S, R, E in Definition 7144.1. Every operation output and every comparison endpoint must pass through the dyadic tolerance ledger, stream windows, regular rational readback, and terminal real seal.

The located and apartness reads remain boundary reads. A location request must use L, a positive-separation request must use A, and an order-facing comparison must use the handoff row I from chapter 1905.

The operation and inverse rows do not add a host real object. They only repack the same inspected rows and, in the inverse case, require displayed apartness from zero.

Transport and replay through H and C, then read provenance and local naming through P and N. The route contains no trichotomy branch, quotient real constructor, selected limit, or completeness witness, so none of those objects can escape through the field-facing interface. □

Falsifiable prediction: Every $\mathsf{LocatedApartnessField}^{\uparrow}$ field-facing read factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedApartness}^{\uparrow}$, $\mathsf{RealApartnessOrderBridge}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: constructive-real-line, locatedreal, located-apartness, real-apartness-order-bridge, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedApartnessField}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries field-operation rows, inverse rows guarded by apartness from zero, locatedness rows, positive-separation rows, order-facing comparison rows, L10 readback rows, transport, replay, provenance, and local naming as one field-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedApartnessField}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedApartnessField}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readback, a terminal RealUp seal, LocatedReal interval rows, LocatedApartness positive-separation rows, field operation rows, inverse rows guarded by apartness from zero, RealApartnessOrderBridge comparison handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedApartnessField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7144.1, Definition 7144.2, and Definition 7144.3 seed the finite located-apartness field interface over ConstructiveRealLineUp, LocatedRealUp, LocatedApartnessUp, RealApartnessOrderBridgeUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedApartnessField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter refuses trichotomy, quotient real equality, selected limits, and ambient Real completeness.

Upgrade path: A formal route can encode the displayed carrier and prove source admission, locatedness and apartness boundaries, field operation closure, inverse guarding by apartness from zero, order-handoff discipline, transport, replay, provenance, and ledger nonescape for BEDC.Derived.LocatedApartnessFieldUp.

Chapter 7145

A Concrete Naming Certificate for $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$ packet records the finite binary comparison surface by which two regular Cauchy windows are compared through one displayed dyadic tolerance ledger. It sits beside the finite stream rows of chapter 126, the dyadic arithmetic core of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the window-step route of chapter 1020. The packet is a finite comparison interface for Real and Completion consumers; it is not quotient stream equality, selected limits, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7145.1 (Cauchy-window comparison principle carrier)**.** *A* $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S_0, S_1, D, R_0, R_1, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened for the compared regular Cauchy names.*
2. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested dyadic radius, the two displayed observations, and the arithmetic comparison budget used by the binary read.*
3. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from* S_0, S_1 *through the same dyadic ledger.*
4. E *is the comparison-evidence row consumed before any downstream* $\mathsf{Real}^{\uparrow}$ *seal or* $\mathsf{CauchyWindowTransducer}^{\uparrow}$ *handoff can be read.*
5. H *records componentwise* hsame *transport for* $S_0, S_1, D, R_0, R_1, E, C, P, N$.
6. C *records the displayed* Cont *replay route from the two stream windows through the dyadic ledger, regular rational readbacks, comparison evidence, transport, provenance, and local naming rows.*
7. P *is the* Pkg *provenance over* $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyWindowTransducer}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these ten rows. It has no coordinate for quotient stream equality, a selected limit, host equality of completed reals, countable choice, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyWindowComparisonPrincipleUp.CauchyWindowComparisonPrincipleTasteGate single carrier alignment`

Theorem 7145.2 (Cauchy-window comparison principle NameCert obligations)**.** *For every accepted* $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$ *carrier*

$$K = (S_0, S_1, D, R_0, R_1, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission for the two displayed* $\mathsf{StreamName}^{\uparrow}$ *windows, shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, comparison-evidence row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyWindowTransducer}^{\uparrow}$ *consumer must read the comparison-evidence row only after the two source windows, the dyadic ledger, and both regular rational readbacks have been displayed.*

Proof. Project the carrier of Definition 7145.1. Its visible inventory is precisely $S_0, S_1, D, R_0, R_1, E, H, C, P, N$.

The binary comparison is finite because S_0 and S_1 list the two inspected windows and D records the single dyadic tolerance ledger used to compare the displayed observations. The readback rows R_0 and R_1 are then the regular rational data available to downstream consumers.

The comparison-evidence row E is not a completed real equality. It is only the local row consumed after the stream windows, dyadic ledger, and readbacks have been exposed.

Finally H and C transport and replay the same rows, while P and N bind provenance and local naming. Since no other coordinate is present, the listed rows exhaust the NameCert obligation surface. □

Theorem 7145.3 (Cauchy-window comparison principle L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$ *packet receives a binary regular-Cauchy comparison only through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ E, H, C, P, N.$$

If the consumer later calls a $\mathsf{Real}^{\uparrow}$ *row or a* $\mathsf{CauchyWindowTransducer}^{\uparrow}$ *row, that call must be supplied by the downstream packet after this route has been displayed. The handoff exports no* $\mathsf{Real}^{\uparrow}$ *completeness theorem, no quotient stream equality, no selected limit, no host equality, and no countable-choice schedule.*

Proof. Start from an accepted packet $K = (S_0, S_1, D, R_0, R_1, E, H, C, P, N)$. The only source rows are the two $\mathsf{StreamName}^{\uparrow}$ windows, and the only tolerance row is the shared $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

The two $\mathsf{RegSeqRat}^{\uparrow}$ rows are read from those displayed windows through the same ledger. Thus the comparison-evidence row E is already tied to finite window observations before any Real-facing or transducer-facing consumer can use it.

Transport, replay, provenance, and local naming preserve the route but do not add another endpoint. A later $\mathsf{Real}^{\uparrow}$ seal or $\mathsf{CauchyWindowTransducer}^{\uparrow}$ handoff must therefore come from its own downstream packet, and the comparison principle itself exports none of the excluded completion, quotient, selection, host-equality, or choice data. □

Falsifiable prediction: Every accepted $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$ read exposes two StreamName finite-window rows, one DyadicRatCore tolerance ledger, two RegSeqRat readback rows, one comparison-evidence row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before any RealUp or CauchyWindowTransducer handoff is consumed.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchy-window-transducer: $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds two finite windows, one shared dyadic comparison ledger, two regular rational readbacks, comparison evidence, transport, replay, provenance, and local naming while refusing quotient stream equality, selected limits, host equality, countable choice, and ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7145.1, Definition 7145.2, and Definition 7145.3 seed the finite binary comparison surface over two StreamName windows, one DyadicRatCore ledger, two RegSeqRat readbacks, comparison evidence, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyWindowComparisonPrincipleUp.CauchyWindowComparisonPrincipleTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host equality, countable choice, standard bridges, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic comparison exactness, readback stability for both rows, transducer handoff nonescape, replay, provenance, local naming, and L10 route exhaustion for BEDC.Derived.CauchyWindowComparisonPrincipleUp.

Constructive story: A $\mathsf{CauchyWindowComparisonPrinciple}^{\uparrow}$ packet is generated from two StreamName finite-window rows, one DyadicRatCore tolerance ledger, two RegSeqRat readbacks, comparison evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7146

A Concrete Naming Certificate for $\mathsf{WhitneyCoveringFinite}^{\uparrow}$

Following Whitney's covering decomposition and constructive metric-analysis finite-net practice, the $\mathsf{WhitneyCoveringFinite}^{\uparrow}$ packet records a finite local covering family as BEDC NameCert data. It sits over the metric source of chapter 57, the doubling control of chapter 2035, the finite-net handoff of chapter 1767, the total-bounded consumer surface of chapter 127, and the multiscale dyadic skeleton of chapter 6909. The packet names only the displayed finite covering route; it does not import measure theory, open-cover compactness, selected infinite covers, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7146.1 (WhitneyCoveringFinite carrier)**.** *A* $\mathsf{WhitneyCoveringFinite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, O, D, F, B, S, E, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, recording the carrier, distance-reading route, and local metric naming surface.*
2. *O is the open-region request row, naming the displayed region whose finite Whitney cells are being read.*
3. *D is the dyadic scale ledger, read through the* $\mathsf{DyadicNetTree}^{\uparrow}$ *scale and parent-child rows.*
4. *F is the selected finite cell family, storing only the displayed cells and their attached centers, radii, and scale indices.*
5. *B is the bounded-overlap ledger, recording the finite overlap budget available for the selected cells.*
6. *S is the shadow-coverage row, asserting only the displayed coverage witnesses for the region requested by O.*
7. *E is the finite-epsilon-net handoff row, read through* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *and supplying the center witnesses consumed by F and S.*
8. *T is the total-bounded consumer row, read through* $\mathsf{TotallyBounded}^{\uparrow}$ *and used only as a finite coverage consumer.*

9. *H records componentwise* hsame *transport for the metric source, open-region request, dyadic ledger, selected cells, bounded-overlap ledger, coverage shadow, finite-net handoff, total-bounded consumer row, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a finite Whitney-covering request through $M, O, D, F, B, S, E, T, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{WhitneyCoveringFinite}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DoublingMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{DyadicNetTree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{WhitneyCoveringFinite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, O, D, F, B, S, E, T, H, C, P, N$. It has no coordinate for a measure algebra, open-cover compactness principle, selected infinite Whitney family, quotient equality of covers, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7146.2 (WhitneyCoveringFinite NameCert obligations)**.** *For every accepted* $\mathsf{WhitneyCoveringFinite}^{\uparrow}$ *carrier*

$$W = (M, O, D, F, B, S, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WhitneyCoveringFinite}^{\uparrow}}$ *surface consists exactly of carrier admission through M, open-region request visibility through O, dyadic scale visibility through D, selected finite-cell admission through F, bounded-overlap accounting through B, shadow coverage through S, finite-epsilon-net handoff through E, total-bounded consumer routing through T, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 7146.1. The metric source is M, the requested open region is O, and the scale information is the dyadic ledger D read through the finite net-tree route.

Next read the finite covering data. The selected cell family F is available only with its displayed centers, radii, and scale indices. The bounded-overlap ledger B and shadow-coverage row S are tied to that same finite family.

The consumer handoff is finite. The row E supplies the $\mathsf{FiniteEpsilonNet}^{\uparrow}$ witnesses, and the row T supplies the $\mathsf{TotallyBounded}^{\uparrow}$ consumer route, with $\mathsf{DoublingMetric}^{\uparrow}$ and $\mathsf{DyadicNetTree}^{\uparrow}$ only serving the displayed scale and overlap controls.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no measure-theoretic coordinate, open-cover compactness principle, infinite-cover selector, quotient-cover equality, or ambient real-completeness row, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{WhitneyCoveringFinite}^{\uparrow}$ read exposes the MetricUp source, open-region request, dyadic scale ledger, selected finite cell family, bounded-overlap ledger, shadow-coverage row, finite-epsilon-net handoff, total-bounded consumer row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any Whitney-covering consumer reads the packet.

Independence witness: metric, doublingmetric, finite-epsilon-net, totallybounded, dyadic-net-tree: no listed sibling is bijective with $\mathsf{WhitneyCoveringFinite}^{\uparrow}$ because this packet jointly stores an open-region request, selected finite cells, bounded-overlap ledger, shadow coverage, finite-net handoff, total-bounded consumer row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{WhitneyCoveringFinite}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WhitneyCoveringFinite}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7146.1 and Definition 7146.2 seed the finite Whitney-covering packet over displayed metric, open-region, dyadic-scale, finite-cell, bounded-overlap, shadow-coverage, finite-net, total-bounded, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{WhitneyCoveringFinite}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim measure theory, open-cover compactness, selected infinite covers, quotient equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, finite-cell selection, bounded-overlap accounting, shadow coverage, finite-net handoff, total-bounded routing, transport, replay, provenance, and local naming for BEDC.Derived.WhitneyCoveringFiniteUp.

Constructive story: A WhitneyCoveringFinite$^{\uparrow}$ packet is generated from a MetricUp source row, an open-region request row, a dyadic scale ledger, selected finite cells, a bounded-overlap ledger, a shadow-coverage row, a FiniteEpsilonNetUp handoff, a TotallyBoundedUp consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7147

A Concrete Naming Certificate for $\mathsf{LebesgueNumberModulus}^{\uparrow}$

Bishop–Bridges style compact metric analysis treats a Lebesgue-number argument as a finite-net calculation once the compact source, metric scale, cover membership rows, and real-valued tolerance readbacks are displayed. The $\mathsf{LebesgueNumberModulus}^{\uparrow}$ packet records that finite route for the L10 compact/metric handoff. It sits over the compact finite-net source of chapter 129, the metric row of chapter 57, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite modulus packet only; it does not assert open-cover compactness, selected covers, ambient completeness, or a host Lebesgue-number theorem.

Definition 7147.1 (Lebesgue-number modulus carrier)**.** *A* $\mathsf{LebesgueNumberModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, U, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the consumed* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the displayed net cells and scale bound available to the compact route.*
2. *M is the consumed* $\mathsf{Met}^{\uparrow}$ *row used to read the distances between a requested point and the finite net witnesses.*
3. *U is the finite cover-admission ledger. It records which displayed cover row receives each named finite-net cell, without asserting open-cover compactness.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the positive radius, the mesh comparison, and the dyadic slack used by the handoff.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the metric and cover requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected windows and dyadic tolerances into regular rational comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the radius and comparison readbacks consumed by downstream uniform-modulus routes.*
8. *H records componentwise* hsame *transport for $K, M, U, D, S, R, E, C, P, N$.*
9. *C records displayed* Cont *replay from the compact finite-net source through metric, cover, dyadic, StreamName, RegSeqRat, and Real rows.*

10. *P is the* Pkg *provenance over* $\mathsf{LebesgueNumberModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, U, D, S, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary cover refinement, a selected global subcover, host real completeness, quotient metric equality, Lean verification, or bridge checking.

Theorem 7147.2 (Lebesgue-number modulus NameCert obligations)**.** *For every accepted* LebesgueNumberModulus *carrier*

$$L = (K, M, U, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LebesgueNumberModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact finite-net source, metric distance row, finite cover-admission ledger, dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming row; scale exactness requiring every radius read to pass through D, S, R, E; cover exactness requiring every cover read to pass through U after the compact finite-net row K; and nonescape from the named rows.*

Proof. Project the carrier of Definition 7147.1. The rows $K, M, U, D, S, R, E, H, C, P, N$ are exactly the inventory available to an accepted packet.

The compact route first reads the finite-net row K and the metric row M. The cover ledger U is then attached to those displayed net cells, so a cover read never becomes an external open-cover compactness principle.

The radius route is finite. The dyadic tolerance row D fixes the mesh and slack comparisons, S lists the inspected windows, R performs regular rational readback, and E seals the comparison as a $\mathsf{Real}^{\uparrow}$ row.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no additional carrier coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 7147.3 (Lebesgue-number modulus finite-net handoff)**.** *Every L10 compact-uniform or metric-continuity consumer of an accepted* $\mathsf{LebesgueNumberModulus}^{\uparrow}$ *carrier*

$$L = (K, M, U, D, S, R, E, H, C, P, N)$$

must factor its modulus read through the finite route

$$K, M \longmapsto U \longmapsto D, S, R, E \longmapsto H, C, P, N.$$

The consumer may export only the compact finite-net row, metric distance row, finite cover ledger, dyadic tolerance ledger, StreamName windows, RegSeqRat readback, terminal Real seal, transport, replay, provenance, and local naming rows. It may not export open-cover compactness, a selected subcover, a host Lebesgue-number theorem, quotient metric equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the compact finite-net and metric rows. They determine which displayed finite witnesses and distance comparisons may be inspected by a downstream L10 consumer.

Next read the finite cover ledger U. Its role is only to attach displayed cover rows to the finite net cells already exposed by K; it does not choose a cover or prove compactness for arbitrary open covers.

The modulus data are then read through D, S, R, E. Dyadic tolerance, finite StreamName windows, regular rational readback, and the Real seal give a finite positive-radius handoff to the consumer.

The structural rows H, C, P, N preserve and name the same route. Therefore every permitted read factors through the displayed finite-net handoff, and every excluded endpoint would require a carrier coordinate that L does not contain. □

Falsifiable prediction: Every accepted $\mathsf{LebesgueNumberModulus}^{\uparrow}$ read exposes a CompactMetric finite-net row, Metric distance row, finite cover ledger, DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row before any compact-uniform consumer reads the modulus.

Independence witness: compactmetric, metric, dyadicratcore, streamname, regseqrat, real: $\mathsf{LebesgueNumberModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact finite-net cells, metric distance reads, finite cover admission, dyadic tolerance, finite windows, regular rational readback, a Real seal, transport, replay, provenance, and local naming while refusing open-cover compactness, selected covers, quotient metric equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueNumberModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueNumberModulus}^{\uparrow}$ packet is generated from a CompactMetric finite-net source, Metric distance row, finite cover ledger, DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueNumberModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7147.1, Definition 7147.2, and Definition 7147.3 seed the finite Lebesgue-number modulus route over compact metric finite-net, metric, dyadic, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueNumberModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host Lebesgue-number theorems, quotient metric equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scale exactness, cover exactness, finite-net handoff, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.LebesgueNumberModulusUp.

Chapter 7148

A Concrete Naming Certificate for HyperbolicWhitneyShadowCover$^{\uparrow}$

The HyperbolicWhitneyShadowCover$^{\uparrow}$ packet realizes the finite shadow-cover branch of chapter 9463 as concrete NameCert data. It sits between the compactification surface of chapter 7019, the Gromov-boundary rows of chapter 6470, the visual-boundary packet of chapter 4181, the visual-metric rows of chapter 3866, and the boundary-shadow route of chapter 3813. The packet names a finite boundary shadow cover only; the Lean TasteGate side later needs Nontrivial and FieldFaithful instances before it can certify the intended hyperbolic comparison surface.

Definition 7148.1 (HyperbolicWhitneyShadowCover carrier)**.** *A* HyperbolicWhitneyShadowCover$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, V, G, B, T, F, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the hyperbolic metric source row, recording the displayed space, basepoint, coarse distance route, and local metric naming surface.*
2. *V is the visual-boundary row, read through* HyperbolicVisualBoundary$^{\uparrow}$ *and naming the boundary side visible to the observer.*
3. *G is the* GromovBoundary$^{\uparrow}$ *row, exposing the ray-equivalence and product data used by the visual boundary.*
4. *B is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row, recording the accepted finite shadow window.*
5. *T is the visual-metric tolerance row, read through* HyperbolicVisualMetric$^{\uparrow}$ *and the* Real$^{\uparrow}$ *seal.*
6. *F is the selected finite shadow family, storing only displayed shadows, centers, apertures, and scale indices.*
7. *R is the Real seal row, recording the finite real-valued tolerance read and no ambient real-completeness principle.*
8. *H records componentwise* hsame *transport for the metric source, visual boundary, Gromov boundary, boundary shadow, visual metric tolerance, selected shadow family, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite hyperbolic shadow-cover request through M, V, G, B, T, F, R, H.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}$, $\mathsf{HyperbolicBoundaryCompactification}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, V, G, B, T, F, R, H, C, P, N$. It has no coordinate for selected infinite shadows, quotient boundary equality, ambient real completeness, measure theory, ergodic density, host group action, or an unsealed visual metric.

Theorem 7148.2 (HyperbolicWhitneyShadowCover NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}$ *carrier*

$$S = (M, V, G, B, T, F, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}}$ *surface consists exactly of hyperbolic metric admission through M, visual-boundary exposure through V, Gromov-boundary exposure through G, boundary-shadow routing through B, visual-metric tolerance through T, selected finite shadow-family admission through F, Real sealing through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7148.1. The hyperbolic metric source is M, while V and G expose the boundary rows before any selected shadow can be read.

Next read the covering data. The boundary-shadow row B and visual-metric tolerance row T admit the shadow windows and tolerance, and the selected finite shadow family F stores only displayed centers, apertures, and scale indices.

The Real seal is explicit. The row R records the finite tolerance read through $\mathsf{Real}^{\uparrow}$, so the packet has a real-valued comparison row without importing ambient real completeness or a host visual-metric theorem.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no selected infinite-shadow family, quotient-boundary equality, measure-theoretic density, ergodic theorem, host group action, or unsealed metric coordinate, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}$ read exposes the gromov-boundary, hyperbolic-visual-metric, hyperbolic-boundary-shadow, hyperbolic-visual-boundary, and real rows before any finite shadow-cover consumer reads the packet.

Independence witness: gromov-boundary, hyperbolic-visual-metric, hyperbolic-boundary-shadow, hyperbolic-visual-boundary, real: no listed sibling is bijective with $\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}$ because this packet jointly stores a hyperbolic metric source, visual boundary, Gromov boundary, boundary shadow, visual-metric tolerance, selected finite shadow family, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7148.1 and Definition 7148.2 seed the finite hyperbolic shadow-cover packet over displayed metric, visual-boundary, Gromov-boundary, boundary-shadow, visual-metric, finite-shadow, Real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicWhitneyShadowCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected infinite shadows, quotient boundary equality, ambient Real completeness, measure theory, ergodic density, host group action, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, boundary exposure, shadow-window routing, visual-metric tolerance, selected finite shadows, Real sealing, transport, replay, provenance, local naming, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.HyperbolicWhitneyShadowCoverUp.

Constructive story: A HyperbolicWhitneyShadowCover$^{\uparrow}$ packet is generated from a hyperbolic metric source, visual-boundary row, Gromov-boundary row, boundary-shadow row, visual-metric tolerance row, selected finite shadow family, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7149

A Concrete Naming Certificate for $\mathsf{ConditionallyPositiveKernel}^{\uparrow}$

Following Schoenberg on conditionally positive definite kernels, the $\mathsf{ConditionallyPositiveKernel}^{\uparrow}$ packet records the finite centered-Gram route as BEDC NameCert data. It sits next to the positive finite Gram packet of chapter 6513, but its classifier is centered: coefficient rows must pass through a zero-sum ledger before a quadratic-form read is admissible. The packet consumes the finite matrix readback of chapter 49, the inner-product row of chapter 86, the Hilbert-facing handoff of chapter 91, and the real scalar seal of chapter 38; it does not assert a full Schoenberg embedding, a negative-type completion theorem, quotient functions, countable choice, or ambient Hilbert completeness.

Definition 7149.1 (Conditionally positive kernel carrier)**.** *A* $\mathsf{ConditionallyPositiveKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, A, Z, Q, M, I, H, R, T, C, P, N)$$

with the following displayed rows:

1. *V is the kernel-value row. It records the finite source list, displayed pairwise kernel values, diagonal reads, and symmetry requests inspected by the packet.*
2. *A is the centered coefficient row. It records the finite coefficient windows whose scalar entries are allowed to test conditional positivity.*
3. *Z is the zero-sum ledger. It records that the displayed coefficient row is centered before any Gram quadratic-form read is admitted.*
4. *Q is the centered Gram quadratic-form row. It records the finite expression $\sum_{i,j} a_i a_j K(x_i, x_j)$ together with the nonnegative comparison requested only after Z is displayed.*
5. *M is the $\mathsf{Mat}^{\uparrow}$ readback row. It records row-column indexing, entry readbacks, centered submatrix projections, and the finite matrix-vector products used by Q.*
6. *I is the $\mathsf{InnerProduct}^{\uparrow}$ handoff row. It records the inner-product readback surface through which a later Hilbert-facing consumer may interpret a centered Gram form.*
7. *H is the $\mathsf{Hilbert}^{\uparrow}$ handoff row. It records only the displayed finite route from centered Gram data toward Hilbert rows, without selecting an ambient feature map.*
8. *R is the $\mathsf{Real}^{\uparrow}$ scalar seal. It records real scalar values, zero-sum comparisons, nonnegative quadratic-form witnesses, and terminal real-name boundaries.*

9. *T records componentwise* hsame *transport for V, A, Z, Q, M, I, H, R.*
10. *C records displayed* Cont *replay for the route*

$$V, A, Z, Q, M, I, H \longmapsto R.$$

11. *P is the* Pkg *provenance over* ConditionallyPositiveKernel$^{\uparrow}$, MooreAronszajnKernel$^{\uparrow}$, Mat$^{\uparrow}$, InnerProduct$^{\uparrow}$, Hilbert$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{ConditionallyPositiveKernel}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $V, A, Z, Q, M, I, H, R, T, C, P, N$ and has no coordinate for uncentered positive-kernel positivity, a selected Hilbert embedding, quotient function equality, negative-type completion, countable choice, or ambient Hilbert completeness.

Theorem 7149.2 (Conditionally positive kernel NameCert obligations)**.** *For the carrier of Definition 7149.1, the local* NameCert$_{\text{ConditionallyPositiveKernel}^{\uparrow}}$ *surface consists exactly of carrier admission, kernel-value exposure, centered coefficient exposure, zero-sum ledger validation, centered Gram quadratic-form exposure,* Mat$^{\uparrow}$ *readback compatibility,* InnerProduct$^{\uparrow}$ *handoff,* Hilbert$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *scalar sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The surface exports no uncentered positive-kernel certificate, selected feature map, quotient function space, countable-choice schedule, negative-type completion, or ambient Hilbert theorem.*

Proof. Carrier admission is projection from Definition 7149.1. The packet displays exactly the finite kernel-value row, centered coefficient row, zero-sum ledger, centered quadratic-form row, matrix readback, inner-product and Hilbert handoff rows, real scalar seal, transport, replay, provenance, and local naming row.

The conditional positivity obligation is centered. The coefficient row A can reach the quadratic-form row Q only through the zero-sum ledger Z, and the scalar comparison at R records nonnegativity only for those displayed centered windows.

The analytic handoff remains local to the sibling certificates. The matrix row supplies finite readback, the inner-product row supplies the readout surface, and the Hilbert row records only the handoff boundary rather than a completed host space.

Finally T and C preserve the same route under hsame transport and Cont replay. Since P and N name no off-packet coordinate, the listed obligations exhaust the local NameCert surface and none of the excluded Hilbert or negative-type objects can be read from the packet. □

Theorem 7149.3 (Conditionally positive kernel centered Gram route)**.** *Every centered-Gram read of an accepted* ConditionallyPositiveKernel$^{\uparrow}$ *packet factors through the kernel-value row V, the centered coefficient row A, the zero-sum ledger Z, the centered quadratic-form row Q, the* Mat$^{\uparrow}$ *readback row M, the* InnerProduct$^{\uparrow}$ *and* Hilbert$^{\uparrow}$ *handoff rows I, H, the* Real$^{\uparrow}$ *scalar seal R,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The route is distinct from chapter 6513: it requires zero-sum centered coefficients before positivity is read, and it does not export full positive finite Gram rows or RKHS completion.*

Proof. Project the carrier rows. The only route from displayed kernel values to a real scalar comparison is

$$V, A, Z, Q, M, I, H \longmapsto R.$$

The zero-sum ledger is therefore unavoidable. An uncentered coefficient row has no path to Q, and the matrix readback row M exposes only the finite entries and products already attached to the centered window.

The sibling handoff is also finite. Rows I and H point to the inner-product and Hilbert surfaces, while R seals the scalar comparison; none of these rows selects a Hilbert embedding or a completed reproducing-kernel object.

Transport, replay, provenance, and local naming preserve that centered route. Thus every accepted read remains inside the centered finite Gram packet and the Moore–Aronszajn positive-kernel surface remains a sibling rather than a duplicate. □

Falsifiable prediction: Every accepted $\mathsf{ConditionallyPositiveKernel}^{\uparrow}$ consumer that reads a centered quadratic-form comparison must first expose the centered coefficient row, zero-sum ledger, Matrix readback, InnerProduct and Hilbert handoff rows, Real scalar seal, componentwise hsame transport, displayed Cont replay, provenance, and local NameCert row.

Independence witness: moore-aronszajn-kernel, matrix, innerproduct, hilbert, real: $\mathsf{ConditionallyPositiveKernel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries centered coefficient windows, a zero-sum ledger, a centered Gram quadratic-form row, Matrix readback, InnerProduct and Hilbert handoff rows, a Real scalar seal, transport, replay, provenance, and local naming as one finite conditional-positivity certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ConditionallyPositiveKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{ConditionallyPositiveKernel}^{\uparrow}$ packet is generated from finite kernel-value rows, centered coefficient rows, a zero-sum ledger, centered Gram quadratic-form rows, Matrix readback, InnerProduct and Hilbert handoff rows, Real scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConditionallyPositiveKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7149.1, Definition 7149.2, and Definition 7149.3 seed the finite centered-Gram certificate for conditionally positive kernels.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConditionallyPositiveKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full Schoenberg embedding, negative-type completion, selected feature maps, quotient function spaces, countable choice, ambient Hilbert completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, centered coefficient exposure, zero-sum ledger validation, centered Gram quadratic-form readback, Matrix readback, InnerProduct and Hilbert handoff, Real scalar sealing, transport, replay, provenance, and local naming for BEDC.Derived.ConditionallyPositiveKernelUp.ConditionallyPositiveKernelNameCertObligat

Chapter 7150

A Concrete Naming Certificate for $\mathsf{ContractionMappingPicard}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{ContractionMappingPicard}^{\uparrow}$ packet records the finite route from displayed contraction data through Picard iteration into completion-facing regular-real seals. It sits over the contraction-map surface of chapter 1418, the finite iterate ledger of chapter 2359, the complete-metric service row of chapter 128, the regular-rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names the route that a constructive fixed-equation consumer may inspect; it does not select a fixed point, quotient Picard streams, use countable choice, assert ambient $\mathsf{Real}^{\uparrow}$ completeness, or supply host equality of maps.

Definition 7150.1 (ContractionMappingPicard carrier)**.** *A* $\mathsf{ContractionMappingPicard}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (K, I, C_m, R, E, H, Q, S, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *source row, including the metric carrier, graph-exact self-map, rational bound below one, and one-step contraction surface.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *finite orbit row generated from the displayed initial point by repeated reads of the same contraction graph.*
3. *C_m is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, kept separate from the contraction packet and consumed only after the finite Picard ledger is visible.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the Picard residual and tail-modulus route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular-rational readback has been displayed.*
6. *H stores componentwise* hsame *transport for the contraction, Picard, complete-metric, regular-rational, real-seal, replay, provenance, and local naming rows.*
7. *Q stores displayed* Cont *replay from contraction admission through Picard iteration, complete-metric service, regular-rational readback, and real-seal exposure.*
8. *S is the* Pkg *provenance over* $\mathsf{ContractionMappingPicard}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ContractionMappingPicard}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected fixed point, quotient equality of Picard streams, countable-choice schedules, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or standard bridge data.*

Theorem 7150.2 (ContractionMappingPicard NameCert obligations)**.** *For an accepted* $\mathsf{ContractionMappingPicard}^{\uparrow}$ *carrier* $P = (K, I, C_m, R, E, H, Q, S, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ContractionMappingPicard}^{\uparrow}}$ *surface consists exactly of contraction-source admission, finite Picard-iteration visibility, complete-metric service separation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback visibility,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, provenance, and local naming for the carrier of Definition 7150.1.*

Proof. Project the carrier rows. The contraction source K supplies the graph-exact self-map, rational contraction bound, and one-step Picard comparison through chapter 1418.

Read the finite iteration row next. The $\mathsf{PicardIteration}^{\uparrow}$ sibling supplies only displayed finite iterates, residual comparisons, and a regular-rational handoff route; it does not supply an endpoint or a quotient stream.

The complete-metric row C_m remains a separate service coordinate. It may be consumed only after the contraction and Picard rows are visible, and it does not turn the contraction packet itself into an ambient completeness theorem.

Finally inspect R, E, H, Q, S, N. These rows read the regular-rational tail, expose the real seal, transport and replay the same route, record provenance, and name the local packet. Since no listed row is a selector, quotient, choice schedule, host equality proof, or ambient real-completeness coordinate, the displayed rows exhaust the local NameCert surface. □

Theorem 7150.3 (ContractionMappingPicard fixed-equation route)**.** *Every fixed-equation consumer of an accepted* $\mathsf{ContractionMappingPicard}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $K, I, C_m, R, E, H, Q, S, N$ *before it may cite endpoint-facing data. The route exposes contraction data, Picard iteration, complete-metric service, regular-rational readback, and a terminal real seal boundary; it does not assert that a selected fixed point exists, that two Picard streams are quotient-equal, that countable choice is available, or that* $\mathsf{Real}^{\uparrow}$ *is ambiently complete.*

Proof. Start from the contraction row K. The consumer first reads the accepted $\mathsf{ContractionMapping}^{\uparrow}$ surface: metric carrier, graph-exact self-map, rational contraction bound, and adjacent Picard comparison data.

Next apply the Picard iteration row I. The iteration sibling turns the contraction data into a finite orbit ledger and residual-distance route, so the consumer receives only displayed finite approximants and their regular-tail budget.

Now read C_m and R. The complete-metric service is separate from the contraction source, and the regular-rational handoff is downstream of the Picard residual route. Thus completion-facing information enters only through the named service and readback rows.

Finally expose the terminal seal and structural rows E, H, Q, S, N. They preserve the same route and mark where real-facing consumers may read a seal after the regular handoff. Because no row selects an endpoint, quotients streams, invokes countable choice, imports host equality, or asserts ambient $\mathsf{Real}^{\uparrow}$ completeness, the fixed-equation consumer receives exactly the displayed route and no stronger theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContractionMappingPicard}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractionMappingPicard}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7150.1, Definition 7150.2, and Definition 7150.3 seed the finite route from contraction data through Picard iteration, complete-metric service, regular-rational readback, and real-seal exposure.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractionMappingPicard}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a selected fixed point, quotient equality of Picard streams, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, contraction-source admission, Picard-iteration visibility, complete-metric service separation, RegSeqRat readback visibility, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContractionMappingPicardUp.

Constructive story: A $\mathsf{ContractionMappingPicard}^{\uparrow}$ packet is generated from a ContractionMapping source row, PicardIteration finite orbit row, CompleteMetric service row, RegSeqRat readback, RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7151

A Concrete Naming Certificate for $\mathsf{MittagLefflerBishop}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley on inverse-limit compactness, the $\mathsf{MittagLefflerBishop}^{\uparrow}$ packet records the finite-window surface of a Mittag–Leffler stabilization argument without quotient completions or selected limit representatives. It sits beside the nested interval carrier of chapter 320, the closed bounded interval carrier of chapter 1591, the dyadic arithmetic core of chapter 291, the stream-name interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only the displayed finite stabilization rows consumed by L10 completion readers.

Definition 7151.1 (Mittag–Leffler Bishop carrier)**.** *A* $\mathsf{MittagLefflerBishop}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, W, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested closed-window row, read through* $\mathsf{NestedInterval}^{\uparrow}$ *or* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*, naming the finite prefix of closed nonempty windows under inspection.*
2. *W is the finite cofinal-window ledger recording which later windows are required to meet each displayed earlier window.*
3. *M is the mesh-budget row, with dyadic radii read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and ordered by the local decrease ledger.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that lists the finite observations exposed by the stabilization request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S through the dyadic mesh budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, W, M, S, R have been displayed.*
7. *H records componentwise* hsame *transport for $I, W, M, S, R, E, C, P, N$.*
8. *C records the displayed* Cont *replay route from nested windows through mesh budgets, StreamName windows, RegSeqRat readback, the Real seal, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{MittagLefflerBishop}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MittagLefflerBishop}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of completions, a countable-choice schedule, a selected point in the inverse limit, host equality of completed reals, or an ambient compactness theorem.

Lean4 (statement) `BEDC.Derived.MittagLefflerBishopUp`

Theorem 7151.2 (Mittag–Leffler Bishop NameCert obligations)**.** *For every accepted* $\mathsf{MittagLefflerBishop}^{\uparrow}$ *carrier*

$$K = (I, W, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MittagLefflerBishop}^{\uparrow}}$ *surface consists exactly of carrier admission for the nested closed windows, stability of the displayed cofinal-window ledger, preservation of nonempty windows along the displayed prefix, dyadic mesh decrease,* $\mathsf{StreamName}^{\uparrow}$ *exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation may replace these rows by countable choice, quotient equality, host completion equality, or selected limit representatives.*

Proof. Project the carrier of Definition 7151.1. The accepted packet exposes exactly $I, W, M, S, R, E, H, C, P, N$.

The finite-window obligations are the rows that can be read from that projection. The row I supplies the nested closed-window prefix, W supplies the stabilization ledger, and M supplies the decreasing dyadic mesh budget. Nonempty-window preservation is read only along the displayed prefix.

The rows S and R then provide the finite observation and regular rational readback used by the completion-facing consumer. The row E is a Real seal reached after those rows, so it cannot detach from the displayed route.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no coordinate for countable choice, quotient equality, host completion equality, or a selected limit representative, none of those objects is part of the local NameCert surface. □

Theorem 7151.3 (Mittag–Leffler Bishop L10 handoff)**.** *Every L10 completion consumer of an accepted* $\mathsf{MittagLefflerBishop}^{\uparrow}$ *packet must read the route*

$$\mathsf{NestedInterval}^{\uparrow} \text{ or } \mathsf{ClosedBoundedInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $I, W, M, S, R, E, H, C, P, N$ *before any terminal seal is used. The handoff exports no quotient completion, no selected inverse-limit point, no countable-choice schedule, and no host equality of completed reals.*

Proof. Let a completion consumer request the terminal seal from an accepted packet K. The only interval source is the displayed row I, and the only mesh source is the dyadic row M.

The finite observations are therefore obtained through S, and their regular rational readback is the row R. The seal row E occurs after those rows in the carrier definition, so a terminal Real read cannot bypass the nested-window, dyadic, stream, and regular-rational route.

Transport, replay, provenance, and local naming preserve that same route without adding a selected endpoint. Thus every L10 completion consumer receives only the displayed finite handoff and none of the excluded quotient, choice, selected-representative, or host-equality data. □

Lean4 ✓ `BEDC.Derived.MittagLefflerBishopUp.MittagLefflerBishopTasteGate single carrier alignment`

Falsifiable prediction: Every accepted $\mathsf{MittagLefflerBishop}^{\uparrow}$ read exposes nested closed-window data, a cofinal-window ledger, a dyadic mesh budget, StreamName windows, RegSeqRat readback,

a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any completion-facing terminal seal is consumed.

Independence witness: nestedinterval, closedboundedinterval, dyadicratcore, streamname, regseqrat, real: $\mathsf{MittagLefflerBishop}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds nested closed windows, cofinal-window stabilization, mesh decrease, finite observations, regular rational readback, Real seal nonescape, transport, replay, provenance, and local naming while refusing countable choice, quotient equality, host completion equality, and selected limit representatives.

Closure status for $\mathsf{NameCert}_{\mathsf{MittagLefflerBishop}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MittagLefflerBishop}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7151.1, Definition 7151.2, and Definition 7151.3 seed the finite Mittag–Leffler stabilization surface over nested windows, dyadic mesh budgets, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MittagLefflerBishop}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MittagLefflerBishopUp.MittagLefflerBishopTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected inverse-limit points, countable choice, host equality of completed reals, standard bridges, checked NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-window stability, nonempty-window preservation, dyadic mesh decrease, StreamName exposure, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, local naming, and L10 route exhaustion for BEDC.Derived.MittagLefflerBishopUp.

Constructive story: A $\mathsf{MittagLefflerBishop}^{\uparrow}$ packet is generated from nested closed windows, a cofinal-window ledger, dyadic mesh budgets, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7152

A Concrete Naming Certificate for $\mathsf{MittagLeffler}^{\uparrow}$

Following Mittag–Leffler and standard constructive complex analysis, the $\mathsf{MittagLeffler}^{\uparrow}$ packet records the finite principal-part and approximation-window surface by which a meromorphic prescription can be read without importing host meromorphic-function theory. It sits beside the complex carrier of chapter 39, the holomorphic source of chapter 68, the argument-principle meromorphic boundary of chapter 7193, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed finite rows for pole loci, local principal parts, approximation windows, rational error budgets, analytic replay, transport, provenance, and local naming.

Definition 7152.1 (Mittag–Leffler carrier)**.** *A* $\mathsf{MittagLeffler}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Z, U, A, E, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Z is the finite pole-locus row, listing the inspected* $\mathsf{Complex}^{\uparrow}$ *centres and separation witnesses for the poles visible to the packet.*
2. *U is the approximation-window row, listing the finite compact windows on which the partial meromorphic expression is tested.*
3. *A is the local principal-part row, assigning to each displayed centre a finite Laurent tail with a bounded negative-degree range.*
4. *E is the finite error-budget row, recorded in* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances and attached to the displayed windows.*
5. *Q is the* $\mathsf{Holomorphic}^{\uparrow}$ *correction row on the complement of the displayed pole loci inside the inspected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational approximants and error budgets seen on the displayed windows.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for scalar error reads obtained after Z, U, A, E, Q, R have been exposed.*
8. *H records componentwise* hsame *transport for Z, U, A, E, Q, R, L.*

9. *C records the displayed* Cont *replay route from complex centres and holomorphic correction rows through approximation windows, rational readback, real sealing, transport, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{MittagLeffler}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MittagLeffler}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a global meromorphic-function object, analytic continuation outside the inspected windows, a selected infinite pole enumeration, countable choice, quotient equality of functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7152.2 (Mittag–Leffler NameCert obligations)**.** *For every accepted* $\mathsf{MittagLeffler}^{\uparrow}$ *carrier* $M = (Z, U, A, E, Q, R, L, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{MittagLeffler}^{\uparrow}}$ *surface consists exactly of pole-locus admission, approximation-window admission, finite principal-part admission, dyadic error-budget exposure, holomorphic-correction exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer receives no host meromorphic-function object, no analytic-continuation oracle, no selected infinite pole enumeration, no countable-choice schedule, no quotient equality of functions, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 7152.1. The visible analytic rows are precisely Z, U, A, E, Q, R, L, and the structural rows are H, C, P, N.

The principal-part obligations come from Z and A. The pole-locus row fixes the centres under inspection, while the principal-part row supplies only finite negative-degree tails at those centres. No further pole or coefficient can be obtained without a displayed row.

The approximation obligations come from U, E, Q, R, L. The windows in U determine where the correction row Q is read, the dyadic row E fixes the allowed error budgets, and the regular rational row R is the only readback route before the terminal real seal L.

Transport, replay, provenance, and local naming preserve this finite route. Since the carrier contains no coordinate for host meromorphic functions, analytic continuation outside the inspected windows, selected infinite pole enumerations, countable choice, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects belongs to the local NameCert surface. □

Theorem 7152.3 (Mittag–Leffler RegSeqRat and Real handoff)**.** *Every completion-facing or contour-facing consumer of an accepted* $\mathsf{MittagLeffler}^{\uparrow}$ *packet must read the route*

$$\mathsf{Complex}^{\uparrow},\ \mathsf{Holomorphic}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $Z, U, A, E, Q, R, L, H, C, P, N$ before it treats the packet as a meromorphic approximation boundary. The handoff exports finite principal parts and inspected approximation windows; it exports no global meromorphic-function object, no unbounded pole search, no selected limiting function, no quotient equality of analytic functions, and no ambient completeness claim.

Proof. Let a consumer request the scalar error seal or contour-facing boundary from an accepted packet M. The complex source is displayed by the pole-locus row Z, and the holomorphic correction is displayed by Q only over the windows named in U.

The error comparison cannot be read before E and R are present. The row E supplies the finite dyadic tolerances, and R converts the visible approximation data into regular rational readback. The terminal real row L is downstream of those rows.

The structural rows H, C, P, N then transport, replay, source, and name exactly this route. Thus the consumer receives a finite approximation-window handoff through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, not a host meromorphic object or a selected limit outside the displayed carrier. □

Falsifiable prediction: Every accepted $\mathsf{MittagLeffler}^{\uparrow}$ read exposes pole loci, finite principal parts, approximation windows, dyadic error budgets, holomorphic correction rows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any contour-facing or completion-facing consumer uses the packet.

Independence witness: complex, holomorphic, argument-principle, regseqrat, real: $\mathsf{MittagLeffler}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite pole loci, principal-part tails, approximation windows, dyadic budgets, holomorphic correction, regular rational readback, Real sealing, transport, replay, provenance, and local naming while refusing host meromorphic functions, analytic-continuation oracles, selected infinite pole enumerations, countable choice, quotient equality, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{MittagLeffler}^{\uparrow}}$.

Constructive story: A $\mathsf{MittagLeffler}^{\uparrow}$ packet is generated from displayed Complex pole centres, finite principal-part tails, inspected approximation windows, dyadic error budgets, Holomorphic correction rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MittagLeffler}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7152.1, Definition 7152.2, and Definition 7152.3 seed the finite Mittag–Leffler NameCert surface over principal parts, approximation windows, RegSeqRat readback, and Real-facing seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MittagLeffler}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global meromorphic-function existence, analytic continuation outside inspected windows, selected infinite pole enumerations, quotient equality of analytic functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite pole-locus admission, principal-part exactness, approximation-window coverage, dyadic error-budget exposure, holomorphic correction routing, RegSeqRat readback, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.MittagLefflerUp.

Chapter 7153

A Concrete Naming Certificate for $\mathsf{Hausdorffization}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on separated reflection and constructive completion, the $\mathsf{Hausdorffization}^{\uparrow}$ packet records the finite non-quotient boundary that turns a pseudometric name into the separated metric route consumed by completion. It sits between the separated-reflection surface of chapter 4151, the pseudometric source of chapter 1614, the separated metric consumer of chapter 1411, and the completion route of chapter 1506. Its readback is exposed through the finite stream windows of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names the constructive separated-reflection boundary; it does not assert host quotient equality, representative selection, ambient Hausdorff completion, trichotomy, countable choice, or a completed Real object.

Definition 7153.1 (Hausdorffization carrier)**.** *A* $\mathsf{Hausdorffization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (P, S, M, C, W, R, E, T, K, G, N)$$

with the following displayed rows:

1. *P is the consumed* $\mathsf{Pseudometric}^{\uparrow}$ *source row, including the displayed zero-distance witness surface and finite distance comparisons.*
2. *S is the* $\mathsf{SeparatedReflection}^{\uparrow}$ *boundary row that records which source names are identified by displayed zero-distance evidence.*
3. *M is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *target row available only after the separated-reflection boundary has been read.*
4. *C is the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer handoff row, recording that completion can read only the separated metric route.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which pseudometric and separated-reflection observations are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite distance and zero-distance windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed distance readbacks.*
8. *T is componentwise* hsame *transport for $P, S, M, C, W, R, E, K, G, N$.*
9. *K is displayed* Cont *replay of the same boundary route.*

10. *G is the* Pkg *provenance over* Hausdorffization$^{\uparrow}$, SeparatedReflection$^{\uparrow}$, Pseudometric$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, MetricCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{Hausdorffization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, S, M, C, W, R, E, T, K, G, N$. It has no coordinate for quotient-set equality, selected representatives, ambient Hausdorff reflection, host metric completion, trichotomy, countable choice, or external Real completeness.

Lean4 (definition) `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier`

Theorem 7153.2 (Hausdorffization NameCert obligations)**.** *For every accepted* Hausdorffization$^{\uparrow}$ *carrier*

$$H = (P, S, M, C, W, R, E, T, K, G, N),$$

the local NameCert$_{\text{Hausdorffization}^{\uparrow}}$ *surface consists exactly of carrier admission for the pseudometric source, separated-reflection boundary, separated metric target row, metric-completion consumer handoff, finite StreamName windows, RegSeqRat readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming; zero-distance exactness requiring every separated identification to pass through P, S, W, R, E; completion-boundary exactness requiring every completion read to pass through M, C after the separated reflection; and nonescape from the named rows.*

Proof. Project the carrier of Definition 7153.1. Its rows are precisely $P, S, M, C, W, R, E, T, K, G, N$, so carrier admission supplies the full local inventory.

The zero-distance route begins in the pseudometric row P. A separated identification is admitted only when the boundary row S displays the corresponding finite evidence, and that evidence is inspected through the windows W, read back by R, and sealed by E.

The separated metric and completion handoff are downstream. The row M is exposed only after the separated-reflection boundary, and the completion row C can consume only that separated metric route.

Transport, replay, provenance, and local naming are the rows T, K, G, N. Because no further carrier coordinate exists, the listed obligations exhaust the NameCert$_{\text{Hausdorffization}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.HausdorffizationCarrier namecert obligations`

Theorem 7153.3 (Hausdorffization separated-reflection boundary)**.** *Every* SeparatedMetric$^{\uparrow}$ *or* MetricCompletion$^{\uparrow}$ *consumer of an accepted* Hausdorffization$^{\uparrow}$ *packet factors through the finite route*

$$P \longmapsto S \longmapsto M, C \longmapsto W, R, E \longmapsto T, K, G, N.$$

The consumer may read pseudometric zero-distance evidence, the separated-reflection boundary, the separated metric target row, the completion handoff, StreamName windows, RegSeqRat readback, a terminal Real seal, transport, replay, provenance, and local naming. It may not read host quotient equality, a selected representative, an ambient Hausdorff reflection object, a quotient completion, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Start with the pseudometric source row P. The only equality-like information available to a consumer is the displayed zero-distance evidence carried there.

The separated-reflection boundary S records how that evidence is admitted by the BEDC packet. It is a finite boundary row, not a quotient set or a selector for representatives.

The separated metric and completion-facing rows are then M and C. They consume the boundary already displayed by S, so no completion reader can bypass the separated-reflection route.

Finally W, R, E, T, K, G, N give the window, readback, seal, transport, replay, provenance, and naming surface for the same packet. The absence of quotient, selector, trichotomy, choice, and ambient-completeness coordinates forces every consumer to remain on the displayed route. □

Lean4 ✓ `BEDC.Derived.HausdorffizationCarrier separated reflection boundary`

Theorem 7153.4 (Hausdorffization ledger non-quotient boundary)**.** *An accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet records a separated-reflection ledger, not a host quotient. Any downstream read by* $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *must retain the same finite rows*

$$P, S, M, C, W, R, E, T, K, G, N.$$

In particular, the read cannot collapse source names by host equality, choose representatives, import quotient-real equality, appeal to Dedekind completion, select an infimum, use countable choice, or invoke ambient completeness.

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier ledger nonquotient boundary`

Proof. The carrier definition gives one finite packet and no quotient carrier. Thus a downstream read must start from the displayed pseudometric row P and the separated-reflection ledger S.

The metric and completion rows M, C are consumer-facing handoffs from that ledger. They do not add a host quotient, selected representative, or completed object.

The analytic readback rows W, R, E expose finite windows, regular rational readback, and the terminal Real seal for the same displayed comparisons. Transport and replay through T, K preserve the packet rather than enlarging it.

The provenance and naming rows G, N name the dependencies and the local certificate. Since quotient equality, Dedekind completion, selected infimum, countable choice, and ambient completeness are absent from the packet, no downstream consumer can recover them from the ledger. □

Theorem 7153.5 (Hausdorffization separated-reflection scope)**.** *For every accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet* $H = (P, S, M, C, W, R, E, T, K, G, N)$*, the separated-reflection read is scoped by the finite rows*

$$\mathsf{SeparatedReflection}^{\uparrow}, \mathsf{Pseudometric}^{\uparrow}, \mathsf{SeparatedMetric}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{h}$$

The row S may compare pseudometric names only through displayed zero-distance evidence from P, finite stream windows W, regular-rational readback R, and the terminal real seal E. It cannot expose host quotient equality, representatives, an external separated reflection, or a completion object outside M, C, T, K, G, N.

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier separated reflection scope`

Proof. Inspect the carrier rows of Definition 7153.1. The separated-reflection row S is present only as part of the same BHist packet as the pseudometric source P and the downstream separated metric and completion rows M, C.

The evidence read by S is finite. It is opened through W, read through R, and sealed by E, so the route has the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ witnesses before any separated-metric consumer can read it.

Transport, replay, provenance, and local naming are exactly T, K, G, N. Since no carrier coordinate names a quotient object, representative selector, or external completion, the separated-reflection scope is exhausted by the listed rows. □

Theorem 7153.6 (Hausdorffization completion consumer route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet must first read the route*

$$P \longmapsto S \longmapsto M \longmapsto C$$

and then authenticate it through W, R, E, T, K, G, N*. Thus completion-facing data are visible only after the* $\mathsf{Pseudometric}^{\uparrow}$ *source,* $\mathsf{SeparatedReflection}^{\uparrow}$ *boundary,* $\mathsf{SeparatedMetric}^{\uparrow}$ *target row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* BHist *carrier,* hsame *transport,* Cont *replay,* Pkg *provenance, and* $\mathsf{NameCert}$ *naming rows have been inspected.*

Proof. Begin with a completion consumer. The carrier gives it no direct completion coordinate; its only completion-facing row is C, and C is recorded as a handoff from the separated metric row M.

The row M is itself downstream of the separated-reflection ledger S. The ledger is admitted from the pseudometric source P by finite zero-distance observations, so the completion route cannot start after S or bypass P.

The analytic readback rows W, R, E and the structural rows T, K, G, N authenticate the same path. Non-quotient ledger exclusion in Definition 7153.4 rules out quotient completion, selected representatives, countable choice, and ambient real completeness as alternate completion inputs. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier completion consumer route`

Theorem 7153.7 (Hausdorffization NameCert scope package)**.** *The local* $\mathsf{NameCert}_{\mathsf{Hausdorffization}^{\uparrow}}$ *package for an accepted packet* $H = (P, S, M, C, W, R, E, T, K, G, N)$ *is exactly the finite scope package over the rows*

$$P, S, M, C, W, R, E, T, K, G, N.$$

It packages carrier admission, separated-reflection evidence, separated-metric handoff, completion-consumer handoff, stream-window inspection, regular-rational readback, real sealing, component-wise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming, with no quotient equality or representative-selection clause.*

Proof. Project the local certificate row N. Its admissible dependencies are named by the provenance row G and are precisely the carrier rows displayed in Definition 7153.1.

Carrier admission and separated-reflection evidence are the rows P, S. The separated metric and completion handoffs are M, C, and their finite readback is supplied by W, R, E.

The remaining authentication data are T, K, G, N. These rows transport, replay, source, and name the same finite package. Because the ledger theorem excludes quotient and representative data, the NameCert package has no further clause beyond the displayed scope. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier namecert scope package`

Theorem 7153.8 (Hausdorffization zero-distance window determinacy)**.** *Let* $H = (P, S, M, C, W, R, E, T, K, G, N)$ *be an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet. Any two separated-identification reads that share the* $\mathsf{Pseudometric}^{\uparrow}$ *row* P*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *determine the same separated-reflection boundary* S *before the separated metric row* M *or completion row* C *is visible.*

Proof. Project the carrier of Definition 7153.1. The separated-reflection row S is the only boundary row between the pseudometric source P and the downstream rows M, C.

Use the separated-reflection scope of Definition 7153.5. It states that S compares source names only through zero-distance evidence from P, finite windows W, regular-rational readback R, and the Real seal E.

Finally apply the ledger non-quotient boundary of Definition 7153.4. Since there is no quotient-equality or representative-selection coordinate, two reads sharing P, W, R, E have no alternate boundary data to distinguish them before M, C are opened. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier zero distance window determinacy`

Theorem 7153.9 (Hausdorffization zero-distance exactness)**.** *Let $H = (P, S, M, C, W, R, E, T, K, G, N)$ be an accepted* Hausdorffization$^{\uparrow}$ *packet. The zero-distance evidence displayed by P, W, R, E determines exactly the separated-reflection row S: every separated identification read by S must be witnessed by the pseudometric row P, the finite window row W, the regular-rational readback row R, and the terminal real seal E, and no downstream row M, C, T, K, G, N can add a further separated-identification clause.*

Proof. Use Definition 7153.8. It states that shared P, W, R, E data determine the same boundary row S before M or C is visible.

The separated-reflection scope theorem, Definition 7153.5, supplies the converse route. The row S compares pseudometric names only through zero-distance evidence from P, finite windows W, regular-rational readback R, and the terminal seal E.

Finally apply Definition 7153.4. Since the carrier has no quotient-equality, representative-selection, trichotomy, choice, or ambient-completeness coordinate, the downstream rows M, C, T, K, G, N authenticate the same boundary rather than extending it. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationZeroDistanceExactness`

Theorem 7153.10 (Hausdorffization completion route stability)**.** *Let $H = (P, S, M, C, W, R, E, T, K, G, N)$ be an accepted* Hausdorffization$^{\uparrow}$ *packet. Every completion consumer preserves the route*

$$P \longmapsto S \longmapsto M \longmapsto C$$

under componentwise hsame *transport T and displayed* Cont *replay K. Thus completion-facing reads may transport or replay the finite route, but they cannot reorder it, bypass S, or replace it by quotient completion data.*

Proof. Begin with Definition 7153.6. It forces each MetricCompletion$^{\uparrow}$ consumer to read $P \longmapsto S \longmapsto M \longmapsto C$ and then authenticate the same path through W, R, E, T, K, G, N.

Transport is componentwise. The row T can identify corresponding pseudometric, separated-reflection, separated-metric, completion, readback, provenance, and naming rows, but it has no coordinate that turns a later completion row into an earlier source row.

Replay is displayed by K. It repeats the same boundary route through the finite packet, and Definition 7153.13 rules out any completion-facing factorization other than $P \longmapsto S \longmapsto M \longmapsto C$. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCompletionRouteStability`

Theorem 7153.11 (Hausdorffization separated-reflection nonescape)**.** *For an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet* $H = (P, S, M, C, W, R, E, T, K, G, N)$*, every separated-reflection or completion-facing read is exhausted by the rows* $P, S, M, C, W, R, E, T, K, G, N$*. In particular, quotient equality, representative selection, trichotomy, countable choice, host separated-reflection objects, quotient completion, and ambient completeness cannot escape the packet as readable data.*

Proof. The NameCert scope package of Definition 7153.7 identifies the local certificate with the finite rows $P, S, M, C, W, R, E, T, K, G, N$. The separated-reflection boundary theorem Definition 7153.3 and completion handoff exactness theorem Definition 7153.12 place every separated metric and completion consumer inside that inventory.

Apply zero-distance exactness, Definition 7153.9. The separated-reflection row is fixed by displayed zero-distance evidence, so there is no remaining boundary slot for host quotient equality, representative choice, or trichotomy.

Apply completion route stability, Definition 7153.10. Completion consumers preserve the finite $P \longmapsto S \longmapsto M \longmapsto C$ route under T and K, so quotient completion, countable choice, and ambient completeness are not readable exports of the packet. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationSeparatedReflectionNonescape`

Theorem 7153.12 (Hausdorffization completion handoff exactness)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet receives the completion row* C *only after the rows* $P, S, M, W, R, E, T, K, G, N$ *have been exposed. Thus completion-facing data are exact over the displayed pseudometric source, separated-reflection boundary, separated metric row, finite windows, regular readback, Real seal, componentwise transport, replay, provenance, and local naming.*

Proof. Start with the completion consumer route of Definition 7153.6. It forces a completion consumer to read $P \longmapsto S \longmapsto M \longmapsto C$ and then authenticate that route through W, R, E, T, K, G, N.

The NameCert scope package of Definition 7153.7 records the same finite inventory as the local certificate. Therefore the row C is not an independent completion object; it is the handoff row reached after the displayed boundary and readback rows.

The non-quotient ledger theorem, Definition 7153.4, excludes quotient completion, selected representatives, countable choice, and ambient real completeness as alternate inputs. Hence the completion handoff is exact over precisely the displayed rows. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCompletionHandoffExactness`

Theorem 7153.13 (Hausdorffization separated completion factorization)**.** *Every completion-facing route out of an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet factors through the finite chain*

$$P \longmapsto S \longmapsto M \longmapsto C.$$

No route can bypass this chain through quotient equality, selected representatives, host separated-reflection objects, or quotient completion equality.

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier separated completion factorization`

Proof. Read the separated-reflection boundary theorem Definition 7153.3. It already identifies every $\mathsf{SeparatedMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer route as passing through the pseudometric source P, separated-reflection boundary S, and separated metric and completion rows M, C.

Apply zero-distance window determinacy, Definition 7153.8. The boundary row S is fixed by the displayed zero-distance window route before M or C is visible, so a completion consumer cannot choose a second separated boundary downstream.

Finally apply completion handoff exactness, Definition 7153.12. It places C after $P, S, M, W, R, E, T, K, G, N$, while the ledger non-quotient boundary rules out quotient equality and selected representatives. The only completion-facing factorization is therefore $P \longmapsto S \longmapsto M \longmapsto C$. □

Theorem 7153.14 (Hausdorffization separated-completion obligation)**.** *Every accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet exposes the* $\mathsf{Pseudometric}^{\uparrow}$ *source,* $\mathsf{SeparatedReflection}^{\uparrow}$ *boundary,* $\mathsf{SeparatedMetric}^{\uparrow}$ *target,* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before a separated-completion consumer reads it. In carrier notation, the consumer route is exhausted by*

$$P, S, M, C, W, R, E, T, K, G, N.$$

Proof. Project the carrier of Definition 7153.1. The displayed rows give exactly the pseudometric source P, separated-reflection boundary S, separated metric target M, completion handoff C, window, readback, seal, transport, replay, provenance, and local naming rows.

Use the separated-reflection scope of Definition 7153.5. It forces separated reads to begin at P and S and to authenticate zero-distance evidence through W, R, E before the separated metric row can be consumed.

Then apply the completion consumer route of Definition 7153.6. It places every completion-facing read after $P \longmapsto S \longmapsto M \longmapsto C$ and preserves the route through T, K, G, N.

Finally use the non-quotient boundary of Definition 7153.4. Since no extra completion coordinate exists, the listed rows are all that a separated-completion consumer can read. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier separated completion obligation`

Theorem 7153.15 (Hausdorffization completion-boundary exhaustion)**.** *Every completion-facing read of an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet is exhausted by the displayed rows*

$$P, S, M, C, W, R, E, T, K, G, N.$$

The route combines zero-distance exactness from Definition 7153.9, completion-route stability from Definition 7153.10, and non-quotient nonescape from Definition 7153.18. Thus a downstream separated-metric or completion consumer may project only the pseudometric source, separated-reflection boundary, separated metric target, completion handoff, finite windows, regular rational readback, Real seal, componentwise transport, displayed replay, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier completion boundary exhaustion`

Proof. Project the accepted carrier through Definition 7153.1. The row projection gives exactly $P, S, M, C, W, R, E, T, K, G, N$, so any completion-facing read must begin from that finite packet.

Apply Definition 7153.9. It fixes the separated-reflection boundary S by the displayed P, W, R, E zero-distance evidence before the separated metric row M or completion handoff C can add any further read.

Apply Definition 7153.10. It preserves the route $P \longmapsto S \longmapsto M \longmapsto C$ under componentwise hsame transport T and displayed Cont replay K, so the completion reader cannot reorder the rows or bypass the boundary.

Finally use Definition 7153.18. Quotient equality, selected representatives, quotient completion, trichotomy, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate. The remaining provenance and naming rows G, N therefore certify the displayed packet rather than extending it. □

Theorem 7153.16 (Hausdorffization Real-completion consumer factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$*-and-*$\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet factors through the displayed chain*

$$\mathsf{Pseudometric}^{\uparrow} \longmapsto \mathsf{SeparatedReflection}^{\uparrow} \longmapsto \mathsf{SeparatedMetric}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSe}$$

before any separated-completion conclusion is read. In carrier notation, the consumer may project only $P, S, M, C, W, R, E, T, K, G, N$*, with* S *fixed by zero-distance evidence,* C *stable under the displayed route, and* W, R, E *supplying the finite observation, readback, and Real seal.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationRealCompletionConsumerFactorization`

Proof. Start with zero-distance exactness from Definition 7153.9. It fixes the separated-reflection row S from the pseudometric source P and the finite W, R, E evidence before either the separated metric row M or the completion row C can be consumed.

Next apply completion-route stability, Definition 7153.10. The completion handoff remains downstream of $P \longmapsto S \longmapsto M \longmapsto C$ under the same hsame transport and Cont replay rows T, K.

Use the non-quotient nonescape obligation Definition 7153.18. It rules out quotient equality, selected representatives, quotient completion, trichotomy, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness as alternate routes to a Real or completion read.

Finally apply completion-boundary exhaustion, Definition 7153.15. The remaining consumer surface is precisely $P, S, M, C, W, R, E, T, K, G, N$, so every Real-and-Completion consumer reads the displayed chain before any separated-completion conclusion is available. □

Theorem 7153.17 (Hausdorffization separated Real-completion scope)**.** *Every separated* $\mathsf{Real}^{\uparrow}$*-completion read of an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet factors through the displayed* $\mathsf{Pseudometric}^{\uparrow}$*,* $\mathsf{SeparatedReflection}^{\uparrow}$*,* $\mathsf{SeparatedMetric}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before any completion conclusion is available. In carrier notation the only readable rows are* $P, S, M, C, W, R, E, T, K, G, N$*: zero-distance evidence fixes* S*, the separated metric and completion route reads* M, C*, finite windows and regular rational readback expose* W, R*, and the Real seal is* E*. The scope contains no quotient completion, representative selection, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use zero-distance exactness, Definition 7153.9. It fixes the separated-reflection boundary from the pseudometric source and the finite readback rows before any separated metric consumer can inspect the packet.

Apply completion-route stability and the Real-completion consumer factorization, Definition 7153.10 and Definition 7153.16. These place the separated metric row and completion handoff downstream of P, S and upstream of the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback rows.

Finally combine non-quotient nonescape with completion-boundary exhaustion, Definition 7153.18 and Definition 7153.15. The refused quotient, representative, trichotomy, countable-choice, and ambient-completeness data are absent from the carrier, so the separated Real-completion scope is exactly the displayed non-quotient row route. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier separated real completion scope`

Theorem 7153.18 (Hausdorffization non-quotient nonescape obligation)**.** *An accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet has no coordinate for host quotient equality, selected representatives, quotient completion, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every separated-reflection or completion-facing read remains inside the finite carrier rows* $P, S, M, C, W, R, E, T, K, G, N$*.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationNonquotientNonescapeObligation`

Proof. Begin with the carrier definition Definition 7153.1. Its coordinates are the pseudometric source, separated-reflection boundary, separated metric target, completion handoff, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

The separated-reflection scope theorem Definition 7153.5 keeps zero-distance comparisons inside P, S, W, R, E. The completion consumer route Definition 7153.6 keeps completion-facing reads inside $P, S, M, C, W, R, E, T, K, G, N$.

The ledger non-quotient boundary Definition 7153.4 explicitly excludes host quotient equality, selected representatives, quotient completion, trichotomy, countable choice, and ambient Real completeness. Therefore none of those data can escape through the local packet. □

Theorem 7153.19 (Hausdorffization separated quotient row)**.** *For every accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet* $H = (P, S, M, C, W, R, E, T, K, G, N)$*, the separated-quotient information visible to a consumer is only the displayed* $\mathsf{SeparatedReflection}^{\uparrow}$ *row* S *read from the* $\mathsf{Pseudometric}^{\uparrow}$ *source row* P*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The packet refuses quotient-space primitives, selected representatives, and any ambient* $\mathsf{Real}^{\uparrow}$ *completeness clause; separated-metric consumers may read only the handoff through* S *into* $\mathsf{SeparatedMetric}^{\uparrow}$ *row* M *and* $\mathsf{MetricCompletion}^{\uparrow}$ *row* C*.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier separated quotient row`

Proof. Project the carrier of Definition 7153.1. The only boundary row between pseudometric source data and separated-metric data is S.

The evidence for S is finite. It must be inspected through the StreamName row W, read back by the RegSeqRat row R, and sealed by the Real row E before M or C can consume it.

Apply the non-quotient nonescape obligation of Definition 7153.18. Since quotient primitives, representatives, and ambient Real completeness are absent, S is the full separated quotient row available to the packet. □

Theorem 7153.20 (Hausdorffization metric-completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet receives its handoff only through the route*

$$\mathsf{Pseudometric}^{\uparrow} \to \mathsf{SeparatedReflection}^{\uparrow} \to \mathsf{SeparatedMetric}^{\uparrow} \to \mathsf{MetricCompletion}^{\uparrow}$$

as displayed by P, S, M, C *and authenticated by* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows* W, R, E, T, K, G, N*. The handoff is not a quotient-space completion, not a selected representative construction, and not a use of ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationMetricCompletionHandoff`
↪ variant `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier metriccompletion handoff`

Proof. Use the completion consumer route Definition 7153.6. It places every completion-facing read after $P \longmapsto S \longmapsto M \longmapsto C$.

Use the separated quotient row theorem Definition 7153.19. It identifies the boundary S as the only separated-reflection row available from the finite pseudometric evidence.

The authentication rows W, R, E, T, K, G, N preserve and name the same route. The nonescape theorem excludes quotient-space primitives, selected representatives, and ambient Real completeness, so the displayed route is the full metric-completion handoff. □

Theorem 7153.21 (Hausdorffization NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{Hausdorffization}^{\uparrow}}$ *obligation surface consists exactly of the* $\mathsf{Pseudometric}^{\uparrow}$ *source row,* $\mathsf{SeparatedReflection}^{\uparrow}$ *boundary row,* $\mathsf{SeparatedMetric}^{\uparrow}$ *target row,* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every separated-reflection or metric-completion consumer must factor through those rows while refusing quotient-space primitives, selected representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier namecert obligation surface`

Proof. Apply the separated quotient row theorem Definition 7153.19. It fixes the boundary read at P, S, W, R, E and excludes quotient-space data.

Apply the metric-completion handoff theorem Definition 7153.20. It places every completion consumer on the route through P, S, M, C with the same readback, transport, replay, provenance, and naming rows.

The NameCert scope package Definition 7153.7 then names exactly that carrier inventory. No selected representative, quotient completion, or ambient Real-completeness coordinate remains for the local certificate to expose. □

Theorem 7153.22 (Hausdorffization complete-metric limit uniqueness route)**.** *Let* $H = (P, S, M, C, W, R, E, T, K,$ *be an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *packet whose separated metric-completion handoff is consumed by* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$*. The consumer can read the handoff only through displayed zero-distance evidence* P, W, R, E*, the separated-classifier row* S*, the separated metric and completion rows* M, C*, and the structural rows* T, K, G, N*. It cannot read quotient equality, selected host representatives, quotient completion, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier complete metric limit uniqueness route`

Proof. Start with zero-distance exactness, Definition 7153.9. It fixes the separated-reflection boundary S from the displayed P, W, R, E evidence before any completion-facing row is available.

Use separated-completion factorization, Definition 7153.13. It keeps every completion read downstream of the boundary S and the separated metric row M.

Apply the metric-completion handoff theorem Definition 7153.20. The handoff to C remains attached to the same finite readback, transport, replay, provenance, and naming rows.

Finally route the consumer through chapter 5983. That packet reads limit uniqueness only after its zero-distance and separated-classifier rows are displayed, so the Hausdorffization handoff supplies exactly those visible rows and no quotient equality, selected representative, quotient completion, or ambient completeness data. □

Theorem 7153.23 (Hausdorffization separated-reflection obligation)**.** *Every accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *carrier exposes its separated read only after the pseudometric, separated-reflection, separated metric,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows are displayed. The separated classifier is therefore a row-projection boundary from* $P, S, M, W, R, E, T, K, G, N$*, not quotient equality of representatives and not an ambient Hausdorff-reflection principle.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier separated reflection obligation`

Proof. Project the accepted carrier of Definition 7153.1. The source pseudometric row P and separated-reflection boundary row S are visible before the separated metric row M can be read.

Apply zero-distance exactness and separated-completion factorization, Definition 7153.9 and Definition 7153.13. They keep the separated classifier attached to displayed zero-distance evidence, finite windows, regular rational readback, and the Real seal.

Finally use the NameCert obligation surface Definition 7153.21. The rows T, K, G, N transport, replay, source, and name the same packet. Since the carrier has no quotient-representative coordinate or ambient reflection row, separated reads can use only the displayed row-projection boundary. □

Theorem 7153.24 (Hausdorffization completion-consumer nonescape)**.** *Let $H = (P, S, M, C, W, R, E, T, K, G, N)$ be an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *carrier. Any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *consumer can read only the displayed zero-distance evidence rows P, W, R, E, the separated-classifier row S, the separated metric row M, the completion handoff C, and the structural rows T, K, G, N. It cannot read quotient representatives, quotient completion, selected host representatives, or ambient completion data.*

Proof. Start with the metric-completion handoff theorem Definition 7153.20. It places completion-facing reads after the pseudometric source, separated-reflection boundary, separated metric row, finite windows, regular rational readback, Real seal, and structural rows.

Use the complete-metric limit uniqueness route Definition 7153.22. That route permits the uniqueness consumer to see only zero-distance evidence, the separated classifier, separated metric data, completion handoff, transport, replay, provenance, and naming.

The same row projection applies to $\mathsf{MetricCompletion}^{\uparrow}$ consumers. Because quotient representatives, quotient completion, selected host representatives, and ambient completion objects are not carrier coordinates, no completion consumer can escape the displayed boundary. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier completion consumer nonescape`

Theorem 7153.25 (Hausdorffization scoped completion readback)**.** *Let $H = (P, S, M, C, W, R, E, T, K, G, N)$ be an accepted* $\mathsf{Hausdorffization}^{\uparrow}$ *carrier. Before any separated completion consumer reads H, the readback route must expose the zero-distance classifier row P, W, R, E, the separated-reflection row S, the metric-completion handoff M, C, the non-quotient ledger boundary, componentwise transport T, replay row K, provenance row G, and local-name row N. The route refuses quotient equality, host equality, selected representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as completion data.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier scoped completion readback`

Proof. Start with zero-distance exactness, Definition 7153.9. It fixes the classifier read at the displayed pseudometric, finite-window, regular-rational, and Real-seal rows P, W, R, E.

Use separated-reflection scope, Definition 7153.5. That theorem places the separated boundary S downstream of the same zero-distance rows and upstream of any separated metric or completion consumer.

Apply the metric-completion handoff theorem Definition 7153.20. The handoff to completion passes through M, C and remains authenticated by transport, replay, provenance, and local naming rows T, K, G, N.

Finally apply completion-consumer nonescape, Definition 7153.24, together with the non-quotient ledger boundary Definition 7153.4. Quotient equality, host equality, selected representatives, and ambient Real completeness are not carrier coordinates, so no separated completion consumer can read them through the scoped route. □

Theorem 7153.26 (Hausdorffization public export)**.** *The public* $\mathsf{NameCert}_{\mathsf{Hausdorffization}^{\uparrow}}$ *export is exactly the composed route*

$$P, S, M, C, W, R, E, T, K, G, N$$

from $\mathsf{Pseudometric}^{\uparrow}$ *zero-distance evidence through* $\mathsf{SeparatedReflection}^{\uparrow}$ *into separated* $\mathsf{MetricCompletion}^{\uparrow}$ *consumption. A separated-metric or completion reader may consume that route as the public certificate surface, but the export excludes quotient equality, selected representatives, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationPublicExport`

Proof. Start with the completion consumer route of Definition 7153.6. It forces completion-facing reads to pass through $P \longmapsto S \longmapsto M \longmapsto C$ and then authenticate the same route through W, R, E, T, K, G, N.

Use the NameCert scope package of Definition 7153.7. It identifies the local certificate with precisely the finite rows $P, S, M, C, W, R, E, T, K, G, N$, so the public export has no additional coordinate beyond the displayed route.

Finally apply separated-reflection nonescape and scoped completion readback, Definition 7153.11 and Definition 7153.25. These theorems rule out quotient equality, selected representatives, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness as readable data, leaving exactly the stated public certificate surface. □

Lean4 ✓ `BEDC.Derived.HausdorffizationUp.HausdorffizationCarrier public export`

Theorem 7153.27 (Hausdorffization public export status)**.** *A public* $\mathsf{Hausdorffization}^{\uparrow}$ *export may expose the separated quotient reading only after it displays the pseudometric row, separated-reflection boundary, separated metric row, metric-completion handoff,* $\mathsf{Real}^{\uparrow}$ *zero-distance seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The export status is therefore the finite route*

$$P, S, M, C, W, R, E, T, K, G, N$$

from pseudometric names through separated reflection into completion-facing data, not a quotient primitive, host equality, selected representative, or ambient completion theorem.

Proof. Inspect the public export theorem and the scoped completion readback. They order the pseudometric source, separated-reflection boundary, separated metric row, completion handoff, finite StreamName windows, RegSeqRat readback, Real zero-distance seal, and structural rows before any separated completion consumer reads the packet.

The public status is exactly that displayed route. The hsame, Cont, Pkg, and NameCert rows keep transport, replay, provenance, and local naming attached to the same Hausdorffization carrier, so the separated quotient reading is only an exported interpretation of the finite certificate surface.

Because the route is read from the displayed rows, it does not create a quotient primitive or appeal to host equality. Selected representatives and ambient completion data are also absent from the carrier, so they cannot be consumed by the public export. □

Falsifiable prediction: Every accepted $\mathsf{Hausdorffization}^{\uparrow}$ read exposes a Pseudometric source row, SeparatedReflection boundary, SeparatedMetric target row, MetricCompletion handoff, StreamName windows, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any separated metric or completion consumer reads it.

Independence witness: separated-reflection, pseudometric, separatedmetric, metriccompletion, streamname, regseqrat, real: $\mathsf{Hausdorffization}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds zero-distance evidence, separated-reflection boundary, separated metric handoff, completion-facing handoff, finite windows, regular rational readback, a Real seal, transport, replay, provenance, and local naming while refusing quotient equality, selected representatives, quotient completion, trichotomy, countable choice, and ambient completeness.

Lean4 (statement) `BEDC.Derived.HausdorffizationUp`

Closure status for $\mathsf{NameCert}_{\mathsf{Hausdorffization}^{\uparrow}}$.

Constructive story: A $\mathsf{Hausdorffization}^{\uparrow}$ packet is generated from a Pseudometric source row, SeparatedReflection boundary, SeparatedMetric target row, MetricCompletion handoff, StreamName finite windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Hausdorffization}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 7153.1, Definition 7153.2, Definition 7153.3, Definition 7153.4, and Definition 7153.6 display the carrier and NameCert obligation surface for the finite separated-reflection boundary from pseudometric names into separated metric completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Hausdorffization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality, representative selection, ambient Hausdorff reflection, quotient completion, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance exactness, completion-boundary exactness, non-quotient ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HausdorffizationUp.

Chapter 7154

A Concrete Naming Certificate for $\mathsf{FriendlyMetricCompletion}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley-style separated metric language, the $\mathsf{FriendlyMetricCompletion}^{\uparrow}$ packet records the finite handoff by which a metric source can be read as completion-ready without quotienting Cauchy names or selecting representatives. It sits after the separated-reflection boundary of chapter 7153, the separated metric surface of chapter 1411, and the completion handoff of chapter 1506. Its analytic readback is the L10 finite route through chapter 126, chapter 301, and chapter 38; the packet names a friendly completion carrier, not a host completed metric space.

Definition 7154.1 (Friendly metric completion carrier)**.** *A* $\mathsf{FriendlyMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, S, M, C, W, R, E, H, K, G, N)$$

with the following displayed rows:

1. *P is the metric-source row, including the finite distance comparisons opened by completion-facing consumers.*
2. *S is the separatedness boundary row, recording the zero-distance identification test exposed by* $\mathsf{Hausdorffization}^{\uparrow}$ *before completion reads begin.*
3. *M is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row obtained from the displayed boundary rather than from a host quotient.*
4. *C is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row for downstream completion consumers.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row through which Cauchy observations are opened.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed distance and Cauchy readbacks.*
8. *H is componentwise* hsame *transport for $P, S, M, C, W, R, E, G, N$.*
9. *K is displayed* Cont *replay of the same friendly route.*
10. *G is the* Pkg *provenance over* $\mathsf{FriendlyMetricCompletion}^{\uparrow}$, $\mathsf{Hausdorffization}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FriendlyMetricCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, S, M, C, W, R, E, H, K, G, N$. It has no coordinate for quotient Cauchy equality, selected representatives, host completion points, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7154.2 (Friendly metric completion NameCert obligations)**.** *For every accepted* $\mathsf{FriendlyMetricCompletion}$ *carrier $F = (P, S, M, C, W, R, E, H, K, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{FriendlyMetricCompletion}^{\uparrow}}$ *surface consists exactly of metric-source admission, separatedness-boundary exposure, separated metric handoff, metric-completion handoff, finite StreamName windows, RegSeqRat readback, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing consumer must read the displayed boundary route*

$$P \longmapsto S \longmapsto M \longmapsto C \longmapsto W, R, E \longmapsto H, K, G, N$$

before it can use the packet as completion data.

Proof. Project the carrier of Definition 7154.1. The displayed rows are exactly $P, S, M, C, W, R, E, H, K, G, N$, so carrier admission supplies the local inventory.

The separatedness boundary is read before the completion handoff. The row S records the zero-distance test visible through the Hausdorffization route, and M is the separated metric row built from that boundary.

The completion row C is downstream of M, while W, R, E provide the finite Cauchy-window, regular-rational, and Real-seal readback. The structural rows H, K, G, N transport, replay, source, and name the same finite route.

Since the carrier has no quotient, selected-representative, host-completion, choice, or ambient-completeness coordinate, the displayed route exhausts the NameCert obligations. □

Theorem 7154.3 (Friendly metric completion finite Cauchy handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Hausdorffization}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FriendlyMetricCompletion}^{\uparrow}$ *packet receives Cauchy-facing data only through the finite rows $P, S, M, C, W, R, E, H, K,$ In particular, the handoff exposes the source metric row, separatedness boundary, separated metric row, completion row, finite Cauchy windows, regular rational readback, Real seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *before any completion consumer reads it.*

Proof. Start with the NameCert obligations of Definition 7154.2. They force every completion-facing read to pass through the source row P, separatedness boundary S, separated metric row M, and completion handoff C.

Next read the L10 finite Cauchy surface. The rows W, R, E expose the finite StreamName window, RegSeqRat readback, and terminal Real seal used by the completion consumer.

Finally replay the structural rows H, K, G, N. They preserve the same route under componentwise hsame, displayed Cont, package provenance, and local naming. The carrier lacks quotient stream equality, selected representatives, host completion points, countable choice, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness, so no other Cauchy handoff is available. □

Falsifiable prediction: Every accepted $\mathsf{FriendlyMetricCompletion}^{\uparrow}$ read exposes a metric source row, Hausdorffization separatedness boundary, SeparatedMetric row, MetricCompletion handoff, StreamName windows, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any completion-facing consumer reads it.

Independence witness: hausdorffization, separatedmetric, metriccompletion, streamname, regseqrat, real: $\mathsf{FriendlyMetricCompletion}^{\uparrow}$ is not identical to any listed sibling because it jointly binds

the non-quotient separatedness boundary, separated metric handoff, completion handoff, finite Cauchy windows, regular rational readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FriendlyMetricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FriendlyMetricCompletion}^{\uparrow}$ packet is generated from a metric source row, separatedness boundary, SeparatedMetric row, MetricCompletion handoff, finite StreamName windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FriendlyMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7154.1, Definition 7154.2, and Definition 7154.3 seed the finite non-quotient completion-friendly route from separated metric data to completion-facing Cauchy consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FriendlyMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected representatives, host completion points, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separatedness-boundary exactness, completion-handoff exactness, finite Cauchy readback, transport, replay, provenance, and local naming for BEDC.Derived.FriendlyMetricCompletionUp.

Chapter 7155

A Concrete Naming Certificate for LocatedIntermediateValueModulus$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the LocatedIntermediateValueModulus$^{\uparrow}$ packet records the finite real-window modulus used when a sign-change interval is inspected by bisection before a Real-facing consumer reads the terminal seal. It sits after the finite-window naming discipline of chapter 126, the regular rational readback of chapter 301, the dyadic arithmetic core of chapter 291, the real-name boundary of chapter 38, the located real intermediate-value route of chapter 3394, and the constructive IVT modulus route of chapter 6431. The packet names the finite modulus surface consumed by L10 real-window arguments; it does not select a zero, decide trichotomy, import open-cover compactness, invoke choice, or assert ambient completeness of Real$^{\uparrow}$.

Definition 7155.1 (LocatedIntermediateValueModulus carrier)**.** *A* LocatedIntermediateValueModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, S, D, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the bracket row, recording the located real interval endpoints, the retained subinterval, and the finite sign-change boundary consumed by the route.*
2. *S is the sign-change row, recording the inspected endpoint signs and the midpoint sign reads used by the retained branch prefix.*
3. *D is the dyadic refinement row, recording the* DyadicRatCore$^{\uparrow}$ *mesh, halving, radius comparison, and retained-width budget.*
4. *B is the bisection-modulus row, recording the finite number of branch reads required before the requested located window is exposed.*
5. *W is the* StreamName$^{\uparrow}$ *finite-window row for endpoint, midpoint, and retained-interval observations.*
6. *R is the* RegSeqRat$^{\uparrow}$ *regular rational readback row attached to the same windows.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row used only after the bracket, sign-change, dyadic refinement, bisection modulus, finite windows, and readback rows have been displayed.*
8. *H stores componentwise* hsame *transport for I, S, D, B, W, R, E and the structural rows.*

9. *C stores displayed* Cont *replay for bracket inspection, sign readback, dyadic refinement, modulus consumption, regular rational readback, and Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedIntermediateValueModulus}^{\uparrow}$, $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$, $\mathsf{ConstructiveIVTModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntermediateValueModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected zero, real trichotomy, open-cover compactness, countable choice, quotient real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7155.2 (LocatedIntermediateValueModulus NameCert obligations)**.** *For every accepted carrier $M = (I, S, D, B, W, R, E, H, C, P, N)$ of Definition 7155.1, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntermediateValueModulus}^{\uparrow}}$ *surface consists exactly of bracket admission, sign-change exposure, dyadic refinement, bisection-modulus consumption, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier rows in order. The bracket and sign-change rows I, S provide the only source of opposite-sign information, while the dyadic row D and bisection-modulus row B record the finite refinement budget.

The observation and readback rows W, R expose only the windows requested by that finite budget. The terminal seal E is therefore downstream of bracket inspection, sign readback, dyadic refinement, and regular rational readback.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no further coordinate appears in M, the NameCert surface exports exactly the displayed rows and excludes selected zeros, trichotomy, choice, open-cover compactness, quotient equality, and ambient completeness. □

Theorem 7155.3 (LocatedIntermediateValueModulus source stability)**.** *Let $M = (I, S, D, B, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedIntermediateValueModulus}^{\uparrow}$ *carrier. Transporting M along its displayed* hsame *row keeps the bracket row I, sign-change row S, dyadic refinement row D, bisection-modulus row B, finite windows W, regular readback R, and Real seal E in the same packet. A consumer cannot replace the transported source by* $\mathsf{Real}^{\uparrow}$ *completeness, real trichotomy, a host root selector, or an off-packet intermediate-value theorem.*

Proof. Read the componentwise transport row H. Its source and target components are indexed by the rows I, S, D, B, W, R, E together with the structural rows, so transport preserves the same bracket, sign-change, refinement, window, readback, and seal inventory.

Replay through C does not add a new source row. It only reopens the displayed bracket, sign, dyadic, modulus, window, readback, and seal routes already present in the packet.

The provenance row P names the $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$ and $\mathsf{ConstructiveIVTModulus}^{\uparrow}$ routes as sources, but it names them through this finite carrier. Thus no transported read can escape to a selected zero, trichotomy, open-cover compactness, choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$. □

Theorem 7155.4 (LocatedIntermediateValueModulus ledger exactness)**.** *For an accepted* LocatedIntermediateValue *carrier $M = (I, S, D, B, W, R, E, H, C, P, N)$, the bisection-modulus row B records exactly the finite branch budget justified by the bracket row I, sign-change row S, dyadic refinement row D, finite observation row W, regular rational readback row R, and Real seal row E. The ledger does not add open-cover compactness, a selected zero, trichotomy, choice, quotient real equality, or a completed* $\mathsf{Real}^{\uparrow}$ *object.*

Proof. The row B is read only after I, S, D have fixed the source bracket, sign boundary, and dyadic refinement budget. It therefore records the modulus for that displayed sign-change route rather than an ambient existence theorem.

The rows W, R, E give the finite observation, regular rational readback, and terminal Real seal attached to the same branch budget. The replay row C may present these reads to a consumer, but it cannot enlarge B into a completed choice sequence or a selected root.

Package provenance P and local naming N keep the ledger attached to $\mathsf{LocatedIntermediateValueModulus}^{\uparrow}$. Since the carrier has no row for open-cover compactness, trichotomy, choice, quotient equality, or complete $\mathsf{Real}^{\uparrow}$, the ledger is exact for the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntermediateValueModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntermediateValueModulus}^{\uparrow}$ packet is generated from bracket, sign-change, dyadic refinement, bisection-modulus, finite StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntermediateValueModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7155.1, Definition 7155.2, Definition 7155.3, and Definition 7155.4 bind the finite L10 real-window modulus surface over $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$, $\mathsf{ConstructiveIVTModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntermediateValueModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected zeros, real trichotomy, countable choice, quotient real equality, bridge checking, or complete $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure asks for checked carrier admission, sign-change stability, dyadic refinement exactness, finite-window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntermediateValu

Chapter 7156

A Concrete Naming Certificate for $\mathsf{CantorSeriesExpansion}^{\uparrow}$

Following Cantor and Hardy–Wright, the $\mathsf{CantorSeriesExpansion}^{\uparrow}$ packet records a variable-base digit expansion as finite denominator-product windows before the expansion can enter the regular rational and Real seal pipeline. It sits beside the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the sibling Engel denominator route of chapter 2007. The packet names only finite base, digit, partial-sum, and tail-bound data; it does not quotient digit streams, select an infinite sum, invoke trichotomy, assume countable choice, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7156.1 (Cantor series expansion carrier)**.** *A* $\mathsf{CantorSeriesExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, D, S, T, W, R, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the variable-base row, listing the accepted finite base prefix and the denominator products generated from it.*
2. *D is the digit-bound row, recording for each displayed base entry the corresponding finite digit and its admissible bound.*
3. *S is the finite partial-sum row, displaying the rational sums obtained from the visible base and digit windows.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger row, bounding the unread tail of the denominator-product expansion for each precision request.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, selecting exactly the base, digit, partial-sum, and tail-ledger prefixes inspected by a read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from B, D, S, T, W and no other numeric coordinate.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback row is displayed.*
8. *H records componentwise* hsame *transport for the base, digit, partial-sum, tolerance-ledger, stream-window, readback, Real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a precision request through*

$$B, D, W \longmapsto S \longmapsto T \longmapsto R \longmapsto L.$$

10. *P is the* Pkg *provenance over* $\mathsf{CantorSeriesExpansion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{EngelExpansion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorSeriesExpansion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient digit-stream equality, selected infinite sums, arbitrary base-choice functions, trichotomy, countable-choice selection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7156.2 (CantorSeriesExpansion NameCert obligations)**.** *For every accepted* $\mathsf{CantorSeriesExpansion}^{\uparrow}$ *carrier $Q = (B, D, S, T, W, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorSeriesExpansion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the variable-base row, digit-bound row, finite partial-sum row, dyadic tolerance ledger, stream windows, regular readback, Real seal, transport, replay, provenance, and local naming;*
2. *base-prefix visibility, requiring each denominator product consumed by a partial sum or tail bound to be generated from the displayed row B;*
3. *digit-bound exactness, requiring every displayed digit in D to be checked against the corresponding displayed base entry before S is read;*
4. *finite partial-sum exactness, requiring S to expose only* $\mathsf{Rat}^{\uparrow}$ *sums generated from the base and digit windows selected by W;*
5. *dyadic tail control, requiring every unread-tail claim consumed by R or L to pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger T;*
6. *readback order, requiring the finite route $B, D, W \longmapsto S \longmapsto T \longmapsto R \longmapsto L$ before any Real-facing consumer receives the packet;*
7. *transport, continuation replay, provenance, and local naming for exactly the rows recorded in H, C, P, N.*

No CantorSeriesExpansion NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier $Q = (B, D, S, T, W, R, L, H, C, P, N)$. The projection exposes the base prefix, digit bounds, partial sums, tolerance ledgers, stream windows, readback rows, and structural rows as finite BEDC coordinates.

The base and digit data are read before the analytic handoff. The row B supplies denominator products, while D supplies only digits whose bounds have been displayed against those bases. The row W fixes the finite window in which both rows may be inspected.

The summation and tail steps are separate. The row S records rational partial sums generated from the displayed base and digit windows, and the row T records dyadic bounds for every unread tail before a regular rational or Real-facing consumer can use the expansion.

Finally R and L are downstream of T. Componentwise transport in H and replay in C preserve the same displayed route, while P and N only source and name it. Since the excluded host and choice data are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7156.3 (CantorSeriesExpansion Real handoff)**.** *Let* $Q = (B, D, S, T, W, R, L, H, C, P, N)$ *be an accepted* $\mathsf{CantorSeriesExpansion}^{\uparrow}$ *carrier. Every Real-facing read of the Cantor series expansion factors through*

$$B, D, W \longmapsto S \longmapsto T \longmapsto R \longmapsto L$$

with structural support H, C, P, N*. Thus the consumer receives variable-base rows, digit-bound rows, finite rational partial sums,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal, all as finite BEDC data.*

The handoff supplies no quotient stream, no selected infinite sum, no arbitrary base-choice function, no trichotomy branch, no countable-choice selector, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle. It is therefore a traditional Cantor-series representation route in the L10 Real and Completion neighborhood, parallel to the Engel route but not identified with it as a host real theorem.*

Proof. Start with a downstream consumer of R or L. By Definition 7156.1, neither row is an independent real object; both are downstream of the displayed base, digit, partial-sum, stream-window, and dyadic tail-ledger rows.

The consumer first reads B, D, and W. These rows expose the accepted denominator-product prefix, the digit bounds, and the finite window in which the expansion is being inspected.

Next the consumer reads S and T. The partial-sum row records finite rational sums, while the dyadic tolerance ledger records the unread-tail control needed before regular rational readback is public.

The row R then repacks the displayed sums and bounds as a $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal row L seals only that regular rational route as a $\mathsf{Real}^{\uparrow}$ presentation. The structural rows transport, replay, package, and name the same route, so none of the excluded principles can be recovered from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorSeriesExpansion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorSeriesExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7156.1, Definition 7156.2, and Definition 7156.3 seed the finite variable-base digit-expansion route through dyadic tail ledgers, stream windows, regular rational readback, and terminal Real seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorSeriesExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient digit streams, selected infinite sums, arbitrary base-choice functions, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, bridge checking, or equivalence with sibling representations as host real objects.

Upgrade path: Obligation closure requires checked carrier admission, base-prefix visibility, digit-bound exactness, finite partial-sum exactness, dyadic tail control, readback order, and Real handoff proofs for BEDC.Derived.CantorSeriesExpansionUp.

Constructive story: A $\mathsf{CantorSeriesExpansion}^{\uparrow}$ packet is generated from variable-base rows, digit-bound rows, finite partial-sum windows, DyadicRatCore tolerance ledgers, StreamName windows, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7157

A Concrete Naming Certificate for $\mathsf{KuratowskiFiniteSet}^{\uparrow}$

Following Kuratowski's finite-set presentation, the $\mathsf{KuratowskiFiniteSet}^{\uparrow}$ packet records a finite family by the displayed membership tree generated from the empty set and singleton adjoining. It sits over the endpoint discipline of chapter 32, the finite spine of chapter 36, the unary length row of chapter 28, the membership interface of chapter 3668, the finite observation windows of chapter 126, and the regular rational ledger route of chapter 301. The packet names finite set data only through displayed rows; it does not import host finite sets, quotient extensionality, selected representatives, powerset choice, or ambient equality of subsets.

Definition 7157.1 (Kuratowski finite set carrier)**.** *A* $\mathsf{KuratowskiFiniteSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, A, L, M, B, S, W, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the empty-set seed row, naming the initial Kuratowski stage.*
2. *A is the singleton-adjoining row, recording the displayed element row and the previous finite family row for each adjoining step.*
3. *L is the* $\mathsf{List}^{\uparrow}$ *spine row listing the adjoining schedule in construction order.*
4. *M is the* $\mathsf{Nat}^{\uparrow}$ *length row recording the finite number of adjoining steps.*
5. *B is the* $\mathsf{Bool}^{\uparrow}$ *membership-decision row for inspected entries.*
6. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership surface exposed to downstream consumers.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when a consumer inspects only a bounded prefix of the adjoining schedule.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *ledger row used by real-facing finite-window consumers that record scheduled rational readbacks beside the finite family.*
9. *H records componentwise* hsame *transport for $E, A, L, M, B, S, W, R, C, P, N$.*
10. *C records displayed* Cont *replay from a Kuratowski finite-set request through the empty seed, adjoining steps, list spine, length, membership decision, SetLike surface, finite window, and regular-rational ledger rows.*

11. *P is the* Pkg *provenance over* $\mathsf{KuratowskiFiniteSet}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiFiniteSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, A, L, M, B, S, W, R, H, C, P, N$. It has no coordinate for a host finite-set type, quotient extensionality of subsets, selected representatives, powerset choice, hidden enumeration equality, or ambient subset equality.

Theorem 7157.2 (Kuratowski finite set NameCert obligations)**.** *For every accepted* $\mathsf{KuratowskiFiniteSet}^{\uparrow}$ *carrier*

$$K = (E, A, L, M, B, S, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KuratowskiFiniteSet}^{\uparrow}}$ *surface consists exactly of empty-stage admission through E, singleton-adjoining admission through A, list-spine exactness through L, unary length exposure through M, membership-decision readback through B, SetLike membership exposure through S, finite-window inspection through W, RegSeqRat ledger handoff through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 7157.1. The rows $E, A, L, M, B, S, W, R, H, C, P, N$ are the full displayed inventory.

The finite-set construction is read from E, A, L, M. The empty row starts the construction, each adjoining row records a singleton step, the list row fixes the finite spine of those steps, and the natural-number row records the length available to bounded consumers.

Membership is then read through B and S. The Boolean row records the inspected membership decision, and the SetLike row exposes that decision as the public membership surface without identifying subsets by quotient extensionality.

Finite-window consumers use W and R. StreamName opens the bounded prefix that is actually inspected, while the RegSeqRat row records the finite ledger used by real-facing schedules such as finite observations and regular rational readbacks.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no host finite-set coordinate, no powerset selector, no representative choice, and no ambient subset-equality row, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{KuratowskiFiniteSet}^{\uparrow}$ read exposes the empty-stage row, singleton-adjoining row, List spine, Nat length, Bool membership decision, SetLike membership surface, StreamName finite window, RegSeqRat ledger handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any finite-window consumer reads the packet.

Independence witness: bool, list, nat, setlike, streamname, regseqrat: $\mathsf{KuratowskiFiniteSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds empty-stage generation, singleton adjoining, finite spine, length, membership decision, SetLike exposure, finite-window inspection, regular-rational ledger handoff, transport, replay, provenance, and local naming while refusing host finite sets and quotient extensionality.

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiFiniteSet}^{\uparrow}}$.

Constructive story: A $\mathsf{KuratowskiFiniteSet}^{\uparrow}$ packet is generated from an empty-stage row, singleton-adjoining rows, a List spine, a Nat length row, Bool membership decisions, a SetLike membership surface, StreamName finite windows, a RegSeqRat ledger handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KuratowskiFiniteSet}^{\uparrow}}$, seed)

Scope closed: Definition 7157.1 and Definition 7157.2 seed the Kuratowski finite-set packet over empty-stage, adjoining, finite-spine, length, membership, SetLike, StreamName, RegSeqRat, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{KuratowskiFiniteSet}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host finite sets, quotient extensionality, powerset choice, selected representatives, hidden enumeration equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, empty-stage generation, singleton adjoining, list-spine exactness, length exposure, membership readback, finite-window handoff, ledger handoff, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.KuratowskiFiniteSetUp.

Chapter 7158

A Concrete Naming Certificate for $\mathsf{KernelCategoryFunctor}^{\uparrow}$

The $\mathsf{KernelCategoryFunctor}^{\uparrow}$ packet realizes the functorial transport branch of chapter 9363 as finite BEDC data. It sits between two $\mathsf{KernelCategory}^{\uparrow}$ packets, reads object and morphism rows through the concrete $\mathsf{Cat}^{\uparrow}$ and $\mathsf{Functor}^{\uparrow}$ surfaces, and replays transport through $\mathsf{ContinuationMonad}^{\uparrow}$-style continuation rows. The packet names functorial transport without importing host function equality, quotient morphisms, external categorical semantics, or a global category library.

Definition 7158.1 (KernelCategoryFunctor carrier)**.** *A* $\mathsf{KernelCategoryFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, O, M, I, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{KernelCategory}^{\uparrow}$ *row, exposing only its finite object, hom, identity, composition, law-transport, provenance, and local naming data.*
2. *T is the target* $\mathsf{KernelCategory}^{\uparrow}$ *row with the same displayed row discipline.*
3. *O is the object-row transport ledger, assigning each visible source object row to a visible target object row.*
4. *M is the morphism-row transport ledger, assigning each visible source continuation-ledger hom row to a visible target continuation-ledger hom row.*
5. *I records identity preservation: empty-continuation identity rows in S transport to empty-continuation identity rows in T.*
6. *Q records composition preservation: each displayed source composite transports to the target composite named by the transported hom rows.*
7. *H records componentwise* hsame *transport for the source, target, object transport, morphism transport, identity, composition, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the object and morphism transport ledgers through the source and target continuation rows.*
9. *P is the* Pkg *provenance over* $\mathsf{KernelCategoryFunctor}^{\uparrow}$, $\mathsf{KernelCategory}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{ContinuationMonad}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KernelCategoryFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, M, I, Q, H, C, P, N$. It has no coordinate for host function equality, quotient morphism equality, external category objects, semantic functor laws outside the displayed rows, or imported category-library data.

Theorem 7158.2 (KernelCategoryFunctor transport obligations)**.** *For every accepted* $\mathsf{KernelCategoryFunctor}^{\uparrow}$ *carrier* $F = (S, T, O, M, I, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KernelCategoryFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission, source kernel-category exposure, target kernel-category exposure, object-row transport, morphism-row transport, identity preservation, composition preservation, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier rows. The source and target packets are the only category-shaped inputs, and the object and morphism transport ledgers are exactly O and M.

Identity preservation is read from I. Since source identities are empty continuation rows and target identities are empty continuation rows, the preservation claim is a displayed row comparison rather than a host identity-function assertion.

Composition preservation is read from Q. Each preserved composite cites the source composite row, the two transported morphism rows, and the target composite row before any functor-facing consumer can use the transported hom.

Rows H, C, P, N then transport, replay, source, and name the same packet. Because the carrier contains no host function equality, quotient morphism equality, external category object, or imported category-library coordinate, the listed rows exhaust the finite certificate surface. □

Theorem 7158.3 (KernelCategoryFunctor continuation handoff)**.** *Every* $\mathsf{Functor}^{\uparrow}$*-facing read from an accepted* $\mathsf{KernelCategoryFunctor}^{\uparrow}$ *carrier factors through the source* $\mathsf{KernelCategory}^{\uparrow}$ *row, target* $\mathsf{KernelCategory}^{\uparrow}$ *row, displayed object transport, displayed morphism transport, identity preservation, composition preservation,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The handoff exports no host function equality, quotient morphism equality, external category object, detached naturality principle, or ambient category semantics.*

Proof. Start from Definition 7158.1. The only source of object data is O, and the only source of hom data is M.

Use Definition 7158.2. It places identity and composition preservation on the displayed rows I and Q, downstream of the source and target kernel-category packets.

The continuation handoff is then C together with provenance and naming through P, N. Componentwise transport through H preserves the same finite route.

Thus a $\mathsf{Functor}^{\uparrow}$ consumer receives functorial transport only as a finite BEDC packet over BHist, hsame, Cont, Pkg, and NameCert, with no additional host categorical coordinate. □

Theorem 7158.4 (KernelCategoryFunctor sibling route)**.** *Every accepted* $\mathsf{KernelCategoryFunctor}^{\uparrow}$ *read factors through the source and target* $\mathsf{KernelCategory}^{\uparrow}$ *packets of chapter 488, the* $\mathsf{Cat}^{\uparrow}$ *object and hom discipline of chapter 61, and the* $\mathsf{Functor}^{\uparrow}$ *transport surface of chapter 62 before* H, C, P, N *can expose local naming. The route is a finite sibling dependency over* $S, T, O, M, I, Q, H, C, P, N$*, not a host categorical semantics principle.*

Proof. Project S and T from the carrier of Definition 7158.1. These are the only rows that expose the source and target kernel-category packets, so the read begins with the sibling surface named by chapter 488.

Next project O, M, I, Q. The object and hom transport rows use the category object and hom discipline, while the identity and composition rows keep the transported data inside the displayed functor surface named by chapter 61 and chapter 62.

Finally project H, C, P, N. These rows transport, replay, source, and name the already displayed sibling route. Since the carrier has no coordinate for ambient categories, quotient morphisms, host functions, or external functor laws, the dependency is finite BEDC sibling routing rather than imported categorical semantics. □

Falsifiable prediction: An accepted $\mathsf{KernelCategoryFunctor}^{\uparrow}$ read is refuted if a functor-facing consumer obtains object transport, morphism transport, identity preservation, or composition preservation without first displaying the source and target KernelCategory packets, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: kernelcategory, category, functor, continuationmonad: $\mathsf{KernelCategoryFunctor}^{\uparrow}$ is not bijective to any listed sibling because it binds two kernel-category packets together with object-row transport, morphism-row transport, identity preservation, composition preservation, hsame transport, Cont replay, Pkg provenance, and local naming as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{KernelCategoryFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{KernelCategoryFunctor}^{\uparrow}$ packet is generated from source and target KernelCategory rows, object-row transport, morphism-row transport, identity and composition preservation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KernelCategoryFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7158.1, Definition 7158.2, and Definition 7158.3 seed the finite functorial transport surface over source and target kernel-category packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KernelCategoryFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient morphism equality, external category objects, detached naturality, imported category-library semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target kernel-category exposure, object-row transport, morphism-row transport, identity preservation, composition preservation, transport, replay, provenance, and local naming for BEDC.Derived.KernelCategoryFunctorUp.

Chapter 7159

A Concrete Naming Certificate for $\mathsf{ConstructiveCantorBaire}^{\uparrow}$

Following Brouwer and Bishop on choice sequences and finite-prefix spaces, the $\mathsf{ConstructiveCantorBaire}^{\uparrow}$ packet records the finite-prefix embedding route by which Cantor-space binary observations and Baire-space natural-number observations are read as one BEDC naming surface. It consumes the Cantor prefix row of chapter 1475, the Baire prefix row of chapter 334, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite bridge for countable names only; it does not add countable choice, completed stream quotients, host equality of functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7159.1 (ConstructiveCantorBaire carrier)**.** *A* $\mathsf{ConstructiveCantorBaire}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (C, B, S, R, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *row exposing binary prefixes, Boolean branch observations, and the finite cylinder classifier;*
2. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *row exposing natural-number finite prefixes, common-prefix comparison, and the Baire cylinder classifier;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row that records every coordinate inspected by the Cantor-to-Baire and Baire-to-Cantor finite-prefix reads;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *window row, used only after the finite prefix route has exposed a regular rational readback and the terminal Real seal;*
5. *H is the componentwise* hsame *transport row for the Cantor prefix, Baire prefix, stream observation, regular-Cauchy readback, Real seal, replay, provenance, and local naming rows;*
6. *K is the displayed* Cont *replay row forcing each consumer to read finite binary prefixes and finite Baire prefixes before any countable-name or Real-facing observation is exported;*
7. *P is the* Pkg *provenance over* $\mathsf{ConstructiveCantorBaire}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCantorBaire}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through these displayed finite-prefix, stream-window, regular-readback, transport, replay, provenance, and local naming rows.

Theorem 7159.2 (ConstructiveCantorBaire NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveCantorBaire}^{\uparrow}$ *carrier* $E = (C, B, S, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCantorBaire}^{\uparrow}}$ *surface consists exactly of these obligations:*

1. *carrier admission for the Cantor prefix row, Baire prefix row, stream observation row, regular-rational and Real readback row, transport row, replay row, provenance row, and local naming row;*
2. *binary-to-Baire exposure, requiring each Cantor binary prefix consumed by the classifier to be replayed as a finite Baire prefix before any countable-name read is public;*
3. *Baire-to-binary exposure, requiring each finite Baire prefix consumed by a Cantor-facing client to expose the finite binary observations used by the handoff;*
4. *regular-Cauchy landing, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read to pass first through the displayed finite-prefix and* $\mathsf{StreamName}^{\uparrow}$ *rows;*
5. *classifier transport through componentwise* hsame *and displayed* Cont *replay;*
6. *non-escape of countable-choice selectors, completed stream quotients, host function equality, selected infinite branches, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No obligation is stored outside the finite packet E*.*

Proof. Project the carrier of Definition 7159.1. Carrier admission exposes exactly the rows C, B, S, R, H, K, P, N, so every local obligation must be read from those coordinates.

For binary-to-Baire exposure, read the $\mathsf{CantorSpace}^{\uparrow}$ prefix row C and replay its inspected bits through the finite observation row S. The $\mathsf{BaireSpace}^{\uparrow}$ row B receives only the finite prefix data recorded by this replay.

For Baire-to-binary exposure, read the finite Baire prefix row B and then inspect only the binary observations displayed by C and S. The route never chooses an infinite branch or a host function representative.

The regular-Cauchy landing is forced by R. A $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can inspect the readback only after the finite prefix rows and stream window have been exposed, and H, K, P, N preserve and name that same route.

The non-escape clauses follow by exhaustion of the carrier. There is no coordinate for countable choice, quotient streams, host equality, selected infinite branches, or ambient Real completeness. □

Theorem 7159.3 (ConstructiveCantorBaire regular-Cauchy induction)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *observation exported by an accepted* $\mathsf{ConstructiveCantorBaire}^{\uparrow}$ *packet is induced from a finite sequence of prefix reads*

$$\mathsf{CantorSpace}^{\uparrow}, \quad \mathsf{BaireSpace}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}$$

inside $E = (C, B, S, R, H, K, P, N)$*. The induction step extends the displayed prefix window by one Cantor bit or one Baire entry, replays the enlarged finite window through* S*, and only then permits the regular-rational readback in* R*.*

Proof. The base window is the empty prefix displayed simultaneously by the Cantor and Baire rows. It has no Real-facing content until the stream observation row records the finite request.

For a Cantor-bit extension, append the displayed bit to the binary prefix in C and replay the corresponding finite request through S. The Baire-facing row B can read only the finite prefix obtained from that replay.

For a Baire-entry extension, append the displayed natural entry to the prefix in B and inspect the finite binary observations recorded by C and S. The replay row K keeps the extension finite.

After either step, R may read the regular-rational window and terminal Real seal. Since the readback is reached only after the finite prefix rows and stream window, the induction exports no selected infinite branch or ambient completeness datum. □

Theorem 7159.4 (ConstructiveCantorBaire Cantor-space handoff)**.** *Every Cantor-facing consumer of a* $\mathsf{ConstructiveCantorBaire}^{\uparrow}$ *packet first reads the* $\mathsf{CantorSpace}^{\uparrow}$ *row of chapter 1475, then the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row of chapter 334, and then the* $\mathsf{StreamName}^{\uparrow}$ *observation row of chapter 126. Only after those rows are displayed may the consumer pass through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *as in chapter 301 and chapter 38.*

Proof. Start with the Cantor prefix row C. It supplies binary cylinder data and no Baire or Real-facing value by itself.

Next expose the Baire prefix row B. The handoff compares only finite prefixes, so the consumer receives a Baire cylinder route rather than an infinite branch or a selected sequence.

The stream observation row S records the actual finite coordinates inspected by both sides. The regular-rational and Real row R is available only after that finite route is displayed, and H, K, P, N preserve the same route for downstream consumers. □

Theorem 7159.5 (ConstructiveCantorBaire L10 status)**.** *The* $\mathsf{ConstructiveCantorBaire}^{\uparrow}$ *packet is a seed-level L10 countable-name bridge. It displays the finite route from Cantor and Baire prefixes to stream observations and regular-Cauchy readback, but it does not close a public countable-name theorem, a Lean verification target, a standard bridge, or a completed Real-space compactness statement.*

Proof. The carrier and obligations display a finite route through C, B, S, R, H, K, P, N. This is enough to name the bridge object and to state how countable-name consumers must enter the Real-facing readback.

The same inventory also fixes the boundary. Public closure would require a downstream exported object surface for countable names, Lean closure would require a checked BEDC target, and bridge closure would require a standard bridge instance. None of those rows is part of this seed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCantorBaire}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveCantorBaire}^{\uparrow}$ packet is generated from CantorSpace binary prefixes, BaireSpace finite prefixes, StreamName observations, RegSeqRat and Real windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCantorBaire}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7159.1, Definition 7159.2, Definition 7159.3, Definition 7159.4, and Definition 7159.5 seed the finite-prefix bridge from Cantor and Baire rows to StreamName, RegSeqRat, and Real readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCantorBaire}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a public countable-name theorem, Lean verification, standard bridge checking, countable choice, completed stream quotients, host function equality, selected infinite branches, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix handoff, regular-Cauchy landing, classifier transport, and non-escape for BEDC.Derived.ConstructiveCantorBaireUp.

Chapter 7160

A Concrete Naming Certificate for $\mathsf{CauchyCriterionSeries}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyCriterionSeries}^{\uparrow}$ packet records the finite tail criterion for convergence of a displayed series as a BEDC NameCert surface. It reads dyadic tolerances through chapter 291, partial-sum readbacks through chapter 301, and terminal endpoint data through chapter 38. The packet is the local tail-Cauchy criterion consumed by product and uniform series routes such as chapter 6968 and $\mathsf{UniformCauchySeries}^{\uparrow}$; it names only finite windows, budgets, transport, replay, provenance, and local certificate rows.

Definition 7160.1 (Cauchy criterion series carrier)**.** *A* $\mathsf{CauchyCriterionSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, P, T, D, R, H, C, G, N)$$

with the following displayed rows:

1. *A is the summand source row, exposing only the inspected series terms and their local arithmetic provenance.*
2. *P is the partial-sum window row, naming the finite prefix sums and the tail windows compared by the criterion.*
3. *T is the tail-budget row, recording the displayed request that every inspected tail beyond the named bound stays inside the requested tolerance.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the dyadic radius, comparison slack, and arithmetic budget used by the tail estimate.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed partial sums after P, T, D have been inspected.*
6. *H records componentwise* hsame *transport for the summand source, partial-sum windows, tail budget, dyadic tolerance, readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of a precision request through the source, window, tail-budget, tolerance, and readback rows.*
8. *G is the* Pkg *provenance over* $\mathsf{CauchyCriterionSeries}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyProductSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionSeries}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, P, T, D, R, H, C, G, N$. It has no coordinate for arbitrary choice of a threshold, quotient equality of series, a selected completed limit, unconditional rearrangement, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7160.2 (Cauchy criterion series obligations)**.** *For every accepted* $\mathsf{CauchyCriterionSeries}^{\uparrow}$ *carrier $S = (A, P, T, D, R, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionSeries}^{\uparrow}}$ *surface consists exactly of carrier admission, tail-Cauchy exactness, partial-sum stability, dyadic tolerance transport,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff, and ledger nonescape through transport, replay, provenance, and local naming.*

Proof. Project the carrier rows. Carrier admission exposes $A, P, T, D, R, H, C, G, N$, with the summand source and partial-sum windows available before any readback.

Tail-Cauchy exactness is the joint read of P, T, D. The row P supplies the displayed partial-sum windows, T supplies the finite tail bound for the requested tolerance, and D supplies the dyadic comparison budget used by the tail estimate.

Partial-sum stability and dyadic tolerance transport are read before the endpoint handoff. Componentwise hsame transport in H preserves the same windows and dyadic budget, while C replays the same precision request through those rows.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback R is downstream of the finite tail rows, and the $\mathsf{Real}^{\uparrow}$ handoff is available only through the provenance route G after R has been displayed. The same route is the one consumed by $\mathsf{CauchyProductSeries}^{\uparrow}$ and $\mathsf{UniformCauchySeries}^{\uparrow}$ when they need a tail-Cauchy series criterion.

Ledger nonescape follows because G and N source and name only the displayed packet. Since the carrier contains no arbitrary choice coordinate, quotient series equality, selected completed limit, or ambient completeness row, the listed obligations exhaust the certificate surface. □

Theorem 7160.3 (Cauchy criterion series finite-tail handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyCriterionSeries}^{\uparrow}$ *packet first reads the summand source A, partial-sum windows P, tail-budget T, and dyadic tolerance row D, then the readback row R, and only then the transport, replay, provenance, and local naming rows H, C, G, N. The handoff exports no arbitrary threshold choice, quotient series equality, selected limit, unconditional rearrangement theorem, or ambient completeness principle.*

Proof. Start from Definition 7160.1. The only numerical rows before readback are A, P, T, D, and together they display the finite tail-Cauchy comparison requested by the consumer.

Apply Definition 7160.2. It places partial-sum stability and dyadic tolerance transport upstream of R, so the regular rational readback cannot be inspected before the finite tail window and tolerance budget have been displayed.

The terminal Real-facing handoff is sourced by G and named by N, with transport and replay through H, C. These structural rows preserve the same packet and add no new analytic coordinate.

Thus the consumer receives a finite tail criterion route rather than a host convergence theorem, arbitrary selected bound, quotient-series equality, selected completed limit, or ambient completeness witness. □

Falsifiable prediction: An accepted $\mathsf{CauchyCriterionSeries}^{\uparrow}$ read is refuted if a series convergence consumer reaches RegSeqRat or Real data without first displaying the summand source, partial-sum windows, tail-budget, dyadic tolerance, transport, replay, provenance, and local NameCert rows.

Independence witness: dyadicratcore, regseqrat, real, cauchyproductseries, uniformcauchyseries: $\mathsf{CauchyCriterionSeries}^{\uparrow}$ is not bijective to any listed sibling because it binds summand source rows, partial-sum windows, finite tail budgets, dyadic tolerances, regular readback, Real handoff, transport, replay, provenance, and local naming as one finite criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCriterionSeries}^{\uparrow}$ packet is generated from summand source rows, partial-sum windows, finite tail budgets, dyadic tolerance rows, RegSeqRat readback, Real handoff provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCriterionSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7160.1, Definition 7160.2, and Definition 7160.3 seed the finite tail-Cauchy criterion surface for series convergence consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCriterionSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary choice of tail thresholds, quotient series equality, a selected completed limit, unconditional rearrangement, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-Cauchy exactness, partial-sum stability, dyadic tolerance transport, RegSeqRat and Real handoff, ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCriterionSeriesUp.

Chapter 7161

A Concrete Naming Certificate for $\mathsf{DarbouxOscillation}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxOscillation}^{\uparrow}$ packet records the finite upper-minus-lower ledger read by partition-refinement arguments before Darboux and regulated integration consume a gap bound. It sits after the Darboux integral route of chapter 1460, the finite Darboux sums of chapter 6436, the finite partition mesh of chapter 3496, the bounded-variation source rows of chapter 398, and the terminal real-name seal of chapter 38. The packet names only finite oscillation data; it does not select partitions by choice, complete a real function space, or quotient functions by external equality.

Definition 7161.1 (Darboux oscillation carrier)**.** *A* $\mathsf{DarbouxOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (P, M, U, L, G, E, H, C, Q, N)$$

with the following displayed rows:

1. *P is the finite partition row, recording the ordered cell list, endpoint coverage, and adjacency route used by the Darboux read.*
2. *M is the* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *row, recording mesh width, refinement comparison, and the finite cell-width budget.*
3. *U and L are the upper and lower Darboux rows over the cells of P, read through the same bounded-function and partition source.*
4. *G is the oscillation-difference row displaying the bound $U - L$ after P, M, U, L have been projected.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed upper-minus-lower comparison.*
6. *H records componentwise* hsame *transport for the partition, mesh, upper row, lower row, oscillation difference, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through finite refinement, Darboux row projection, oscillation comparison, regular readback, and Real sealing.*
8. *Q is the* Pkg *provenance over* $\mathsf{DarbouxOscillation}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{DarbouxSums}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, M, U, L, G, E, H, C, Q, N$. It has no coordinate for host completeness, quotient equality of functions, choice-selected partitions, selected tags, or a detached supremum principle.

Lean4 (statement) `BEDC.Derived.DarbouxOscillationUp`

Theorem 7161.2 (Darboux oscillation refinement bound)**.** *Let $O = (P, M, U, L, G, E, H, C, Q, N)$ be an accepted* $\mathsf{DarbouxOscillation}^{\uparrow}$ *carrier. Every accepted refinement read preserves the displayed upper-minus-lower oscillation bound by first transporting the finite partition row P and mesh row M, then replaying the upper and lower Darboux rows U, L, and only then reading the difference row G and terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The exported surface is the finite oscillation ledger over the displayed mesh route; it exports no host completeness, quotient equality, choice-selected partition, selected tag family, or detached supremum.*

Lean4 ✓ `BEDC.Derived.DarbouxOscillationUp.DarbouxOscillationCarrier refinement bound`

Proof. Project the carrier rows. The only analytic data available before the oscillation comparison are the partition row P, mesh row M, and Darboux rows U, L.

Transport through H preserves these rows component by component. A refinement therefore changes only the displayed finite mesh route and keeps the upper and lower Darboux ledgers attached to the same cell history.

Replay through C exposes the comparison row G only after the transported partition, mesh, upper, and lower rows are visible. The Real seal E is downstream of that comparison, and provenance Q names only the Darboux, finite-mesh, bounded-variation, regulated-integral, and Real rows already displayed.

Since the packet has no coordinate for host completeness, quotient equality, selected partitions, tags, or detached suprema, a refinement consumer can export only the finite oscillation bound carried by G and sealed by E. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxOscillation}^{\uparrow}$ packet is generated from finite partition, mesh, upper Darboux row, lower Darboux row, oscillation difference, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7161.1 and Definition 7161.2 seed the finite upper-minus-lower oscillation ledger over DarbouxIntegralUp, DarbouxSumsUp, FinitePartitionMeshUp, BoundedVariationUp, RegulatedIntegralUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxOscillation}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close host completeness, quotient function equality, choice-selected partitions, selected tags, detached suprema, theorem checking, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, refinement transport, mesh exactness, oscillation-difference nonescape, Real-seal nonescape, replay, provenance, and local naming for BEDC.Derived.DarbouxOscillationUp.

Chapter 7162

A Concrete Naming Certificate for $\mathsf{FiniteFanCompactness}^{\uparrow}$

Following Bishop–Bridges compact metric analysis, the $\mathsf{FiniteFanCompactness}^{\uparrow}$ packet records the finite fan of cover probes used by the compact-uniform-continuity construction of chapter 9237. It sits after the compact carrier of chapter 60, the metric distance rows of chapter 57, the continuous pointwise-modulus surface of chapter 59, the uniform-modulus consumer of chapter 369, the rational tolerance rows of chapter 37, and the finite lower-bound fold of chapter 619. The packet names finite cover and uniform-modulus data only; it does not expose open-cover compactness, external choice, or ambient completeness.

Definition 7162.1 (Finite fan compactness carrier)**.** *A* $\mathsf{FiniteFanCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, K, M, A, U, R, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite* $\mathsf{ProbeBundle}$ *fan row, recording the bundled probe names, center histories, and coverage witnesses.*
2. *K is the consumed* $\mathsf{Compact}^{\uparrow}$ *row, restricted to the displayed finite fan and its located cover evidence.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *row used to read source distances from points to fan centers and between source points.*
4. *A is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row at each bundled center.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced only after the finite fan and centerwise modulus rows have been read.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *tolerance and positive-radius ledger attached to the same fan.*
7. *L is the* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *lower-bound fold row, recording primitive recursion over the finite fan and the certified minimum radius used by the uniform-modulus route.*
8. *H records componentwise* hsame *transport for fan, compact, metric, continuous, uniform-modulus, rational, lower-bound, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through finite cover recursion, centerwise modulus reads, rational lower-bound folding, metric triangle estimates, and uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* FiniteFanCompactness$^\uparrow$, Compact$^\uparrow$, Met$^\uparrow$, Continuous$^\uparrow$, UniformModulus$^\uparrow$, Rat$^\uparrow$, FiniteNetMinimumFold$^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{FiniteFanCompactness}^\uparrow}$ *row.*

The classifier compares accepted packets only through $B, K, M, A, U, R, L, H, C, P, N$. It has no coordinate for open-cover compactness, selected subcovers, countable choice, quotient metric equality, or ambient completion of the metric space.

Lean4 (statement) `BEDC.Derived.FiniteFanCompactnessUp`

Theorem 7162.2 (Finite fan compactness uniform-modulus route)**.** *Let $F = (B, K, M, A, U, R, L, H, C, P, N)$ be an accepted* FiniteFanCompactness$^\uparrow$ *carrier. Every compact-uniform-continuity consumer must read the finite* ProbeBundle *fan B, the compact and metric rows K, M, the centerwise continuous rows A, the rational tolerance ledger R, and the finite lower-bound fold L before the* UniformModulus$^\uparrow$ *handoff U is exported. The route is constructive finite ProbeBundle recursion and exports no open-cover compactness, selected subcover, countable choice, quotient metric equality, or ambient completeness.*

Proof. Project the finite fan row B. It lists the probe names and center histories consumed by the compact row K, so the cover data are already finite before any modulus is read.

For each bundled probe, replay C through the metric row M and continuous row A. These rows produce only centerwise pointwise-modulus data attached to the displayed fan.

The rational ledger R and finite lower-bound fold L then perform primitive recursion over the probes. The fold keeps a certified positive lower bound for the displayed center radii and supplies the tolerance-only precision needed by U.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no row stores an arbitrary open cover, selected subcover, choice principle, quotient metric equality, or ambient completion, the uniform-modulus handoff can only be read through the finite fan route. □

Closure status for NameCert$_{\text{FiniteFanCompactness}^\uparrow}$.

Constructive story: A FiniteFanCompactness$^\uparrow$ packet is generated from a finite ProbeBundle fan, CompactUp cover row, MetricUp distance row, ContinuousUp centerwise modulus rows, UniformModulusUp handoff, RatUp tolerance ledger, FiniteNetMinimumFoldUp lower-bound fold, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{FiniteFanCompactness}^\uparrow}$, seed)

Scope closed: Definition 7162.1 and Definition 7162.2 seed the finite fan compactness route feeding compact-uniform-continuity through CompactUp, MetricUp, ContinuousUp, UniformModulusUp, RatUp, and FiniteNetMinimumFoldUp rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteFanCompactness}^\uparrow}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, quotient metric equality, ambient completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure asks for checked fan admission, compact-cover exactness, metric triangle replay, centerwise-modulus extraction, rational fold stability, uniform-modulus nonescape, transport, provenance, and local naming for BEDC.Derived.FiniteFanCompactnessUp.

Chapter 7163

A Concrete Naming Certificate for $\mathsf{UniformConvergenceTheorem}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformConvergenceTheorem}^{\uparrow}$ packet records the finite certificate surface for the standard theorem that a uniformly convergent family of continuous displayed maps has a continuous Real-facing limit read. It sits after the continuous-map source of chapter 130, the uniform-limit endpoint route of chapter 463, the shared uniform-Cauchy family row of chapter 1555, the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet exposes the theorem as a finite BEDC handoff; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, host equality of functions, quotient equality of maps, countable choice, trichotomy, or a selected external limit.

Definition 7163.1 (Uniform convergence theorem carrier)**.** *A* $\mathsf{UniformConvergenceTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, F, U, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the source-domain row inspected by the continuous maps and by the limit read.*
2. *F is the finite family row of* $\mathsf{ContinuousMap}^{\uparrow}$ *carriers, each read through the same source-domain surface.*
3. *U is the* $\mathsf{UniformCauchyFamily}^{\uparrow}$ *or* $\mathsf{UniformLimit}^{\uparrow}$ *ledger row that supplies one displayed uniform tail discipline over the family row.*
4. *L is the limiting graph row whose endpoint reads are admitted only after F and U have been displayed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for source points, family indices, continuity-modulus requests, and value names.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the value windows and their rational tolerance budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the uniform ledger, stream windows, and regular rational readback have been consumed.*
8. *H records componentwise* hsame *transport for source rows, continuous-map rows, uniform-tail rows, limit graph rows, windows, readbacks, Real seals, provenance, and local names.*

9. *C records displayed* Cont *replay from source admission through continuity inspection, uniform-tail inspection, finite-window readback, graph comparison, and Real-seal handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformConvergenceTheorem}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformCauchyFamily}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformConvergenceTheorem}^{\uparrow}}$ *row.*

The classifier relates accepted packets only by the displayed componentwise rows $D, F, U, L, W, R, E, H, C, P, N$. It has no coordinate for host function equality, quotient map equality, a selected limit outside the packet, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7163.2 (Uniform convergence theorem NameCert obligations)**.** *For every accepted* $\mathsf{UniformConvergenceTheorem}^{\uparrow}$ *carrier*

$$T = (D, F, U, L, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformConvergenceTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, continuous-source compatibility for D and F, uniform-tail exactness through U, limit-graph admission through L, finite-window readback through W and R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No obligation row supplies host equality of functions, quotient equality of maps, a selected external limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7163.1. The visible rows are the source-domain row, the continuous-map family row, the uniform-tail row, the limiting graph row, the stream-window row, the regular rational readback, the Real seal, transport, replay, provenance, and local naming.

Continuous-source compatibility is read from D and F. Each family member is a displayed $\mathsf{ContinuousMap}^{\uparrow}$ row over the same source-domain surface, so a downstream continuity consumer has no separate host function space from which to read equality.

Uniform-tail exactness is read from U. Whether the row is consumed through the $\mathsf{UniformCauchyFamily}^{\uparrow}$ surface or through the endpoint-facing $\mathsf{UniformLimit}^{\uparrow}$ surface, the same finite ledger supplies the shared threshold discipline for every displayed source window.

The limit graph and endpoint read are downstream. The row L is admitted only after the continuous family and the uniform ledger have been exposed, while W, R, E turn the scheduled value windows into regular rational data and then into the terminal Real seal.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the excluded principles are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7163.3 (Uniform convergence theorem Real completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{UniformConvergenceTheorem}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UniformCauchyFamily}^{\uparrow},\ \mathsf{UniformLimit}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer first reads the displayed continuous-map family over the common source row, then the shared uniform-tail ledger, then the finite stream windows and regular rational readbacks, and only then the terminal Real seal. The handoff exports no ambient completeness theorem, no host equality of functions, no quotient equality of maps, no countable-choice schedule, no trichotomy principle, and no selected external limit.

Proof. Begin with a completion-facing consumer asking for the limiting endpoint. The packet admits such a read only through the displayed source and continuous-map rows D, F, so the consumer must inspect the same finite source surface used by the family.

Next use the uniform ledger U. It binds all requested source windows to one displayed tail discipline, matching the uniform-limit endpoint route of chapter 463 and the shared-family route of chapter 1555.

The limiting graph row L then records the theorem handoff: continuity data from the family and the uniform tail data are read before any endpoint row is visible. The stream windows W and regular rational row R provide the only value readback accepted by the packet.

Finally the Real seal E is reached through the same transport, replay, provenance, and local naming rows H, C, P, N. Because no refused object is a coordinate of the carrier, every Real or completion-facing read remains inside this finite route. □

Falsifiable prediction: Every accepted UniformConvergenceTheoremUp read exposes a source-domain row, a ContinuousMapUp family row, a UniformCauchyFamilyUp or UniformLimitUp tail ledger, a limiting graph row, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before a completion-facing consumer can inspect the endpoint.

Independence witness: continuousmap, uniformlimit, uniform-cauchy-family, streamname, regseqrat, real: $\mathsf{UniformConvergenceTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries continuous-map source compatibility, shared uniform-tail exactness, limiting graph admission, finite-window readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformConvergenceTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformConvergenceTheorem}^{\uparrow}$ packet is generated from a common source-domain row, ContinuousMap family rows, a UniformCauchyFamily or UniformLimit tail ledger, a limiting graph row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformConvergenceTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7163.1, Definition 7163.2, and Definition 7163.3 seed the finite theorem route from displayed continuous-map families and uniform-tail ledgers to Real-facing completion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformConvergenceTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, host function equality, quotient map equality, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.UniformConvergenceTheoremUp covering carrier admission, continuous-source compatibility, uniform-tail exactness, limit-graph admission, readback, Real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 7164

A Concrete Naming Certificate for $\mathsf{HamiltonianFlow}^{\uparrow}$

Following Arnold and Abraham–Marsden on Hamiltonian mechanics, the $\mathsf{HamiltonianFlow}^{\uparrow}$ packet records the finite BEDC surface where a phase-state carrier, Hamiltonian scalar readback, symplectic variation row, ODE vector-field row, dynamic-flow replay, and energy ledger are exposed before a mechanics consumer may cite Hamiltonian flow. It sits beside the Lagrangian mechanics packet of chapter 337, the ODE vector-field surface of chapter 193, the routed dynamics surface of chapter 195, the symplectic source of chapter 138, the terminal scalar seal of chapter 38, and the conservation-current boundary of chapter 269. The packet names a finite Hamiltonian-flow obligation surface; it does not select a global trajectory, complete a smooth phase manifold, identify Lagrangian and Hamiltonian formalisms, or assert Liouville volume preservation outside displayed rows.

Definition 7164.1 (HamiltonianFlowUp carrier)**.** *A* $\mathsf{HamiltonianFlow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, A, V, Y, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the phase-state carrier row, naming the finite phase coordinates or state tokens available to the flow packet.*
2. *A is the Hamiltonian scalar readback row, recording the displayed* $\mathsf{Real}^{\uparrow}$ *value route for the energy function on the phase-state rows.*
3. *V is the symplectic and variation row, recording the finite* $\mathsf{Symplectic}^{\uparrow}$ *source, admissible variation probes, and the pairing used to read the Hamiltonian vector field.*
4. *Y is the* $\mathsf{Ode}^{\uparrow}$ *vector-field row, exposing the finite right-hand-side data accepted for the Hamiltonian flow request.*
5. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *flow-replay row, recording how the displayed vector-field request is replayed as routed state evolution.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *energy-ledger row, comparing scalar reads along the displayed replay route and exposing only the finite conservation ledger admitted by the packet.*
7. *H records componentwise* hsame *transport for phase states, Hamiltonian scalar reads, symplectic and variation rows, ODE vector-field rows, dynamic replay, energy ledgers, and local naming.*

8. *C records displayed* Cont *replay from state and scalar rows through symplectic pairing, vector-field admission, dynamic-flow replay, and energy-ledger inspection.*
9. *P is the* Pkg *provenance over* $\mathsf{HamiltonianFlow}^{\uparrow}$, $\mathsf{LagrangianMechanics}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{Symplectic}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NoetherSymmetry}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HamiltonianFlow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, V, Y, D, E, H, C, P, N$. It has no coordinate for a host smooth phase space, selected integral curve, quotient trajectory equality, unrecorded conservation law, global Liouville theorem, or ambient completeness principle.

Theorem 7164.2 (HamiltonianFlowUp NameCert obligation surface)**.** *For every accepted* $\mathsf{HamiltonianFlow}^{\uparrow}$ *carrier $F = (S, A, V, Y, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HamiltonianFlow}^{\uparrow}}$ *surface consists exactly of phase-state carrier exposure through S, Hamiltonian scalar readback through A, symplectic and variation exposure through V, ODE vector-field admission through Y, dynamic-system flow replay through D,* $\mathsf{Real}^{\uparrow}$ *energy-ledger inspection through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Every Hamiltonian consumer must inspect those rows before reading a flow, an energy comparison, or a conservation-current handoff. The surface exports no selected trajectory, no global existence theorem for solutions, no quotient equality of flows, no unledgered Liouville-volume assertion, and no equivalence with a host Lagrangian model.

Proof. Project the carrier of Definition 7164.1. The rows S, A, V, Y, D, E are the only coordinates storing phase-state data, Hamiltonian scalar reads, symplectic and variation probes, vector-field admission, dynamic replay, and energy-ledger observations.

The structural rows then preserve the same route. Componentwise transport through H keeps comparisons on the displayed rows, while replay through C records how the scalar, symplectic, vector-field, flow, and energy reads are consumed. Provenance through P names the Lagrangian, ODE, dynamic-system, symplectic, Real, and Noether-facing siblings, and N registers the local packet.

Since no additional coordinate stores a smooth ambient phase space, a selected integral curve, a quotient of trajectories, a global conservation theorem, or a host equivalence with Lagrangian mechanics, the stated rows exhaust the NameCert obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{HamiltonianFlow}^{\uparrow}$ consumer must expose phase-state, Hamiltonian scalar, symplectic-variation, ODE vector-field, DynSystem replay, Real energy-ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before it can read Hamiltonian flow data.

Independence witness: lagrangianmechanics, ode, dynsystem, symplectic, real, noethersymmetry: HamiltonianFlowUp is not bijective with any listed sibling because it binds Hamiltonian scalar readback, symplectic vector-field admission, routed flow replay, and the energy ledger in one finite NameCert packet while those siblings expose only their own source or consumer surfaces.

Closure status for $\mathsf{NameCert}_{\mathsf{HamiltonianFlow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HamiltonianFlow}^{\uparrow}$ packet is generated from phase-state rows, Hamiltonian scalar readback, symplectic and variation rows, ODE vector-field admission, DynSystem flow replay, RealUp energy-ledger inspection, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HamiltonianFlow}^{\uparrow}}$, seed)

Scope closed: Definition 7164.1 and Definition 7164.2 seed the finite Hamiltonian flow surface over LagrangianMechanics, Ode, DynSystem, Symplectic, Real, and NoetherSymmetry rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HamiltonianFlow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected trajectories, global solution theory, quotient flow equality, Liouville volume preservation, or Hamiltonian–Lagrangian equivalence.

Upgrade path: Obligation closure asks for checked carrier admission, flow replay, scalar energy ledger, transport, replay, provenance, and local naming for BEDC.Derived.HamiltonianFlowUp.

Chapter 7165

A Concrete Naming Certificate for $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$

Following Bishop and Bridges on compact intervals and finite fan barriers, the $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$ packet records the finite boundary object that prevents an L10 located-interval cover route from being read as open-cover compactness. It sits beside the located interval source of chapter 394, the closed bounded interval fan surface of chapter 3939, the finite fan compactness packet of chapter 7162, the dyadic tolerance core of chapter 291, the finite window source of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the barrier row used before finite-cover handoff; it does not import open-cover compactness, selected branches, quotient streams, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7165.1 (Located interval fan barrier carrier)**.** *A* $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, K, F, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row carrying located endpoint comparison and interval-membership data.*
2. *K is the closed bounded interval fan row that supplies the finite binary-prefix and bar boundary.*
3. *F is the finite fan compactness row read only as a bounded fan of cover probes, not as an open-cover compactness oracle.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare barrier prefixes and interval endpoints.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row for endpoint names, barrier prefixes, and finite cover probes.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and dyadic tolerance checks.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, K, F, D, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for interval, fan, dyadic, stream, rational, real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a located-interval request through the finite fan barrier and then through D, S, Q, E.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalFan}^{\uparrow}$, $\mathsf{FiniteFanCompactness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalFanBarrier}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, K, F, D, S, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected infinite branches, quotient streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.LocatedIntervalFanBarrierUp`

Theorem 7165.2 (Located interval fan barrier NameCert obligations)**.** *For every accepted* LocatedIntervalFanBarrie *carrier*

$$B = (I, K, F, D, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalFanBarrier}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, located interval admission through I, closed bounded interval fan admission through K, finite fan compactness admission through F, dyadic tolerance admission through D, stream-window admission through S, regular rational readback through Q, terminal real sealing through E, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7165.1. Its public rows are exactly $I, K, F, D, S, Q, E, H, C, P, N$, so every local obligation is attached to one displayed row.

The located interval row is read before the fan boundary rows, and the fan boundary rows are read before dyadic tolerance, finite stream, regular rational, and real-seal rows. Thus a finite-cover consumer cannot skip from an interval request directly to a completed cover theorem.

Transport, replay, provenance, and local naming preserve the same packet route. Since no excluded coordinate occurs in the carrier, the NameCert surface cannot call on open-cover compactness, selected branches, quotient streams, countable choice, or ambient real completeness. □

Theorem 7165.3 (Located interval fan barrier finite-cover handoff)**.** *Every L10 finite-cover consumer of an accepted* $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$ *packet factors through the route*

$$\mathsf{LocatedInterval}^{\uparrow},\ \mathsf{ClosedBoundedIntervalFan}^{\uparrow},\ \mathsf{FiniteFanCompactness}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},$$

In carrier notation, every cover handoff first reads I, K, F, D, S, Q, E and then the structural rows H, C, P, N. The handoff exports only the displayed finite barrier route and exports no open-cover compactness, branch selector, quotient stream equality, countable-choice row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the located interval row I. It supplies the endpoint comparison and interval-membership surface consumed by the barrier.

The closed bounded interval fan row K and finite fan compactness row F then expose a finite prefix and probe boundary. These rows are barrier data: they bound the cover handoff before any real-facing conclusion is read.

The dyadic ledger D, stream windows S, regular rational readback Q, and terminal real seal E are downstream of that barrier. The structural rows H, C, P, N replay and name the same route. Therefore the finite-cover handoff remains inside the displayed packet and cannot export any excluded compactness or choice principle. □

Lean4 ✓ `BEDC.Derived.LocatedIntervalFanBarrierUp.LocatedIntervalFanBarrierFiniteCoverHandoff`

Theorem 7165.4 (Located interval fan barrier obligation package)**.** *For every accepted* $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$ *carrier*

$$B = (I, K, F, D, S, Q, E, H, C, P, N),$$

the rows $I, K, F, D, S, Q, E, H, C, P, N$ *project the full local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalFanBarrier}^{\uparrow}}$ *obligation surface. The surface contains carrier admission, located-interval admission, fan-barrier admission, finite-cover handoff, dyadic tolerance, StreamName window, regular-rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming obligations, and it contains no open-cover compactness, branch selector, quotient stream, countable-choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the displayed carrier of Definition 7165.1. The first seven rows I, K, F, D, S, Q, E are the only mathematical rows available to a cover-facing consumer: located interval data, closed bounded interval fan data, finite fan compactness data, dyadic tolerance data, stream-window data, regular rational readback, and terminal real sealing.

The structural rows then exhaust the remaining NameCert clauses. The row H supplies componentwise transport, C supplies displayed replay, P supplies provenance, and N supplies local naming for exactly the same packet.

Since every obligation is attached to one of the displayed rows, there is no residual coordinate from which open-cover compactness, a selected branch, quotient stream equality, countable choice, or ambient completeness could be read. Thus the carrier rows project the stated obligation package. □

Theorem 7165.5 (Located interval fan barrier dyadic-window induction)**.** *Every finite consumer induction over an accepted* $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$ *packet reads dyadic tolerance,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after the located interval row* I *and finite fan rows* K, F *have been exposed. In particular, no induction step may consume* D, S, Q, E *as an initial cover premise independent of the located interval and finite barrier rows.*

Proof. Use induction over the displayed finite row list of the carrier. The base segment consists of I, K, F: first the located interval row supplies endpoint and membership data, then the closed bounded interval fan row and finite fan compactness row expose the finite barrier boundary.

For the downstream segment, the next rows D, S, Q, E are introduced only after that base segment has been displayed. The dyadic row D compares barrier prefixes and endpoints, the window row S names the finite observations, the readback row Q records the regular rational values, and the seal row E closes the real-facing boundary.

The structural rows H, C, P, N preserve the same order because they transport, replay, source, and name the already displayed packet. Hence every finite row induction consumes dyadic tolerance, window, readback, and seal data downstream of I, K, F, and the finite-cover consumer cannot treat them as independent initial cover premises. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalFanBarrier}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalFanBarrier}^{\uparrow}$ packet is generated from a located interval row, closed bounded interval fan row, finite fan compactness row, dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedIntervalFanBarrier}^{\uparrow}}$, obligation)

Scope closed: Definition 7165.1, Definition 7165.2, Definition 7165.3, Definition 7165.4, and Definition 7165.5 bind the carrier, full NameCert obligation package, finite-cover handoff, and dyadic-window induction order for L10 located-interval finite-cover consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedIntervalFanBarrier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected branches, quotient streams, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, fan-barrier admission, finite-cover handoff, dyadic tolerance, stream-window, regular-rational, real-seal, transport, replay, provenance, and local naming obligations for BEDC.Derived.LocatedIntervalFanBarrierUp.

Chapter 7166

A Concrete Naming Certificate for $\mathsf{CompactEmbedding}^{\uparrow}$

Following Rellich–Kondrachov compactness in the form used by Brezis and Adams–Fournier, the $\mathsf{CompactEmbedding}^{\uparrow}$ packet records the finite certificate surface for a compact embedding from displayed Sobolev source windows into a compact complete metric target. It sits after the Sobolev embedding carrier of chapter 2217, the compact and complete metric surfaces of chapter 60 and chapter 128, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only the finite embedding, readback, and compact-window rows available to BEDC consumers.

Definition 7166.1 (Compact embedding carrier)**.** *A* $\mathsf{CompactEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, S, K, M, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite source-function window family naming the Sobolev functions, source-domain observations, target observations, and boundedness gauges inspected by this packet.*
2. *S is the* $\mathsf{SobolevEmbedding}^{\uparrow}$ *row that records the displayed embedding comparison for the source windows, including the exponent and codomain route visible to the consumer.*
3. *K is the* $\mathsf{Compact}^{\uparrow}$ *row exposing the finite compactness window used for target observations.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row used only to read Cauchy and limit-window data inside the target surface.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance and regular readback row attached to the source-function and target-metric windows.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after F, S, K, M, Q have been displayed.*
7. *H records componentwise* hsame *transport for source windows, Sobolev-embedding rows, compact rows, complete-metric rows, regular rational readbacks, Real seals, continuation rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from source-function windows through embedding comparison, compact target inspection, complete-metric readback, regular rational tolerance, Real sealing, transport, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactEmbedding}^{\uparrow}$, $\mathsf{SobolevEmbedding}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected subsequence, open-cover compactness, quotient equality of functions, host representatives, countable choice, trace theory, or ambient $\mathsf{Real}^{\uparrow}$ *completeness beyond the displayed seal row.*

Theorem 7166.2 (Compact embedding NameCert obligations)**.** *For every accepted* $\mathsf{CompactEmbedding}^{\uparrow}$ *carrier*

$$E = (F, S, K, M, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite source-function windows, SobolevEmbedding row, Compact row, CompleteMetric row, RegSeqRat tolerance readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. These rows bind the compact-embedding handoff without adding selected subsequences, open-cover compactness, quotient function equality, host representatives, countable choice, trace theory, or ambient Real completeness.*

Proof. Project the carrier of Definition 7166.1. The accepted packet exposes exactly $F, S, K, M, Q, R, H, C, P, N$.

The analytic route is then read row by row. The source-function windows are in F, the embedding comparison is in S, the compact target window is in K, and the complete-metric readback is in M.

The tolerance and endpoint observations are finite. They are read through Q and then sealed through R, so a consumer cannot replace the displayed RegSeqRat route by an ambient completeness theorem or a selected limit.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no excluded analytic principle is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7166.3 (Compact embedding finite route)**.** *Every consumer read exported by an accepted* $\mathsf{CompactEmbedding}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{SobolevEmbedding}^{\uparrow},\ \mathsf{Compact}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

using the displayed rows $F, S, K, M, Q, R, H, C, P, N$. The route first exposes source-function windows and the SobolevEmbedding comparison, then compact and complete-metric target windows, then regular rational tolerance readback, and only then the terminal Real seal. It supplies no selected subsequence, open-cover compactness principle, quotient function space, host representative, countable-choice schedule, trace theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with a consumer asking for compact-embedding data. Carrier admission confines the request to the finite source-function windows F and the embedding comparison row S, so the consumer first sees the same SobolevEmbedding surface cited in chapter 2217.

Next read the target side. The rows K and M expose only the compact and complete-metric windows named by this packet; the regular rational tolerances in Q are the only numerical readbacks supplied to the consumer.

The terminal seal R is downstream of those rows. Componentwise transport, displayed replay, provenance, and local naming preserve the same finite route and do not add a second analytic endpoint.

The L10 completion anchor is therefore the RegSeqRat tolerance readback of chapter 301 together with the displayed Real seal. No quotient equality, choice schedule, selected subsequence,

open-cover compactness principle, trace theorem, or Real completeness object can be read from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{CompactEmbedding}^{\uparrow}$ read exposes finite source-function windows, a SobolevEmbeddingUp row, CompactUp target windows, CompleteMetricUp readback, RegSeqRatUp tolerances, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any compact-embedding consumer can inspect the endpoint.

Independence witness: sobolev-embedding, compact, completemetric, regseqrat, real: $\mathsf{CompactEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source-function windows, embedding comparison, compact target windows, complete-metric readback, regular rational tolerances, Real sealing, transport, replay, provenance, and local naming while refusing selected subsequences, quotient function equality, choice, trace theory, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactEmbedding}^{\uparrow}$ packet is generated from finite source-function windows, a SobolevEmbedding row, Compact and CompleteMetric target rows, RegSeqRat tolerance readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7166.1, Definition 7166.2, and Definition 7166.3 seed the finite compact-embedding handoff over SobolevEmbedding, Compact, CompleteMetric, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subsequences, open-cover compactness, quotient function equality, host representatives, trace theory, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration covering carrier admission, embedding comparison access, compact target access, complete-metric readback, RegSeqRat tolerance readback, Real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 7167

A Concrete Naming Certificate for $\mathsf{FiniteProofTraceSieve}^{\uparrow}$

The $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ packet realizes the MetaCIC proof-search frontier as a finite sieve over candidate proof traces, bounded normal endpoints, discharge sockets, obstruction rows, and replayable audit data. It sits after the proof-search frontier of chapter 4284, the critical-path and bounded equality-checking surfaces of chapter 765 and chapter 752, the normalization boundary of chapter 892, and the closure-preservation witness of chapter 3344. The chapter records only finite candidate, endpoint, discharge, obstruction, transport, replay, provenance, and NameCert rows; it does not claim global normalization, confluence, or subject reduction.

Definition 7167.1 (Finite proof-trace sieve carrier)**.** *A* $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, E, D, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite candidate trace table, listing proof-search candidates, local rule tags, dependency windows, and the bounded endpoints to be checked.*
2. *E is the bounded normal endpoint row, read through* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *and the MetaCIC normalization frontier, that records which displayed candidates have finished endpoint witnesses.*
3. *D is the discharge-socket row, recording the subject-reduction, closedness, and proof-obligation sockets that a candidate must fill before it can be consumed.*
4. *O is the obstruction row, naming the residual open frontier when a candidate endpoint, discharge socket, or closure-preservation trace is missing.*
5. *H records componentwise* hsame *transport for trace rows, endpoint rows, discharge sockets, obstruction rows, replay rows, provenance, and local naming.*
6. *C records displayed* Cont *replay from candidate enumeration through endpoint checking, discharge inspection, obstruction retention, transport, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteProofTraceSieve}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, *proof-trace audit witness rows, closure-preservation trace rows,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteProofTraceSieve}^{\uparrow}}$ *row.*

The carrier has no coordinate for a complete proof-search procedure, global normalization, unrestricted confluence, closed subject reduction, quotient equality of proof traces, hidden oracle discharge, or host equality of MetaCIC terms.

Theorem 7167.2 (Finite proof-trace sieve NameCert obligations)**.** *For every accepted* $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ *carrier*

$$S = (T, E, D, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteProofTraceSieve}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite candidate table, bounded normal endpoint row, discharge-socket row, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. These obligations keep each proof-search candidate inside the displayed sieve and expose any missing endpoint, discharge, or closure-preservation witness as an obstruction rather than a hidden success.*

Proof. Project the carrier of Definition 7167.1. The packet exposes only T, E, D, O, H, C, P, N.

The finite candidate table T supplies the traces that may be inspected. Endpoint checking is confined to E, so a consumer sees only bounded normal endpoint witnesses and cannot infer a global normalization theorem.

The discharge row D records which subject-reduction, closedness, and proof-obligation sockets are filled. If any socket or endpoint is absent, the obstruction row O is the exported frontier, not a replacement proof.

Finally H, C, P, N transport, replay, source, and name the same finite sieve. Because the carrier contains no global confluence, subject-reduction, quotient trace equality, or oracle-discharge coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7167.3 (Finite proof-trace sieve frontier handoff)**.** *Every consumer read from an accepted* $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ *packet factors through the route*

$$\mathsf{MetaCICCriticalPath}^{\uparrow},\ \mathsf{BoundedNormalEqualityChecker}^{\uparrow},\ \mathsf{MetaCICNormalizationFrontier}^{\uparrow},\ T, E, D, O, H, C, P, N.$$

The route first enumerates finite proof-trace candidates, then checks bounded normal endpoints, then inspects discharge sockets and closure-preservation traces, and finally exports either a replayable candidate row or the displayed obstruction row. It does not export global normalization, unrestricted confluence, closed subject reduction, quotient equality of proof traces, hidden oracle discharge, or host equality of MetaCIC terms.

Lean4 ✓ `BEDC.Derived.FiniteProofTraceSieveUp.FiniteProofTraceSieveFrontierHandoff`

Proof. Begin with a consumer asking whether a proof-search candidate can be consumed. Carrier admission restricts the request to the finite table T, so only the listed trace candidates and dependency windows are visible.

Next the endpoint row E is read through the bounded normal-equality checker and normalization frontier. This gives bounded endpoint evidence for displayed candidates only, not a normalization theorem for all closed terms.

The discharge row D is then inspected together with the closure-preservation trace. A filled socket can be replayed as part of the finite candidate route; an unfilled socket is recorded by O as the frontier handoff.

Transport, replay, provenance, and naming preserve this same sieve. Since the packet contains no global confluence, subject-reduction, quotient trace equality, oracle discharge, or host equality coordinate, every consumer receives either the finite replayable rows or the explicit obstruction row. □

Falsifiable prediction: Every accepted $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ read exposes finite candidate proof traces, bounded normal endpoints, discharge sockets, obstruction rows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any proof-search consumer can inspect a candidate endpoint.

Independence witness: metaciccriticalpath, bounded-normal-equality-checker, metacicnormalizationfrontier, prooftraceauditwitness, closurepreservationtrace: $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite candidate trace tables, bounded endpoint checks, discharge sockets, obstruction retention, closure-preservation replay, transport, provenance, and local naming while refusing global normalization, confluence, subject reduction, quotient trace equality, and hidden oracle discharge.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteProofTraceSieve}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ packet is generated from finite candidate proof traces, bounded normal endpoint rows, discharge sockets, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteProofTraceSieve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7167.1, Definition 7167.2, and Definition 7167.3 seed the finite MetaCIC proof-search sieve over candidate, endpoint, discharge, obstruction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteProofTraceSieve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global normalization, unrestricted confluence, closed subject reduction, quotient equality of proof traces, hidden oracle discharge, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration covering carrier admission, finite candidate enumeration, bounded endpoint checking, discharge-socket inspection, obstruction retention, transport, replay, provenance, and local naming.

Chapter 7168

A Concrete Naming Certificate for $\mathsf{BishopIntervalBisection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalBisection}^{\uparrow}$ packet names the finite constructive bisection route by which a located rational interval is repeatedly halved, inspected through rational locator rows, repacked as a regular rational readback, and sealed only at the terminal real-name boundary. It is the Bishop-style neighbor of chapter 394, chapter 1711, and chapter 4202: the packet consumes located endpoint rows, rational endpoint bracketing, dyadic midpoint cells, finite window schedules, and regular rational readbacks before any $\mathsf{Real}^{\uparrow}$ consumer may inspect the result.

Definition 7168.1 (Bishop interval bisection carrier)**.** *A* $\mathsf{BishopIntervalBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, Q, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row. It supplies the located endpoint surface and the endpoint-window discipline consumed from chapter 394.*
2. *Q is the* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *bracketing row. It records the rational endpoint cells and comparison boundary consumed from chapter 4202.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint and radius ledger for the requested finite bisection depth.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule that records which endpoint and midpoint observations are inspected at each finite branch.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained rational cells and stream windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is read only after L, Q, D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the located interval, rational locator, dyadic midpoint ledger, stream windows, readback, and seal rows.*
8. *C records displayed* Cont *replay from the bisection request through rational bracketing, midpoint halving, retained-window readback, and the terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalBisection}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalIntervalLocator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalBisection}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite Bishop interval bisection packet. It has no coordinate for a selected completed endpoint, quotient real equality, host interval equality, open-cover compactness, countable choice, or an ambient completeness theorem.

Theorem 7168.2 (Bishop interval bisection halving stability)**.** *Let $B = (L, Q, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopIntervalBisection}^{\uparrow}$ *carrier. Every finite halving step requested by the packet is stable under the displayed* hsame *transport and* Cont *replay rows: the located interval row L, rational locator row Q, dyadic midpoint ledger D, stream-window schedule S, regular readback R, and terminal seal E move as one packet, and the retained child interval remains attached to the same rational bracketing route.*

Proof. Project the packet through Definition 7168.1. The halving step has no independent host interval coordinate; it can read only the located endpoint row L, the rational locator row Q, and the dyadic midpoint ledger D.

Transport is componentwise. The row H moves L, Q, D, S, R, E together, while the row C replays the same bisection route after transport. Thus the retained child interval is still the child selected by the displayed rational bracketing and midpoint rows.

The stream and readback rows are downstream of that retained child. Since S and R are transported with the same history and provenance, the finite halving route remains stable before the terminal $\mathsf{Real}^{\uparrow}$ seal is inspected. □

Theorem 7168.3 (Bishop interval bisection Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopIntervalBisection}^{\uparrow}$ *carrier factors through the finite route*

$$L, Q, D, S, R, E, H, C, P, N.$$

The consumer first reads the located interval surface, then the rational interval locator, then the dyadic halving ledger, then the finite stream windows and $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The packet exports no selected limit, no quotient equality of real names, no countable-choice sequence, no open-cover compactness witness, and no ambient real-completeness coordinate.*

Proof. Begin with the displayed carrier. The only Real-facing coordinate is E, and the definition places E after the located interval, rational locator, dyadic midpoint, stream-window, and regular-readback rows.

The rational locator row Q supplies endpoint bracketing before any midpoint branch is retained. The dyadic ledger D records the finite halving data, and the stream schedule S records exactly which finite observations are inspected.

The regular readback R is therefore the last non-Real row on the route. Componentwise transport, replay, provenance, and local naming are exactly H, C, P, N, so no host analytic object can be inserted between R and the terminal seal E. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalBisection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7168.1, Definition 7168.2, and Definition 7168.3 seed the finite Bishop interval bisection surface over located interval, rational locator, dyadic midpoint, stream-window, regular-readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalBisection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient Real equality, countable choice, open-cover compactness, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, halving stability, regular-readback routing, Real-seal nonescape, and the corresponding BEDC.Derived.BishopIntervalBisectionUp target.

Constructive story: A BishopIntervalBisection$^{\uparrow}$ packet is generated from a LocatedInterval$^{\uparrow}$ source row, RationalIntervalLocator$^{\uparrow}$ rational bracketing, DyadicRatCore$^{\uparrow}$ midpoint data, StreamName$^{\uparrow}$ finite windows, RegSeqRat$^{\uparrow}$ readback, a terminal Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7169

A Concrete Naming Certificate for $\mathsf{RegulatedStepFunction}^{\uparrow}$

Following Bishop and Bridges on regulated functions and Riemann integration, the $\mathsf{RegulatedStepFunction}^{\uparrow}$ packet records the finite step ledger that sits between the single-step partition surface and the regulated or Riemann integration consumers. It refines the finite $\mathsf{StepFunction}^{\uparrow}$ route of chapter 3780, remains readable by the regulated-function approximation surface of chapter 1554, and supplies the step-integral primitive consumed by chapter 1557 and chapter 1526.

Definition 7169.1 (Regulated step function carrier)**.** *A* $\mathsf{RegulatedStepFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, S, A, J, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval source row, naming the closed domain, endpoint order data, and finite cell boundary reads used by every step request.*
2. *S is a finite* $\mathsf{StepFunction}^{\uparrow}$ *schedule, read through chapter 3780, listing the displayed partition cells, carried* $\mathsf{Real}^{\uparrow}$ *values, and constant-on-cell admission data.*
3. *A is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *approximation row, read through chapter 1554, stating that the same finite step schedule is accepted as a regulated-function approximation surface.*
4. *J is the primitive step-integral ledger, computing finite cell sums from I and S without importing a limiting integration theorem.*
5. *D is the Darboux/Riemann compatibility row, recording that the primitive ledger fits the Darboux gap route and the tagged-mesh route before any integration-facing handoff is exported.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed finite sums and tolerance windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, S, A, J, D, Q are displayed.*
8. *H records componentwise* hsame *transport for interval, schedule, regulated approximation, primitive step-integral, compatibility, readback, seal, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from interval reads to step schedule reads, from step schedules to primitive sums, from compatibility rows to Darboux and Riemann consumers, and from readback rows to the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RegulatedStepFunction}^{\uparrow}$, $\mathsf{StepFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedStepFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by these rows. It has no coordinate for a host function quotient, selected refinement limit, measure completion, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7169.2 (Regulated step function NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedStepFunction}^{\uparrow}$ *carrier $K = (I, S, A, J, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedStepFunction}^{\uparrow}}$ *surface consists exactly of interval source admission, finite* $\mathsf{StepFunction}^{\uparrow}$ *schedule exposure,* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *approximation admission, primitive step-integral computation, Darboux/Riemann compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7169.1. The rows I, S, A display the interval source, the finite step schedule, and the regulated-function approximation surface before any integration-facing consumer can inspect a value.

The integration rows are downstream of that displayed surface. The primitive ledger J computes only finite cell sums from I and S, while D records that the same ledger is readable by Darboux and Riemann consumers.

The readback and structural rows preserve the same route. The rows Q, E, H, C, P, N add regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming, but no hidden function quotient, selected refinement, measure-completion object, compactness proof, or ambient completeness coordinate. □

Theorem 7169.3 (Regulated step function Riemann handoff)**.** *Every Riemann-facing or regulated-integral-facing read of an accepted* $\mathsf{RegulatedStepFunction}^{\uparrow}$ *packet factors through*

$$\mathsf{StepFunction}^{\uparrow}, \quad \mathsf{RegulatedRealFunction}^{\uparrow}, \quad \mathsf{RegulatedIntegral}^{\uparrow}, \quad \mathsf{RiemannIntegral}^{\uparrow}$$

by first reading the finite interval and step schedule rows I, S, then the regulated approximation row A, then the primitive step-integral ledger J, then the Darboux/Riemann compatibility row D, and finally the $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal Q, E. The packet exports a finite regulated step primitive, not a quotient function, a selected mesh limit, a measure-completion integral, or ambient Real completeness.*

Proof. Start with the finite step side. The $\mathsf{StepFunction}^{\uparrow}$ schedule S exposes the cell partition and carried values over the interval row I, so the primitive sum ledger has a finite source.

Next read the regulated-function side. The row A makes the same finite schedule available to the $\mathsf{RegulatedRealFunction}^{\uparrow}$ approximation surface, and no integration row is present before this approximation row is displayed.

Finally read the integration side. The primitive ledger J supplies finite sums, the compatibility row D routes those sums through the regulated-integral and Riemann boundaries, and Q, E provide regular rational readback and the terminal Real seal. Since every remaining coordinate is structural, no consumer can replace this handoff by a host quotient, selected mesh limit, measure completion, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedStepFunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegulatedStepFunction}^{\uparrow}$ packet is generated from an interval source row, a finite StepFunction schedule, a RegulatedRealFunction approximation row, a primitive step-integral ledger, a Darboux/Riemann compatibility

row, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegulatedStepFunction}\uparrow}$, seed)

Scope closed: Definition 7169.1, Definition 7169.2, and Definition 7169.3 seed the finite regulated step primitive between step functions and regulated or Riemann integration.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegulatedStepFunction}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a measure-theoretic integral, quotient function equality, selected refinement limit, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite step schedule exposure, regulated approximation routing, primitive step-integral computation, Darboux/Riemann compatibility, RegSeqRat readback, Real sealing, and structural transport for BEDC.Derived.RegulatedStepFunctionUp.

Chapter 7170

A Concrete Naming Certificate for HyperbolicShadowBoundary$^{\uparrow}$

Following Gromov boundary and visual shadow constructions in hyperbolic geometry, the HyperbolicShadowBounda packet records the observer-facing boundary window as finite shadow and visual-boundary NameCert data. It sits between the boundary-shadow packet of chapter 3813, the visual-boundary readback of chapter 4181, the visual-shadow metric surface of chapter 4142, and the observer-expansion route of chapter 4167. This realizes the observer-shadow portion of chapter 9463 without adding a completed ideal boundary or a host hyperbolic space.

Definition 7170.1 (Hyperbolic shadow boundary carrier)**.** *A* HyperbolicShadowBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, O, W, V, S, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the hyperbolic metric source row, naming the finite metric comparison data used by every shadow read.*
2. *O is the observer window row, recording the displayed basepoint, aperture, and finite visible-shadow request.*
3. *W is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row that supplies the boundary-shadow window.*
4. *V is the* HyperbolicVisualBoundary$^{\uparrow}$ *row that reads the same shadow window as visible boundary data.*
5. *S is the* HyperbolicVisualShadowMetric$^{\uparrow}$ *row that records visual-shadow metric comparison before observer expansion consumes the boundary read.*
6. *R is the* HyperbolicObserverExpansion$^{\uparrow}$ *handoff row, read only after M, O, W, V, S are displayed.*
7. *H records componentwise* hsame *transport for metric source, observer window, boundary shadow, visual boundary, visual-shadow metric, observer handoff, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from observer-window reads to boundary-shadow windows, visual-boundary reads, visual-shadow metric comparisons, and observer-expansion handoffs.*
9. *P is the* Pkg *provenance over* HyperbolicShadowBoundary$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicVisualBounda HyperbolicVisualShadowMetric$^{\uparrow}$, HyperbolicObserverExpansion$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicShadowBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only by these rows. It has no coordinate for a completed ideal boundary, quotient geodesic-end equality, selected geodesic ray, global compactification, or physical observer trajectory.

Theorem 7170.2 (Hyperbolic shadow boundary NameCert obligations)**.** *For every accepted* HyperbolicShadowBou *carrier $B = (M, O, W, V, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicShadowBoundary}^{\uparrow}}$ *surface consists exactly of metric source admission, observer-window exposure,* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *window admission,* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *readback,* $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ *comparison,* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7170.1. The rows M, O, W, V, S, R are the only analytic rows, and H, C, P, N are the only structural rows.

The boundary side is finite. The observer row O exposes the window request, the boundary-shadow row W supplies the visible shadow, and the visual-boundary row V reads that same window as boundary data.

The observer side is downstream. The visual-shadow metric row S compares the visible shadow before the observer-expansion handoff R is available. Transport, replay, provenance, and local naming preserve this route without adding a completed ideal boundary, quotient ray equality, selected geodesic, compactification theorem, or physical observer path. □

Theorem 7170.3 (Hyperbolic shadow boundary observer handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicShadowBoundary}^{\uparrow}$ *packet must read the route*

$$\mathsf{HyperbolicBoundaryShadow}^{\uparrow} \longmapsto \mathsf{HyperbolicVisualBoundary}^{\uparrow} \longmapsto \mathsf{HyperbolicVisualShadowMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicObs}$$

through the displayed observer window and structural rows of Definition 7170.1. The handoff exports finite shadow-window and visual-boundary data for chapter 9463; it exports no completed ideal boundary, quotient geodesic equality, selected ray, global compactification, or physical observer trajectory.

Proof. Begin with the boundary-shadow row. It records the finite visible window, and the visual-boundary row reads the same window as boundary data rather than as a completed ideal boundary.

Next read the visual-shadow metric row. It compares only the displayed shadow and visible-boundary rows, so the observer-expansion handoff receives finite metric readback data rather than a global compactification.

Finally consume the structural rows. Componentwise hsame transport and displayed Cont replay carry the same window through provenance and local naming. Since the carrier has no coordinate for quotient ray equality, selected geodesics, completed boundary objects, or physical observer paths, the observer handoff remains exactly the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicShadowBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicShadowBoundary}^{\uparrow}$ packet is generated from hyperbolic metric source rows, observer-window rows, HyperbolicBoundaryShadow rows, HyperbolicVisualBoundary rows, HyperbolicVisualShadowMetric rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicShadowBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 7170.1, Definition 7170.2, and Definition 7170.3 seed the finite observer-shadow boundary packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicShadowBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed ideal-boundary construction, quotient geodesic equality, selected geodesic rays, global compactification, physical observer dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked metric source admission, observer-window exposure, boundary-shadow admission, visual-boundary readback, visual-shadow metric comparison, observer-expansion handoff, and structural transport for BEDC.Derived.HyperbolicShadowBoundaryUp.

Chapter 7171

A Concrete Naming Certificate for $\mathsf{RationalNullSequence}^{\uparrow}$

Following Bishop and Bridges on constructive real sequences, the $\mathsf{RationalNullSequence}^{\uparrow}$ packet records a rational sequence whose tail is certified to converge to zero by finite tolerance windows rather than by a selected limit or quotient stream. It sits between the rational source of chapter 37, the dyadic tolerance ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a finite null-tail interface without importing countable choice, quotient sequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7171.1 (Rational null sequence carrier)**.** *A* $\mathsf{RationalNullSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (A, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Rat}^{\uparrow}$ *value row, naming the rational source values used by the sequence.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the positive dyadic precision requests used to test the tail.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, displaying the inspected indices and the tail bound witness for each requested precision.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same rational values, dyadic tolerances, and finite windows.*
5. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary, exposed only after A, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the rational values, tolerance ledger, finite windows, readback, seal boundary, replay, provenance, and local name.*
7. *C records displayed* Cont *replay from the rational source and dyadic request through the finite tail window, regular rational readback, and terminal seal.*
8. *P records* Pkg *provenance over* $\mathsf{RationalNullSequence}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalNullSequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, D, W, R, E, H, C, P, N$. It has no coordinate for quotient sequence equality, a chosen limiting index function, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7171.2 (Rational null sequence NameCert obligations)**.** *For every accepted* $\mathsf{RationalNullSequence}^{\uparrow}$ *carrier $Z = (A, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalNullSequence}^{\uparrow}}$ *surface consists exactly of five displayed obligations:*

1. *rational-source admission through A;*
2. *dyadic tolerance admission through D;*
3. *finite tail-window exposure through W;*
4. *regular rational readback through R before the* $\mathsf{Real}^{\uparrow}$ *seal E is visible;*
5. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

Every public read of the rational null sequence must pass through these obligations in this order.

Proof. Project the accepted carrier of Definition 7171.1. The rational values appear only in A, and the requested tail precisions appear only in the dyadic ledger D.

The finite tail evidence is then forced through W. A consumer sees the inspected indices and the displayed tail bound witness before any regular rational readback is available.

Rows R and E remain downstream. The regular rational readback is attached to the same A, D, W route, and the Real seal is exposed only after that readback has been named.

Finally H, C, P, N preserve, replay, source, and name the same packet. Since the carrier has no row for quotient sequence equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the five obligations exhaust the public NameCert surface. □

Theorem 7171.3 (Rational null sequence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalNullSequence}^{\uparrow}$ *packet must read the rational source row A, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the* $\mathsf{StreamName}^{\uparrow}$ *finite tail windows W before it receives the readback row R. The handoff exports no quotient sequence equality, chosen tail selector, countable-choice schedule, or ambient completeness principle.*

Proof. Use the obligation surface of Definition 7171.2. It places R after the rational source, dyadic tolerance ledger, and finite tail-window rows.

The handoff is therefore finite at each request. The consumer reads the specific rational values and the displayed dyadic precision rows used by the tail window; it cannot replace them by a quotient stream or by a selected global limiting witness.

The transport and provenance rows keep the same order. Thus the $\mathsf{RegSeqRat}^{\uparrow}$ readback is a finite rational-tail interface and not an import of countable choice or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7171.4 (Rational null sequence Real seal nonescape)**.** *An accepted* $\mathsf{RationalNullSequence}^{\uparrow}$ *packet exposes its* $\mathsf{Real}^{\uparrow}$ *seal boundary only after the rational source row, dyadic tolerance ledger, finite StreamName tail windows, and RegSeqRat readback have been displayed. Any consumer route that tries to read the Real seal while omitting one of A, D, W, R leaves the accepted NameCert surface.*

Proof. Apply Definition 7171.1. The Real-facing row is E, and the carrier definition places it downstream of the rational, dyadic, StreamName, and RegSeqRat rows.

The NameCert obligations of Definition 7171.2 make that order public: A, D, W are exposed before R, and R is exposed before E.

If a consumer omits any of A, D, W, R, the structural rows H, C, P, N have no displayed packet to transport, replay, source, or name. The route therefore cannot export a valid Real seal, and it cannot smuggle host real equality, selected limits, or ambient completeness through the seal boundary. □

Falsifiable prediction: A route that reads a Real seal for a rational null sequence while omitting the finite StreamName tail window or the RegSeqRat readback is rejected by the RationalNullSequenceUp NameCert surface.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real: $\mathsf{RationalNullSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds rational values, dyadic tolerances, finite tail windows, regular rational readback, a terminal Real seal, transport, replay, provenance, and local naming as one null-tail packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalNullSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalNullSequence}^{\uparrow}$ packet is generated from rational source values, DyadicRatCore tolerance requests, StreamName finite tail windows, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalNullSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7171.1, Definition 7171.2, Definition 7171.3, and Definition 7171.4 seed the rational null-tail route over $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalNullSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient sequence equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked rational-source admission, dyadic tolerance admission, finite tail-window exposure, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RationalNullSequenceUp.

Chapter 7172

A Concrete Naming Certificate for $\mathsf{CauchyOrderReflection}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of Cauchy real names, the $\mathsf{CauchyOrderReflection}^{\uparrow}$ packet records the finite route by which Cauchy-tail comparisons are reflected into Real-facing order reads. It sits after the Cauchy criterion surface of chapter 392, the regular rational sequence row of chapter 301, the order interfaces of chapter 1378 and chapter 54, the dyadic arithmetic core of chapter 291, and the terminal Real seal of chapter 38. The packet exposes only displayed tail windows, dyadic comparison ledgers, order rows, and Real-facing seals; it does not assert trichotomy, Dedekind completeness, quotient real classes, selected representatives, or host $\mathsf{Real}^{\uparrow}$ equality.

Definition 7172.1 (CauchyOrderReflection carrier)**.** *A* $\mathsf{CauchyOrderReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (C, T, O, D, R, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *row recording the accepted tail-window request and its finite Cauchy evidence.*
2. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail row that turns the accepted Cauchy window into regular rational read-back data.*
3. *O is the* $\mathsf{Order}^{\uparrow}$ *or* $\mathsf{TotalOrder}^{\uparrow}$ *comparison row used only after C and T have been displayed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger for the inspected dyadic tolerances and rational cuts.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row that records the Real-facing order read after the finite tail comparison has passed through O and D.*
6. *H records componentwise* hsame *transport for Cauchy criteria, regular-tail rows, order rows, dyadic ledgers, Real seals, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from a Real-facing order request back through R, D, O, T, C and then forward through the same rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyOrderReflection}^{\uparrow}$*,* $\mathsf{CauchyCriterion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Order}^{\uparrow}$*,* $\mathsf{TotalOrder}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyOrderReflection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed coordinates. It contains no host quotient of Cauchy names, no chosen representative, no trichotomy branch, no Dedekind-completeness row, and no ambient host $\mathsf{Real}^{\uparrow}$ *equality.*

Theorem 7172.2 (CauchyOrderReflection NameCert obligations)**.** *For every accepted* $\mathsf{CauchyOrderReflection}^{\uparrow}$ *carrier*

$$Q = (C, T, O, D, R, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyOrderReflection}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy criterion row, RegSeqRat tail row, order comparison row, dyadic comparison ledger, Real seal row, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming row; tail-stability of accepted comparisons; and ledger nonescape for quotient real classes, selected representatives, trichotomy, Dedekind completeness, and host Real equality.*

Proof. Project the carrier of Definition 7172.1. The visible rows are $C, T, O, D, R, H, K, P, N$, and every NameCert obligation is read from one of those rows.

Carrier admission records the Cauchy criterion, regular-tail readback, order comparison, dyadic ledger, Real seal, transport, replay, provenance, and local name. No other analytic row is present in the packet.

Tail-stability is the compatibility of C, T, O, D, R under the componentwise transport H and replay K. The nonescape clauses follow by inventory: quotient classes, selected representatives, trichotomy, Dedekind completeness, and host Real equality are not coordinates of the carrier. □

Theorem 7172.3 (CauchyOrderReflection tail stability)**.** *Let* $Q = (C, T, O, D, R, H, K, P, N)$ *be an accepted* $\mathsf{CauchyOrderReflection}^{\uparrow}$ *carrier. Any accepted replacement of a Cauchy tail window transported by* H *and replayed by* K *preserves the displayed order read only through the same* C, T, O, D, R *route. The reflected Real-facing comparison is stable as finite tail and dyadic comparison data, not as host equality of completed Real objects.*

Proof. Start with the Cauchy criterion row C. It names the accepted tail window and supplies the finite Cauchy evidence used by the comparison request.

Read the regular-tail row T and the dyadic ledger D. These rows translate the tail replacement into finite regular rational and dyadic comparison data before any order row is consumed.

Now inspect O and R. The order comparison row reads only the displayed finite comparison, and the Real seal records the reflected comparison only after that route is visible.

Transport by H is componentwise and replay by K follows the same displayed route. Since no coordinate stores host equality of completed Real objects, the stable comparison remains a finite $\mathsf{CauchyOrderReflection}^{\uparrow}$ read. □

Theorem 7172.4 (CauchyOrderReflection nonescape)**.** *Every Real-facing order consumer of an accepted* $\mathsf{CauchyOrderReflection}^{\uparrow}$ *packet must pass through the finite route*

$$\mathsf{CauchyCriterion}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Order}^{\uparrow},\ \mathsf{TotalOrder}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer may inspect Cauchy-tail windows, regular rational readback, order comparison rows, dyadic comparison ledgers, Real seals, transport, replay, provenance, and local naming, but it cannot obtain trichotomy, Dedekind completeness, quotient classes, selected representatives, or host Real equality from this packet.

Proof. Apply Definition 7172.2. It lists the admitted rows of the carrier and the only stability and nonescape obligations attached to the local name.

Use Definition 7172.3. A tail replacement reaches a Real-facing comparison only through the displayed C, T, O, D, R route, so an order consumer cannot bypass the Cauchy and dyadic windows by invoking a host quotient or selected representative.

The remaining exclusions are carrier inventory. The packet has no trichotomy branch, Dedekind-completeness coordinate, quotient-class coordinate, representative selector, or host Real-equality row, so no Real-facing order read can export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyOrderReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyOrderReflection}^{\uparrow}$ packet is generated from a CauchyCriterion row, a RegSeqRat tail row, an Order or TotalOrder comparison row, a DyadicRatCore comparison ledger, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyOrderReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7172.1, Definition 7172.2, Definition 7172.3, and Definition 7172.4 seed the finite route from Cauchy-tail comparisons to Real-facing order reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyOrderReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, Dedekind completeness, quotient classes, selected representatives, host Real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-stability, order-read reflection, dyadic comparison exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyOrderReflectionUp.

Chapter 7173

A Concrete Naming Certificate for $\mathsf{CompactOscillationSelector}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CompactOscillationSelector}^{\uparrow}$ packet records the finite selector route behind compact uniform continuity as one BEDC NameCert carrier. It realizes the compact-uniform-continuity vision of chapter 9237 by reading compact finite nets from chapter 129, pointwise radius rows from chapter 130, rational lower-bound folds from chapter 37, metric distance rows from chapter 57, terminal Real seals from chapter 38, finite stream windows from chapter 126, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369. The packet selects only by finite displayed rows; it does not expose host open-cover compactness, semantic continuity, selected centers outside the finite net, a quotient point equality, an external modulus selector, or ambient completeness.

Definition 7173.1 (Compact oscillation selector carrier)**.** *A* $\mathsf{CompactOscillationSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, F, L, M, R, E, W, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, carrying bundled centers and located coverage witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-radius row, attaching a local oscillation estimate and source radius to each bundled center.*
3. *L is the rational lower-bound fold row over the displayed local radii, read through* $\mathsf{Rat}^{\uparrow}$*.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to route source and target triangle estimates.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for Real-facing distance and oscillation reads.*
6. *E is the dyadic or rational tolerance ledger that connects requested oscillation bounds to the lower-bound fold.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for center names, source points, metric reads, and Real seals.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exported only after K, F, L, M, R, E, W have been displayed.*
9. *H records componentwise* hsame *transport for compact-net, pointwise-radius, lower-bound, metric, Real, tolerance, stream-window, uniform-modulus, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a tolerance request through finite net selection, pointwise-radius rows, rational lower-bound fold, metric triangle estimates, Real sealing, and the uniform-modulus handoff.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactOscillationSelector}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationSelector}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host compactness, semantic continuity, quotient point equality, choice-selected centers outside the displayed net, an external modulus selector, or ambient completeness.

Theorem 7173.2 (Compact oscillation selector NameCert obligations)**.** *For every accepted* CompactOscillationSele *carrier*

$$S = (K, F, L, M, R, E, W, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOscillationSelector}^{\uparrow}}$ *surface consists exactly of compact finite-net admission, pointwise-radius admission, rational lower-bound fold exactness, metric triangle-read admission, Real-seal nonescape, tolerance-ledger visibility, finite stream-window readback, UniformModulus handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. The obligations do not include host open-cover compactness, semantic continuity, quotient point equality, choice-selected centers outside the finite net, external modulus selection, or ambient completeness.*

Proof. Project the carrier of Definition 7173.1. The displayed rows $K, F, L, M, R, E, W, U, H, C, P, N$ are the whole accepted packet.

Compact finite-net admission comes from K, and pointwise-radius admission comes from F. The lower-bound row L folds the finitely many local radii read from those rows, while E records the requested tolerance scale.

The metric row M, Real seal R, and stream-window row W provide the only route for source and target triangle estimates. The uniform-modulus row U is exported only after those finite rows are visible.

The structural rows H, C, P, N preserve, replay, source, and name the same finite selector route. Since the refused objects are not carrier coordinates, the listed obligations exhaust the local NameCert surface. □

Theorem 7173.3 (Compact oscillation selector finite-net fold)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactOscillationSelector}^{\uparrow}$ *packet receives a precision row only after the finite net K, pointwise-radius row F, rational lower-bound fold L, metric row M, Real seal R, tolerance ledger E, and stream-window row W have been displayed. The handoff is the finite net, pointwise-radius, rational lower-bound fold, and Real-seal route, not an external compactness or continuity theorem.*

Proof. Start with the compact finite-net row K. It supplies the finite bundled centers and coverage witnesses available to the selector.

Read the pointwise-radius row F at each bundled center. These rows are finite local oscillation records, so they do not invoke semantic continuity outside the displayed carrier.

Fold the displayed local radii through L using the tolerance ledger E. The result is a rational lower-bound history carried by the packet rather than a chosen external modulus.

Finally replay the metric and Real-facing estimates through M, R, W and hand them to U. Transport and replay through H and C keep the same finite route, so the consumer receives only the displayed selector data. □

Theorem 7173.4 (Compact oscillation selector nonescape)**.** *Every downstream consumer of an accepted* $\mathsf{CompactOscillationSelector}^{\uparrow}$ *packet remains inside the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow}.$$

The consumer may inspect finite nets, pointwise radii, rational lower-bound folds, metric triangle rows, Real seals, finite stream windows, uniform-modulus handoff rows, transport, replay, provenance, and local naming, but it cannot obtain host open-cover compactness, semantic continuity, quotient point equality, choice-selected centers outside the displayed net, an external modulus selector, or ambient completeness from this packet.

Proof. Apply Definition 7173.2. It lists the finite analytic and structural rows that form the local NameCert surface.

Use Definition 7173.3. Every UniformModulus-facing read consumes the compact net, pointwise-radius rows, rational lower-bound fold, metric row, Real seal, tolerance ledger, and stream-window row before the handoff row is public.

The nonescape conclusion is the carrier inventory. None of the refused objects is a coordinate of S, and the transport and replay rows are componentwise over the displayed route, so no downstream consumer can acquire them from $\mathsf{CompactOscillationSelector}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOscillationSelector}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ContinuousMap pointwise-radius rows, a RatUp lower-bound fold, Metric triangle rows, RealUp seals, tolerance and StreamName windows, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactOscillationSelector}^{\uparrow}}$, seed)

Scope closed: Definition 7173.1, Definition 7173.2, Definition 7173.3, and Definition 7173.4 seed the finite selector route from compact nets and pointwise radii to UniformModulus consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactOscillationSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host open-cover compactness, semantic continuity, quotient point equality, choice-selected centers outside the finite net, external modulus selection, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net admission, pointwise-radius admission, lower-bound fold exactness, metric triangle reads, Real-seal nonescape, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactOscillationSelectorUp.

Chapter 7174

A Concrete Naming Certificate for $\mathsf{CompactOscillationVariation}^{\uparrow}$

Following Bishop–Bridges compact metric analysis and Jordan's finite-variation ledger, the CompactOscillationVariat packet records the finite route by which compact finite-net data synchronizes bounded oscillation windows with bounded-variation partition rows. It sits over the compact metric source of chapter 129, the bounded oscillation ledger of chapter 6787, the bounded-variation real-function route of chapter 3654, the Real oscillation interface of chapter 1839, the variation-measure ledger of chapter 3593, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The chapter names a compact finite-net bridge for Darboux and Riemann–Stieltjes consumers; it does not assert open-cover compactness, host total-variation suprema, measure completion, quotient function equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7174.1 (CompactOscillationVariation carrier)**.** *A* $\mathsf{CompactOscillationVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, O, V, R, E, H, C, P, N),$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the center-radius windows through which compact consumers read the inspected domain;*
2. *O is the* $\mathsf{BoundedOscillation}^{\uparrow}$ *row, exposing bounded oscillation windows over the same compact finite-net cells;*
3. *V is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *partition ledger, read as finite variation data over the displayed compact source;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the oscillation and variation windows;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal attached to endpoint and value reads;*
6. *H records the componentwise* hsame *transport rows for compact-net, oscillation, variation, readback, and seal coordinates;*
7. *C records the displayed* Cont *replay rows through which compact, oscillation, variation, RegSeqRat, and Real consumers read the same packet;*
8. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{BoundedOscillation}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{CompactOscillationVariation}^{\uparrow}}$ *row.*
The classifier accepts exactly those packets whose compact finite-net row, oscillation windows, variation partition ledger, regular-rational readback, Real seal, transport, replay, provenance, and local naming rows are all displayed in these positions. It exports no open-cover compactness theorem, total-variation supremum, measure completion, quotient equality of functions, selected limit, or ambient Real-completeness row.

Theorem 7174.2 (CompactOscillationVariation NameCert obligations)**.** *For every accepted* CompactOscillationVar *carrier $Q = (K, O, V, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationVariation}^{\uparrow}}$ *surface consists exactly of the finite compact-net source row K, bounded oscillation window row O, bounded-variation partition ledger V, regular-rational readback row R, terminal Real seal E, componentwise transport row H, replay row C, package provenance row P, and local naming row N.*

Every Darboux-facing, variation-facing, or Riemann–Stieltjes-facing consumer must read the compact finite-net row before reading the oscillation and variation rows, and must read R, E before treating endpoint or value data as Real-facing output. No consumer receives a host compactness theorem, a total-variation supremum, a completed measure object, quotient function equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7174.1. Its rows list exactly the compact source, oscillation windows, variation partition ledger, readback, Real seal, transport, replay, provenance, and local naming coordinates available to the classifier.

The compact row K is the only source of center-radius finite-net data. Thus any oscillation read through O and any variation read through V must remain attached to the displayed compact finite-net route before a downstream consumer can inspect the ledger.

The rows R and E then provide the regular-rational and Real-facing boundary for window values and endpoints. Since the carrier has no coordinate for an open-cover theorem, total-variation supremum, completed measure, quotient function equality, selected limit, or ambient completeness, the local NameCert obligations are exhausted by the stated finite rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationVariation}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOscillationVariation}^{\uparrow}$ packet is generated from compact finite-net rows, bounded oscillation windows, bounded-variation partition ledgers, RegSeqRat readback, Real seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactOscillationVariation}^{\uparrow}}$, seed)

Scope closed: Definition 7174.1 and Definition 7174.2 seed the finite compact-net bridge from bounded oscillation windows to bounded-variation partition ledgers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactOscillationVariation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host total-variation suprema, measure completion, quotient function equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net synchronization, oscillation-window confinement, variation-ledger readback, RegSeqRat and Real seal exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompactOscillationVariationUp.

Chapter 7175

A Concrete Naming Certificate for $\mathsf{FiniteOscillationVariation}^{\uparrow}$

Following Jordan and Bishop-style finite variation arguments, the $\mathsf{FiniteOscillationVariation}^{\uparrow}$ packet records the finite route by which a displayed partition controls both oscillation windows and variation budgets before any compact or completion-facing consumer reads the data. It sits beside the bounded-variation surface of chapter 398, the compact synchronization route of chapter 7174, the bounded oscillation ledger of chapter 6787, the bounded-variation real-function route of chapter 3654, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names only the finite partition, local oscillation windows, edge-variation ledger, readback, Real seal, transport, replay, provenance, and local naming rows; it does not assert a host total-variation supremum, selected refinements outside the displayed partition, function quotient equality, measure completion, compact open-cover extraction, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7175.1 (FiniteOscillationVariation carrier)**.** *A* $\mathsf{FiniteOscillationVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, O, V, R, E, H, C, S, N),$$

with the following visible rows:

1. *P is the finite partition row, including the displayed endpoints and adjacent edge windows inspected by the packet.*
2. *O is the finite oscillation row, recording an oscillation budget for each displayed partition cell.*
3. *V is the finite edge-variation ledger, recording the adjacent value changes consumed by bounded-variation arguments.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the oscillation and variation budgets.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint, value, oscillation, and variation reads.*
6. *H records componentwise* hsame *transport for partition, oscillation, variation, readback, seal, replay, provenance, and local naming coordinates.*
7. *C records displayed* Cont *replay through which finite-partition consumers read the same packet.*
8. *S is the* Pkg *provenance over* $\mathsf{FiniteOscillationVariation}^{\uparrow}$, $\mathsf{BoundedOscillation}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationVariation}^{\uparrow}}$ *row.*

The classifier accepts exactly those packets whose finite partition, oscillation budget, variation ledger, readback, Real seal, transport, replay, provenance, and local naming rows are displayed in these positions. It exports no host total-variation supremum, unlisted partition refinement, quotient equality of functions, measure completion, compact open-cover theorem, selected limit, or ambient Real-completeness row.

Theorem 7175.2 (FiniteOscillationVariation NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOscillationVariation}^{\uparrow}$ *carrier* $F = (P, O, V, R, E, H, C, S, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationVariation}^{\uparrow}}$ *surface consists exactly of the finite partition row* P*, oscillation budget row* O*, edge-variation ledger* V*, regular-rational readback row* R*, terminal Real seal* E*, componentwise transport row* H*, replay row* C*, package provenance row* S*, and local naming row* N*.*

Every bounded-variation, Darboux-facing, or compact-oscillation consumer must read the finite partition row before reading O *or* V*, and must read* R, E *before treating any endpoint, value, oscillation, or variation data as Real-facing output. No consumer receives a host total-variation supremum, an unlisted refinement selector, quotient equality of functions, measure completion, compact open-cover extraction, a selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7175.1. Its rows list exactly the finite partition, oscillation budget, edge-variation ledger, readback, Real seal, transport, replay, provenance, and local naming coordinates available to the classifier.

The partition row P is the only source of displayed edge windows. Thus any oscillation read through O and any variation read through V remains attached to the same finite partition before a downstream bounded-variation or Darboux-facing consumer can inspect the ledger.

The rows R and E then provide the regular-rational and Real-facing boundary for endpoint and value data. Since the carrier has no coordinate for a host supremum, refinement selector, quotient function equality, completed measure, compact open-cover theorem, selected limit, or ambient completeness, the local NameCert obligations are exhausted by the stated finite rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOscillationVariation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteOscillationVariation}^{\uparrow}$ packet is generated from finite partition rows, oscillation budgets, edge-variation ledgers, RegSeqRat readback, Real seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteOscillationVariation}^{\uparrow}}$, seed)

Scope closed: Definition 7175.1 and Definition 7175.2 seed the finite partition route from oscillation budgets to variation ledgers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteOscillationVariation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host total-variation suprema, unlisted refinement selectors, quotient equality of functions, measure completion, compact open-cover extraction, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-window synchronization, oscillation-budget confinement, variation-ledger readback, RegSeqRat and Real seal exactness, transport, replay, provenance, and local naming for BEDC.Derived.FiniteOscillationVariationUp.

Chapter 7176

A Concrete Naming Certificate for $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the Heine–Cantor finite-net route, the $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$ packet records the finite oscillation-to-uniform-modulus handoff for compact sources. It sits after the compact finite-net surfaces of chapter 60 and chapter 129, the pointwise continuity surfaces of chapter 59 and chapter 130, the oscillation rows of chapter 1839 and chapter 2224, the tolerance readbacks of chapter 291, chapter 301, and chapter 38, and the downstream uniform-modulus packet of chapter 369. The packet names the router by which compact finite-net data and pointwise oscillation ledgers become a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ row; it does not assert open-cover compactness, semantic continuity, quotient function equality, selected centers outside the finite net, an external modulus oracle, or ambient Real completeness.

Definition 7176.1 (Compact modulus oscillation router carrier)**.** *A* $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, M, F, O, Q, D, S, A, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *admission row naming the compact source as BEDC data.*
2. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, carrying bundled centers, coverage witnesses, and the finite net inspected by the router.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise continuity row at each displayed center.*
4. *O is the* $\mathsf{RealOscillation}^{\uparrow}$ *pointwise oscillation ledger read from the same center and tolerance data.*
5. *Q is the* $\mathsf{OscillationModulus}^{\uparrow}$ *row converting the displayed oscillation ledger into a tolerance-to-window modulus route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the pointwise oscillation and modulus rows.*
7. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row for the rational windows opened by D, Q.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for source and target distance or oscillation comparisons.*
9. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, exposed only after K, M, F, O, Q, D, S, A have been displayed.*

10. *H records componentwise* hsame *transport for compact, compact-metric, continuity, oscillation, modulus, dyadic, regular, Real, uniform-modulus, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a target tolerance request through the compact finite net, pointwise continuity rows, oscillation ledger, oscillation modulus, dyadic and regular readback, Real seal, and uniform-modulus handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RealOscillation}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusOscillationRouter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for open-cover compactness, semantic continuity outside the displayed pointwise rows, quotient equality of functions or points, selected centers outside M, an external modulus oracle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactModulusOscillationRouterUp.TasteGate.CompactModulusOscillationRouterTasteGa`
`single carrier alignment`

Theorem 7176.2 (Compact modulus oscillation router NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$ *carrier*

$$R = (K, M, F, O, Q, D, S, A, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactModulusOscillationRouter}^{\uparrow}}$ *surface consists exactly of compact admission, compact-metric finite-net admission, pointwise continuity admission, pointwise oscillation exposure, oscillation-modulus exactness, dyadic tolerance visibility, regular readback stability, Real-seal nonescape, UniformModulus handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming through the displayed rows.*

Proof. Project the carrier of Definition 7176.1. The rows $K, M, F, O, Q, D, S, A, U, H, C, P, N$ are the whole accepted packet.

Compact admission and finite-net admission are read from K and M. The pointwise continuity row F is then inspected only at the displayed centers and windows supplied by those compact rows.

The oscillation route is carried by O, Q, D, S, A. The ledger O records the pointwise oscillation data, Q turns it into a displayed modulus route, D supplies the dyadic tolerance, S supplies regular rational readback, and A seals the Real-facing comparison.

The uniform-modulus handoff U is downstream of those rows. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route, so the listed obligations exhaust the local NameCert surface and none of the refused host objects is exported. □

Theorem 7176.3 (Compact modulus oscillation router handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$ *packet receives a tolerance-only ledger only after reading the finite route*

$\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RealOscillation}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$,

The handoff is the displayed compact finite-net and pointwise oscillation route, not an open-cover compactness theorem, semantic continuity principle, quotient equality, selected external center, external modulus oracle, countable-choice schedule, or ambient Real-completeness claim.

Proof. Start with the compact and metric rows K, M. They provide the finite centers and coverage witnesses available to the router.

Read the pointwise continuity and oscillation rows F, O at those centers. The oscillation-modulus row Q converts the displayed oscillation ledger into a tolerance-to-window route over the dyadic row D and regular readback row S.

The Real seal A records the numerical comparison reached by the same route. Only then is the $\mathsf{UniformModulus}^{\uparrow}$ row U visible to a downstream consumer.

The structural rows H, C, P, N transport, replay, source, and name that finite route. Since the packet contains no coordinate for the excluded host objects, every uniform-modulus consumer remains inside the displayed compact finite-net and pointwise oscillation handoff. □

Falsifiable prediction: Every accepted $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$ read factors through CompactUp admission, CompactMetric finite-net rows, Continuous or ContinuousMap pointwise rows, RealOscillation and OscillationModulus ledgers, DyadicRatCore tolerance rows, RegSeqRat readback, RealUp seals, UniformModulusUp handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: compact, compactmetric, continuous, continuousmap, real-oscillation, oscillation-modulus, dyadicratcore, regseqrat, real, uniformmodulus: none is bijective with CompactModulusOscillat because this packet alone binds the compact finite-net route to pointwise oscillation and a downstream tolerance-only uniform-modulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusOscillationRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusOscillationRouter}^{\uparrow}$ packet is generated from Compact and CompactMetric rows, Continuous and ContinuousMap pointwise rows, RealOscillation and OscillationModulus ledgers, DyadicRatCore tolerance rows, RegSeqRat readback, RealUp seals, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusOscillationRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7176.1, Definition 7176.2, and Definition 7176.3 seed the compact finite-net and pointwise oscillation route before UniformModulus consumers inspect the tolerance-only ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusOscillationRouter}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompactModulusOscillationRouterUp.TasteGate.CompactModulusOscillationRouterTasteGate\_s`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, semantic continuity, quotient function or point equality, selected centers outside the finite net, external modulus selection, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact admission, finite-net admission, pointwise continuity admission, oscillation exposure, oscillation-modulus exactness, tolerance visibility, regular readback stability, Real-seal nonescape, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactModulusOscillationRouterUp

Chapter 7177

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ packet records the object-level completion carrier before theorem-facing dense-embedding, universal-property, functoriality, or $\mathsf{Real}^{\uparrow}$ sealing routes are consumed. It sits over the regular rational source of chapter 301, the finite observation surface of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real-name boundary of chapter 38. The packet names the completion object as displayed regular Cauchy data with transport, replay, provenance, and local naming; it does not assert quotient completion equality, select limits, identify host real equality, invoke countable choice, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7177.1 (Regular Cauchy completion object carrier)**.** *A* $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (R, W, D, E, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational name and its regularity readback surface.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row, naming the windows opened by completion-facing requests.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, slack cells, and comparison rows used by the regular Cauchy read.*
4. *E is the object-admission row saying that R, W, D jointly form the displayed completion carrier before any theorem route is inspected.*
5. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *boundary row available to Real-facing consumers only as a downstream seal over R, W, D, E.*
6. *H records componentwise* hsame *transport for the regular source, window, dyadic tolerance, object admission, Real boundary, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through W, D, R, E, A and the structural rows.*

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionObject}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R, W, D, E, A, H, C, P, N$. It has no coordinate for quotient streams, selected representatives, selected limits, countable-choice schedules, host real equality, theorem-level universal properties, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7177.2 (Regular Cauchy completion object NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ *carrier*

$$X = (R, W, D, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionObject}^{\uparrow}}$ *surface consists exactly of regular rational source admission, finite StreamName observation, DyadicRatCore tolerance visibility, object-admission exactness, Real-boundary nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows. Dense-embedding, universal-property, functoriality, and Real-sealing chapters may cite this object only through those rows.*

Proof. Project the carrier of Definition 7177.1. The rows $R, W, D, E, A, H, C, P, N$ are the full accepted packet.

The object rows are R, W, D, E. The regular rational source, finite observation windows, and dyadic tolerance ledger are displayed before the admission row E may name the completion carrier.

The Real-facing row A is downstream of the same displayed data. It seals the route for consumers of chapter 38 without adding quotient equality, a selected representative, a selected limit, or ambient completeness.

The structural rows H, C, P, N transport, replay, source, and name only that finite route. Therefore the listed obligations exhaust the local NameCert surface and give theorem-facing consumers a single object-level carrier to cite. □

Theorem 7177.3 (Regular Cauchy completion object dense-embedding handoff)**.** *Every dense-embedding, universal-property, functoriality, or* $\mathsf{Real}^{\uparrow}$ *sealing consumer that cites an accepted* $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ *packet first reads the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The handoff is the object-level completion carrier $R, W, D, E, A, H, C, P, N$, not a theorem route itself, not quotient completion equality, not a selected limit, not countable choice, and not ambient Real completeness.

Proof. Begin with an accepted carrier $X = (R, W, D, E, A, H, C, P, N)$. The completion-facing consumer first opens the finite StreamName windows W and dyadic tolerance ledger D attached to the regular rational source R.

The admission row E then names those displayed rows as the completion object. This is the object-level boundary that theorem chapters may consume before proving dense embedding, universal mapping, or functorial transport.

If a Real-facing seal is needed, it is read through A after the same regular source, window, tolerance, and admission rows. The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming.

Since no carrier coordinate stores a quotient completion, selected representative, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem, the consumer receives only the displayed completion object. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ read factors through a RegSeqRat source row, StreamName finite observation row, DyadicRatCore tolerance ledger, object-admission row, RealUp boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any theorem-facing completion route is consumed.

Independence witness: regseqrat, streamname, dyadicratcore, real: none is bijective with $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ because this packet alone binds regular rational source data, finite observation windows, dyadic tolerance ledgers, object admission, Real boundary sealing, transport, replay, provenance, and local naming as one completion object carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionObject}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName finite observation rows, DyadicRatCore tolerance rows, an object-admission row, a RealUp boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionObject}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7177.1, Definition 7177.2, and Definition 7177.3 seed the object-level regular Cauchy completion carrier for later dense-embedding, universal-property, functoriality, and RealUp sealing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionObject}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close dense embedding, universal properties, functoriality, quotient completion equality, selected representatives, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked regular source admission, finite observation, dyadic tolerance visibility, object-admission exactness, Real-boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionObjectUp.

Chapter 7178

A Concrete Naming Certificate for $\mathsf{YoungTableau}^{\uparrow}$

Following Fulton, *Young Tableaux*, the $\mathsf{YoungTableau}^{\uparrow}$ packet records the finite row-and-column filling surface of a Young diagram as BEDC NameCert data. It consumes the partition-shape discipline of chapter 201, supplies a tableau row ledger usable by character-theoretic consumers such as chapter 245, and exposes a representation-ring-facing finite classifier route for chapter 246. The packet names only displayed shape, alphabet, row, column, transport, provenance, and local certificate rows; it does not import a host set of boxes, quotient equality of tableaux, a Schur polynomial calculation, or a Littlewood–Richardson rule.

Definition 7178.1 (Young tableau carrier)**.** *A* $\mathsf{YoungTableau}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (S, A, R, C, T, P, N)$$

with the following displayed rows:

1. *S is the consumed* $\mathsf{Partition}^{\uparrow}$ *shape row, including the finite Young-diagram box list and its row-length ledger.*
2. *A is the entry-alphabet row, recording the finite alphabet visible to the tableau and the admissible entry names used by downstream readers.*
3. *R is the row ledger, listing each displayed row, its ordered boxes, and the weak row comparison data carried by the packet.*
4. *C is the column ledger, listing each displayed column, its ordered boxes, and the strict column comparison data carried by the packet.*
5. *T records componentwise* hsame *transport for the shape, alphabet, row, column, replay, provenance, and local naming rows.*
6. *P records displayed* Cont *replay and* Pkg *provenance over* $\mathsf{YoungTableau}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungTableau}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through S, A, R, C, T, P, N. It has no coordinate for host box equality, quotient tableau equality, an ambient symmetric-function algebra, a Schur functor construction, or a plactic monoid quotient.

Theorem 7178.2 (Young tableau NameCert obligations)**.** *For every accepted* $\mathsf{YoungTableau}^{\uparrow}$ *carrier* $Y = (S, A, R, C, T, P, N)$ *of Definition 7178.1, the local* $\mathsf{NameCert}_{\mathsf{YoungTableau}^{\uparrow}}$ *surface consists exactly of carrier admission, partition-shape exposure through* S*, entry-alphabet exposure through* A*, row-ledger exposure through* R*, column-ledger exposure through* C*, componentwise* hsame *transport through* T*, displayed* Cont *replay and* Pkg *provenance through* P*, and local naming through* N*. These obligations do not include a host tableau set, quotient equality of fillings, a Schur-polynomial identity, a Littlewood–Richardson coefficient, or a representation-theoretic completeness theorem.*

Lean4 ✓ `BEDC.Derived.YoungTableauUp.YoungTableauCarrier namecert obligations`

Proof. Project the carrier of Definition 7178.1. The packet exposes only the seven displayed rows S, A, R, C, T, P, N.

The combinatorial surface is read from S, A, R, C. The shape row fixes the finite box list, the alphabet row fixes the admissible entry names, and the row and column ledgers display the only comparison data available to the classifier.

The structural surface is then T, P, N. Componentwise transport, replay, provenance, and local naming preserve the already displayed rows and add no ambient tableau semantics. Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 7178.3 (Young tableau shape-row-column stability)**.** *Let* $Y = (S, A, R, C, T, P, N)$ *and* $Y' = (S', A', R', C', T', P', N')$ *be accepted* $\mathsf{YoungTableau}^{\uparrow}$ *carriers. If the shape rows* S *and* S' *are equal as displayed partition-shape rows, the alphabet rows* A *and* A' *expose the same entry names, and the row and column ledgers* R, C *and* R', C' *agree componentwise under the displayed* hsame *transport, then the tableau classifier gives the same read to* Y *and* Y'*. The stability claim is internal to the finite rows* S, A, R, C, T, P, N *and does not assert equality of host fillings.*

Proof. Begin with the shape rows. Equality of S and S' identifies the same finite Young-diagram box list and row-length ledger, so both packets expose the same positions before any tableau read begins.

Use the displayed alphabet, row, and column ledgers next. The alphabet agreement identifies the admissible entry names, while the componentwise agreement of R, C with R', C' preserves the weak row and strict column comparison data carried by the packets.

Finally apply the structural rows. The transports T, T' and the replay/provenance rows P, P' preserve only the displayed shape, alphabet, row, and column data, and N, N' locally name that same finite route. Thus the classifier has no remaining coordinate on which to distinguish the two accepted reads. □

Closure status for $\mathsf{NameCert}_{\mathsf{YoungTableau}^{\uparrow}}$**.**

Constructive story: A $\mathsf{YoungTableau}^{\uparrow}$ packet is generated from a partition-shape row, a finite entry-alphabet row, displayed row and column ledgers, componentwise hsame transport, displayed Cont replay with Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{YoungTableau}^{\uparrow}}$, seed)

Scope closed: Definition 7178.1, Definition 7178.2, and Definition 7178.3 seed the finite tableau carrier, obligation surface, and classifier-stability route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{YoungTableau}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Schur polynomial identities, Littlewood–Richardson coefficients, plactic monoid quotients, Schur functor exactness, representation-theoretic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shape exposure, alphabet exposure, row-ledger exposure, column-ledger exposure, transport, replay, provenance, and local naming for BEDC.Derived.YoungTableauUp.

Chapter 7179

A Concrete Naming Certificate for $\mathsf{CauchyTailSpace}^{\uparrow}$

Following Bishop and Bridges on Cauchy sequences and Kelley on filters, the $\mathsf{CauchyTailSpace}^{\uparrow}$ packet records the finite tail-stability carrier that sits between the stream-name schedule of chapter 126, the regular rational-name surface of chapter 301, the dyadic tolerance core of chapter 291, and the real-seal boundary of chapter 38. It is the local object read by the Cauchy-name map surface of chapter 1401 when a consumer needs tail truncation, not selected limits or host equality of reals.

Definition 7179.1 (CauchyTailSpace carrier)**.** *A* $\mathsf{CauchyTailSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, K, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the base regular Cauchy name row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *and its underlying* $\mathsf{StreamName}^{\uparrow}$ *window schedule;*
2. *K is the tail cutoff schedule, listing the finite windows after which the carrier permits a tail read;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed tail windows;*
4. *Q is the tail-equivalence classifier, comparing two accepted packets only by the regular-name windows and dyadic tolerances visible past the displayed cutoffs;*
5. *H records componentwise* hsame *transport for R, K, D, Q and for the local naming row;*
6. *C records the displayed* Cont *replay routes by which a consumer reopens the same regular-name, cutoff, tolerance, and classifier rows;*
7. *P is the* Pkg *provenance over the stream-name, regular-rational, dyadic-tolerance, real-seal boundary, transport, replay, and local naming rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailSpace}^{\uparrow}}$ *row.*

The classifier has no coordinate for quotient streams, selected limits, host real equality, completeness, countable choice, or a hidden real-valued representative.

Theorem 7179.2 (Tail truncation stability)**.** *For every accepted* $\mathsf{CauchyTailSpace}^{\uparrow}$ *carrier $T = (R, K, D, Q, H, C, P, N)$, any consumer that discards an initial finite prefix must still expose the base*

regular Cauchy name row R, the cutoff schedule K, and the dyadic tolerance ledger D before it may read the tail-equivalence classifier Q. The truncation therefore preserves the finite $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *tail surface, without choosing a limit or quotient-stream representative.*

Proof. Project the carrier of Definition 7179.1. The only rows that can witness a tail read are the base regular name R, the cutoff schedule K, and the tolerance ledger D.

After a finite prefix is ignored, the displayed continuation route C still reopens R, K, D before Q is visible. The prefix removal changes which finite windows are inspected, but it does not add a new carrier coordinate.

Transport through H preserves the same rows componentwise. Hence the accepted tail read remains a finite regular-Cauchy read and cannot export a selected limit, quotient stream, or host real value. □

Theorem 7179.3 (Tail classifier transport)**.** *If two accepted* $\mathsf{CauchyTailSpace}^{\uparrow}$ *carriers are related by the displayed* hsame *rows of their packets, then every tail-equivalence read through Q transports along the same R, K, D rows. A transported classifier cannot replace those rows by host real equality, ambient completeness, or an unrecorded filter equality.*

Proof. Read the transport row H. It stores componentwise transport for the base regular name, cutoff schedule, dyadic ledger, classifier, and local naming row.

Replay the classifier through C. The classifier row Q is available only after the transported R, K, D rows are displayed, so its comparison remains tied to the finite packet.

Since the carrier has no coordinate for host real equality, filter equality, quotient streams, completeness, or choice, the transported classifier cannot use any of those objects as a substitute for the displayed tail rows. □

Theorem 7179.4 (Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyTailSpace}^{\uparrow}$ *packet must factor its read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, the tail cutoff schedule K, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the classifier row Q, displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The read does not create a selected limit, a host real equality proof, a completeness theorem, a quotient-stream function, or a choice principle.*

Proof. Start with the carrier inventory. The only route from a tail packet toward $\mathsf{Real}^{\uparrow}$ is the displayed regular-rational and dyadic-tolerance route through R, K, D, Q.

The replay row C forces a consumer to reopen that route before any real-seal boundary can be cited. The transport row H and provenance row P keep the same finite data attached to the local naming row N.

The refused objects are absent from the carrier. Therefore a $\mathsf{Real}^{\uparrow}$-facing read may consume the finite tail-stability packet, but it cannot manufacture selected limits, host real equality, completeness, quotient-stream functions, or choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailSpace}^{\uparrow}$ packet is generated from a base regular Cauchy name, a finite tail cutoff schedule, a dyadic tolerance ledger, a tail-equivalence classifier, displayed transport, replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7179.1, Definition 7179.2, Definition 7179.3, and Definition 7179.4 bind the finite Cauchy-tail carrier and its nonescape surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, completeness, or choice.

Upgrade path: A later verification route can encode BEDC.Derived.CauchyTailSpaceUp and prove the carrier, classifier transport, truncation stability, and Real-seal nonescape rows.

Chapter 7180

CandidateNormalizationDischargeUp NameCert Construction

The $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ packet realizes the normalization remaining question of chapter 9386 as finite discharge data. It reads the normalization audit map of chapter 9383 beside the frontier carrier of chapter 892, the candidate-normalization witness of chapter 6577, the normal-endpoint budget of chapter 4292, and the SN candidate interface of chapter 3567. The packet binds the discharge row connecting candidate evidence to endpoint use; it is not a blanket normalization theorem for arbitrary closed typed terms.

Definition 7180.1 (Candidate-normalization discharge carrier)**.** *A* $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, K, E, S, O, H, C, P, N)$$

with the following displayed rows:

1. *A is the audit-map anchor row for chapter 9383;*
2. *K is the candidate-evidence row, reading candidate, closed-candidate, or candidate-set evidence through the existing MetaCIC normalization frontier;*
3. *E is the endpoint-seal row, recording the normal endpoint that may be consumed only after K is displayed;*
4. *S is the discharge row connecting the candidate evidence in K to the endpoint use in E;*
5. *O is the obstruction-retention row, keeping absent candidate evidence, subject-reduction obstruction, and evidence-free endpoint requests visible;*
6. *H records componentwise* hsame *transport for A, K, E, S, O and for the local naming row;*
7. *C records the displayed* Cont *replay routes for audit, candidate, endpoint, discharge, and obstruction reads;*
8. *P is the* Pkg *provenance over* $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$, $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$, $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CandidateNormalizationDischarge}^{\uparrow}}$ *row.*

Theorem 7180.2 (Candidate discharge obligation surface)**.** *Every accepted* $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ *packet exposes exactly the candidate-evidence row* K*, endpoint-seal row* E*, discharge row* S*, obstruction-retention row* O*, displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows needed before a normalization-facing consumer may use a strong-normalization endpoint. No consumer can reach the endpoint seal through the packet while omitting the candidate evidence or the discharge row.*

Proof. Project the carrier of Definition 7180.1. The endpoint row E is stored beside K and S, not as an independent normalization theorem.

Replay the read through C. A normalization-facing consumer must display the audit anchor, candidate evidence, endpoint seal, discharge link, and obstruction row in the carrier order before using the endpoint.

Transport and provenance through H and P preserve those same rows. Thus the local NameCert surface is exhausted by the displayed finite packet. □

Theorem 7180.3 (Endpoint seal nonescape)**.** *An accepted* $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ *packet is refuted as a discharge certificate if a normalization-facing consumer obtains a strong-normalization endpoint without displaying candidate evidence, endpoint seal, obstruction retention,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The packet does not export evidence-free strong normalization, host evaluation soundness, unrestricted subject reduction, quotient syntax equality, or closed consistency.*

Proof. Use the obligation surface of Definition 7180.2. It places candidate evidence and the discharge row before endpoint use.

The obstruction row O records exactly the refused bypasses. If the consumer reaches a strong-normalization endpoint while erasing K, S, O, H, C, P, N, then the read no longer factors through the accepted carrier.

Because the carrier has no row for evidence-free strong normalization, host evaluation soundness, unrestricted subject reduction, quotient syntax equality, or closed consistency, those endpoints remain outside the packet. □

Theorem 7180.4 (Sibling separation)**.** *The* $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ *carrier is not bijective, row for row, with* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$*,* $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$*, or* $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$*. It binds the discharge row connecting candidate evidence to endpoint use, while the siblings respectively expose frontier, witness, endpoint budget, or candidate interface rows without the same discharge packet.*

Proof. Compare first with $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$. The frontier exposes candidate and endpoint boundary rows, but it does not by itself store the local discharge row S together with this packet's obstruction-retention and endpoint-use contract.

Compare next with $\mathsf{MetaCICCandidateNormalizationWitness}^{\uparrow}$ and $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$. The witness records evidence for a candidate-facing route, and the budget records endpoint consumption constraints; neither is the single carrier that binds both sides through S.

Finally compare with $\mathsf{MetaCICSnCandidateInterface}^{\uparrow}$. The interface describes candidate admission, while $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ records the finite discharge packet through which an endpoint read is allowed. A row-preserving bijection would have to preserve $A, K, E, S, O, H, C, P, N$ simultaneously, which no listed sibling carries. □

Falsifiable prediction: An accepted $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ packet is refuted if a normalization-facing consumer obtains a strong-normalization endpoint without displaying candidate evidence, endpoint seal, obstruction retention, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: metacicnormalizationfrontier, metacic-candidate-normalization-witness, metacic-normal-endpoint-budget, metacic-sn-candidate-interface: $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ is not bijective to these siblings because it binds the discharge row connecting candidate evidence to endpoint use, while the siblings respectively expose frontier, witness, endpoint budget, or candidate interface rows without the same discharge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateNormalizationDischarge}^{\uparrow}}$.

Constructive story: A $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$ packet is generated from audit-map anchoring, candidate evidence, endpoint seal, discharge, obstruction retention, displayed transport, replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CandidateNormalizationDischarge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7180.1, Definition 7180.2, Definition 7180.3, and Definition 7180.4 bind the finite candidate-mediated endpoint discharge packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CandidateNormalizationDischarge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global strong normalization, unrestricted subject reduction, host evaluation soundness, quotient syntax equality, or closed consistency.

Upgrade path: A later Lean route should encode BEDC.Derived.CandidateNormalizationDischargeUp and provide Nontrivial and FieldFaithful instances in BEDC.Derived.CandidateNormalizationDischargeUp.TasteGate.

Chapter 7181

A Concrete Naming Certificate for $\mathsf{ExactCouple}^{\uparrow}$

Following Cartan–Eilenberg and McCleary, the $\mathsf{ExactCouple}^{\uparrow}$ packet records the finite precursor by which graded-object data, two degree-preserving maps, and one connecting map generate the page handoff later consumed by $\mathsf{SpectralSeq}^{\uparrow}$. It sits over the abelian-category surface of chapter 176, the homology and cohomology rows of chapter 98 and chapter 99, and before the spectral-sequence packet of chapter 178. The certificate names the finite exact-couple ledger only; it does not export an ambient derived-category calculus, quotient page object, or unrecorded convergence theorem.

Definition 7181.1 (Exact-couple carrier)**.** *An* $\mathsf{ExactCouple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, G, D, I, J, K, W, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *source row in which the displayed graded objects and maps are read.*
2. *G is the graded-object row, carrying the inspected bidegree window and its neighboring degree shifts.*
3. *D is the degree-preserving self-map row on the displayed graded object data.*
4. *I is the second degree-preserving map row, recording the visible inclusion or transition map used by the exact couple.*
5. *J is the connecting-map row from the companion graded object into the shifted inspected object.*
6. *K is the* $\mathsf{Homology}^{\uparrow}$ *or* $\mathsf{Cohomology}^{\uparrow}$ *kernel-image readback row attached to the same degree window.*
7. *W records the finite exactness windows for the rows D, I, J, K, with every kernel and image comparison read through the displayed certificate rows.*
8. *R is the derived-page handoff row, exposing the finite page data later consumed by* $\mathsf{SpectralSeq}^{\uparrow}$*.*
9. *H records componentwise* hsame *transport for the graded-object row, the two degree-preserving maps, the connecting map, exactness windows, derived-page handoff, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an exact-couple read through $A, G, D, I, J, K, W, R, H$.*

11. *P is the* Pkg *provenance over* $\mathsf{ExactCouple}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{SpectralSeq}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ExactCouple}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient page equality, host exactness outside the finite windows, derived-category localization, selected representatives, countable choice, or convergence data beyond the handoff row R.

Theorem 7181.2 (Exact-couple NameCert obligations)**.** *For every accepted* $\mathsf{ExactCouple}^{\uparrow}$ *carrier $Q = (A, G, D, I, J, K, W, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ExactCouple}^{\uparrow}}$ *surface is exhausted by the abelian-category source row, graded-object data, two degree-preserving maps, one connecting map, kernel-image readback, finite exactness windows, derived-page handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may not infer an ambient exact-couple object, quotient page equality, host exactness theorem, selected cycle representative, hidden derived-category localization, or spectral-sequence convergence claim.*

Proof. Project the carrier of Definition 7181.1. The rows A, G, D, I, J expose the abelian source, graded data, two degree-preserving maps, and the connecting map before any exactness or page read is available.

Next read K and W. These rows attach kernel-image comparisons to the same finite degree window and keep exactness inside the displayed $\mathsf{Homology}^{\uparrow}$ or $\mathsf{Cohomology}^{\uparrow}$ readback rather than in a host theorem.

Finally R, H, C, P, N package the derived-page handoff, transport, replay, provenance, and local naming rows. Since none of these rows adds quotient page equality, a selected representative, derived localization, countable choice, or convergence data, the listed rows exhaust the local NameCert obligations. □

Theorem 7181.3 (Exact-couple spectral-sequence handoff)**.** *Every* $\mathsf{SpectralSeq}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{ExactCouple}^{\uparrow}$ *packet must reach the page-generation boundary through the finite route*

$$\mathsf{AbelianCat}^{\uparrow},\ G,\ D,\ I,\ J,\ K,\ W \longmapsto R \longmapsto \mathsf{SpectralSeq}^{\uparrow}.$$

The route exports the derived-page handoff row R together with H, C, P, N, not an ambient exact-couple object, not a quotient page primitive, and not convergence data outside the spectral-sequence packet that consumes the handoff.

Proof. Start with the carrier rows A, G, D, I, J, K, W. They display the exact-couple data and the finite exactness windows before any page-generation read can be replayed.

The handoff is then the row R. By definition R exposes only finite page data derived from the same graded-object and exactness-window ledger, and the structural rows H, C, P, N transport and replay that same handoff.

Therefore a $\mathsf{SpectralSeq}^{\uparrow}$ consumer receives a finite precursor route rather than a primitive page oracle. Any quotient page equality, ambient exact-couple object, hidden representative choice, or convergence assertion lies outside the accepted $\mathsf{ExactCouple}^{\uparrow}$ carrier. □

Falsifiable prediction: A spectral-sequence page-generation read is rejected as an $\mathsf{ExactCouple}^{\uparrow}$ handoff when it preserves R but omits the graded-object row G, degree-preserving map rows D, I, connecting map row J, kernel-image readback K, or exactness-window row W.

Independence witness: abeliancat, homology, cohomology, spectralseq: none is bijective with $\mathsf{ExactCouple}^{\uparrow}$ because the packet jointly carries graded-object data, two degree-preserving maps,

one connecting map, exactness windows, derived-page handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ExactCouple}^{\uparrow}}$.

Constructive story: An $\mathsf{ExactCouple}^{\uparrow}$ packet is generated from an abelian-category source row, displayed graded-object data, two degree-preserving maps, one connecting map, kernel-image readback, finite exactness windows, a derived-page handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExactCouple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7181.1, Definition 7181.2, and Definition 7181.3 seed the finite exact-couple precursor to the spectral-sequence page handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExactCouple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, ambient exact-couple objects, quotient page equality, selected representatives, derived-category localization, countable choice, or convergence theorems.

Upgrade path: Obligation closure requires checked graded-object rows, two degree-preserving map rows, connecting-map rows, finite exactness-window compatibility, derived-page handoff compatibility, and structural transport for BEDC.Derived.ExactCoupleUp

Chapter 7182

A Concrete Naming Certificate for $\mathsf{SeminormFamily}^{\uparrow}$

Following Bourbaki and Treves on locally convex spaces and families of seminorms, the $\mathsf{SeminormFamily}^{\uparrow}$ packet isolates the finite seminorm-family ledger consumed by chapter 5868, chapter 3386, chapter 205, chapter 47, and chapter 38. It names the family before downstream packets read convex balanced neighbourhoods, induced uniform probes, seminormed-space comparisons, or completion-facing data.

Definition 7182.1 (SeminormFamily carrier)**.** *A* $\mathsf{SeminormFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (V, R, I, F, Z, T, A, B, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *vector source, exposing vector zero, addition, negation, and scalar action only through the displayed vector-space packet.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar source, exposing nonnegative value rows, scalar absolute values, addition, multiplication, and order budgets used by the seminorm reads.*
3. *I is the finite family-index row listing exactly the seminorm labels admitted by the packet.*
4. *F is the seminorm-row ledger; for each displayed index in I, it records the value probe and the corresponding nonnegativity, zero, triangle, and scalar rows.*
5. *Z is the zero-compatibility row, comparing the vector-zero classifier of V with every zero-value row in F.*
6. *T is the triangle-budget row, routing each displayed read of $p_i(x+y)$ through vector addition in V, the selected seminorm row in F, and the Real addition and order rows in R.*
7. *A is the scalar-budget row, routing each displayed read of $p_i(ax)$ through scalar action in V, the absolute-value and multiplication rows in R, and the selected seminorm row in F.*
8. *B is the generated-neighbourhood probe row, recording the finite seminorm balls and finite intersections handed to topological-vector-space and locally convex consumers.*
9. *H records componentwise* hsame *transport for $V, R, I, F, Z, T, A, B, C, P, N$.*
10. *C records displayed* Cont *replay through vector source, Real source, family index, seminorm rows, zero, triangle, scalar, generated-neighbourhood probes, transport, provenance, and local naming.*

11. *P is the* Pkg *provenance over* $\mathsf{SeminormFamily}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{TopVecSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SeminormFamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for an unbounded family, a hidden host topology, a selected quotient completion, a continuous dual, or a norm that replaces the family ledger.

Theorem 7182.2 (SeminormFamily NameCert obligations)**.** *For every accepted* $\mathsf{SeminormFamily}^{\uparrow}$ *carrier*

$$S = (V, R, I, F, Z, T, A, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeminormFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed vector source, Real scalar source, finite family index, seminorm rows, zero compatibility, triangle budget, scalar budget, generated neighbourhood probes, transport, replay, provenance, and local naming; index exposure through I before any seminorm row in F is consumed; zero compatibility through Z; triangle and scalar budget routing through T and A; neighbourhood handoff through B; and transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Carrier admission is projection from Definition 7182.1. The accepted packet displays $V, R, I, F, Z, T, A, B, H, C, P, N$ and no further coordinate.

Index exposure is row exhaustion. A seminorm read first names an index from I, then reads the matching entry of F together with its zero, triangle, and scalar evidence.

The compatibility budgets are the displayed rows Z, T, A. The row Z compares zero-value data with the vector-zero classifier, T routes sums through vector addition and Real addition-order data, and A routes scalar multiplication through the Real absolute-value and multiplication rows.

Finally B is the only generated-neighbourhood handoff, while H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no hidden topology, unbounded index set, selected completion, continuous-dual selector, or replacement norm coordinate, these rows exhaust the NameCert surface. □

Theorem 7182.3 (SeminormFamily locally convex handoff)**.** *Every* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *consumer and every Frechet-facing consumer that reads convex balanced neighbourhoods or completion-facing data from a finite seminorm family must first pass through the* $\mathsf{SeminormFamily}^{\uparrow}$ *rows*

$$V, R, I, F, Z, T, A, B, H, C, P, N.$$

The handoff exports finite indexed seminorm probes and generated neighbourhood rows; it exports no unbounded seminorm family, no hidden host topology, no selected quotient completion, and no detached norm substitute.

Proof. Start with a locally convex or Frechet-facing request. The vector and scalar sources are V and R, while the admissible seminorm labels are exactly the finite row I.

Use the NameCert obligations of Definition 7182.2. A consumer reaches any seminorm value only through F after index exposure, and it reaches zero, triangle, and scalar budgets only through Z, T, A.

The neighbourhood route is then B. Convex balanced neighbourhoods and completion-facing probes consume the generated finite seminorm balls and finite intersections recorded there, with transport, replay, provenance, and local naming preserved by H, C, P, N.

Thus a downstream consumer receives only the displayed finite family route. With no coordinate for an unbounded family, host topology, selected quotient completion, or detached norm substitute, the named handoff is exactly the packet displayed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeminormFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{SeminormFamily}^{\uparrow}$ packet is generated from displayed VecSpace and Real source rows, a finite family-index row, seminorm rows, zero, triangle, and scalar budgets, generated-neighbourhood probes, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeminormFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7182.1, Definition 7182.2, and Definition 7182.3 seed the finite seminorm-family ledger consumed by seminormed-space, locally convex, topological-vector, vector-space, Real, and completion-facing packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeminormFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unbounded seminorm families, host locally convex topology, quotient completion, selected continuous duals, or norm replacement.

Upgrade path: Scoped closure requires checked preservation of the displayed rows $V, R, I, F, Z, T, A, B, H, C, P, N$ through every locally convex and completion-facing consumer route.

Chapter 7183

A Concrete Naming Certificate for $\mathsf{BihariLaSalle}^{\uparrow}$

Following Bihari and LaSalle, the $\mathsf{BihariLaSalle}^{\uparrow}$ packet records the finite nonlinear integral-inequality surface used when a nonnegative comparison function is controlled by an Osgood-type modulus before a Real-facing stability consumer reads the bound. It sits after the linear Gronwall route of chapter 2034, the Bellman integral-comparison route of chapter 6270, the finite integration rows of chapter 1526, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only interval, unknown-envelope, window, Osgood-modulus, inverse-modulus, readback, Real-seal, transport, replay, provenance, and local naming rows.

Definition 7183.1 (Bihari–LaSalle carrier)**.** *A* $\mathsf{BihariLaSalle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, U, W, O, G, R, Z, H, C, P, N)$$

with the following visible rows:

1. *I is the interval row, recording the displayed time window, endpoint names, and the finite partition cells on which the nonlinear comparison is inspected.*
2. *U is the unknown-envelope row, storing the nonnegative comparison quantity and its initial bound as finite* $\mathsf{Real}^{\uparrow}$*-readable data.*
3. *W is the weight row, recording the displayed integral coefficient, cellwise majorant, and finite error budget used by the comparison.*
4. *O is the Osgood-modulus row, displaying the nondecreasing positive modulus and the finite inverse-modulus windows on which the Bihari separation read is made.*
5. *G is the Gronwall/Osgood handoff row, identifying the linear Gronwall route when O is linear and the nonlinear Osgood route when the inverse-modulus ledger is required.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the interval endpoints, envelope samples, coefficient bounds, Osgood-modulus values, inverse-modulus windows, and comparison budget.*
7. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row for the final Bihari–LaSalle bound after the finite rows have been replayed.*
8. *H records componentwise* hsame *transport for the interval, envelope, weight, Osgood-modulus, handoff, readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through*

$$I, U, W, O, G, R \longmapsto Z \longmapsto \mathsf{NameCert}_{\mathsf{BihariLaSalle}^{\uparrow}}.$$

10. *P is the* Pkg *provenance over* $\mathsf{BihariLaSalle}^{\uparrow}$, $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{GronwallBellman}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BihariLaSalle}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows and their displayed transports. It has no coordinate for a host nonlinear integral operator, selected inverse function, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or analytic ODE solver.*

Lean4 (statement) `BEDC.Derived.BihariLaSalleUp`

Theorem 7183.2 (Bihari–LaSalle NameCert obligations)**.** *For every accepted* $\mathsf{BihariLaSalle}^{\uparrow}$ *carrier* $B = (I, U, W, O, G, R, Z, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BihariLaSalle}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed interval, unknown-envelope, weight, Osgood-modulus, Gronwall/Osgood handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. No obligation is discharged by a host integral theorem, selected inverse-modulus function, quotient real equality, countable-choice schedule, ambient Real completeness, or external ODE solver.*

Proof. Project the accepted carrier of Definition 7183.1. The rows I, U, W, O, G, R, Z are the only analytic-facing coordinates, and the structural rows H, C, P, N only transport, replay, source, and name those coordinates.

The interval, envelope, and weight rows determine the finite nonlinear comparison problem. The Osgood-modulus row supplies the displayed modulus and inverse-window ledger, while the handoff row identifies the linear Gronwall branch as a special finite route and the nonlinear branch as the inverse-modulus route.

The regular-rational readback and Real seal bind the comparison to displayed observations. Since every endpoint of the comparison passes through R before Z is consumed, the certificate cannot import a host integral theorem, selected inverse function, quotient equality, choice schedule, completeness theorem, or external solver. □

Theorem 7183.3 (Bihari–LaSalle Gronwall handoff)**.** *Every accepted* $\mathsf{BihariLaSalle}^{\uparrow}$ *carrier routes a nonlinear integral-inequality read through the finite handoff*

$$\mathsf{GronwallBellman}^{\uparrow} \longmapsto \mathsf{BihariLaSalle}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

When the Osgood-modulus row O is linear, the handoff row G exposes the Gronwall comparison of chapter 2034. When O is nonlinear, G keeps the read on the displayed inverse-modulus windows before the regular-rational readback R and Real seal Z are available.

Proof. Begin with an accepted carrier B. The comparison can inspect the interval row I, unknown envelope U, and weight row W before it reaches any bound.

Read the Osgood-modulus row next. If the displayed modulus is the linear one, the row G cites the Gronwall and Bellman comparison routes already present in the sibling chapters. Otherwise the same row keeps the comparison inside the inverse-modulus windows listed by O.

Finally expose R and Z. The regular-rational row records the finite observations from both branches, and the Real seal is terminal for those observations. Thus the handoff cannot bypass the displayed rows through host integration, selected inverse functions, quotient equality, countable choice, or ambient completeness. □

Theorem 7183.4 (Bihari–LaSalle Real seal nonescape)**.** *For every accepted* $\mathsf{BihariLaSalle}^{\uparrow}$ *carrier* $B = (I, U, W, O, G, R, Z, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* Z *exposes only the bound obtained from the interval, unknown-envelope, weight, Osgood-modulus, Gronwall/Osgood handoff, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows. It exports no host nonlinear integral value, selected inverse-modulus function, quotient stream equality, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness result, or analytic ODE continuation theorem.*

Proof. Use Definition 7183.2 to identify the local obligation surface. The seal row is listed there only as the terminal read of the finite carrier rows.

Use Definition 7183.3 to locate the route into Z. The handoff opens I, U, W, O, G, R before the Real seal is available, so the seal cannot be an independent host integral value or selected inverse-modulus function.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Therefore a consumer of Z receives only the finite Bihari–LaSalle comparison packet and none of the excluded host analytic objects. □

Falsifiable prediction: Every accepted $\mathsf{BihariLaSalle}^{\uparrow}$ consumer that reads a Real nonlinear comparison bound without the displayed interval, unknown-envelope, weight, Osgood-modulus, Gronwall/Osgood handoff, RegSeqRat readback, transport, replay, provenance, and local NameCert rows refutes the packet surface.

Independence witness: gronwall-inequality, gronwall-bellman, riemannintegral, regseqrat, real: none is bijective to $\mathsf{BihariLaSalle}^{\uparrow}$ because this packet binds finite nonlinear modulus data, inverse-window readback, Gronwall/Osgood handoff, Real seal, transport, replay, provenance, and local naming into one integral-inequality certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BihariLaSalle}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BihariLaSalle}^{\uparrow}$ packet is generated from one interval row, one unknown-envelope row, one weight row, one Osgood-modulus row, one Gronwall/Osgood handoff row, one RegSeqRat readback row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BihariLaSalle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7183.1, Definition 7183.2, Definition 7183.3, and Definition 7183.4 seed the finite nonlinear integral-inequality packet over interval, envelope, coefficient, Osgood-modulus, inverse-window, readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BihariLaSalle}^{\uparrow}}, \mathsf{encodedDef})$

Bridge status: none

Not claimed: This chapter does not claim host nonlinear integral operators, selected inverse-modulus functions, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, analytic ODE continuation, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Osgood-modulus stability, Gronwall/Osgood handoff, inverse-window accounting, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BihariLaSalleUp.

Chapter 7184

A Concrete Naming Certificate for $\mathsf{RegularRealTailSelector}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularRealTailSelector}^{\uparrow}$ packet records the finite tail-selection surface used when a regular rational name is read through a terminal real-name seal. It sits over the dyadic tolerance core of chapter 291, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the equality-boundary discipline of chapter 1820. The packet selects a displayed finite tail window for one regular real-name read; it is not countable choice, quotient real equality, a representative selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7184.1 (Regular real tail selector carrier)**.** *A* $\mathsf{RegularRealTailSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, W, D, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the tail-threshold row naming the first index admitted for the regular real-name read.*
2. *W is the finite window row inspected beyond the displayed threshold.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the tail request.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected regular rational window.*
5. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, W, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the threshold, window, tolerance, readback, and seal rows.*
7. *C records displayed* Cont *replay of the same tail-selection route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularRealTailSelector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularRealTailSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, W, D, Q, A, H, C, P, N$. It has no coordinate for countable choice, quotient equality of real names, a selected representative, hidden completeness, or an external real-number selector.

Theorem 7184.2 (RegularRealTailSelector tail-window stability)**.** *Let $S = (T, W, D, Q, A, H, C, P, N)$ be an accepted* $\mathsf{RegularRealTailSelector}^{\uparrow}$ *carrier. Any read of the selected tail window is stable under the displayed* hsame *transports H and the displayed* Cont *replay C: the threshold row T, finite window W, dyadic tolerance D, regular rational readback Q, and real seal A remain in the same local packet. A transported read cannot replace these rows by countable choice, quotient real equality, a selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7184.1. The tail read is exhausted by $T, W, D, Q, A, H, C, P, N$, with T naming the threshold and W naming the finite window actually inspected.

Use the componentwise transport row H. It moves the threshold, window, tolerance, regular rational readback, and real seal together, so a transported read cannot keep the seal while changing the displayed tail data.

Replay is displayed through C and sourced by P. These rows keep the route inside the local $\mathsf{NameCert}_{\mathsf{RegularRealTailSelector}^{\uparrow}}$ packet. Since the carrier has no coordinate for countable choice, quotient real equality, selected representatives, or ambient completeness, the transported tail-window read remains stable only as finite packet data. □

Theorem 7184.3 (RegularRealTailSelector NameCert obligations)**.** *For every accepted* $\mathsf{RegularRealTailSelector}^{\uparrow}$ *carrier $S = (T, W, D, Q, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularRealTailSelector}^{\uparrow}}$ *surface consists of carrier admission, tail-window stability, regular readback through* $\mathsf{RegSeqRat}^{\uparrow}$*, Real-seal non-escape through* $\mathsf{Real}^{\uparrow}$*, componentwise transport, displayed replay, provenance, and local naming. The same surface refuses countable choice, quotient real equality, selected representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as available outputs.*

Proof. Carrier admission is the inventory of Definition 7184.1. The rows $T, W, D, Q, A, H, C, P, N$ are the complete local packet.

Tail-window stability is supplied by Definition 7184.2. The regular readback row Q is consumed only with the dyadic tolerance row D and the inspected window W, and the Real seal row A appears only after those rows have been displayed.

The non-escape clauses are inspection of the same carrier. No row is a countable-choice schedule, quotient equality over real names, representative selector, or ambient completeness theorem; therefore no accepted local read can export one. □

Falsifiable prediction: An accepted $\mathsf{RegularRealTailSelector}^{\uparrow}$ consumer is refuted if it reaches a Real seal before displaying the tail threshold, finite window, dyadic tolerance, RegSeqRat readback, hsame transport, Cont replay, provenance, and local NameCert rows.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-equivalence-setoid: $\mathsf{RegularRealTailSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a tail threshold, inspected finite window, dyadic tolerance, regular rational readback, Real seal, transport, replay, provenance, and local naming in one accepted tail-selection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealTailSelector}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularRealTailSelector}^{\uparrow}$ packet is generated from tail-threshold rows, finite window rows, DyadicRatCore tolerance rows, RegSeqRat readback, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularRealTailSelector}^{\uparrow}}$, seed)

Scope closed: Definition 7184.1, Definition 7184.2, and Definition 7184.3 seed the finite regular real tail-selection surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularRealTailSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient real equality, selected representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window stability, regular readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularRealTailSelectorUp.

Chapter 7185

A Concrete Naming Certificate for RegularCauchyDoubleLimitInterchange$^{\uparrow}$

Following Moore and Osgood, the RegularCauchyDoubleLimitInterchange$^{\uparrow}$ packet records the finite constructive data needed to compare two iterated regular Cauchy reads of a two-parameter rational grid. It sits over the dyadic tolerance core of chapter 291, the rectangular observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the scheduled two-axis route of chapter 460. The packet names a finite-window double-limit interchange surface; it does not assert quotient equality of arrays, select either iterated limit, use countable choice, or assume ambient completeness of Real$^{\uparrow}$.

Definition 7185.1 (Regular Cauchy double-limit interchange carrier)**.** *A* RegularCauchyDoubleLimitInterchange$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the two-parameter* RegSeqRat$^{\uparrow}$ *grid row, recording the row and column rational reads admitted by the packet.*
2. *W is the rectangular* StreamName$^{\uparrow}$ *window row, naming the finite row, column, and diagonal observation rectangles opened by an interchange request.*
3. *R is the row-column regularity ledger, recording the two iterated* RegSeqRat$^{\uparrow}$ *readback routes and their shared diagonal handoff.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *rectangle-budget row, carrying dyadic tolerances, slack cells, and comparison entries for every admitted rectangle.*
5. *E is the* Real$^{\uparrow}$ *seal row visible to downstream real consumers only after G, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for G, W, R, D, E and for replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route from rectangular windows and dyadic budgets to the two iterated readbacks and the shared seal.*
8. *P is the* Pkg *provenance over* RegularCauchyDoubleLimitInterchange$^{\uparrow}$*,* CauchyDoubleSequence$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $G, W, R, D, E, H, C, P, N$. It has no coordinate for a quotient double sequence, a selected row limit, a selected column limit, a global choice schedule, or an ambient real-completeness principle.

Theorem 7185.2 (Regular Cauchy double-limit interchange NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}$ *carrier*

$$I = (G, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed grid, window, readback, budget, seal, transport, replay, provenance, and naming rows;*
2. *classifier stability under componentwise transport of $G, W, R, D, E, H, C, P, N$;*
3. *rectangle stability saying that each row, column, and diagonal observation used by R is named by W and bounded by the dyadic ledger D;*
4. *diagonal handoff saying that the common diagonal read factors through the same scheduled window route as the underlying* $\mathsf{CauchyDoubleSequence}^{\uparrow}$ *packet;*
5. *nonescape for quotient arrays, selected iterated limits, countable choice, hidden real completeness, and bridge data.*

Proof. Project the carrier of Definition 7185.1. The rows $G, W, R, D, E, H, C, P, N$ are the full accepted packet, so carrier admission and classifier stability are componentwise on those rows.

Rectangle stability is read from the pair W, D. The window row names every finite row, column, and diagonal rectangle inspected by the two iterated readbacks, while the dyadic budget row supplies the visible tolerance and slack comparisons for those same rectangles.

The diagonal handoff uses the scheduled two-axis route of chapter 460. The packet can reuse the diagonal route only after the rectangular StreamName windows, RegSeqRat grid rows, and DyadicRatCore budget entries have been displayed.

The rows H, C, P, N preserve that route under transport, replay, provenance, and local naming. Since the carrier contains no quotient array, selected limit, choice schedule, hidden completeness field, or bridge row, the nonescape clauses follow from absence of those coordinates. □

Theorem 7185.3 (Regular Cauchy double-limit interchange consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}$ *packet first reads the finite route*

$$\mathsf{CauchyDoubleSequence}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The consumer receives a rectangular window comparison surface and a diagonal seal handoff, not a theorem of host double-limit convergence and not a selected value for either iterated limit.

Proof. Let $I = (G, W, R, D, E, H, C, P, N)$ be an accepted carrier. Any consumer first opens the rectangular StreamName windows W and dyadic budget D attached to the regular rational grid G.

The iterated readbacks and common diagonal handoff are then read from R. The seal row E becomes visible only after those finite rows have been displayed, so the Real-facing route is mediated by the same finite packet.

Transport and replay do not add coordinates: H is componentwise and C replays only the displayed rectangle-to-seal route. Thus the consumer boundary is exactly the listed dependency route and cannot export a host convergence theorem, a quotient array, or a selected iterated limit. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}$ read factors through a RegSeqRat grid row, rectangular StreamName window row, DyadicRatCore rectangle-budget row, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any Real-facing comparison is visible.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-double-sequence: none is bijective with $\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}$ because this packet alone binds rectangular finite windows, two iterated regular readbacks, a shared diagonal handoff, dyadic rectangle budgets, a Real seal, transport, replay, provenance, and local naming as one interchange carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}$ packet is generated from a two-parameter RegSeqRat grid, rectangular StreamName windows, dyadic rectangle budgets, two iterated readback routes, a shared diagonal handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7185.1, Definition 7185.2, and Definition 7185.3 seed the finite-window double-limit interchange packet over rectangular observations, regular rational grid rows, dyadic budgets, diagonal handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDoubleLimitInterchange}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of arrays, selected row or column limits, countable choice, host double-limit convergence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, rectangle stability, diagonal handoff, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyDoubleLimitInterchangeUp.

Chapter 7186

A Concrete Naming Certificate for $\mathsf{FiniteKernelClosureGate}^{\uparrow}$

The $\mathsf{FiniteKernelClosureGate}^{\uparrow}$ packet concretizes the closure-admission discipline of chapter 9459. It binds a candidate kernel surface to the finite rows that decide whether an AI-origin chapter may report closure: a TasteGate admission row, a closure-status reference row, an axiom-purity audit row, transport, replay, provenance, and local naming. The packet is a gate over displayed evidence, not a semantic approval oracle, not a proof of the candidate theorem, and not a bridge checker.

The finite gate consumes the admission row of chapter 545, the closure-ledger row of chapter 1265, and the dependency-purity row of chapter 1259 before a closure-admission decision is visible. Those siblings supply the displayed evidence read by A, S, Q; this packet only binds them into the finite kernel gate surface.

Definition 7186.1 (Finite kernel closure gate carrier)**.** *A* $\mathsf{FiniteKernelClosureGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, A, S, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the candidate kernel-surface row, recording the chapter label, origin row, finite carrier surface, and requested closure grade.*
2. *A is the consumed* $\mathsf{TasteGateAdmission}^{\uparrow}$ *row, exposing the candidate's ChapterTasteGate admission evidence and refused-case ledger.*
3. *S is the consumed* $\mathsf{ClosureStatusReference}^{\uparrow}$ *row, recording the current theory-closure grade, formal-status grade, bridge status, not-claimed surface, and next-grade route.*
4. *Q is the consumed* $\mathsf{AxiomPurityGate}^{\uparrow}$ *row, recording the finite dependency audit and forbidden-dependency refusal surface for the candidate target.*
5. *F is the field ledger for the gate itself, listing which visible fields of X, A, S, Q are read by closure admission and which fields remain outside the gate.*
6. *H records componentwise* hsame *transport for X, A, S, Q, F and for replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the route from candidate surface through admission evidence, closure-status reference, axiom-purity audit, and field ledger.*

8. *P is the* Pkg *provenance over* $\mathsf{FiniteKernelClosureGate}^{\uparrow}$, $\mathsf{TasteGateAdmission}^{\uparrow}$, $\mathsf{ClosureStatusReference}^{\uparrow}$, $\mathsf{AxiomPurityGate}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteKernelClosureGate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, A, S, Q, F, H, C, P, N$. It has no coordinate for hidden prompt state, host-side approval, theorem truth, bridge checking, global horizon admission, or a closure grade stronger than the displayed status row.

Theorem 7186.2 (Finite kernel closure gate NameCert obligations)**.** *For every accepted* $\mathsf{FiniteKernelClosureGate}^{\uparrow}$ *carrier*

$$K = (X, A, S, Q, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteKernelClosureGate}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; classifier stability under componentwise transport of $X, A, S, Q, F, H, C, P, N$; TasteGate-admission exposure through A; closure-status reference exposure through S; axiom-purity exposure through Q; field-ledger exactness through F; displayed replay through C; provenance through P; local naming through N; and nonescape for hidden prompt state, host-side approval, theorem truth, bridge checking, and unreported closure strength.*

Proof. Project the carrier of Definition 7186.1. The finite packet exposes exactly the candidate surface, admission row, closure-status row, axiom-purity row, field ledger, transport row, replay row, provenance row, and local naming row.

The admission, status, and audit obligations are read from A, S, Q. The row A supplies the TasteGate admission surface, S supplies the two-axis closure-status reference, and Q supplies the forbidden-dependency audit surface.

The field ledger F records which visible fields the gate reads. Transport through H and replay through C preserve those fields componentwise, while P and N record source and local naming.

Since the carrier has no hidden prompt, host approval, theorem-truth, bridge-checking, global-admission, or stronger-status coordinate, no consumer can extract one from the accepted gate packet. □

Theorem 7186.3 (Finite kernel closure gate TasteGate expectation)**.** *A future Lean realization of* $\mathsf{FiniteKernelClosureGate}^{\uparrow}$ *must expose a nontrivial carrier and a field-faithful carrier: the nontrivial witness separates an accepted gate row from a refused gate row, and the field-faithful witness proves that equality of the displayed rows $X, A, S, Q, F, H, C, P, N$ determines equality of the carrier token. These are TasteGate expectations for the finite gate surface, not paper claims that the Lean declarations already exist.*

Proof. The carrier in Definition 7186.1 has visible admission and refusal branches because A and S record accepted and refused gate reads and Q records forbidden-dependency refusals. A nontrivial Lean instance should therefore choose one accepted row and one refused row from that displayed surface.

Field faithfulness is also determined by the displayed carrier. The rows $X, A, S, Q, F, H, C, P, N$ are the entire classifier surface, so a Lean proof may compare carriers by projecting and comparing exactly those fields.

The theorem records only this expected shape. Until those Lean declarations are present, the paper chapter remains at seed closure and does not add a Lean marker. □

Falsifiable prediction: Every accepted $\mathsf{FiniteKernelClosureGate}^{\uparrow}$ report factors through a TasteGateAdmission row, ClosureStatusReference row, AxiomPurityGate row, finite field ledger, com-

ponentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any closure-admission decision is visible.

Independence witness: tastegateadmission, closurestatusreference, axiompuritygate, namecert: none is bijective with $\mathsf{FiniteKernelClosureGate}^{\uparrow}$ because this packet alone binds candidate closure request, TasteGate admission, closure-status reference, axiom-purity audit, gate-local field ledger, transport, replay, provenance, and local naming as one finite closure-admission carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteKernelClosureGate}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{FiniteKernelClosureGate}^{\uparrow}$ packet is generated from a candidate kernel-surface row, a TasteGateAdmission row, a ClosureStatusReference row, an AxiomPurityGate row, a gate-local field ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteKernelClosureGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7186.1, Definition 7186.2, and Definition 7186.3 seed the finite closure-admission gate over TasteGate admission, closure-status reference, axiom-purity audit, field ledger, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteKernelClosureGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove the candidate theorem, certify host semantics, close bridge checking, assert a Lean declaration, or authorize closure stronger than the displayed status and audit rows.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, TasteGate-admission exposure, closure-status exposure, axiom-purity exposure, field-ledger exactness, nonescape, and TasteGate nontrivial and field-faithful instances for BEDC.Derived.FiniteKernelClosureGateUp.

Chapter 7187

A Concrete Naming Certificate for $\mathsf{AbelDirichletTest}^{\uparrow}$

Following Abel, Dirichlet, and Hardy-style summation tests, the $\mathsf{AbelDirichletTest}^{\uparrow}$ packet records the combined convergence-test surface in which an Abel summation row, an Abel-test face, and a Dirichlet-test face share one completion-facing tail route. It sits beside the summation-by-parts certificate of chapter 1763, the Abel-test certificate of chapter 1496, the Dirichlet-test certificate of chapter 1497, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the comparison packet of chapter 2230. The packet is a finite naming certificate for the shared Abel–Dirichlet convergence route; it is not a selected infinite sum, a quotient equality of series streams, a countable-choice selector, an order-trichotomy principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7187.1 (Abel–Dirichlet test carrier)**.** *An* $\mathsf{AbelDirichletTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, A, B, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source series row, exposing only the finite term and partial-sum windows read by the test.*
2. *A is the* $\mathsf{AbelSummation}^{\uparrow}$ *row, carrying the finite summation-by-parts window and boundary-term data.*
3. *B is the* $\mathsf{AbelTest}^{\uparrow}$ *face row, exposing the bounded partial-sum, monotone null coefficient, and Abel tail ledger visible to the combined packet.*
4. *D is the* $\mathsf{DirichletTest}^{\uparrow}$ *face row, exposing the bounded partial-sum, coefficient-window, null-tail, and Dirichlet tail-schedule rows visible to the combined packet.*
5. *Q is the* $\mathsf{AbelDirichletComparison}^{\uparrow}$ *row, forcing the two test faces to meet at one displayed comparison and shared-tail request before readback.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed source, summation, test-face, and comparison windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after S, A, B, D, Q, R have been displayed.*
8. *H records componentwise* hsame *transport for the source, summation, Abel face, Dirichlet face, comparison, readback, endpoint, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the finite route*

$$S \longmapsto A \longmapsto B, D \longmapsto Q \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{AbelDirichletTest}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{AbelDirichletComparison}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelDirichletTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven displayed rows. It has no coordinate for a selected infinite sum, quotient series equality, countable choice, trichotomy, or ambient real completeness.

Theorem 7187.2 (Abel–Dirichlet test NameCert obligations)**.** *For every accepted* $\mathsf{AbelDirichletTest}^{\uparrow}$ *carrier $T = (S, A, B, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbelDirichletTest}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed eleven-row packet;*
2. *source-window exposure through S;*
3. *Abel summation exposure through A, preserving the finite summation-by-parts and boundary-term rows;*
4. *Abel-test face exposure through B, preserving the bounded partial-sum, monotone null coefficient, and tail ledger rows;*
5. *Dirichlet-test face exposure through D, preserving the bounded partial-sum, coefficient-window, null-tail, and tail-schedule rows;*
6. *comparison exactness through Q, requiring the two test faces to meet at the displayed* $\mathsf{AbelDirichletComparison}^{\uparrow}$ *row before completion-facing readback;*
7. $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *endpoint exposure through R and E;*
8. *componentwise transport, displayed replay, provenance, and local naming through exactly H, C, P, N.*

No NameCert obligation is stored outside those rows.

Lean4 ✓ `BEDC.Derived.AbelDirichletTestUp.AbelDirichletTestTasteGate single carrier alignment`

Proof. Project the accepted carrier of Definition 7187.1. The source, summation, test-face, comparison, readback, endpoint, transport, replay, provenance, and local naming rows are exactly the coordinates of T.

Read the analytic rows in order. The Abel summation row A supplies the finite summation-by-parts window. The Abel face B and Dirichlet face D then contribute their displayed bounded-partial-sum and tail-control data.

The common convergence-test obligation is the row Q. It forces the two faces to pass through the existing Abel–Dirichlet comparison surface before R and E can be read by a completion-facing consumer.

Finally read H, C, P, N. These structural rows transport, replay, source, and name the same finite route, so the listed obligations exhaust the local certificate surface. □

Theorem 7187.3 (Abel–Dirichlet test tail handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{AbelDirichletTest}^{\uparrow}$ *carrier must factor through*

$$S \longmapsto A \longmapsto B, D \longmapsto Q \longmapsto R \longmapsto E$$

together with H, C, P, N. Thus the combined Abel–Dirichlet test exports one finite tail handoff to Real-and-Completion consumers, not two independent informal convergence claims.

Proof. Start with a completion-facing read. The source row S is the only source entry point, so the consumer first sees only the displayed finite term and partial-sum windows.

The summation row A supplies the shared Abel summation-by-parts data. The Abel-test face B and Dirichlet-test face D may then be read, but neither face can export a real endpoint directly from this carrier.

The comparison row Q is the unique handoff from the two test faces to later regular readback. Therefore R and E are public only after the displayed Abel–Dirichlet comparison route has been read.

Transport, replay, provenance, and local naming through H, C, P, N preserve that same route. Since the carrier has no excluded host-side coordinate, no consumer can bypass the finite tail handoff. □

Falsifiable prediction: An accepted $\mathsf{AbelDirichletTest}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, or downstream summability handoff without first reading the source row, $\mathsf{AbelSummation}^{\uparrow}$ row, $\mathsf{AbelTest}^{\uparrow}$ face, $\mathsf{DirichletTest}^{\uparrow}$ face, and $\mathsf{AbelDirichletComparison}^{\uparrow}$ row refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, abel-dirichlet-comparison, regseqrat, real: no listed sibling supplies the whole combined packet $T = (S, A, B, D, Q, R, E, H, C, P, N)$, because each sibling contributes only a summation row, a test face, a comparison handoff, a readback, or a seal while this chapter binds them as one finite convergence-test certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelDirichletTest}^{\uparrow}}$.

Constructive story: An $\mathsf{AbelDirichletTest}^{\uparrow}$ packet is generated from source windows, an $\mathsf{AbelSummation}^{\uparrow}$ summation-by-parts row, $\mathsf{AbelTest}^{\uparrow}$ and $\mathsf{DirichletTest}^{\uparrow}$ face rows, an $\mathsf{AbelDirichletComparison}^{\uparrow}$ shared-tail row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelDirichletTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7187.1, Definition 7187.2, and Definition 7187.3 seed the finite combined convergence-test surface over $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{AbelDirichletComparison}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelDirichletTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, quotient series equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Abel summation exposure, Abel and Dirichlet face exposure, comparison exactness, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AbelDirichletTestUp.

Chapter 7188

A Concrete Naming Certificate for $\mathsf{ResidualSet}^{\uparrow}$

Following Baire, Oxtoby, and Bishop–Bridges, the $\mathsf{ResidualSet}^{\uparrow}$ packet records the positive side of a constructive Baire argument: a residual evidence carrier is accepted only when the dense-open schedule and the meagre-complement ledger are both displayed as finite BEDC rows. It sits beside the meagre-set carrier of chapter 2267, the nowhere-dense component carrier of chapter 4186, the dense-open schedule of chapter 6670, and the Baire-category theorem packet of chapter 3570. The packet names residual evidence; it does not choose a generic point, assert arbitrary countable intersections, or import a host category theorem.

Definition 7188.1 (ResidualSet carrier)**.** *A* $\mathsf{ResidualSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, D, M, N, B, H, C, P, L)$$

with the following displayed rows:

1. *T is the ambient topology or complete-metric context in which the residual read is made.*
2. *D is the* $\mathsf{BaireDenseOpen}^{\uparrow}$ *dense-open schedule row whose finite requests are visible to the Baire argument.*
3. *M is the* $\mathsf{MeagreSet}^{\uparrow}$ *complement ledger, decomposed through the* $\mathsf{NowhereDense}^{\uparrow}$ *component rows named by the meagre packet.*
4. *N records the nowhere-dense component interface read from chapter 4186.*
5. *B is the* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *handoff row certifying that the displayed dense-open and meagre-complement evidence are the rows consumed by the Baire route.*
6. *H stores componentwise* hsame *transport for T, D, M, N, B, C, P, L.*
7. *C stores displayed* Cont *replay of the dense-open schedule, meagre-complement ledger, Baire handoff, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{ResidualSet}^{\uparrow}$, $\mathsf{BaireDenseOpen}^{\uparrow}$, $\mathsf{MeagreSet}^{\uparrow}$, $\mathsf{NowhereDense}^{\uparrow}$, $\mathsf{BaireCategoryTheorem}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{ResidualSet}^{\uparrow}}$ *row.*

The carrier has no coordinate for a chosen generic point, an unrestricted set-theoretic complement, a host countable-intersection principle, or a classical comeagre-subset theorem outside the displayed BEDC rows.

Theorem 7188.2 (ResidualSet Baire handoff)**.** *Every accepted* $\mathsf{ResidualSet}^{\uparrow}$ *packet read by a Baire-category consumer factors through the displayed dense-open schedule* D*, meagre-complement ledger* M*, nowhere-dense component interface* N*, and Baire handoff row* B*. Thus a residual conclusion is handed to downstream constructive Baire arguments only as the positive face of the same finite evidence that records the meagre complement.*

Proof. Project the carrier of Definition 7188.1. The only analytic rows are the dense-open schedule, meagre-complement ledger, nowhere-dense component interface, and Baire handoff.

Read the sibling packets in order. chapter 6670 supplies the finite dense-open requests, chapter 2267 supplies the complement ledger, and chapter 4186 supplies the component interface used by that ledger.

The Baire-category row B can therefore export residual evidence only through those displayed rows. Since R has no coordinate for a selected generic point or host countable intersection, the handoff is the finite BEDC residual carrier and nothing stronger. □

Theorem 7188.3 (ResidualSet NameCert obligations)**.** *For every accepted* $\mathsf{ResidualSet}^{\uparrow}$ *carrier* $R = (T, D, M, N, B, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{ResidualSet}^{\uparrow}}$ *surface consists exactly of ambient context admission through* T*, dense-open schedule exposure through* D*, meagre-complement exposure through* M*, nowhere-dense component visibility through* N*, Baire-category handoff through* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* L*.*

Proof. Inspect the displayed tuple. Each accepted row of the residual packet is one of $T, D, M, N, B, H, C, P, L$, and the structural rows only transport, replay, source, and name those coordinates.

The negative side is exhausted by M and N: the meagre ledger supplies the complement surface, while the nowhere-dense component rows record the finite decomposition interface consumed by that ledger. The positive side is exhausted by D and B: the dense-open schedule supplies the Baire requests and the Baire-category handoff records the route by which the residual read reaches a consumer.

No listed coordinate stores a generic point, an arbitrary complement, or a host countable-intersection theorem. The local NameCert obligations are therefore precisely the displayed rows and their structural support. □

Theorem 7188.4 (ResidualSet dense G-delta boundary)**.** *Every accepted* $\mathsf{ResidualSet}^{\uparrow}$ *packet whose dense-open schedule and meagre-complement ledger are displayed through a* $\mathsf{DenseGDelta}^{\uparrow}$ *carrier factors through chapter 7204, chapter 3547, chapter 1542, and chapter 3570 before a residual consumer reads the positive side.*

Proof. Project the carrier of Definition 7188.1 as $R = (T, D, M, N, B, H, C, P, L)$. The residual packet exposes its dense-open schedule through D, its meagre-complement ledger through M, its nowhere-dense interface through N, and its Baire handoff through B.

When the positive side is displayed through a $\mathsf{DenseGDelta}^{\uparrow}$ carrier, read that carrier's D, M, N, B-facing route as the corresponding countable open schedule, dense-open schedule, Baire route, and residual handoff. The route first passes through the dense G_δ certificate, then through the $\mathsf{GDeltaSet}^{\uparrow}$ schedule, then through the Baire-category surface, and then through the Baire-category theorem packet.

The consumer therefore receives residual evidence only after the positive dense-open face has been displayed. No step chooses a generic point, forms a host intersection, imports countable choice, or identifies quotient sets outside the displayed BEDC rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{ResidualSet}^{\uparrow}}$.

Constructive story: A $\mathsf{ResidualSet}^{\uparrow}$ packet is generated from ambient topology or complete-metric context rows, a $\mathsf{BaireDenseOpen}^{\uparrow}$ schedule, a $\mathsf{MeagreSet}^{\uparrow}$ complement ledger, $\mathsf{NowhereDense}^{\uparrow}$ component rows, a $\mathsf{BaireCategoryTheorem}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ResidualSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7188.1, Definition 7188.2, and Definition 7188.3 bind the residual evidence carrier to the displayed Baire dense-open, meagre-complement, nowhere-dense, and Baire-category rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ResidualSet}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close generic-point choice, arbitrary countable intersections, unrestricted set-theoretic complements, host category theorems, or a Lean carrier for $\mathsf{ResidualSet}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exposure, meagre-complement exactness, nowhere-dense component visibility, Baire handoff, transport, replay, provenance, and local naming for the displayed residual evidence packet.

Chapter 7189

A Concrete Naming Certificate for CompactUniformLocalToGlobalModulus$^{\uparrow}$

Following Bishop–Bridges compact metric analysis, the CompactUniformLocalToGlobalModulus$^{\uparrow}$ packet records the finite local-to-global route that turns compact finite-net coverage and local pointwise modulus rows into a tolerance-only UniformModulus$^{\uparrow}$ handoff. It realizes the compact finite-net lower-bound route of chapter 9237 through the compact carrier of chapter 60, the compact-metric finite-net surface of chapter 129, the continuous-map rows of chapter 130, the rational lower-bound fold of chapter 619, the metric-triangle estimate of chapter 1159, and the uniform-modulus consumer row of chapter 369. The packet is finite NameCert data; it is not an open-cover compactness principle, a selected global minimum outside the fold, or a host modulus function.

Definition 7189.1 (CompactUniformLocalToGlobalModulus carrier)**.** *A* CompactUniformLocalToGlobalModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, L, R, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-net row, including the compact source and the finite* ProbeBundle *coverage surface.*
2. *F is the* ContinuousMap$^{\uparrow}$ *local pointwise-modulus row read at the bundled centers.*
3. *L is the local-radius ledger that ties each bundled center to its pointwise modulus request.*
4. *R is the* Rat$^{\uparrow}$ *lower-bound fold row over the finite radius ledger.*
5. *T is the metric-triangle row that transports local estimates from centers to arbitrary source points.*
6. *U is the resulting* UniformModulus$^{\uparrow}$ *consumer handoff.*
7. *H stores componentwise* hsame *transport for $K, F, L, R, T, U, C, P, N$.*
8. *C stores displayed* Cont *replay of compact-net extraction, local-modulus reading, lower-bound folding, metric-triangle transport, uniform-modulus export, provenance, and local naming.*
9. *P is the* Pkg *provenance over* CompactUniformLocalToGlobalModulus$^{\uparrow}$, Compact$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Rat$^{\uparrow}$, FiniteNetMinimumFold$^{\uparrow}$, MetricTriangleUniformEstimate$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, ProbeBundle, hsame, Cont, Pkg, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformLocalToGlobalModulus}^{\uparrow}}$ *row.*
The carrier has no coordinate for open-cover compactness, countable choice, a selected minimum outside the finite fold, quotient function equality, or an ambient Heine–Cantor theorem.

Lean4 ✓ `BEDC.Derived.CompactUniformLocalToGlobalModulusUp.CompactUniformLocalToGlobalModulusTasteGate`
`single carrier alignment`

Theorem 7189.2 (CompactUniformLocalToGlobalModulus obligations)**.** *For every accepted* CompactUniformLoca *carrier $G = (K, F, L, R, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformLocalToGlobalModulus}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, local pointwise-modulus exposure through F, local-radius ledger visibility through L, rational lower-bound fold exactness through R, metric-triangle transport through T, uniform-modulus export through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The compact side is exhausted by K: it supplies the finite ProbeBundle coverage row over the compact metric source.

The local side is exhausted by F and L. These rows record the pointwise modulus read at each bundled center and the radius ledger attached to that read. The global precision row is then computed only by R, the finite rational lower-bound fold over the displayed ledger.

The handoff to a consumer uses T and U. The metric-triangle row transports center estimates to arbitrary source points, and the uniform-modulus row records the tolerance-only output. Since H, C, P, N only preserve, replay, source, and name the displayed rows, the listed obligations exhaust the packet. □

Theorem 7189.3 (CompactUniformLocalToGlobalModulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read exported by an accepted* $\mathsf{CompactUniformLocalToGlobalModulus}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{FiniteNetMinimumFold}^{\uparrow} \longmapsto \mathsf{MetricTriangleUniformEstimate}^{\uparrow} \longmapsto$$

In particular, the exported modulus is a finite lower-bound and metric-triangle handoff, not a host-selected modulus or an open-cover compactness theorem.

Proof. Read the carrier rows in order. The compact metric row K supplies the finite net, and the continuous-map row F supplies local pointwise-modulus evidence at the bundled centers.

The local radii do not become a global modulus until the rational fold row R is displayed. This row is finite because it folds over the ProbeBundle ledger named by K and the local-radius row L.

Finally the metric-triangle row T is the only row that transports the local estimates to arbitrary source points, and U is the only uniform-modulus consumer row. No coordinate in G stores open-cover compactness, countable choice, or a host-selected modulus, so every accepted handoff remains on the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformLocalToGlobalModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformLocalToGlobalModulus}^{\uparrow}$ packet is generated from compact finite-net rows, continuous-map local modulus rows, local-radius ledgers, a RatUp lower-bound fold, metric-triangle transport, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformLocalToGlobalModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7189.1, Definition 7189.2, and Definition 7189.3 bind the compact finite-net, local-modulus, RatUp fold, metric-triangle, and UniformModulus rows of the local-to-global route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformLocalToGlobalModulus}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CompactUniformLocalToGlobalModulusUp.CompactUniformLocalToGlobalModulusTasteGate\_singl`
Bridge status: none
Origin: human
Not claimed: This chapter does not close open-cover compactness, selected global minima outside the finite fold, countable choice, quotient function equality, ambient Heine–Cantor semantics, or a Lean carrier for CompactUniformLocalToGlobalModulus$^{\uparrow}$.
Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, local-modulus exposure, lower-bound fold exactness, metric-triangle transport, uniform-modulus export, replay, provenance, and local naming for the displayed local-to-global packet.

Chapter 7190

A Concrete Naming Certificate for $\mathsf{LocatedCauchyLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedCauchyLimit}^{\uparrow}$ packet records the finite located-limit boundary that sits between regular Cauchy readback and the terminal real-name seal. It reads StreamName windows from chapter 126, RegSeqRat readback from chapter 301, dyadic tolerance ledgers from chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal from chapter 38, and uniqueness discipline from chapter 3942. The packet names a located candidate-limit route; it does not assert quotient completion, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7190.1 (LocatedCauchyLimit carrier)**.** *A* $\mathsf{LocatedCauchyLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, T, L_0, U, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the Cauchy source stream.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare requested precision with the displayed rational windows.*
4. *T is the located tail schedule, recording the finite threshold and neighbourhood data that make the candidate limit inspectable.*
5. *L_0 is the candidate-limit row consumed by the terminal real-name seal.*
6. *U is the uniqueness boundary, read through* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *before any two candidate-limit rows are classified together.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed candidate limit.*
8. *H records componentwise* hsame *transport for all displayed rows.*
9. *C records displayed* Cont *replay from stream windows through readback, tolerance, located tail schedule, candidate limit, uniqueness boundary, real seal, provenance, and naming.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyLimit}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient limits, selected representatives, countable-choice schedules, host real equality, arbitrary completion objects, or ambient real completeness.

Lean4 (statement) `BEDC.Derived.LocatedCauchyLimitUp`

Theorem 7190.2 (LocatedCauchyLimit NameCert obligations)**.** *For an accepted* $\mathsf{LocatedCauchyLimit}^{\uparrow}$ *carrier* $L = (S, R, D, T, L_0, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyLimit}^{\uparrow}}$ *surface consists exactly of StreamName window exposure, RegSeqRat readback exposure, DyadicRatCore tolerance comparison, located tail schedule admission, candidate-limit row admission, uniqueness-boundary routing, terminal RealUp sealing, componentwise transport, displayed replay, provenance, and local naming. No obligation is stored outside* $S, R, D, T, L_0, U, E, H, C, P, N$*.*

Proof. Project the accepted carrier. The analytic rows are S, R, D, T, L_0, U, E, and the structural rows are H, C, P, N.

The source route is forced by the carrier order: stream windows are read by S, regular rational data by R, and dyadic tolerance comparison by D. The located tail schedule T is the only row that can expose the neighbourhood threshold needed by the candidate-limit row L_0.

The uniqueness row U and the terminal seal E are downstream of the candidate-limit row. Transport, replay, provenance, and naming preserve exactly this finite route.

Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7190.3 (LocatedCauchyLimit RegSeqRat route)**.** *Every accepted* $\mathsf{LocatedCauchyLimit}^{\uparrow}$ *read reaches a candidate-limit row only through the finite route*

$$\mathsf{StreamName}^{\uparrow}(S) \longmapsto \mathsf{RegSeqRat}^{\uparrow}(R) \longmapsto \mathsf{DyadicRatCore}^{\uparrow}(D) \longmapsto T \longmapsto L_0.$$

The route then passes through the uniqueness boundary U and the terminal $\mathsf{Real}^{\uparrow}$ *seal E before any consumer reads H, C, P, N.*

Proof. Read S first. It is the only stream-window source in the carrier, so a regular rational readback cannot bypass it.

The row R is then compared against the requested precision by the dyadic ledger D. The located schedule T records the finite tail threshold that lets the candidate-limit row L_0 be inspected.

The remaining analytic rows U and E place uniqueness and terminal real-name sealing after the candidate-limit read. The structural rows preserve the same route and add no second source. □

Theorem 7190.4 (LocatedCauchyLimit nonescape)**.** *No accepted* $\mathsf{LocatedCauchyLimit}^{\uparrow}$ *packet exports quotient completion, selected representatives, countable choice, host real equality, arbitrary completion data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every completion-facing consumer receives only* $S, R, D, T, L_0, U, E, H, C, P, N$*.*

Proof. Apply Definition 7190.2. It identifies the full local obligation surface as the displayed finite rows.

Apply Definition 7190.3. It orders the analytic source rows before the candidate-limit, uniqueness, and RealUp seal rows.

The carrier definition has no field for the excluded objects. Thus transport, replay, provenance, and naming cannot synthesize them for a completion-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchyLimit}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledgers, a located tail schedule, candidate-limit row, uniqueness boundary, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7190.1, Definition 7190.2, Definition 7190.3, and Definition 7190.4 seed the finite located Cauchy limit route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, arbitrary completion objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, RegSeqRat route exactness, uniqueness-boundary routing, terminal RealUp seal routing, and nonescape for BEDC.Derived.LocatedCauchyLimitUp.

Chapter 7191

A Concrete Naming Certificate for $\mathsf{EisensteinCriterion}^{\uparrow}$

Following Eisenstein's irreducibility criterion, the $\mathsf{EisensteinCriterion}^{\uparrow}$ packet records a finite prime-divisibility route for a displayed polynomial before any irreducibility-facing consumer may use it. It sits over the polynomial carrier of chapter 50, the ring carrier of chapter 43, the integer row of chapter 31, and the prime row of chapter 64. The packet names coefficient inspection, prime divisibility, primitive-content control, and irreducibility handoff as displayed BHist and $\mathsf{NameCert}$ data; it is not a host factorization oracle, a quotient polynomial equality, a selected algebraic root, or an ambient unique-factorization theorem.

Definition 7191.1 (Eisenstein criterion carrier)**.** *An* $\mathsf{EisensteinCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, p, V, L, Q, G, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the polynomial coefficient window, listing the finitely many inspected coefficients of the displayed* $\mathsf{Poly}^{\uparrow}$ *row over the* $\mathsf{Ring}^{\uparrow}$ *and* $\mathsf{Int}^{\uparrow}$ *interfaces.*
2. *p is the displayed* $\mathsf{Prime}^{\uparrow}$ *row naming the prime used by the divisibility test.*
3. *V is the divisibility ledger requiring every non-leading coefficient inspected by F to be divisible by p.*
4. *L is the leading-coefficient nondivisibility row, recording that the leading coefficient is not divisible by p.*
5. *Q is the constant-coefficient square-nondivisibility row, recording that p^2 does not divide the constant coefficient.*
6. *G is the primitive-content boundary, exposing the displayed content data needed before irreducibility may be read.*
7. *I is the irreducibility handoff row, available only after F, p, V, L, Q, G have been displayed.*
8. *H records componentwise* hsame *transport for the coefficient, prime, divisibility, nondivisibility, content, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the coefficient window through the prime-divisibility route and the irreducibility handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{EisensteinCriterion}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EisensteinCriterion}^{\uparrow}}$ *row.*

The carrier exposes only the polynomial coefficient window, displayed prime, divisibility ledger, leading nondivisibility, constant square-nondivisibility, primitive-content boundary, irreducibility handoff, transport, replay, provenance, and local naming. It has no coordinate for host factorization, quotient polynomial equality, selected roots, ambient unique factorization, or algebraic-closure reasoning.

Theorem 7191.2 (Eisenstein criterion NameCert obligations)**.** *For every accepted* $\mathsf{EisensteinCriterion}^{\uparrow}$ *carrier*

$$E = (F, p, V, L, Q, G, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EisensteinCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the coefficient window, prime row, divisibility ledger, nondivisibility rows, primitive-content boundary, irreducibility handoff, transport, replay, provenance, and local name;*
2. *coefficient-window exactness, requiring F to expose the inspected polynomial coefficients through the* $\mathsf{Poly}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, *and* $\mathsf{Int}^{\uparrow}$ *rows;*
3. *prime-row exactness, requiring the divisibility ledger to read the displayed* $\mathsf{Prime}^{\uparrow}$ *row p;*
4. *divisibility exactness, requiring V to cover every non-leading coefficient and no coefficient outside the displayed window;*
5. *leading and constant boundary checks, requiring L and Q to record respectively leading nondivisibility and constant square-nondivisibility;*
6. *primitive-content routing, requiring G to be displayed before the irreducibility handoff I is consumed;*
7. *structural stability through H, C, P, N for the same finite rows;*
8. *refusal of host factorization, quotient polynomial equality, selected roots, ambient unique factorization, and algebraic-closure reasoning as local certificate data.*

No Eisenstein criterion obligation is stored outside these rows.

Proof. Project the carrier of Definition 7191.1. The visible rows are exactly $F, p, V, L, Q, G, I, H, C, P, N$, so carrier admission and local naming can mention no further algebraic data.

The coefficient and prime obligations are read first. The row F supplies the displayed polynomial coefficients through the polynomial, ring, and integer interfaces, while p supplies the displayed prime row used by all divisibility checks.

The local divisibility surface is then exhausted by V, L, Q. The row V covers the non-leading coefficients, L covers the leading coefficient, and Q covers the constant coefficient against p^2.

Finally G must be displayed before I, and H, C, P, N only transport, replay, source, and name the same route. Since the excluded host principles do not occur as carrier coordinates, they cannot discharge a local NameCert obligation. □

Theorem 7191.3 (Eisenstein criterion prime-divisibility route)**.** *Every irreducibility-facing consumer of an accepted* $\mathsf{EisensteinCriterion}^{\uparrow}$ *carrier*

$$E = (F, p, V, L, Q, G, I, H, C, P, N)$$

must read the finite route

$$F, p \longmapsto V, L, Q \longmapsto G \longmapsto I \longmapsto H, C, P, N$$

before any irreducibility handoff is exported. Thus the consumer receives the coefficient window, displayed prime, non-leading divisibility ledger, leading nondivisibility row, constant square-nondivisibility row, and primitive-content boundary before it can inspect the handoff row.

Proof. Start with an irreducibility-facing read of the row I. By Definition 7191.1, the row I has no independent source of polynomial or prime data; it is downstream of F, p, V, L, Q, G.

Apply Definition 7191.2. The certificate obligations force the coefficient window and prime row to be exposed before the divisibility ledger, force the leading and constant boundary rows to be exposed beside that ledger, and force the primitive-content row before the handoff.

The structural rows do not insert a second handoff. The rows H, C, P, N preserve and name the same finite route, so any irreducibility-facing consumer reads only the displayed coefficient, prime, divisibility, nondivisibility, content, and handoff rows.

Because the carrier contains no host factorization oracle, quotient polynomial equality, selected root, ambient unique-factorization theorem, or algebraic-closure coordinate, none of those principles can be exported with the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{EisensteinCriterion}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EisensteinCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7191.1, Definition 7191.2, and Definition 7191.3 seed the finite prime-divisibility certificate over polynomial coefficients, a displayed prime, divisibility and nondivisibility ledgers, primitive-content routing, irreducibility handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EisensteinCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host factorization, quotient polynomial equality, selected roots, ambient unique factorization, algebraic-closure reasoning, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-window exactness, prime-row exactness, divisibility exactness, primitive-content routing, structural stability, and local naming for BEDC.Derived.EisensteinCriterionUp.

Constructive story: An $\mathsf{EisensteinCriterion}^{\uparrow}$ packet is generated from a polynomial coefficient window, displayed prime row, non-leading divisibility ledger, leading nondivisibility row, constant square-nondivisibility row, primitive-content boundary, irreducibility handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7192

A Concrete Naming Certificate for $\mathsf{CauchyRealModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{CauchyRealModulus}^{\uparrow}$ packet records a real-name carrier whose convergence evidence is an explicit modulus row rather than a host completeness principle. It sits between the dyadic tolerance core of chapter 291, the stream schedule of chapter 126, the regular rational-name surface of chapter 301, and the real-seal boundary of chapter 38. The packet gives downstream completion consumers a finite place to cite the modulus evidence attached to a Cauchy real name; it does not select a limit, quotient streams, or import countable choice.

Definition 7192.1 (CauchyRealModulus carrier)**.** *A* $\mathsf{CauchyRealModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, D, \mu, Q, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *schedule whose finite windows are available to a real-name consumer.*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row reading the rational approximants through the displayed stream schedule.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the regular-name comparisons.*
4. μ *is the modulus row assigning each displayed dyadic tolerance request to a visible stream window.*
5. Q *is the Cauchy coherence classifier, comparing accepted packets only through* S, R, D, μ.
6. H *stores componentwise* hsame *transport for* S, R, D, μ, Q, C, P, N.
7. C *stores displayed* Cont *replay of the stream schedule, regular rational readback, dyadic tolerance ledger, modulus row, coherence classifier, provenance, and local naming.*
8. P *is the* Pkg *provenance over* $\mathsf{CauchyRealModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected real limit, host real equality, quotient-stream equality, ambient completeness, or countable choice.

Theorem 7192.2 (CauchyRealModulus obligation surface)**.** *For every accepted* $\mathsf{CauchyRealModulus}^{\uparrow}$ *carrier* $M = (S, R, D, \mu, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealModulus}^{\uparrow}}$ *surface consists exactly of stream-window admission through* S*, regular rational-name exposure through* R*, dyadic tolerance exposure through* D*, explicit modulus visibility through* μ*, Cauchy coherence classification through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The analytic rows are exhausted by the stream schedule, the regular rational readback, the dyadic tolerance ledger, the modulus row, and the coherence classifier.

The modulus evidence is not inferred from ambient completeness. It is a row of the same packet, so a consumer must expose μ together with S, R, D before reading the classifier Q.

The structural rows H, C, P, N only transport, replay, source, and name those displayed coordinates. Since the carrier lists no selected limit, quotient-stream equality, host real equality, completeness theorem, or choice principle, the obligation surface is exactly the finite inventory above. □

Theorem 7192.3 (CauchyRealModulus Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyRealModulus}^{\uparrow}$ *packet factors its read through the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*, the explicit modulus row* μ*, the coherence classifier* Q*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The read cannot manufacture a selected limit, quotient equality of streams, host real equality, ambient completeness, or countable choice.*

Proof. Begin with the carrier inventory of Definition 7192.1. The only route from the real-name packet toward a $\mathsf{Real}^{\uparrow}$ consumer is the displayed chain S, R, D, μ, Q.

The replay row C forces the same stream, regular-name, tolerance, and modulus rows to be reopened before the real-seal boundary is consumed. Transport through H preserves those rows componentwise, and provenance through P records the same source route for the local naming row N.

The excluded objects are absent from the packet. Therefore the $\mathsf{Real}^{\uparrow}$ read may cite an explicitly modulated Cauchy real name, but it cannot create a selected limit, quotient-stream equality, host equality of reals, completeness theorem, or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRealModulus}^{\uparrow}$ packet is generated from stream-window rows, regular rational-name rows, dyadic tolerance rows, an explicit modulus row, a Cauchy coherence classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRealModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7192.1, Definition 7192.2, and Definition 7192.3 bind the explicit-modulus Cauchy real-name carrier to the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRealModulus}^{\uparrow}}$, formalTarget)

Bridge status: none

Origin: human

Not claimed: This chapter does not close selected limits, quotient equality of streams, host real equality, ambient completeness, countable choice, or a Lean carrier for $\mathsf{CauchyRealModulus}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, regular rational readback, dyadic tolerance exposure, explicit modulus visibility, classifier coherence, replay, provenance, and local naming for the displayed packet.

Chapter 7193

A Concrete Naming Certificate for $\mathsf{ArgumentPrinciple}^{\uparrow}$

Following Cauchy's argument principle, the $\mathsf{ArgumentPrinciple}^{\uparrow}$ packet records the finite contour-and-winding ledger by which a holomorphic input with displayed zero and pole boundary data can be read as a certified counting relation. It sits after the complex carrier of chapter 39, the holomorphic source of chapter 68, the contour-integral operation of chapter 521, the residue-facing handoff of chapter 3978, and the reparameterization ledger of chapter 7037. The packet exposes only finite contour, meromorphic boundary, winding-count, residue-handoff, transport, replay, provenance, and local naming rows; it does not import a host path quotient, an analytic-continuation principle, or an unregistered zero-counting theorem.

Definition 7193.1 (Argument principle carrier)**.** *An* $\mathsf{ArgumentPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, F, Z, P_0, W, I, R, Q, H, C, K, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{PLContour}$ *row with* $\mathsf{Complex}^{\uparrow}$ *endpoints, segment rows, and a displayed non-boundary locus for zeros and poles.*
2. *F is the* $\mathsf{Holomorphic}^{\uparrow}$ *row on the displayed contour neighbourhood outside the recorded pole locus.*
3. *Z is the finite zero ledger, listing local zero witnesses and multiplicity rows that are visible to the packet.*
4. *P_0 is the finite pole ledger, listing local pole witnesses and order rows that are visible to the packet.*
5. *W is the winding-number row computed from the contour row and the displayed zero-pole boundary data.*
6. *I is the* $\mathsf{ContourIntegralOperation}^{\uparrow}$ *row for the logarithmic-derivative contour read.*
7. *R is the* $\mathsf{ContourResidueHandoff}^{\uparrow}$ *row that exposes the corresponding residue-facing data.*
8. *Q is the* $\mathsf{ContourReparameterizationLedger}^{\uparrow}$ *row recording that allowed contour refinements preserve the same visible winding and integral rows.*
9. *H records componentwise* hsame *transport for G, F, Z, P_0, W, I, R, Q.*

10. *C records displayed* Cont *replay for contour, holomorphic, zero, pole, winding, integral, residue, reparameterization, provenance, and naming reads.*
11. *K is* Pkg *provenance over* ArgumentPrinciple$^{\uparrow}$, Complex$^{\uparrow}$, Holomorphic$^{\uparrow}$, ContourIntegralOperation$^{\uparrow}$, ContourResidueHandoff$^{\uparrow}$, ContourReparameterizationLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ArgumentPrinciple}^{\uparrow}}$ *row.*

The classifier accepts only packets with these displayed rows. It has no coordinate for quotient path equality, analytic continuation outside the displayed domain, unbounded zero searches, or a host meromorphic-function object.

Lean4 (definition) `BEDC.Derived.ArgumentPrincipleUp.ArgumentPrincipleUp`

Theorem 7193.2 (Argument principle NameCert obligations)**.** *For the carrier of Definition 7193.1, the local* $\mathsf{NameCert}_{\mathsf{ArgumentPrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission, contour exposure, holomorphic-source exposure, zero-ledger exposure, pole-ledger exposure, winding-number exposure, contour-integral operation exposure, residue-handoff exposure, reparameterization-ledger exposure, componentwise transport, displayed replay, provenance, and local naming. An argument-principle consumer receives no host path quotient, analytic-continuation oracle, unbounded zero search, or global meromorphic-function principle.*

Proof. Project the carrier. The contour row G, holomorphic row F, zero ledger Z, pole ledger P_0, winding row W, integral row I, residue handoff R, and reparameterization ledger Q are the only analytic coordinates available to the local certificate.

The counting read is therefore forced through the displayed zero and pole ledgers before it may inspect the winding row. The contour-integral operation and residue handoff expose the corresponding logarithmic-derivative route, while the reparameterization ledger keeps permitted contour refinements attached to the same visible rows.

Transport, replay, provenance, and local naming preserve this finite inventory. Since the packet contains no coordinate for quotient path equality, analytic continuation outside the displayed domain, unbounded zero search, or a host meromorphic-function object, none of those objects can be exported by the NameCert surface. □

Theorem 7193.3 (Argument principle winding-number route)**.** *Let $A = (G, F, Z, P_0, W, I, R, Q, H, C, K, N)$ be an accepted* ArgumentPrinciple$^{\uparrow}$ *carrier. Every consumer that reads the argument-principle count must first expose the* Complex$^{\uparrow}$ *contour endpoints in G, the* Holomorphic$^{\uparrow}$ *source row F, the finite zero ledger Z, the finite pole ledger P_0, the winding-number row W, the* ContourIntegralOperation$^{\uparrow}$ *row I, the* ContourResidueHandoff$^{\uparrow}$ *row R, the* ContourReparameterizationLedger$^{\uparrow}$ *row Q, and the structural rows H, C, K, N. The resulting route identifies the visible winding count with the displayed zero-minus-pole ledger count without using a host path quotient or analytic-continuation principle.*

Proof. Begin with the NameCert obligations. They expose $G, F, Z, P_0, W, I, R, Q, H, C, K, N$ as the complete carrier surface for any public count read.

The zero and pole ledgers provide the finite counting side, while the winding row records the contour-facing count. The contour-integral operation row supplies the logarithmic-derivative read, and the residue handoff ties that read to the displayed local residue data.

Finally use the reparameterization ledger to transport allowed refinements back to the same displayed contour surface. Componentwise hsame transport and Cont replay keep all rows under the same provenance and local naming certificate, so the consumer obtains only the finite winding-count route displayed by the packet. □

Falsifiable prediction: An accepted $\mathsf{ArgumentPrinciple}^{\uparrow}$ count read is refuted if it omits any displayed contour row, holomorphic row, zero ledger, pole ledger, winding row, contour-integral operation row, residue-handoff row, reparameterization ledger, transport row, replay row, provenance row, or local NameCert row.

Independence witness: complex, holomorphic, contourintegraloperation, contour-residue-handoff, contour-reparameterization-ledger: none is bijective to $\mathsf{ArgumentPrinciple}^{\uparrow}$ because this packet jointly binds the visible zero and pole ledgers, winding row, logarithmic-derivative contour operation, residue handoff, contour-reparameterization ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArgumentPrinciple}^{\uparrow}}$.

Constructive story: An $\mathsf{ArgumentPrinciple}^{\uparrow}$ packet is generated from a displayed PL-contour row, holomorphic source row, finite zero ledger, finite pole ledger, winding-number row, contour-integral operation row, residue-handoff row, reparameterization ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArgumentPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7193.1, Definition 7193.2, and Definition 7193.3 seed the finite argument-principle carrier, obligation surface, and winding-count consumer route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArgumentPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient path equality, analytic continuation outside the displayed domain, unbounded zero search, or a host meromorphic-function theorem for $\mathsf{ArgumentPrinciple}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, zero-ledger exposure, pole-ledger exposure, winding-row exactness, contour-integral routing, residue handoff, reparameterization stability, transport, replay, provenance, and local naming for BEDC.Derived.ArgumentPrincipleUp.

Chapter 7194

A Concrete Naming Certificate for $\mathsf{UniformModulusErrorBudget}^{\uparrow}$

Following Bishop and Bridges compact-uniform continuity, the $\mathsf{UniformModulusErrorBudget}^{\uparrow}$ packet records the finite error-budget ledger used to pass from compact finite nets and pointwise moduli to a tolerance-only uniform-modulus handoff. It reads the compact metric source of chapter 129, the continuous-map graph of chapter 130, the uniform-modulus consumer of chapter 369, the rational lower-bound surface of chapter 37, the metric triangle rows of chapter 57, and the Real seal of chapter 38. The packet names only finite epsilon-third, compact-net, rational-fold, metric-triangle, transport, replay, provenance, and local naming rows.

Definition 7194.1 (Uniform modulus error-budget carrier)**.** *A* $\mathsf{UniformModulusErrorBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, F, U, Q, M, R, B, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row over the same metric source.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row that receives the tolerance-only precision history.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *positive-radius and lower-bound fold row over the displayed compact-net probes.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *source-and-target triangle row used to split and recombine the error estimate.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed source and target distance estimates.*
7. *B is the epsilon-third budget row, recording the three visible tolerances, their rational comparisons, and the folded precision consumed by U.*
8. *T is the compact-net triangle ledger tying X, F, Q, M, R, B to one finite estimate route.*
9. *H records componentwise* hsame *transport for X, F, U, Q, M, R, B, T.*
10. *C records displayed* Cont *replay for compact-net reads, pointwise-modulus reads, rational-fold reads, metric-triangle reads, Real-seal reads, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{UniformModulusErrorBudget}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{UniformModulusErrorBudget}^{\uparrow}}$ *row.*

Accepted packets are compared only through $X, F, U, Q, M, R, B, T, H, C, P, N$. They have no coordinate for a selected Lebesgue number, an external modulus selector, quotient equality of metric points, sequential compactness, countable choice, or ambient Real completeness.

Theorem 7194.2 (Uniform modulus error-budget NameCert obligations)**.** *For the carrier of Definition 7194.1, the local* $\mathsf{NameCert}_{\mathsf{UniformModulusErrorBudget}^{\uparrow}}$ *surface consists exactly of compact-metric finite-net exposure, continuous-map pointwise-modulus exposure, uniform-modulus consumer exposure, rational lower-bound fold exposure, metric triangle exposure, Real-seal exposure, epsilon-third budget exposure, compact-net triangle-ledger exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier. The compact finite-net row X, continuous-map row F, rational fold Q, metric row M, Real seal R, and budget row B are the only rows from which a tolerance estimate can be read.

The budget row splits the requested tolerance into three displayed rational comparisons. The compact-net ledger T then routes the source point to a displayed center, applies the pointwise-modulus row at that center, and uses the metric triangle row to recombine the three estimates before the uniform-modulus consumer row U is exposed.

Transport, replay, provenance, and local naming keep this same finite inventory. Since the carrier contains no selected Lebesgue number, external modulus selector, quotient point equality, sequence extractor, choice principle, or ambient Real-completeness row, none of those objects can be exported by the NameCert surface. □

Theorem 7194.3 (Uniform modulus error-budget triangle route)**.** *Let $E = (X, F, U, Q, M, R, B, T, H, C, P, N)$ be an accepted* $\mathsf{UniformModulusErrorBudget}^{\uparrow}$ *carrier. Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer must read the epsilon-third budget B, the compact-net row X, the continuous-map row F, the* $\mathsf{Rat}^{\uparrow}$ *fold row Q, the* $\mathsf{Met}^{\uparrow}$ *triangle row M, and the* $\mathsf{Real}^{\uparrow}$ *seal row R before reaching U. The handoff realizes the compact-uniform-continuity estimate as a finite triangle budget and exports no host compactness theorem or external modulus function.*

Proof. Begin with the accepted carrier and expose the budget row B. Its three rational comparisons are displayed histories, so the tolerance split is part of the packet rather than a hidden arithmetic choice.

Next read the compact-net route. The row X supplies the finite centers, F supplies pointwise-modulus data at those centers, and Q folds the visible positive radii to a common precision history.

Finally apply the metric triangle ledger. The row M combines the source-center, source-pair, and target-distance estimates, while R seals the displayed Real distance rows before U consumes the resulting tolerance-only modulus. The structural rows H, C, P, N transport and replay this route without adding host compactness, quotient equality, or an external modulus function. □

Falsifiable prediction: An accepted $\mathsf{UniformModulusErrorBudget}^{\uparrow}$ consumer is refuted if it reaches the UniformModulusUp handoff without displaying the epsilon-third budget, CompactMetric row, ContinuousMap row, RatUp fold, Metric triangle row, RealUp seal, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: compactmetric, continuousmap, uniformmodulus, rat, metric, real: none is bijective to $\mathsf{UniformModulusErrorBudget}^{\uparrow}$ because this packet jointly carries the epsilon-third budget, compact finite-net route, pointwise-modulus rows, rational lower-bound fold, metric triangle estimates, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformModulusErrorBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformModulusErrorBudget}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise-modulus rows, a UniformModulus consumer row, Rat positive-radius folds, Metric triangle rows, Real distance seals, an epsilon-third budget row, a compact-net triangle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformModulusErrorBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7194.1, Definition 7194.2, and Definition 7194.3 seed the finite epsilon-third and metric-triangle budget consumed by compact-uniform-continuity routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformModulusErrorBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected Lebesgue numbers, external modulus selection, quotient metric equality, sequential compactness, countable choice, or ambient Real completeness for $\mathsf{UniformModulusErrorBudget}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, budget-row exactness, compact-net exposure, continuous-map exposure, rational-fold exactness, metric-triangle compatibility, Real-seal nonescape, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformModulusErrorBudgetUp.

Chapter 7195

A Concrete Naming Certificate for $\mathsf{RegularSequenceCompletion}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences and constructive completion, the $\mathsf{RegularSequenceCompletion}^{\uparrow}$ packet records the finite BEDC route by which a regular rational sequence is admitted to a real-name seal without quotient streams, countable choice, or an ambient completeness theorem. It sits after the stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the cofinal tail-budget surface of chapter 698, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers a displayed completion route for regular sequences, not a selected host limit.

Definition 7195.1 (Regular sequence completion carrier)**.** *A* $\mathsf{RegularSequenceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, D, R, T, E, H, K, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing finite windows of the sequence name.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row exposing dyadic tolerances and arithmetic comparison data.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row reading the regular rational approximants through S and D.*
4. *T is the* $\mathsf{CofinalTailBudget}^{\uparrow}$ *row recording which tail windows are cofinal for each displayed tolerance request.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal route, allowing a completion-facing consumer to read a real-name boundary only through S, D, R, T.*
6. *H stores componentwise* hsame *transport for S, D, R, T, E, K, P, N.*
7. *K stores displayed* Cont *replay of the stream, dyadic, regular-rational, tail-budget, real-seal, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CofinalTailBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, T, E, H, K, P, N$. It has no coordinate for a quotient of streams, a selected representative, host real equality, countable choice, or ambient completeness.

Theorem 7195.2 (Regular sequence completion NameCert obligations)**.** *For every accepted* RegularSequenceComp *carrier* $C = (S, D, R, T, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceCompletion}^{\uparrow}}$ *surface consists of the following five obligation rows:*

1. *carrier admission for the displayed* BHist *packet* C*;*
2. *window and tolerance exposure through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
3. *regular rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$*;*
4. *cofinal tail-budget exposure through* $\mathsf{CofinalTailBudget}^{\uparrow}$*;*
5. *real-seal replay through* $\mathsf{Real}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7195.1. The analytic data are exactly the finite stream row, dyadic tolerance row, regular-rational row, tail-budget row, and real-seal row.

The structural rows do not add analytic content. Transport through H preserves the displayed rows componentwise, replay through K reopens the same finite route, and P, N record provenance and local naming.

Since the packet contains no quotient-stream coordinate, selected representative, host real equality, choice functional, or ambient completeness field, the NameCert obligations are exhausted by the five rows above. □

Theorem 7195.3 (Regular sequence completion Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularSequenceCompletion}^{\uparrow}$ *packet must factor its read through the finite window row* S*, dyadic tolerance row* D*, regular rational readback row* R*, cofinal tail-budget row* T*, real-seal route* E*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The consumer cannot extract quotient-stream equality, a selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Begin with the obligation surface of Definition 7195.2. It requires the stream, dyadic, regular-rational, tail-budget, and real-seal rows before the packet can be consumed as a completion route.

The sibling route is finite: chapter 301 supplies the regular rational readback, chapter 698 supplies the cofinal tail budget, and chapter 38 supplies the terminal seal. The present packet binds those rows to one completion-facing carrier.

Therefore a consumer may cite a displayed regular-sequence completion route, but it cannot manufacture any of the refused quotient, selection, equality, choice, or ambient-completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularSequenceCompletion}^{\uparrow}$ packet is generated from stream-window rows, dyadic tolerance rows, regular rational readback, a cofinal tail-budget row, a real-seal route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularSequenceCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 7195.1, Definition 7195.2, and Definition 7195.3 bind the regular-sequence completion carrier to the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CofinalTailBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularSequenceCompletion}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close quotient equality of streams, selected limits, host real equality, countable choice, ambient completeness, or a Lean carrier for $\mathsf{RegularSequenceCompletion}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, dyadic tolerance exposure, regular rational readback, cofinal tail-budget exposure, real-seal replay, provenance, and local naming for the displayed packet.

Chapter 7196

A Concrete Naming Certificate for $\mathsf{DyadicNewtonSqrt}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Newton method for square roots, the $\mathsf{DyadicNewtonSqrt}^{\uparrow}$ packet records the finite dyadic data needed to run a guarded Newton square-root computation before any completed real quotient, selected limit, or host square-root function is available. It sits between the dyadic arithmetic surfaces of chapter 1658 and chapter 291, the regular rational readback of chapter 301, the Cauchy schedule of chapter 292, the terminal seal of chapter 38, and the Heron square-root consumer of chapter 3818. The carrier exposes a Newton-specific square-residual and quadratic-window ledger as named rows; it does not assert a total square-root operation on arbitrary $\mathsf{Real}^{\uparrow}$ data.

Definition 7196.1 (Dyadic Newton square-root carrier)**.** *A* $\mathsf{DyadicNewtonSqrt}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (A, G, W, R, Q, M, S, E, H, C, P, L)$$

with the following displayed rows:

1. *A is the radicand* $\mathsf{DyadicRatCore}^{\uparrow}$ *row, carrying the dyadic rational value, denominator witness, square ledger, and comparison data used by every Newton step.*
2. *G is the positive-window ledger, recording the lower bound, upper guard, and nonzero denominator witnesses that keep each displayed iterate inside the positive dyadic window.*
3. *W is the Newton iterate window, a finite row of dyadic iterates computed by the visible step $x \mapsto (x + A/x)/2$ from A and G.*
4. *R is the residual-square tolerance row, storing the finite comparisons between x_i^2 and A together with the requested dyadic error budget.*
5. *Q is the quadratic contraction budget, recording the local guard under which the next residual is bounded by the displayed square of the previous residual.*
6. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *handoff row, translating a requested output precision into the displayed iterate threshold and residual tolerance.*
7. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by replaying A, G, W, R, Q, M as a regular rational name.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the dyadic Newton ledger and regular readback row have been displayed.*

9. *H records componentwise* hsame *transport for the radicand, positive-window ledger, iterate window, residual tolerance, contraction budget, modulus handoff, readback, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of each square-root precision request through $A, G, W, R, Q, M, S, E, H, P, L$.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicNewtonSqrt}^{\uparrow}$, $\mathsf{Dyadic}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HeronSquareRoot}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{DyadicNewtonSqrt}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, G, W, R, Q, M, S, E, H, C, P, L$. It has no coordinate for quotient real equality, selected completed limits, arbitrary trichotomy, total square root on all $\mathsf{Real}^{\uparrow}$ *names, ambient completeness, or a host square-root theorem.*

Theorem 7196.2 (Dyadic Newton square-root NameCert obligations)**.** *For every accepted* $\mathsf{DyadicNewtonSqrt}^{\uparrow}$ *carrier*

$$N = (A, G, W, R, Q, M, S, E, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicNewtonSqrt}^{\uparrow}}$ *surface consists exactly of the displayed carrier admission row, radicand* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness, positive-window exactness, Newton iterate-window stability, residual-square tolerance accounting, quadratic contraction budget visibility,* $\mathsf{CauchyModulus}^{\uparrow}$ *handoff exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The radicand row A and positive-window row G supply the dyadic arithmetic and positivity witnesses before any iterate is visible.

The numerical work is finite. The window row W lists the displayed Newton iterates, the residual row R stores the square-error comparisons, and the contraction row Q records the guarded quadratic estimate for the next residual.

The output rows are downstream of that ledger. The modulus row M selects a finite threshold for the requested precision, the $\mathsf{RegSeqRat}^{\uparrow}$ row S is obtained by replaying the displayed dyadic rows, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after S has been displayed.

Finally H, C, P, L transport, replay, source, and name the same finite packet. Since the carrier contains no host square-root coordinate, selected limit, quotient equality, trichotomy classifier, or ambient completeness row, the listed rows exhaust the local NameCert obligation surface. □

Theorem 7196.3 (Dyadic Newton square-root quadratic window route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{HeronSquareRoot}^{\uparrow}$ *consumer that reads a square-root approximation from an accepted* $\mathsf{DyadicNewtonSqrt}^{\uparrow}$ *carrier must factor through the finite route*

$$A, G \longmapsto W, R, Q \longmapsto M \longmapsto S \longmapsto E.$$

Thus the consumer first reads the $\mathsf{Dyadic}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic surface, then the positive Newton window, residual-square tolerance, quadratic contraction budget,* $\mathsf{CauchyModulus}^{\uparrow}$ *precision handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route exports no host square-root function, quotient real equality, selected completed limit, arbitrary trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier inventory of Definition 7196.1. The rows A, G are the only source of radicand, positivity, and denominator data, so every Newton iterate must read them before any residual comparison can be formed.

The finite window is then inspected through W, R, Q. The row W stores the displayed Newton iterates, R stores the square-residual tolerance checks, and Q stores the guarded quadratic contraction estimate that makes the window a Cauchy-facing ledger.

The precision handoff uses M. It turns the requested output tolerance into a finite iterate threshold, after which S supplies the regular rational readback and E supplies the terminal Real seal.

The structural rows H, C, P, L preserve the same dependency order under transport, replay, provenance, and naming. Therefore a downstream $\mathsf{HeronSquareRoot}^{\uparrow}$ or Real-facing consumer receives only the displayed DyadicRatCore-to-RegSeqRat-to-Real route, not an external square-root value or ambient completeness principle. □

Falsifiable prediction: Every accepted DyadicNewtonSqrtUp read factors through a DyadicRatCore radicand row, a positive-window ledger, a finite Newton iterate window, residual-square tolerance checks, a quadratic contraction budget, a CauchyModulus handoff, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadic, dyadicratcore, cauchymodulus, regseqrat, real, heronsquareroot: $\mathsf{DyadicNewtonSqrt}^{\uparrow}$ is not bijective to any listed sibling because it binds a positive dyadic radicand, Newton iterate windows, residual-square tolerances, a quadratic contraction budget, CauchyModulus handoff, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming as one finite square-root certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicNewtonSqrt}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicNewtonSqrt}^{\uparrow}$ packet is generated from a DyadicRatCore radicand row, a positive-window ledger, finite Newton iterate windows, residual-square tolerance checks, a quadratic contraction budget, CauchyModulus handoff, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicNewtonSqrt}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7196.1, Definition 7196.2, and Definition 7196.3 seed the finite Newton square-root packet over $\mathsf{Dyadic}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HeronSquareRoot}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicNewtonSqrt}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total square root on arbitrary $\mathsf{Real}^{\uparrow}$ names, quotient real equality, selected completed limits, arbitrary trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radicand exactness, positive-window exactness, Newton iterate stability, residual-square tolerance accounting, quadratic contraction visibility, CauchyModulus handoff, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicNewtonSqrtUp.

Chapter 7197

A Concrete Naming Certificate for $\mathsf{CantorBendixsonRank}^{\uparrow}$

Following Cantor and Bendixson, the $\mathsf{CantorBendixsonRank}^{\uparrow}$ packet records a finite derivative-rank certificate for the displayed compact-metric part of a Cantor–Bendixson analysis. It sits after the derivative ledger of chapter 2024, the reusable perfect-kernel face of chapter 3863, the nowhere-dense boundary of chapter 4186, the compact metric carrier of chapter 129, and the source metric row of chapter 57. The packet names only a finite rank budget, its inspected derivative rows, and its residual-kernel handoff; it does not assert a host ordinal rank, transfinite powerset construction, selected enumeration of isolated points, quotient closed-set equality, countable choice, or ambient compactness theorem.

Definition 7197.1 (Cantor–Bendixson rank carrier)**.** *A* $\mathsf{CantorBendixsonRank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, K, D, r, I, P, N_0, W, H, C, Q, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, carrying the metric observation surface used by the derivative requests.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row, exposing the finite compact inspection and cover budgets on which the derivative search is allowed to depend.*
3. *D is the* $\mathsf{CantorBendixson}^{\uparrow}$ *derivative ledger, listing the displayed derivative stages already admitted by the sibling Cantor–Bendixson packet.*
4. *r is the finite rank budget row, recording the displayed natural-number depth at which the inspected derivative route stops.*
5. *I is the isolated-remnant ledger, recording only those isolated reads witnessed before the budget row r is exhausted.*
6. *P is the* $\mathsf{PerfectSet}^{\uparrow}$ *residual-kernel row, read only for the part that survives the displayed derivative budget.*
7. *N_0 is the* $\mathsf{NowhereDense}^{\uparrow}$ *boundary row, recording the nowhere-dense refusal surface consumed by scattered-remnant or category-facing reads.*
8. *W is the finite window schedule for metric neighborhoods, compact inspections, derivative rows, isolated-remnant reads, perfect-kernel reads, and nowhere-dense boundary reads.*

9. *H records componentwise* hsame *transport for M, K, D, r, I, P, N_0, W and for the replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of every accepted rank request through*

$$M, K, D, r, I, P, N_0, W \longmapsto H, C, Q, N.$$

11. *Q is the* Pkg *provenance over* $\mathsf{CantorBendixsonRank}^{\uparrow}$, $\mathsf{CantorBendixson}^{\uparrow}$, $\mathsf{PerfectSet}^{\uparrow}$, $\mathsf{NowhereDense}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorBendixsonRank}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host ordinals, transfinite derivative intersections, ambient powersets, quotient closed-set equality, a selected enumeration of isolated points, countable choice, or compactness outside the displayed compact-metric route.

Theorem 7197.2 (Cantor–Bendixson rank NameCert obligations)**.** *For every accepted* $\mathsf{CantorBendixsonRank}^{\uparrow}$ *carrier*

$$R = (M, K, D, r, I, P, N_0, W, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorBendixsonRank}^{\uparrow}}$ *surface is exhausted by the following finite obligation rows:*

1. *metric and compact admission through M and K, exposing only displayed metric observations, compact inspection rows, and finite cover budgets;*

2. *derivative-ledger admission through D, requiring every rank read to cite the displayed* $\mathsf{CantorBendixson}^{\uparrow}$ *derivative stages it consumes;*

3. *finite-rank exactness through r and W, requiring the rank budget to name the inspected derivative depth and the windows used at that depth;*

4. *isolated-remnant exactness through I, requiring every scattered read to carry a displayed isolation witness before the rank budget is exhausted;*

5. *residual-kernel and nowhere-dense compatibility through P and N_0, requiring perfect-kernel reads and nowhere-dense refusals to remain attached to the same displayed derivative route;*

6. *structural nonescape through H, C, Q, N, requiring transport, replay, provenance, and local naming to export no host ordinal rank, transfinite powerset construction, selected isolated-point enumeration, quotient closed-set equality, countable choice, or ambient compactness theorem.*

No finite derivative-rank obligation is stored outside these rows.

Proof. Project the carrier of Definition 7197.1. The metric and compact inputs are exactly M and K, so every rank request begins with displayed observations and compact inspection data rather than with a host powerset.

The rank work is finite. The derivative ledger D supplies the Cantor–Bendixson stages already visible to the packet, while r and W record the finite depth and the windows inspected at that depth.

The two outputs stay attached to that same route. The isolated-remnant row I records only witnessed scattered reads before the budget is exhausted, and the residual rows P, N_0 record the perfect-kernel and nowhere-dense boundaries that survive the displayed route.

Finally H, C, Q, N transport, replay, source, and name those rows. Since the carrier has no coordinate for host ordinal ranks, transfinite intersections, selected isolated-point enumerations,

quotient closed-set equality, countable choice, or external compactness, the six obligation rows exhaust the local certificate. □

Theorem 7197.3 (Cantor–Bendixson rank finite derivative budget)**.** *Every accepted* $\mathsf{CantorBendixsonRank}^{\uparrow}$ *consumer that asks for a derivative-rank read must first display the route*

$$M, K, D, r, W \longmapsto I, P, N_0 \longmapsto H, C, Q, N.$$

Thus the exported rank is a finite BEDC budget over the $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{CantorBendixson}^{\uparrow}$*,* $\mathsf{PerfectSet}^{\uparrow}$*, and* $\mathsf{NowhereDense}^{\uparrow}$ *rows. The consumer receives no host ordinal, transfinite derivative chain, powerset decomposition, selected isolated-point enumeration, quotient closed-set equality, countable-choice schedule, or ambient compactness theorem.*

Proof. Begin with the metric and compact rows. The source metric observations and compact inspection budgets are the only neighborhood data available to the derivative read.

Next read the derivative ledger and budget. The row D supplies the displayed Cantor–Bendixson stages, while r and W identify the finite depth and windows at which the rank request is inspected.

The scattered and residual faces are downstream of that budget. Row I records isolated remnants only when they have displayed witnesses, and rows P, N_0 record the retained perfect-kernel and nowhere-dense boundaries without detaching from the same derivative ledger.

The structural rows preserve the route and add no new mathematical coordinates. Therefore the exported object is exactly a finite derivative-rank budget over the named sibling packets, not any of the excluded host-level or choice-dependent data. □

Falsifiable prediction: Every accepted $\mathsf{CantorBendixsonRank}^{\uparrow}$ consumer that reads a derivative-rank packet while omitting one of the Metric, CompactMetric, CantorBendixson derivative, finite rank budget, isolated-remnant, PerfectSet residual, NowhereDense boundary, window, hsame, Cont, Pkg, or NameCert rows has left the packet.

Independence witness: cantorbendixson, perfectset, nowheredense, compactmetric, metric: $\mathsf{CantorBendixsonRank}^{\uparrow}$ is not bijective with any listed sibling because it joins metric observations, compact inspection, derivative stages, a finite rank budget, isolated remnants, residual perfect-kernel data, nowhere-dense refusals, windows, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorBendixsonRank}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CantorBendixsonRank}^{\uparrow}$ packet is generated from MetricUp observations, CompactMetricUp inspection rows, CantorBendixsonUp derivative ledgers, a finite rank budget, isolated-remnant witnesses, PerfectSetUp residual rows, NowhereDenseUp boundary rows, finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorBendixsonRank}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7197.1, Definition 7197.2, and Definition 7197.3 seed the finite derivative-rank surface for compact-metric Cantor–Bendixson packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorBendixsonRank}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host ordinal rank, transfinite powerset decomposition, selected isolated-point enumeration, quotient closed-set equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-ledger admission, finite-rank exactness, isolated-remnant exactness, residual-kernel compatibility, nowhere-dense boundary compatibility, structural nonescape, and route replay for BEDC.Derived.CantorBendixsonRankUp.

Chapter 7198

A Concrete Naming Certificate for ConstructiveCauchyTailOperator$^{\uparrow}$

Following Bishop and Bridges, the ConstructiveCauchyTailOperator$^{\uparrow}$ packet names the finite tail-shift operation needed by constructive Cauchy completion without selecting a hidden quotient representative. It sits over StreamName$^{\uparrow}$ of chapter 126, RegSeqRat$^{\uparrow}$ of chapter 301, Real$^{\uparrow}$ of chapter 38, DyadicRatCore$^{\uparrow}$ of chapter 291, FiniteTailFilter$^{\uparrow}$ of chapter 1119, SelectedTailSeed$^{\uparrow}$ of chapter 1207, and TailCofinalityBudget$^{\uparrow}$ of chapter 1231. Those siblings expose streams, regular rational readback, dyadic tolerances, finite tail admission, selected seeds, and cofinal threshold budgets; this chapter packages the operator that transports a displayed Cauchy tail across those rows before the terminal Real seal consumes it.

Definition 7198.1 (Constructive Cauchy tail-operator carrier)**.** *A* ConstructiveCauchyTailOperator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, k, W, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* StreamName$^{\uparrow}$ *row naming the rational stream whose tail is being read;*
2. *k is the unary tail threshold row, exposed as finite data rather than as a hidden natural-number choice;*
3. *W is the shifted stream-window row, recording the finite read of S after threshold k;*
4. *B is the* TailCofinalityBudget$^{\uparrow}$ *row certifying that the requested tail is cofinal for the displayed Cauchy use;*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row over the shifted window;*
6. *E is the* DyadicRatCore$^{\uparrow}$ *error ledger used by the regularity estimate;*
7. *H is the componentwise* hsame *transport row for replacing S by an extensionally same stream window;*
8. *C is the displayed* Cont *replay route through S, k, W, B, R, E, H;*
9. *P is the* Pkg *provenance over* ConstructiveCauchyTailOperator$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, FiniteTailFilter$^{\uparrow}$, SelectedTailSeed$^{\uparrow}$, TailCofinalityBudget$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient stream equality, countable choice, an ambient completeness theorem, a selected limit outside the packet, or host-side equality of real numbers.

Theorem 7198.2 (Constructive Cauchy tail-operator NameCert obligations)**.** *For the carrier of Definition 7198.1, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}}$ *surface consists of carrier admission for $T = (S, k, W, B, R, E, H, C, P, N)$, source stream exposure through S, finite threshold exposure through k, shifted window exposure through W, cofinal budget exposure through B, regular-rational readback through R, dyadic error exposure through E, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier row of Definition 7198.1. The admitted object is exactly the ten-row packet $T = (S, k, W, B, R, E, H, C, P, N)$.

The source and shift rows expose the operator input. The stream row S, threshold row k, and shifted window row W are the only data from which a consumer may read the tail.

The Cauchy rows expose the constructive estimate. The cofinal budget B, regular-rational readback R, and dyadic error ledger E are displayed before any Real-facing handoff can be made.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier admits no other coordinates, these rows exhaust the local NameCert obligations. □

Theorem 7198.3 (Constructive Cauchy tail-operator shift stability)**.** *Let $T = (S, k, W, B, R, E, H, C, P, N)$ be an accepted* $\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}$ *packet. If a later finite threshold k' refines k through the same* $\mathsf{TailCofinalityBudget}^{\uparrow}$ *route, then the shifted-window readback can be repacked as another accepted* $\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}$ *packet with the same source stream, dyadic ledger discipline, componentwise transport surface, replay route, provenance, and local naming format.*

Proof. Begin with the finite threshold rows. A refinement of k through the same cofinal budget row B gives a later finite tail read of the same source stream S.

The shifted window is then rebuilt by reading S after k'. The regular-rational readback row R and dyadic error ledger E are reused at the later threshold because the budget row records cofinality rather than a single isolated prefix.

The remaining rows are structural. Componentwise hsame transport still acts on the displayed stream window, the Cont route replays the same operator shape, and the Pkg and local $\mathsf{NameCert}$ rows name the repacked packet. Therefore the tail operator is stable under displayed tail refinement. □

Theorem 7198.4 (Constructive Cauchy tail-operator Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}$ *packet factors through the displayed finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{FiniteTailFilter}^{\uparrow} \longrightarrow \mathsf{TailCofinalityBudget}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff exports only the shifted window, cofinal budget, regular-rational readback, dyadic error ledger, componentwise transport, replay, provenance, and local NameCert rows; it does not export quotient streams, host real equality, countable choice, detached limits, or ambient completeness.

Proof. Read the operator packet through its displayed rows. The only route from the source stream to a Real-facing seal passes through the finite threshold row, shifted window row, cofinal budget row, regular-rational readback row, and dyadic error ledger.

The terminal consumer sees the Real seal through those rows, not through an external equality principle. The componentwise transport and replay rows show how the same displayed data is carried along the handoff.

Because the carrier has no quotient, choice, detached-limit, host-equality, or ambient-completeness coordinate, no such datum can be exported by the handoff. The Real-facing read is therefore exactly the displayed finite route. □

Falsifiable prediction: No accepted ConstructiveCauchyTailOperatorUp packet exports quotient stream equality, host real equality, countable choice, a detached limit, or ambient completeness outside the displayed finite tail-operator rows.

Independence witness: streamname, regseqrat, real, dyadicratcore, finite-tail-filter, selected-tail-seed, tail-cofinality-budget: none is bijective to ConstructiveCauchyTailOperatorUp because the operator packet combines a source stream, finite threshold, shifted window, cofinal budget, regular-rational readback, dyadic error ledger, componentwise transport, replay, provenance, and local NameCert row in one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}$ packet is generated from a source stream, unary tail threshold, shifted stream window, cofinal budget, regular-rational readback, dyadic error ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7198.1, Definition 7198.2, Definition 7198.3, and Definition 7198.4 give the seed finite tail-operator carrier and its displayed Real-seal handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyTailOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, host real equality, countable choice, detached limits, or ambient completeness.

Upgrade path: Scoped closure requires Lean-backed NameCert obligations, shift stability, and Real-seal handoff evidence for the displayed tail-operator rows.

Chapter 7199

A Concrete Naming Certificate for $\mathsf{HyperbolicConvexDisk}^{\uparrow}$

The $\mathsf{HyperbolicConvexDisk}^{\uparrow}$ packet realizes the finite geodesic-window convexity route suggested by chapter 9463 as standard hyperbolic convexity inside a displayed Poincare disk surface. It sits over $\mathsf{PoincareDiskMetric}^{\uparrow}$ of chapter 6209, $\mathsf{HyperbolicMetric}^{\uparrow}$ of chapter 3474, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ of chapter 3491, $\mathsf{Real}^{\uparrow}$ of chapter 38, and $\mathsf{StreamName}^{\uparrow}$ of chapter 126. These siblings expose disk metric reads, hyperbolic length, boundary endpoints, Real sealing, and finite stream windows; this chapter packages the finite convexity certificate consumed by geodesic and observer-phase routes.

Definition 7199.1 (Hyperbolic convex disk carrier)**.** *A* $\mathsf{HyperbolicConvexDisk}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (U, M, G, B, W, R, H, C, P, N)$$

with the following displayed rows:

1. *U is the finite Poincare-disk window row naming the disk points under inspection;*
2. *M is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *metric-read row on U;*
3. *G is the finite geodesic-window row, listing the displayed geodesic segments whose endpoints lie in U;*
4. *B is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *endpoint and boundary-transport row for the same windows;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *sampling row used to enumerate the inspected endpoints and interior witnesses;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the finite metric and parameter reads;*
7. *H is the componentwise* hsame *transport row for replacing the displayed disk window by an extensionally same one;*
8. *C is the displayed* Cont *replay route through U, M, G, B, W, R, H;*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicConvexDisk}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicConvexDisk}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary host subset of the disk, an infinite convex hull, quotient boundary equality, hidden geodesic existence, or an ambient completeness principle.

Theorem 7199.2 (Hyperbolic convex disk NameCert obligations)**.** *For the carrier of Definition 7199.1, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicConvexDisk}^{\uparrow}}$ *surface consists of carrier admission for* $D = (U, M, G, B, W, R, H, C, P, N)$*, disk-window exposure through* U*, metric-read exposure through* M*, finite geodesic-window exposure through* G*, boundary endpoint exposure through* B*, stream sampling through* W*, Real sealing through* R*, componentwise transport through* H*, replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7199.1. The admitted object is exactly the ten-row finite packet $D = (U, M, G, B, W, R, H, C, P, N)$.

The geometric rows expose the convexity test. The disk window U, metric row M, geodesic-window row G, and boundary row B are the only rows from which a consumer can read hyperbolic convexity.

The sampling and seal rows make the finite measurement explicit. The stream row W enumerates the inspected endpoints and witnesses, while R records the Real-facing metric and parameter seal.

Finally H, C, P, N transport, replay, source, and name the displayed rows. Since no host subset, infinite hull, hidden geodesic, quotient boundary equality, or ambient completeness coordinate is admitted, these rows exhaust the local NameCert obligations. □

Theorem 7199.3 (Hyperbolic convex disk geodesic stability)**.** *Let* $D = (U, M, G, B, W, R, H, C, P, N)$ *be an accepted* $\mathsf{HyperbolicConvexDisk}^{\uparrow}$ *packet. If a displayed geodesic segment has endpoints in the finite disk window and its sampled interior witnesses are carried by the same stream and Real-seal rows, then replacing the disk window by an extensionally same window preserves the accepted convex disk packet through the same boundary, transport, replay, provenance, and local naming rows.*

Proof. Begin with the geodesic-window row G. Its endpoints are recorded inside the finite disk window U, and its metric read is governed by M.

The interior witness read is finite. The stream row W lists the sampled witnesses, while the Real seal R records the metric and parameter values needed by the displayed segment check.

Now apply the componentwise transport row H to replace U by an extensionally same disk window. The boundary row B transports the endpoint read, the replay row C repeats the same finite route, and the provenance and NameCert rows keep the packet identity fixed. Therefore the convex disk certificate is stable under displayed geodesic-window transport. □

Falsifiable prediction: No accepted HyperbolicConvexDiskUp packet exports an arbitrary host disk subset, infinite convex hull, quotient boundary equality, hidden geodesic existence, or ambient completeness principle outside the displayed finite geodesic-window rows.

Independence witness: poincare-disk-metric, hyperbolic-metric, hyperbolic-geodesic-boundary, real, streamname: none is bijective to HyperbolicConvexDiskUp because the convex disk packet combines disk-window rows, metric reads, finite geodesic windows, boundary endpoints, stream sampling, Real sealing, transport, replay, provenance, and local NameCert rows in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicConvexDisk}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicConvexDisk}^{\uparrow}$ packet is generated from a finite Poincare-disk window, metric read, geodesic-window list, boundary endpoint row, stream sampling row, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicConvexDisk}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7199.1, Definition 7199.2, and Definition 7199.3 give the seed finite convex disk carrier and its geodesic-window stability route.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicConvexDisk}\uparrow}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close Lean verification, bridge checking, arbitrary host disk subsets, infinite convex hulls, quotient boundary equality, hidden geodesic existence, or ambient completeness.
Upgrade path: Scoped closure requires Lean-backed NameCert obligations and geodesic-window stability evidence for the displayed convex disk rows.

Chapter 7200

A Concrete Naming Certificate for $\mathsf{BishopCompactIntervalModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCompactIntervalModulus}^{\uparrow}$ packet records the finite compact-interval modulus route used by Real-and-Completion consumers. It sits between the closed bounded interval source of chapter 1591, the completion-modulus handoff of chapter 1469, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic threshold ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the displayed finite cover and modulus rows; it does not assert open-cover compactness, choose a subcover from an ambient family, quotient real names, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7200.1 (Bishop compact interval modulus carrier)**.** *A* $\mathsf{BishopCompactIntervalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, F, M, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, including lower endpoint, upper endpoint, endpoint-order, containment, and terminal interval seal data.*
2. *F is the dyadic finite-cover row over I, listing the inspected dyadic subintervals and their finite containment evidence.*
3. *M is the compact interval modulus row, assigning each displayed precision request a finite cover depth and a dyadic threshold.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect the endpoint names, finite cover cells, and modulus request.*
5. *W is the StreamName window selected by M at the requested depth.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold ledger containing dyadic scale, endpoint comparison, finite-cover containment, and tolerance rows for W.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected window and dyadic ledger.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, F, M, S, W, D, R have been displayed.*
9. *H records componentwise* hsame *transport for the interval source, finite cover, modulus, window rows, dyadic ledger, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the interval source through the finite cover and modulus row to the selected StreamName window, then through the dyadic ledger and regular readback to the Real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopCompactIntervalModulus}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, BishopCompletionModulu $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It contains no coordinate for an ambient open cover, selected subcover, host uniform-continuity theorem, quotient real equality, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7200.2 (Bishop compact interval modulus obligations)**.** *For every accepted* BishopCompactIntervalModul *carrier $K = (I, F, M, S, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; closed bounded interval source exposure through I; dyadic finite-cover exposure through F; compact interval modulus readback through M; StreamName window selection through S, W; DyadicRatCore threshold compatibility through D; RegSeqRat readback through R; RealUp seal non-escape through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7200.1. The rows $I, F, M, S, W, D, R, E, H, C, P, N$ are the full public packet, so a consumer cannot introduce an unlisted open cover, selected subcover, quotient real representative, or completeness witness.

Read the analytic rows in order. The closed bounded interval source I comes first, the finite dyadic cover F is attached to that same source, and the modulus row M selects the cover depth and threshold used for the requested precision.

The completion-facing rows are downstream. The selected window W is read through S, the dyadic ledger D records the same threshold and cover scale, and the regular readback R is available before the seal E.

The structural rows close the NameCert surface. Componentwise transport, replay, provenance, and local naming preserve exactly the displayed route, so the listed obligations exhaust the carrier. □

Theorem 7200.3 (Bishop compact interval modulus completion handoff)**.** *Every accepted* BishopCompactIntervalM *carrier hands a compact interval modulus to Real-and-Completion consumers through the finite route*

$$I, F, M \longmapsto S, W, D \longmapsto R \longmapsto E.$$

The handoff first exposes the $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source and dyadic finite cover, then the compact interval modulus row, then the StreamName window, DyadicRatCore threshold ledger, RegSeqRat readback, and RealUp seal. It exports no ambient open-cover compactness, selected subcover, quotient real equality, countable-choice row, or Real completeness principle.*

Proof. Begin with the source and cover rows. The accepted packet displays I and F before the modulus row can be consumed, so the interval and finite dyadic cover are fixed by carrier data rather than by an ambient compactness theorem.

Next read the modulus and window rows. The row M selects the requested finite cover depth and threshold, S names the finite observation schedule, and W is the selected window attached to that request.

Finally read the completion-facing rows. The dyadic ledger D keeps the threshold and cover scale visible, R is the regular rational readback obtained from the displayed window, and E is downstream from that readback. Since the carrier has no coordinate for the refused principles, the handoff exports only the finite route above. □

Falsifiable prediction: An accepted $\mathsf{BishopCompactIntervalModulus}^{\uparrow}$ read fails if a Real-and-Completion consumer reaches a compact interval modulus without displaying the ClosedBoundedInterval source, dyadic finite cover, StreamName window, RegSeqRat readback, DyadicRatCore threshold ledger, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: closedboundedinterval, bishopcompletionmodulus, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{BishopCompactIntervalModulus}^{\uparrow}$ because this packet binds the closed interval source, finite dyadic cover, compact interval modulus row, completion window, threshold ledger, regular readback, Real seal, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompactIntervalModulus}^{\uparrow}$ packet is generated from a ClosedBoundedInterval source, a dyadic finite cover, a compact interval modulus row, StreamName windows, a DyadicRatCore threshold ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompactIntervalModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7200.1, Definition 7200.2, and Definition 7200.3 seed the compact-interval modulus route through the closed interval source, finite cover, completion window, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompactIntervalModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient Real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cover exposure, compact modulus readback, StreamName and DyadicRatCore threshold compatibility, RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompactIntervalModulusUp.

Chapter 7201

A Concrete Naming Certificate for TailWindowModulusSynchronization$^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences, the TailWindowModulusSynchronization$^{\uparrow}$ packet realizes the regular-Cauchy route of section 9238.1 as a finite synchronization certificate. It sits after the StreamName window surface of chapter 126, the RegSeqRat readback of chapter 301, the DyadicRatCore threshold ledger of chapter 291, the terminal RealUp seal of chapter 38, and the shared tail threshold discipline of chapter 1231. The packet names the finite synchronization between a tail-window request and a displayed modulus row; it does not choose an infinite subsequence, quotient regular Cauchy names, select a limit, invoke countable choice, or assume ambient Real completeness.

Definition 7201.1 (Tail-window modulus synchronization carrier)**.** *A* TailWindowModulusSynchronization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, B, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the displayed modulus row assigning a unary precision request to a tail threshold.*
2. *B is the* TailCofinalityBudget$^{\uparrow}$ *row recording that later tail requests refine the same finite threshold route.*
3. *S is the* StreamName$^{\uparrow}$ *schedule for the regular Cauchy family being inspected.*
4. *W is the finite tail window selected by M and admitted by B.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *ledger containing the tolerance, threshold comparison, and synchronization scale for W.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the synchronized window and dyadic ledger.*
7. *E is the* Real$^{\uparrow}$ *seal row reached only after the modulus, cofinality, window, dyadic, and regular readback rows have been displayed.*
8. *H records componentwise* hsame *transport for the modulus, cofinality budget, stream schedule, selected window, dyadic ledger, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay of the route*

$$M, B, S, W, D \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* TailWindowModulusSynchronization$^{\uparrow}$, TailCofinalityBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{TailWindowModulusSynchronization}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, B, S, W, D, R, E, H, C, P, N$. It has no coordinate for host sequence equality, quotient real equality, selected limits, countable choice, or ambient completeness of Real$^{\uparrow}$.

Theorem 7201.2 (Tail-window modulus synchronization obligations)**.** *For every accepted* TailWindowModulusSync *carrier $T = (M, B, S, W, D, R, E, H, C, P, N)$, the local* NameCert$_{\text{TailWindowModulusSynchronization}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; modulus threshold exposure through M; cofinal tail-budget exposure through B; StreamName window selection through S, W; DyadicRatCore synchronization through D; RegSeqRat readback through R; RealUp seal non-escape through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier. The rows $M, B, S, W, D, R, E, H, C, P, N$ are the only classifier-visible coordinates, so no host sequence equality, quotient real equality, selected limit, choice schedule, or completeness principle can be read from the packet.

Read the synchronization rows in order. The modulus row M chooses the threshold for the displayed precision request, and the tail cofinality budget B records how later requests remain on the same finite route.

The window and readback rows then consume that shared threshold. The StreamName schedule S supplies W, the dyadic ledger D records the synchronized tolerance comparison, and the regular readback R is downstream from those rows.

Finally the Real seal and structural rows preserve the route. The row E is available only after R, while H, C, P, N transport, replay, source, and name the same finite packet. □

Theorem 7201.3 (Tail-window modulus synchronization handoff)**.** *Every Real-completion consumer admitted by an accepted* TailWindowModulusSynchronization$^{\uparrow}$ *packet reads a single finite synchronization route*

$$M, B \longmapsto S, W, D \longmapsto R \longmapsto E.$$

The route synchronizes the modulus threshold with the tail-window budget before any RegSeqRat readback or RealUp seal is available. It exports no quotient regular Cauchy equality, hidden subsequence selector, selected limit, countable-choice row, or ambient Real completeness principle.

Proof. Start from the regular Cauchy vision site section 9238.1. A completion-facing read asks for a finite tail window at a displayed precision, so the packet first exposes the modulus row M and the cofinal budget row B.

Next the window is synchronized with those rows. The schedule S names the finite observations, W is the selected tail window, and D records the dyadic threshold comparison that keeps the modulus and budget aligned.

The readback and seal are downstream. The row R is obtained from the displayed window and ledger, and the terminal row E is available only after R. Since the carrier contains no refused coordinate, the consumer receives exactly the finite synchronization route. □

Falsifiable prediction: An accepted TailWindowModulusSynchronization$^{\uparrow}$ read fails if a Real-completion consumer reaches RegSeqRat readback or a RealUp seal before displaying the modulus row, TailCofinalityBudget row, StreamName window, DyadicRatCore synchronization ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: tail-cofinality-budget, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{TailWindowModulusSynchronization}^{\uparrow}$ because this packet binds a modulus threshold and a cofinal tail budget to one synchronized StreamName window, DyadicRatCore ledger, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming surface.

Closure status for $\mathsf{NameCert}_{\mathsf{TailWindowModulusSynchronization}^{\uparrow}}$.

Constructive story: A $\mathsf{TailWindowModulusSynchronization}^{\uparrow}$ packet is generated from a modulus threshold row, a TailCofinalityBudget row, StreamName windows, a DyadicRatCore synchronization ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TailWindowModulusSynchronization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7201.1, Definition 7201.2, and Definition 7201.3 seed the finite tail-window modulus synchronization route for regular-Cauchy Real-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TailWindowModulusSynchronization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient regular Cauchy equality, hidden subsequence selection, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus threshold exposure, tail cofinality exposure, StreamName window selection, DyadicRatCore synchronization, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.TailWindowModulusSynchronizationUp.

Chapter 7202

A Concrete Naming Certificate for $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ packet records the finite modulus data used to answer an absolute-continuity request on a displayed located real interval. It sits after the real-name seal of chapter 38, the dyadic arithmetic core of chapter 291, the regular rational readback route of chapter 301, and the located interval surface of chapter 1709. The packet gives later integration and uniform-continuity consumers a choice-free finite budget for controlled variation; it does not import Lebesgue measure, measurable sets, null-set completion, countable choice, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7202.1 (Absolute-continuity modulus carrier)**.** *An* $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (E, D, P, R, H, C, G, N)$$

with the following displayed rows:

1. *E is the epsilon request row, naming the positive* $\mathsf{Real}^{\uparrow}$ *tolerance asked of the controlled-variation read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *delta-budget row, recording the dyadic size bound offered in response to E.*
3. *P is the finite partition ledger over a displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source, listing the disjoint subinterval reads whose total dyadic length is compared with D.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the epsilon request, dyadic delta budget, and partition ledger have been displayed.*
5. *H records componentwise* hsame *transport for E, D, P, R and for the replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of every accepted modulus request through*

$$E, D, P, R \longmapsto H, C, G, N.$$

7. *G is the* Pkg *provenance over* $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

8. N is the local $\mathsf{NameCert}_{\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for Lebesgue measure, measurable-set completion, almost-everywhere equality, quotient function equality, selected covers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7202.2 (Absolute-continuity modulus NameCert obligations)**.** *For every accepted* AbsoluteContinuityMod *carrier*

$$A = (E, D, P, R, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}}$ *surface is exhausted by epsilon-request exposure through E, dyadic delta-budget exposure through D, finite partition-ledger exposure through P,* $\mathsf{Real}^{\uparrow}$ *seal exposure through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through G, and local naming through N. Every variation read must pass through the displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows before it may consume the terminal Real seal.*

Proof. Project the carrier of Definition 7202.1. The epsilon request, dyadic budget, finite partition ledger, and terminal Real seal are the only analytic coordinates available to a consumer.

The partition row is finite. Its interval reads are attached to the displayed $\mathsf{LocatedRealInterval}^{\uparrow}$ source and its dyadic length comparisons are read through the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before the regular-rational handoff is replayed.

Finally H, C, G, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for measure completion, almost-everywhere equality, selected covers, countable choice, or ambient Real completeness, the listed rows exhaust the local certificate surface. □

Theorem 7202.3 (Absolute-continuity modulus partition stability)**.** *Let $A = (E, D, P, R, H, C, G, N)$ be an accepted* $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ *carrier. Replacing P by a displayed refinement whose subinterval ledger has the same* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row and whose dyadic total remains bounded by D yields an accepted partition read with the same epsilon request E, Real seal R, transport row H, replay row C, provenance row G, and local name N.*

Proof. Begin with the finite partition ledger. A displayed refinement only subdivides rows already named by P, so every new subinterval still reads from the same located real interval source.

The dyadic comparison is preserved by the budget row D. The refined ledger is accepted only when its displayed total remains below the same delta budget attached to E.

The structural rows then replay the same route. Componentwise hsame transport keeps E, D, R, G, N fixed, and the Cont row replays the refined partition ledger through the same budgeted Real-facing surface. □

Theorem 7202.4 (Absolute-continuity modulus RealUp handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ *packet reaches the terminal seal only through the route*

$$\mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports a finite epsilon–delta partition budget and not a Lebesgue-measure theorem, a null-set completion, a selected cover, quotient function equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Read the carrier in order. The epsilon request E is answered by the dyadic budget D, and the finite partition ledger P is checked against that same budget before any terminal seal is available.

The regular-rational readback is the only completion-facing bridge in the packet. It carries the dyadic ledger to the terminal $\mathsf{Real}^{\uparrow}$ row R without adding measure-theoretic or host-side data.

Thus R is downstream of E, D, P, H, C, G, N and of the displayed sibling rows. A consumer that omits this route is not reading the accepted $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ carrier. □

Falsifiable prediction: Every accepted $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ consumer that reads a terminal Real seal while omitting the epsilon request, dyadic delta budget, finite partition ledger, hsame transport, Cont replay, Pkg provenance, or local NameCert row has left the packet.

Independence witness: real, dyadicratcore, regseqrat, locatedrealinterval: $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ is not bijective with any listed sibling because it joins an epsilon request, a dyadic delta budget, a finite partition ledger, a terminal Real seal, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}}$.

Constructive story: An $\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}$ packet is generated from an epsilon request, a DyadicRatCore delta budget, a finite partition ledger over a LocatedRealInterval source, a RegSeqRat readback route, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7202.1, Definition 7202.2, Definition 7202.3, and Definition 7202.4 seed the finite epsilon–delta partition-modulus surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbsoluteContinuityModulusReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lebesgue measure, measurable-set completion, almost-everywhere equality, quotient function equality, selected covers, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, epsilon-request exposure, dyadic delta-budget exactness, partition-ledger stability, RealUp handoff, structural nonescape, and route replay for BEDC.Derived.AbsoluteContinuityModulusReal

Chapter 7203

A Concrete Naming Certificate for $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ packet records the finite enclosure data used to pass from dyadic interval evidence to a regular rational readback and then to a terminal real-name seal. It sits after the dyadic arithmetic core of chapter 291, the dyadic number surface of chapter 1658, the finite stream-window route of chapter 126, the regular rational sequence route of chapter 301, and the real-name seal of chapter 38. The packet gives completion consumers a non-quotient interval interface; it does not assert arbitrary Cauchy completeness, selected limits, trichotomy, host real equality, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7203.1 (Dyadic interval enclosure carrier)**.** *A* $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, N, S, R, E, H, C, P, A)$$

with the following displayed rows:

1. *L is the lower* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row.*
2. *U is the upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row.*
3. *N is the nesting and order ledger, recording $L \leq U$ and the finite refinement relation between successive enclosure rows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing exactly the finite interval windows consumed by the readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the displayed dyadic endpoints and stream windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, N, S, R have been displayed.*
7. *H records componentwise* hsame *transport for all analytic rows and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of every accepted enclosure read through*

$$L, U, N, S, R, E \longmapsto H, C, P, A.$$

9. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Dyadic}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. A is the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalEnclosure}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a quotient of Cauchy streams, a selected real representative, trichotomy, host real equality, countable choice, or an ambient completeness principle.

Theorem 7203.2 (Dyadic interval enclosure NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ *carrier*

$$I = (L, U, N, S, R, E, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalEnclosure}^{\uparrow}}$ *surface is exhausted by lower endpoint exposure through L, upper endpoint exposure through U, nesting and order exposure through N, finite window exposure through S, regular rational readback through R, terminal real seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through A. Every completion-facing read must pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Dyadic}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows before it may consume the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the carrier of Definition 7203.1. The only endpoint data available to a consumer are L and U, and both are dyadic-core rows. The only order and refinement evidence is the finite ledger N.

The readback path is then fixed. The finite stream window S exposes the displayed enclosure windows, R reads them as regular rational data, and E is downstream of that readback.

Finally H, C, P, A transport, replay, source, and name the same finite rows. Since the carrier has no coordinate for quotient stream equality, selected representatives, trichotomy, host equality, countable choice, or ambient Real completeness, the listed rows exhaust the local certificate surface. □

Theorem 7203.3 (Dyadic interval enclosure nesting stability)**.** *Let $I = (L, U, N, S, R, E, H, C, P, A)$ be an accepted* $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ *carrier. Replacing the displayed window row S by a finite subwindow whose endpoint rows are transported by H and whose refinement relation is recorded by N yields an accepted enclosure read with the same readback row R, terminal seal E, provenance row P, and local name A.*

Proof. Begin with the nesting ledger. A finite subwindow is accepted only when N records its lower and upper endpoints as refinements of the displayed dyadic rows.

The transport row H keeps the endpoint identity visible while the window changes. Thus the refined lower and upper rows still read through the same $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint surface.

The downstream rows are structural. The Cont replay C sends the accepted subwindow through the same regular rational readback R, and the terminal seal E, provenance row P, and local name A remain attached to that replay. □

Theorem 7203.4 (Dyadic interval enclosure Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ *packet reaches the terminal seal only through the route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Dyadic}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff exports a finite nested dyadic interval interface and not a quotient stream, a selected limit, host real equality, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Read the carrier in order. The dyadic endpoint rows L and U are exposed before the nesting ledger N can certify the interval relation.

The stream row S and regular rational row R are the only readback bridge to the terminal real seal. They carry finite dyadic window evidence to E without adding quotient or host-side equality data.

Thus any accepted terminal seal read is attached to the displayed route through the dyadic core, dyadic surface, stream window, regular rational readback, and local structural rows. A consumer that omits this route is not reading the accepted $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ carrier. □

Theorem 7203.5 (Dyadic interval enclosure classifier stability)**.** *Two accepted* $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ *packets are classifier-equivalent whenever their lower endpoint rows, upper endpoint rows, nesting ledgers, stream windows, regular rational readbacks, terminal real seals, transport rows, replay rows, provenance rows, and local NameCert rows are pairwise* hsame*. No extra classifier coordinate may distinguish them by a host representative, a selected limit, a quotient stream class, trichotomy data, countable choice data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The classifier of Definition 7203.1 reads only the ten displayed rows. Pairwise hsame therefore identifies the endpoint surface, nesting ledger, finite window, readback, terminal seal, transport, replay, provenance, and local naming data.

There is no hidden coordinate left to inspect. The excluded host representative, selected limit, quotient stream class, trichotomy, countable-choice, and ambient-completeness data are not fields of the carrier.

Consequently the two packets have the same local classifier read precisely when the listed finite rows agree componentwise. □

Falsifiable prediction: Every accepted $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ consumer that reads a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting a lower endpoint row, upper endpoint row, nesting ledger, StreamName window, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, or local NameCert row has left the packet.

Independence witness: dyadicratcore, dyadic, streamname, regseqrat, real: $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ is not bijective with any listed sibling because it joins dyadic endpoint rows, a finite nesting ledger, stream windows, regular rational readback, a terminal real seal, transport, replay, provenance, and local naming as one packet.

Lean4 (statement) `BEDC.Derived.DyadicIntervalEnclosureUp`

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalEnclosure}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalEnclosure}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint rows, a finite nesting and order ledger, a StreamName window row, a RegSeqRat readback row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalEnclosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7203.1, Definition 7203.2, Definition 7203.3, Definition 7203.4, and Definition 7203.5 seed the finite dyadic interval enclosure surface for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalEnclosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary Cauchy completeness, selected limits, quotient stream equality, trichotomy, host real equality, countable choice, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, nesting stability, regular rational readback, RealUp handoff, classifier stability, structural nonescape, and route replay for BEDC.Derived.DyadicIntervalEnclosureUp.

Chapter 7204

A Concrete Naming Certificate for $\mathsf{DenseGDelta}^{\uparrow}$

Following Baire and Oxtoby, the $\mathsf{DenseGDelta}^{\uparrow}$ packet records the standard dense G_δ surface as finite BEDC NameCert data. It sits between the countable open-row schedule of chapter 3547, the residual evidence carrier of chapter 7188, the dense-open Baire route of chapter 1542, and the complete-metric inspection surface of chapter 3535. The packet names the positive dense-open face of residual evidence; it does not choose a generic point, assert a host intersection, import countable choice, or identify quotient subsets.

Definition 7204.1 (DenseGDelta carrier)**.** *A* $\mathsf{DenseGDelta}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, G, S, O, B, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the ambient topology or complete-metric source row over which density is read.*
2. *G is the* $\mathsf{GDeltaSet}^{\uparrow}$ *countable open-row schedule, displayed as finite prefix data.*
3. *S is the dense-open schedule row, read through the Baire-category surface before any residual consumer receives the packet.*
4. *O records the open-row readback and local density witnesses for the schedule positions visible through G and S.*
5. *B is the Baire route row linking the dense-open schedule to the inspected complete-metric Baire surface.*
6. *R is the* $\mathsf{ResidualSet}^{\uparrow}$ *handoff row exposed only after the positive dense G_δ side has been displayed.*
7. *H records componentwise* hsame *transport for $T, G, S, O, B, R, C, P, N$.*
8. *C records displayed* Cont *replay of the schedule, density, Baire, residual, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{DenseGDelta}^{\uparrow}$, $\mathsf{GDeltaSet}^{\uparrow}$, $\mathsf{ResidualSet}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurfa}$ BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseGDelta}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected generic point, a host-level countable intersection, unrestricted set equality, quotient subset equality, or countable-choice selector outside the displayed BEDC rows.

Theorem 7204.2 (DenseGDelta NameCert obligations)**.** *For every accepted* $\mathsf{DenseGDelta}^{\uparrow}$ *carrier* $D = (T, G, S, O, B, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DenseGDelta}^{\uparrow}}$ *surface consists exactly of ambient source admission through* T*, countable open-schedule exposure through* G*, dense-open schedule exposure through* S*, open-row and density readback through* O*, Baire route handoff through* B*, residual handoff through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7204.1. The accepted packet displays exactly the ambient source row, countable open-row schedule, dense-open schedule, open-row readback, Baire route, residual handoff, transport, replay, provenance, and local name.

The positive topological content is exhausted by G, S, O, B. The G row supplies the G_δ schedule, the S row supplies the dense-open requests, O records the local readback and density witnesses, and B routes the read through the Baire surface.

The residual side is only a downstream handoff. The row R may be consumed after the positive dense G_δ evidence has been displayed, while H, C, P, N transport, replay, source, and name the same finite route.

No coordinate stores a chosen generic point, a host intersection object, countable-choice data, or quotient subset equality. The listed rows therefore exhaust the local NameCert obligations. □

Theorem 7204.3 (DenseGDelta residual handoff)**.** *Every residual consumer of an accepted* $\mathsf{DenseGDelta}^{\uparrow}$ *packet factors through chapter 3547, chapter 1542, and chapter 3535 before it reads the* $\mathsf{ResidualSet}^{\uparrow}$ *row. Thus the residual route receives a positive dense-open* G_δ *certificate, not a hidden host intersection or selected generic point.*

Proof. Project $D = (T, G, S, O, B, R, H, C, P, N)$. A residual consumer cannot read R until the preceding rows expose the countable open schedule, dense-open schedule, local density readback, and Baire route.

The G row routes through the $\mathsf{GDeltaSet}^{\uparrow}$ certificate, while S and O display the dense-open and local readback data. The Baire row B then passes through the complete-metric Baire surface before the residual handoff is available.

Since the carrier contains no host intersection coordinate, no selected generic point, no countable-choice selector, and no quotient subset equality, the residual consumer receives only the displayed positive dense G_δ route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DenseGDelta}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DenseGDelta}^{\uparrow}}$, seed)

Scope closed: Definition 7204.1, Definition 7204.2, and Definition 7204.3 seed the positive dense G_δ route over GDeltaSet, BaireCategory, CompleteMetricBaireSurface, ResidualSet, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DenseGDelta}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close generic-point choice, host intersections, countable choice, quotient subset equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exactness, GDeltaSet exposure, residual handoff, Baire routing, transport, replay, provenance, local naming, and refusal of hidden host intersections for BEDC.Derived.DenseGDeltaUp.

Constructive story: A $\mathsf{DenseGDelta}^{\uparrow}$ packet is generated from an ambient source row, a $\mathsf{GDeltaSet}^{\uparrow}$ schedule, a dense-open schedule, local open-row and density readback, a Baire route, a $\mathsf{ResidualSet}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7205

A Concrete Naming Certificate for DyadicRoundingProjection$^{\uparrow}$

Following Bishop and Bridges, the DyadicRoundingProjection$^{\uparrow}$ packet records the finite floor-and-ceiling projection surface by which a dyadic approximation request is bracketed before any RegSeqRat$^{\uparrow}$ readback or terminal Real$^{\uparrow}$ seal is consumed. It sits over the arithmetic carrier of chapter 291, the interval endpoint ledger of chapter 306, the finite window source of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet names only a finite rounding projection route; it does not assert quotient real equality, selected limits, omniscient rounding, or ambient completeness of Real$^{\uparrow}$.

Definition 7205.1 (Dyadic rounding projection carrier)**.** *A* DyadicRoundingProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, I, S, R, E, F, G, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *arithmetic and comparison row for the inspected dyadic precision.*
2. *I is the* DyadicInterval$^{\uparrow}$ *endpoint row containing the lower and upper dyadic cells visible at that precision.*
3. *S is the* StreamName$^{\uparrow}$ *finite-window row whose inspected values are rounded.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row that receives the rounded dyadic bracket.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row read only after D, I, S, R have been displayed.*
6. *F is the floor projection row selecting the greatest displayed dyadic cell not above the inspected window value.*
7. *G is the ceiling projection row selecting the least displayed dyadic cell not below the inspected window value.*
8. *H is the componentwise* hsame *transport row for $D, I, S, R, E, F, G, C, P, N$.*
9. *C is the displayed* Cont *replay row forcing every downstream consumer through the same floor, ceiling, interval, stream, readback, seal, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* DyadicRoundingProjection$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicInterval$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRoundingProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for an exact host real value, a selected limit, a quotient real representative, countable choice, or ambient completeness.

Theorem 7205.2 (Dyadic rounding projection NameCert obligations)**.** *For every accepted* DyadicRoundingProjectio *carrier $Q = (D, I, S, R, E, F, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicRoundingProjection}^{\uparrow}}$ *surface consists exactly of these five obligation rows:*

1. *carrier admission for the dyadic arithmetic row, dyadic interval row, stream window row, regular rational readback row, real seal row, floor row, ceiling row, transport row, replay row, provenance row, and local name;*
2. *floor exactness, requiring F to expose a displayed dyadic endpoint from I whose comparison is certified by D and whose inspected value is read from S;*
3. *ceiling exactness, requiring G to expose a displayed dyadic endpoint from I whose comparison is certified by D and whose inspected value is read from S;*
4. *bracket replay, requiring the ordered pair (F, G) to be consumed by* $\mathsf{RegSeqRat}^{\uparrow}$ *through R before the* $\mathsf{Real}^{\uparrow}$ *seal row E is visible;*
5. *classifier transport and non-escape, requiring componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and local naming while excluding host real values, selected limits, quotient representatives, countable choice, and ambient completeness.*

No rounding obligation is stored outside this finite carrier.

Proof. Project the carrier of Definition 7205.1. The arithmetic, interval, stream, readback, seal, floor, ceiling, transport, replay, provenance, and local naming rows are exactly $D, I, S, R, E, F, G, H, C, P, N$.

The floor and ceiling rows are read through the same dyadic interval row I and the same arithmetic comparison row D. The finite window row S supplies the inspected values, while F and G choose only displayed dyadic cells.

The bracket replay row then routes (F, G) into the regular rational readback R and only afterward into the real seal E. Transport through H and replay through C keep the classifier attached to the same displayed rows.

Since the packet has no coordinate for exact host real values, selected limits, quotient representatives, countable choice, or ambient completeness, the five listed rows exhaust the local certificate. □

Theorem 7205.3 (Dyadic rounding projection floor-ceiling bracket)**.** *Every accepted* $\mathsf{DyadicRoundingProjection}^{\uparrow}$ *carrier exposes a finite bracket in which the floor row F and ceiling row G are dyadic endpoints from the displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *row I, both comparisons are witnessed by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D, and both endpoints are tied to the same* $\mathsf{StreamName}^{\uparrow}$ *window row S. A downstream consumer cannot replace the bracket by a host real comparison, selected representative, quotient equality, or ambient completeness principle.*

Proof. Use the obligation surface of Definition 7205.2. The floor row and ceiling row are admitted only as cells in the same displayed interval row I.

The comparison evidence is supplied by D, and the inspected source value is supplied by S. Thus the two endpoints form one finite bracket over the same dyadic precision and the same stream window.

The non-escape row of the certificate rules out a second bracket supplied by host real comparison, selected representatives, quotient equality, or ambient completeness. □

Theorem 7205.4 (Dyadic rounding projection RegSeqRat readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicRoundingProjection}^{\uparrow}$ *packet reads the rounded approximation through the ordered route*

$$(D, I, S) \longmapsto (F, G) \longmapsto R \longmapsto E$$

with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row attached. The route exports a finite dyadic bracket for regular rational readback and does not export a selected completed real, quotient equality of real names, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer read. By Definition 7205.2, the read must first expose the dyadic arithmetic row, interval row, and stream window row.

Next apply the floor-ceiling bracket theorem. It identifies F and G as the only rounded endpoints available to the consumer.

Finally replay the bracket through R and then through E. The transport, replay, provenance, and local naming rows H, C, P, N keep the route finite, and the carrier has no coordinate for selected completed reals, quotient equality, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRoundingProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicRoundingProjection}^{\uparrow}$ packet is generated from dyadic arithmetic rows, dyadic interval endpoints, stream windows, floor and ceiling projection rows, regular rational readback, a terminal real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicRoundingProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7205.1, Definition 7205.2, Definition 7205.3, and Definition 7205.4 seed the finite floor-ceiling rounding projection surface for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicRoundingProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, selected real limits, quotient equality of real names, countable choice, omniscient rounding, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, floor exactness, ceiling exactness, bracket replay, classifier transport, and non-escape for BEDC.Derived.DyadicRoundingProjectionUp.

Chapter 7206

A Concrete Naming Certificate for $\mathsf{BishopRealRegularization}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopRealRegularization}^{\uparrow}$ packet records the terminal real-name regularization route for the L10 Real and Completion corridor. It sits after the raw-to-regular service of chapter 4100, the sequential tightening surface of chapter 3615, the located regularization boundary of chapter 1935, the finite window service of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the displayed regularization certificate from raw Cauchy data to a sealed Real row; it does not quotient streams, choose a host limit, use countable choice, invoke trichotomy, identify host sequences, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7206.1 (Bishop real regularization carrier)**.** *A* $\mathsf{BishopRealRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, T, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the raw Cauchy source row, exposing the finite source requests and their Cauchy-window evidence.*
2. *T is the Bishop regularization threshold row, recording the finite stage at which each requested tolerance is served by a regularized window.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, naming the source windows and the regularized output windows inspected at the threshold supplied by T.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational name produced by T and W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording source tolerances, threshold tolerances, readback tolerances, and the Real-facing output budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after Q, T, W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for $Q, T, W, R, D, E, C, P, N$.*
8. *C records the displayed* Cont *replay from a Bishop regularization request through $Q, T, W, R, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRealRegularization}^{\uparrow}$, $\mathsf{RegularCauchyRegularization}^{\uparrow}$, SequentialCauchyRegulari $\mathsf{LocatedRegularization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopRealRegularization}^{\uparrow}}$ *row.*
The carrier predicate asserts exactly that these rows form one finite Bishop real-name regularization history. It has no coordinate for quotient stream equality, selected host limits, countable choice, trichotomy, host sequence equality, or ambient Real completeness.

Theorem 7206.2 (Bishop real regularization NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealRegularization}^{\uparrow}$ *carrier* $B = (Q, T, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRealRegularization}^{\uparrow}}$ *surface consists exactly of raw Cauchy source exposure, Bishop threshold exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No consumer receives quotient streams, selected host limits, countable-choice schedules, trichotomy decisions, host sequence equality, or ambient Real completeness from the packet.*

Proof. Project the carrier of Definition 7206.1. Its analytic rows are Q, T, W, R, D, E, so every accepted regularization read must expose the raw Cauchy source, threshold, finite windows, rational readback, tolerance ledger, and terminal seal.

The regularization obligations are read from T, W, R, D. The threshold row supplies the finite stage, the window row displays the source and output observations at that stage, the readback row packages those observations as a regular rational name, and the dyadic ledger records the tolerances used by the whole route.

The structural rows preserve the same route. Transport H is componentwise, replay C consumes the displayed rows in dependency order, and P, N record provenance and local naming.

Since the carrier contains no quotient-stream, selected-limit, choice, trichotomy, host-equality, or completeness coordinate, none of those objects can be exported through the local NameCert surface. □

Theorem 7206.3 (Bishop real regularization Real-seal handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{BishopRealRegularization}^{\uparrow}$ *packet factors through the finite route*

$$Q \longmapsto T \longmapsto W, D \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the consumer reads the raw Cauchy source, then the Bishop regularization threshold, then finite stream windows and dyadic tolerance data, then the regular rational readback, and only then the terminal $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports no quotient stream, selected limit, countable-choice selector, trichotomy row, host sequence equality, or ambient completeness theorem.*

Proof. Begin with an accepted carrier $B = (Q, T, W, R, D, E, H, C, P, N)$. The source row Q is the only raw Cauchy source coordinate, so a Real-facing read starts there.

Use the threshold and window rows next. The row T supplies the finite Bishop regularization stage, while W and D record the finite observations and tolerances checked at that stage.

The readback row R is downstream of the threshold and window data. It is the only regular rational name available before the terminal seal is inspected.

Finally read E, H, C, P, N. These rows seal, transport, replay, source, and name the same finite route. They do not add quotient, selection, choice, trichotomy, host-equality, or completeness data. □

Theorem 7206.4 (Bishop real regularization no-choice boundary)**.** *An accepted* $\mathsf{BishopRealRegularization}^{\uparrow}$ *carrier is a finite regularization packet over* $Q, T, W, R, D, E, H, C, P, N$ *and not a countable-choice principle. Any attempt to read a chosen limit, a selected representative stream, a host sequence-equality decision, or a trichotomy comparison must leave the displayed carrier surface before the* $\mathsf{Real}^{\uparrow}$ *seal can be used.*

Proof. Project the carrier through Definition 7206.1. The rows available to a consumer are exactly $Q, T, W, R, D, E, H, C, P, N$.

Apply the NameCert obligations of Definition 7206.2. They force every accepted read to expose the raw source, threshold, windows, readback, tolerance ledger, seal, and structural rows.

Use the Real-seal handoff of Definition 7206.3. The terminal seal is downstream of the finite route and cannot be reached from a selected limit or representative stream.

Therefore countable choice, trichotomy, host sequence equality, selected limits, and quotient streams are outside the packet boundary. A consumer that uses any of them is no longer reading the displayed $\mathsf{BishopRealRegularization}^{\uparrow}$ carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealRegularization}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealRegularization}^{\uparrow}$ packet is generated from a raw Cauchy source row, Bishop regularization threshold, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealRegularization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7206.1, Definition 7206.2, Definition 7206.3, and Definition 7206.4 seed the finite route from raw Cauchy source data through Bishop regularization, regular rational readback, dyadic tolerance accounting, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealRegularization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, trichotomy, host sequence equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold stability, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance routing, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealRegularizationUp.

Chapter 7207

A Concrete Naming Certificate for $\mathsf{ConstructiveUniformBoundedImage}^{\uparrow}$

Bishop-style constructive compact metric analysis bounds the image of a uniformly continuous map by reading finite source nets through a displayed modulus and then sealing the resulting radius as a real-name row. The $\mathsf{ConstructiveUniformBoundedImage}^{\uparrow}$ packet records that finite-net bounded-image route as NameCert data. It consumes the compact source surface of chapter 129, the compact interval source route of chapter 3986, the graph data of chapter 130, the tolerance ledger of chapter 369, the dyadic-radius arithmetic of chapter 291, the rational readback of chapter 301, and the terminal seal of chapter 38. The packet names a bounded-image certificate; it does not introduce open-cover compactness, a host image subset, selected extrema, quotient real equality, or ambient completeness.

Definition 7207.1 (Constructive uniform bounded-image carrier)**.** *A* $\mathsf{ConstructiveUniformBoundedImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, U, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is a compact finite-net source row, read either through* $\mathsf{CompactMetric}^{\uparrow}$ *or through the interval finite-net source data of* $\mathsf{CompactInterval}^{\uparrow}$*.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row from the displayed source carrier to the target metric carrier.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row that sends a target-radius request to a source-net radius request for the same graph row.*
4. *M is the target* $\mathsf{Met}^{\uparrow}$ *distance row used to compare all displayed image centers with the chosen base image center.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger containing the source radius, target tolerance, finite maximum-radius fold, and comparison scale.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that packages the dyadic radius ledger as a regular rational bound schedule.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *bound seal reached only after the compact source row, map graph, uniform modulus, target metric distance row, dyadic ledger, and rational readback have been displayed.*
8. *H records componentwise* hsame *transport for K, F, U, M, D, R, E and the local structural rows.*

9. *C records displayed* Cont *replay from a bounded-image request through source nets, graph evaluation, uniform-modulus routing, dyadic radius folding, rational readback, and the terminal bound seal.*

10. *P is the* Pkg *provenance over* ConstructiveUniformBoundedImage$^{\uparrow}$, CompactMetric$^{\uparrow}$, CompactInterval$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, Met$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{ConstructiveUniformBoundedImage}^{\uparrow}}$ *row.*

The carrier contains no coordinate for open-cover compactness, host image subsets, selected extrema, quotient equality of real names, choice-selected image centers, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7207.2 (Constructive uniform bounded-image NameCert obligations)**.** *For every accepted* ConstructiveUniformBoundedImage$^{\uparrow}$ *carrier $B = (K, F, U, M, D, R, E, H, C, P, N)$, the local* NameCert$_{\text{ConstructiveUniformBoundedImage}^{\uparrow}}$ *surface consists exactly of carrier admission, compact finite-net source admission through K, continuous-map graph admission through F, uniform-modulus compatibility through U, target metric-distance admission through M, dyadic radius-ledger admission through D, regular rational readback through R, terminal* Real$^{\uparrow}$ *bound sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 7207.1. The packet displays the compact source row, graph row, modulus row, target metric row, dyadic ledger, rational readback, real seal, transport, replay, provenance, and local naming as the only available coordinates.

The analytic rows are read in finite order. First the compact source row K supplies finite net centers, then the graph row F evaluates the map on those centers, and the uniform modulus row U ties the requested target radius to the displayed source coverage radius.

The boundedness rows are then forced through M, D, R, E. The target metric row measures finite image-center distances, the dyadic ledger records the finite radius fold, the regular rational row reads the radius schedule, and the Real$^{\uparrow}$ row seals the resulting bound.

Finally H, C, P, N preserve, replay, source, and name the same route. Since no excluded host-image, selected-extremum, quotient, choice, open-cover, or completeness coordinate occurs in the carrier, those data cannot be exported by the local NameCert surface. □

Theorem 7207.3 (Constructive uniform bounded-image finite-net bound)**.** *Every bounded-image consumer of an accepted* ConstructiveUniformBoundedImage$^{\uparrow}$ *carrier receives only the finite route*

$$K, F, U, M, D, R, E, H, C, P, N.$$

The bound is obtained by evaluating the displayed ContinuousMap$^{\uparrow}$ *graph on the compact finite-net centers from* CompactMetric$^{\uparrow}$ *or* CompactInterval$^{\uparrow}$*, transporting the tolerance request through* UniformModulus$^{\uparrow}$*, folding the resulting target distances in the* DyadicRatCore$^{\uparrow}$ *ledger, reading the radius through* RegSeqRat$^{\uparrow}$*, and sealing it through* Real$^{\uparrow}$*. The route is a finite bounded-image modulus, not an open-cover compactness theorem, a host image subset, a selected maximum, quotient real equality, or an ambient completeness claim.*

Proof. Start with the compact source row K. It exposes finite source centers and coverage radii only; if the source is an interval packet, the interval row is read as the same finite-net source surface.

Read the map and modulus rows F, U. The graph row supplies the image centers, while the uniform modulus converts the requested target radius into the source-net radius used by K.

Now compute the displayed radius ledger. The target metric row M measures distances from the chosen base image center to the finite list of image centers, and the dyadic ledger D records the finite maximum-radius fold together with the target tolerance scale.

Finally read R and E. The $\mathsf{RegSeqRat}^{\uparrow}$ row packages the dyadic radius as a regular rational bound schedule, and the $\mathsf{Real}^{\uparrow}$ row seals that schedule as the bounded-image radius. Transport, replay, provenance, and local naming preserve this route without adding open-cover compactness, host image subsets, selected extrema, quotient real equality, choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveUniformBoundedImage}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveUniformBoundedImage}^{\uparrow}$ packet is generated from CompactMetric or CompactInterval finite-net source data, ContinuousMap graph rows, a UniformModulus ledger, target Metric distance rows, a DyadicRatCore radius ledger, RegSeqRat readback, a RealUp bound seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveUniformBoundedImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7207.1, Definition 7207.2, and Definition 7207.3 seed the finite-net bounded-image carrier and its radius-seal route over compact source data, continuous maps, uniform moduli, dyadic ledgers, regular rational readback, and RealUp seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveUniformBoundedImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host image subsets, selected extrema, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net source admission, graph and modulus compatibility, dyadic radius folding, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local NameCert registration for BEDC.Derived.ConstructiveUniformBoundedImageUp.

Chapter 7208

A Concrete Naming Certificate for $\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}$

Following Bishop–Bridges compact metric analysis and the Arzela–Ascoli family-modulus route, the $\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}$ packet records the finite envelope by which compact finite nets, equicontinuity rows, and rational lower-bound folds produce one uniform-modulus handoff for a displayed family. It realizes the compact-uniform-continuity vision of chapter 9237 through the compact metric source of chapter 129, the equicontinuity surface of chapter 4076, the uniform-modulus consumer of chapter 369, the continuous-map rows of chapter 130, the metric-distance rows of chapter 57, the rational fold interface of chapter 37, and the terminal real-name seal of chapter 38. The packet names a finite family envelope; it does not import open-cover compactness, a selected subcover, quotient equality of maps, a host compact-image theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7208.1 (CompactUniformEquicontinuityEnvelope carrier)**.** *A* $\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, M, Q, U, D, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including the compact source, center rows, coverage radii, and located metric data.*
2. *F is the* $\mathsf{Equicontinuity}^{\uparrow}$ *family row, exposing the shared family modulus requests read at the bundled centers.*
3. *M is the family-modulus envelope row, tying each center and family observation to one displayed radius ledger.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over the finite family-radius ledger.*
5. *U is the resulting* $\mathsf{UniformModulus}^{\uparrow}$ *handoff consumed by compact-uniform family arguments.*
6. *D is the* $\mathsf{Met}^{\uparrow}$ *source and target distance row used for the triangle transport of the shared radius.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for real-valued family reads after the finite fold and metric rows have been displayed.*
8. *H records componentwise* hsame *transport for $K, F, M, Q, U, D, R, C, P, N$.*

9. *C records displayed* Cont *replay from compact-net extraction to family-modulus reads, rational lower-bound folding, metric-triangle transport, uniform-modulus export, Real sealing, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, selected subcovers, unrestricted host equality of maps, a quotient function space, countable choice, or ambient Real completeness.

Theorem 7208.2 (CompactUniformEquicontinuityEnvelope NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}$ *carrier* $E = (K, F, M, Q, U, D, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, equicontinuity family exposure through F, family-modulus envelope visibility through M, rational lower-bound fold exactness through Q, uniform-modulus export through U, metric-distance transport through D, Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7208.1. The compact source is exhausted by K, which supplies the finite net and located metric coverage data.

The family side is exhausted by F and M. These rows display the equicontinuity request and the family-radius envelope at the compact-net centers. The single global radius can only be read after Q folds those finitely many rational rows.

The consumer side is exhausted by U, D, R. The uniform-modulus row exports the shared radius, the metric row performs the source and target triangle transports, and the Real row seals the real-valued reads after those finite data are public. The structural rows H, C, P, N only transport, replay, source, and name the same packet, so the listed obligations exhaust the local certificate. □

Theorem 7208.3 (CompactUniformEquicontinuityEnvelope family-modulus handoff)**.** *Every compact-uniform, equicontinuity, or Arzela–Ascoli consumer of an accepted* $\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Equicontinuity}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer receives compact finite nets, displayed family moduli, rational lower-bound folds, metric-triangle transport, uniform-modulus export, and the Real seal, but it receives no host compactness theorem, selected subcover, quotient equality of maps, family choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the compact and family rows first. The compact metric row K supplies the finite net, and the equicontinuity row F supplies the shared family-modulus requests visible at those centers.

Next read the envelope and fold rows. The row M binds the finitely many center and family observations to radius ledgers, and Q is the only coordinate that turns those ledgers into one rational lower bound. Thus the proposed family modulus is a finite fold, not a selected external function.

Finally read the consumer rows. The metric row D transports the center estimates to arbitrary source points, U records the tolerance-only uniform-modulus handoff, and R seals the Real-facing

reads. Since the carrier has no coordinate for host compactness, selected subcovers, quotient equality, family choice, or ambient completeness, every accepted handoff remains on the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, Equicontinuity family-modulus rows, a displayed family envelope, a RatUp lower-bound fold, UniformModulus export, Metric transport, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7208.1, Definition 7208.2, and Definition 7208.3 seed the compact family-modulus envelope over compact finite nets, equicontinuity rows, RatUp folds, UniformModulus handoff, Metric transport, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, selected subcovers, quotient equality of maps, family choice principles, Arzela–Ascoli compactness, standard bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, family-modulus envelope exactness, rational lower-bound fold exactness, uniform-modulus export, metric transport, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformEquicontinuityEnvelopeUp.

Chapter 7209

A Concrete Naming Certificate for $\mathsf{CofinalReindexing}^{\uparrow}$

Following Bishop and Bridges on cofinal subsequences of regular Cauchy names, the $\mathsf{CofinalReindexing}^{\uparrow}$ packet records the finite reindexing route by which a displayed tail request is moved along a monotone cofinal index row before any regular rational readback or Real seal is consumed. It sits between the general reindexing surface of chapter 1568, the regular Cauchy specialization of chapter 6960, the finite tail-map packet of chapter 2141, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite cofinal-tail reindex certificate; it is not quotient stream equality, not a selected subsequence limit, not countable choice, not host real equality, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7209.1 (Cofinal reindexing carrier)**.** *A* $\mathsf{CofinalReindexing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, T, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the cofinal monotone index row, recording the finite target-to-source request map, its displayed order comparisons, and the finite reachability witnesses for the target requests under inspection.*
2. *T is the tail-window row, recording the target tail cuts and the source cuts selected by M for the current finite request window.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row read after T has fixed the target and source windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the stream windows have been routed through M and T.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular rational readback has been displayed.*
6. *H records componentwise* hsame *transport for M, T, S, R, E, C, P, N.*
7. *C records displayed* Cont *replay from a target precision request through the cofinal index row, tail-window row, StreamName window, RegSeqRat readback, and Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CofinalReindexing}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{RegularCauchyReindexing}^{\uparrow}$, $\mathsf{CofinalTailMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CofinalReindexing}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient stream equality, selected subsequence limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7209.2 (Cofinal reindexing NameCert obligations)**.** *For every accepted* $\mathsf{CofinalReindexing}^{\uparrow}$ *carrier $G = (M, T, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalReindexing}^{\uparrow}}$ *surface consists exactly of carrier admission for the cofinal monotone index row, tail-window row,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. The obligations require each target request to reach a displayed source cut through M and T before any stream window, regular readback, or Real seal is consumed.*

Proof. Project the carrier of Definition 7209.1. The rows M, T, S, R, E are the complete analytic route, while H, C, P, N transport, replay, source, and name that route.

The index row M supplies only finite monotone comparisons and cofinal reachability witnesses for the requests under inspection. The tail-window row T records the target cuts and the corresponding source cuts selected by that row.

Once M and T are fixed, the $\mathsf{StreamName}^{\uparrow}$ row S may be read, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is downstream of the same finite windows. The terminal seal E is therefore a Real-facing read of the displayed reindexing route, not a host-selected subsequence, quotient stream, countable-choice schedule, or ambient completeness claim. □

Theorem 7209.3 (Cofinal reindexing tail-window stability)**.** *Let $G = (M, T, S, R, E, H, C, P, N)$ and $G' = (M', T', S', R', E', H', C', P', N')$ be accepted* $\mathsf{CofinalReindexing}^{\uparrow}$ *carriers whose cofinal index rows and tail-window rows agree through the displayed classifier. Then every* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *read transported from G to G' uses the same finite target cuts, source cuts, monotone comparisons, and cofinal reachability witnesses before reaching the Real seal.*

Proof. Use the classifier of Definition 7209.1. Agreement of M, T fixes the target requests, source cuts, order comparisons, and cofinal witnesses visible to both packets.

Apply Definition 7209.2. The stream window S and regular readback R cannot be read until the index and tail-window rows have been displayed, so their transported versions remain attached to the same finite route.

The structural rows H, C, P, N preserve only componentwise transport, replay, provenance, and naming. They do not add a selected subsequence, quotient equality, countable-choice schedule, host equality, or ambient completeness row, so the transported Real seal remains downstream of the same tail-window data. □

Theorem 7209.4 (Cofinal reindexing Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CofinalReindexing}^{\uparrow}$ *carrier factors through the finite route*

$$M \longmapsto T \longmapsto S \longmapsto R \longmapsto E.$$

Thus the terminal seal is reached only after the cofinal monotone index row, tail-window row, $\mathsf{StreamName}^{\uparrow}$ *window, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed. The read exports no quotient stream equality, selected subsequence limit, countable-choice schedule, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of the seal row E. By Definition 7209.2, the seal is downstream of R, and R is downstream of the stream window S.

The stream window is not free-standing. It is read only after M has selected displayed source cuts for the target requests and T has recorded the corresponding tail windows.

Componentwise transport, replay, provenance, and local naming keep that route visible. Since none of the excluded host or quotient objects is a carrier coordinate, the Real-facing consumer cannot bypass the finite cofinal reindexing packet. □

Theorem 7209.5 (Cofinal reindexing seed scope)**.** *The* $\mathsf{CofinalReindexing}^{\uparrow}$ *seed closes exactly the finite cofinal reindexing route from displayed target requests to source cuts, StreamName windows, RegSeqRat readback, and the terminal Real seal. It supplies a handoff surface for Real and Completion consumers using chapter 1568, chapter 6960, and chapter 2141; it does not close quotient stream equality, selected limits, countable choice, ambient completeness, Lean verification, or bridge checking.*

Proof. The seed route is the carrier route of Definition 7209.1. It displays the cofinal index row, tail windows, stream window, regular readback, Real seal, transport, replay, provenance, and local naming.

Use Definition 7209.3 for stability of the finite source and target windows, and use Definition 7209.4 for the terminal Real-facing boundary.

These results are exactly the finite handoff needed by the surrounding reindexing, tail-map, StreamName, RegSeqRat, and Real chapters. They do not add any row for the excluded quotient, selection, choice, completeness, verification, or bridge claims. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalReindexing}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalReindexing}^{\uparrow}$ packet is generated from a cofinal monotone index row, a tail-window row, a StreamName window, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalReindexing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7209.1, Definition 7209.2, Definition 7209.3, Definition 7209.4, and Definition 7209.5 seed the finite cofinal reindexing route from displayed target requests through StreamName windows and RegSeqRat readback to the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalReindexing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected subsequence limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal monotone index exposure, tail-window stability, regular readback ordering, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CofinalReindexingU

Chapter 7210

A Concrete Naming Certificate for BishopCompletionModulusSelection$^{\uparrow}$

Following Bishop and Bridges, the BishopCompletionModulusSelection$^{\uparrow}$ packet names the finite threshold-selection surface that sits between a displayed completion modulus and the terminal Real-facing seal. It refines the finite completion route of chapter 1469, reads monotone thresholds from chapter 292, opens finite windows through chapter 126, accounts for dyadic tolerances through chapter 291, repacks the selected window through chapter 301, and hands the result to the terminal boundary of chapter 38. The packet names only a displayed finite threshold selection; it does not select a completed limit, quotient stream representative, host real equality witness, countable-choice schedule, or ambient completeness principle.

Definition 7210.1 (Bishop completion modulus selection carrier)**.** *A* BishopCompletionModulusSelection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, n, k, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* BishopCompletionModulus$^{\uparrow}$ *row whose visible modulus route is being queried.*
2. *n is the displayed precision request.*
3. *k is the finite threshold row selected from M at request n.*
4. *W is the* StreamName$^{\uparrow}$ *finite window read at the selected threshold.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger attached to the same threshold and window.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed window and dyadic ledger.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row available only after M, n, k, W, D, R are displayed.*
8. *H records componentwise* hsame *transport for the modulus, request, threshold, window, dyadic ledger, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the precision request through the selected threshold to the window, dyadic ledger, readback, and seal.*
10. *P is the* Pkg *provenance over* BishopCompletionModulusSelection$^{\uparrow}$, BishopCompletionModulus$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionModulusSelection}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient stream equality, a selected completed limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.BishopCompletionModulusSelectionUp.BishopCompletionModulusSelectionUp`
Lean4 ✓ `BEDC.Derived.BishopCompletionModulusSelectionUp.BishopCompletionModulusSelectionTasteGate`
`single carrier alignment`

Theorem 7210.2 (Bishop completion modulus selection NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionModulusSelection}^{\uparrow}$ *carrier* $S = (M, n, k, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionModulusSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-modulus row exposure, precision request exposure, finite threshold selection,* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside those rows.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusSelectionUp.BishopCompletionModulusSelectionNameCertObligat`

Proof. Project the carrier of Definition 7210.1. The analytic route rows are M, n, k, W, D, R, E, and the structural rows are H, C, P, N.

The threshold obligation is local. The row k is read from the displayed completion-modulus row M at the request n, and the window row W is read only after that threshold is visible.

The dyadic and regular rows are downstream from the same threshold. The ledger D records the tolerance data for W, while R repacks W, D as the regular rational handoff before the seal E is available.

Finally H, C, P, N transport, replay, source, and name exactly that route. Since no other carrier coordinate exists, quotient stream equality, selected limits, countable choice, host real equality, and ambient completeness cannot be local obligations of the packet. □

Theorem 7210.3 (Bishop completion modulus selection threshold choice)**.** *Every accepted* BishopCompletionModul *carrier selects its finite threshold through the displayed route*

$$M, n \longmapsto k \longmapsto W, D.$$

The selected threshold is therefore a row of the packet rather than a hidden choice function: downstream $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers may inspect only the displayed threshold, the finite window opened at that threshold, and the dyadic tolerance ledger attached to the same window.*

Proof. Start from the carrier projection. The request n and threshold k are displayed before the stream window and dyadic ledger rows.

Apply the obligation surface of Definition 7210.2. It forces the threshold read to pass through M, n, k before W or D can be consumed.

The structural rows preserve the same finite route. Thus a downstream consumer cannot replace k by an external choice function or by a selected limit without leaving the accepted carrier surface. □

Theorem 7210.4 (Bishop completion modulus selection Real-seal nonescape)**.** *Every Real-facing read of an accepted* $\mathsf{BishopCompletionModulusSelection}^{\uparrow}$ *carrier factors through*

$$M, n \longmapsto k \longmapsto W, D \longmapsto R \longmapsto E.$$

Consequently the terminal $\mathsf{Real}^{\uparrow}$ *seal receives only the displayed completion-modulus threshold, finite stream window, dyadic tolerance ledger, and regular rational handoff. It does not export quotient stream equality, selected completed limits, countable-choice schedules, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 7210.3. It places the selected threshold and finite window before the dyadic ledger is read.

The regular handoff is then forced by the carrier order. The row R is downstream from W, D, and the seal row E is downstream from R.

Finally apply the non-escape part of Definition 7210.2. The excluded quotient, selection, choice, host-equality, and completeness data have no carrier projection, so the terminal seal cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionModulusSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionModulusSelection}^{\uparrow}$ packet is generated from a displayed BishopCompletionModulus row, a precision request, a selected finite threshold, a StreamName window, a DyadicRatCore tolerance ledger, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionModulusSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7210.1, Definition 7210.2, Definition 7210.3, and Definition 7210.4 seed the finite threshold-selection surface between completion-modulus data and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionModulusSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, quotient stream equality, selected completed limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite threshold selection, StreamName window readback, DyadicRatCore tolerance routing, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionModulusSelectionUp.

Chapter 7211

A Concrete Naming Certificate for $\mathsf{ConstructiveRealNormalization}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ConstructiveRealNormalization}^{\uparrow}$ packet records the finite normal-form handoff from a raw Cauchy source through Bishop real regularization to the public constructive real-line interface. It reads the regularization row of chapter 7206, the public line row of chapter 4041, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the non-quotient route by which regularized Cauchy data becomes a public $\mathsf{Real}^{\uparrow}$ row without importing selected limits, trichotomy, countable choice, quotient streams, or host real equality.

Definition 7211.1 (ConstructiveRealNormalization carrier)**.** *A* $\mathsf{ConstructiveRealNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (Q, B, W, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the raw Cauchy source row, exposing the finite source requests and their Cauchy-window evidence.*
2. *B is the* $\mathsf{BishopRealRegularization}^{\uparrow}$ *row that regularizes the raw source before any public real-line consumer can read it.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row shared by the source, regularized output, and public interface read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational name delivered by the regularization route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording source budgets, regularization budgets, readback budgets, and Real-facing output budgets.*
6. *L is the* $\mathsf{ConstructiveRealLine}^{\uparrow}$ *interface row through which public real-line consumers inspect the same regularized readback.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after Q, B, W, R, D, L have been displayed.*
8. *H records componentwise* hsame *transport for $Q, B, W, R, D, L, E, C, P, N$.*

9. *C records the displayed* Cont *replay from a normalization request through* $Q, B, W, R, D, L, E, H, P, N$.
10. *P is the* Pkg *provenance over* ConstructiveRealNormalization$^{\uparrow}$, BishopRealRegularization$^{\uparrow}$, ConstructiveRealLine$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ConstructiveRealNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7211.2 (ConstructiveRealNormalization window determinacy)**.** *Let $Z = (Q, B, W, R, D, L, E, H, C, P, N$ be an accepted* ConstructiveRealNormalization$^{\uparrow}$ *packet. Every public* ConstructiveRealLine$^{\uparrow}$ *or* Real$^{\uparrow}$ *read of E determines the same finite normalization window*

$$W_{\text{norm}}(Z) = (Q, B, W, R, D, L)$$

through the raw Cauchy source, Bishop regularization row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, and constructive real-line interface row. No second source window, quotient stream, selected limit, countable-choice schedule, trichotomy branch, host real equality, or ambient completeness principle can supply an alternate public read of the same seal.

Proof. Project the carrier of Definition 7211.1. The only analytic rows before the seal are Q, B, W, R, D, L, so every public read starts with the raw source, regularization packet, finite windows, readback row, tolerance ledger, and real-line interface.

Read chapter 7206. Its regularization handoff forces the raw source through the displayed Bishop row before the terminal real-name seal can be inspected.

Read chapter 4041 next. The public interface row consumes the same StreamName, RegSeqRat, and DyadicRatCore route before exposing a Real$^{\uparrow}$ consumer surface.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host equality, or ambient completeness, none of those objects can determine a second window for the seal. □

Closure status for NameCert$_{\text{ConstructiveRealNormalization}^{\uparrow}}$.

Constructive story: A ConstructiveRealNormalization$^{\uparrow}$ packet is generated from a raw Cauchy source row, Bishop real regularization row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, ConstructiveRealLine interface row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ConstructiveRealNormalization}^{\uparrow}}$, seed)

Scope closed: Definition 7211.1 and Definition 7211.2 seed the finite route from raw Cauchy source data through Bishop regularization, public real-line interface, and Real sealing.

Formal verification: FormalStatus(NameCert$_{\text{ConstructiveRealNormalization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Bishop regularization exposure, StreamName window exactness, RegSeqRat readback, DyadicRatCore tolerance routing, ConstructiveRealLine interface handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveRealNormalizationUp.

Chapter 7212

A Concrete Naming Certificate for $\mathsf{LawvereMetric}^{\uparrow}$

Following Lawvere's enriched-category account of generalized metric spaces, the $\mathsf{LawvereMetric}^{\uparrow}$ packet records a directed distance interface as finite BEDC NameCert data rather than as an ambient completed metric object. It sits between the directed comparison surface of chapter 2158, the Yoneda-facing route of chapter 2148, the formal-ball surface of chapter 1510, the symmetric metric sibling of chapter 57, the dyadic and regular rational readbacks of chapter 291 and chapter 301, the terminal real seal of chapter 38, and the completion consumer of chapter 3947. The packet names the base directed-distance ledger; it does not claim Real completeness, Cauchy completion, selected colimits, quotient equality of points, symmetry, or separatedness.

Definition 7212.1 (Lawvere metric carrier)**.** *A* $\mathsf{LawvereMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Z, T, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the directed source row naming the finite object-window on which directed distances are read.*
2. *Z is the zero/self ledger, recording that each displayed source entry carries the directed self-distance row expected by a Lawvere-style metric interface.*
3. *T is the triangle ledger, recording finite composable directed-distance triples before any completion or formal-ball consumer sees them.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *distance budget row used for finite tolerance reads.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row converting displayed dyadic distance windows into regular rational observations.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for directed distance values after D and Q have been exposed.*
7. *H records componentwise* hsame *transport for X, Z, T, D, Q, R and for the structural rows.*
8. *C records displayed* Cont *replay from the source row through*

$$X, Z, T, D, Q \longmapsto R \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{LawvereMetric}^{\uparrow}$, $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LawvereMetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LawvereMetric}^{\uparrow}}$ *row.*

The carrier contains no coordinate for symmetry, separatedness, selected Yoneda limit, completed formal-ball object, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification row, or bridge credential.*

Lean4 (statement) `BEDC.Derived.LawvereMetricUp`

Theorem 7212.2 (Lawvere metric triangle ledger stability)**.** *For every accepted* $\mathsf{LawvereMetric}^{\uparrow}$ *carrier* $L = (X, Z, T, D, Q, R, H, C, P, N)$*, any* $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *consumer of a displayed directed-distance comparison must read the same directed source row X, zero/self ledger Z, triangle ledger T, dyadic budget D, regular rational readback Q, and real seal R before it treats the comparison as stable under* hsame *transport and* Cont *replay.*

Proof. Project the carrier of Definition 7212.1. The directed source row X fixes the finite window of points, while Z and T are the only rows naming self-distance and triangle data.

The numeric side is not read directly as host real equality. The dyadic row D supplies finite tolerance data, Q repacks it as regular rational readback, and R is the terminal $\mathsf{Real}^{\uparrow}$ seal visible to distance consumers.

The structural rows preserve that route. Componentwise hsame transport in H carries the same displayed rows, and Cont replay in C permits the consumer to replay the path from directed source data to real-sealed distance data.

Thus any sibling consumer must factor through $X, Z, T, D, Q, R, H, C, P, N$. The carrier has no additional coordinate from which to extract symmetry, separatedness, selected completion data, quotient point equality, or ambient Real completeness. □

Theorem 7212.3 (Lawvere metric directed source exposure)**.** *For every accepted* $\mathsf{LawvereMetric}^{\uparrow}$ *carrier* $L = (X, Z, T, D, Q, R, H, C, P, N)$*, any* $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *consumer must expose the directed source row X before it reads D, Q, or R as distance data.*

Proof. Project the carrier of Definition 7212.1. The row X is the only displayed source row, while D, Q, and R are downstream numeric rows: the dyadic budget, the regular rational readback, and the terminal Real seal.

Apply Definition 7212.2. Every listed consumer of a displayed directed-distance comparison must read the same X, Z, T, D, Q, R surface before treating the comparison as stable under hsame transport and Cont replay. Hence the numeric read of D, Q, R has no independent source; it is exposed only after the directed source row X is fixed. □

Theorem 7212.4 (Lawvere metric zero-self exactness)**.** *For every accepted* $\mathsf{LawvereMetric}^{\uparrow}$ *carrier* $L = (X, Z, T, D, Q, R, H, C, P, N)$*, the self-distance row Z and the triangle row T are mandatory finite ledger rows. They are not consequences of symmetry, separatedness, quotient point equality, selected completion data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The carrier in Definition 7212.1 lists Z and T as displayed rows of the packet. The row Z records the directed self-distance ledger for the displayed source entries, and T records finite composable directed-distance triples before any completion or formal-ball consumer sees them.

The same definition also exhausts the excluded coordinates. The carrier contains no row for symmetry, separatedness, selected Yoneda limit, completed formal-ball object, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge credential. Therefore Z and T are finite NameCert obligations carried by L itself, not consequences imported from any excluded structure. □

Theorem 7212.5 (Lawvere metric NameCert obligation surface)**.** *Every accepted* $\mathsf{LawvereMetric}^{\uparrow}$ *carrier* $L = (X, Z, T, D, Q, R, H, C, P, N)$ *exposes the following finite NameCert obligation rows:*

1. *directed source exposure through* X*;*
2. *zero/self ledger exactness through* Z *and triangle ledger stability through* T*;*
3. *dyadic-RegSeqRat-Real sealing through* D, Q, R*;*
4. *structural replay through* H *and* C*;*
5. *provenance exhaustion and local naming through* P *and* N*.*

Proof. The carrier definition supplies the rows $X, Z, T, D, Q, R, H, C, P, N$ and assigns each row its role. This gives the finite object-window, self-distance ledger, triangle ledger, dyadic budget, regular rational readback, Real seal, componentwise transport, replay route, provenance, and local NameCert name.

The directed source row is exposed by Definition 7212.3. The exactness of the mandatory zero/self and triangle rows follows from Definition 7212.4, while the consumer-facing stability of the same directed-distance surface follows from Definition 7212.2.

The remaining rows are structural rather than optional. The definition routes D, Q, R as the dyadic-RegSeqRat-Real distance seal, H and C as transport and replay, and P, N as provenance and local naming. Since the carrier has no coordinate for the excluded symmetry, separatedness, completion, quotient, Real-completeness, Lean, or bridge data, the five displayed clauses are exactly the finite obligation surface presented by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LawvereMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LawvereMetric}^{\uparrow}$ packet is generated from a directed source row, zero/self ledger, triangle ledger, DyadicRatCore distance budget, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LawvereMetric}^{\uparrow}}$, seed)

Scope closed: Definition 7212.1, Definition 7212.2, and Definition 7212.5 seed the finite directed-distance interface consumed by QuasiMetric, FormalBall, YonedaCompletion, Metric, and LawvereMetricCompletion packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LawvereMetric}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.LawvereMetricUp`

Bridge status: none

Not claimed: This chapter does not close symmetry, separatedness, Cauchy completion, selected Yoneda limits, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed source exposure, zero/self ledger exactness, triangle ledger stability, dyadic and regular rational readback, RealUp sealing, replay stability, provenance exhaustion, and local naming for BEDC.Derived.LawvereMetricUp.

Chapter 7213

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusComparison}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyModulusComparison}^{\uparrow}$ packet records the finite comparison object that lets a completion-facing modulus row be checked against a regular Cauchy readback before any Real or Completion consumer reads a terminal seal. It sits between the completion-modulus discipline of chapter 1469, the generic Cauchy threshold surface of chapter 292, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet names a comparison route for L10 Real and Completion work; it does not select limits, quotient streams, host representatives, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7213.1 (Regular Cauchy modulus comparison carrier)**.** *A* $\mathsf{RegularCauchyModulusComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row, recording the completion-facing modulus budget that later consumers may reuse.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row, recording the finite tail request attached to the same tolerance.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite observations inspected after B and M have fixed the requested budget.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational data obtained from those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic comparison ledger shared by B, M, W, R.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the displayed completion-modulus, threshold, window, readback, and dyadic rows have been read.*
7. *H stores componentwise* hsame *transport for the analytic rows and the structural rows.*
8. *C stores displayed* Cont *replay from a tolerance request through B, M, W, R, D, E.*

9. *P records* Pkg *provenance over* RegularCauchyModulusComparison$^{\uparrow}$, BishopCompletionModulus$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *data.*

10. *N is the local* NameCert$_{\text{RegularCauchyModulusComparison}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $B, M, W, R, D, E, H, C, P, N$. No coordinate stores a quotient stream, selected limit, host real equality, ambient completion object, or Real$^{\uparrow}$ *completeness theorem.*

Theorem 7213.2 (Regular Cauchy modulus comparison NameCert obligations)**.** *For every accepted* RegularCauchyModulusComparison$^{\uparrow}$ *carrier $K = (B, M, W, R, D, E, H, C, P, N)$, the local* NameCert$_{\text{RegularCauchyModulusComparison}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the completion modulus B, Cauchy threshold M, finite windows W, regular readback R, dyadic tolerance ledger D, Real seal E, transport H, replay C, provenance P, and local naming N;*

2. *modulus compatibility, requiring B and M to answer the same displayed dyadic tolerance request before any window row is inspected;*

3. *readback comparison, requiring R to be obtained only from the* StreamName$^{\uparrow}$ *windows W under the dyadic ledger D and the threshold discipline supplied by B and M;*

4. *Real-seal nonescape, requiring the terminal row E to be downstream of B, M, W, R, D and to export no selected limit, quotient stream, host equality, countable choice, or ambient completeness;*

5. *structural preservation, requiring H, C, P, N to transport, replay, source, and name the same finite comparison packet.*

No additional NameCert obligation is available from the comparison carrier.

Proof. Carrier admission is the projection of Definition 7213.1. The tuple lists exactly the completion-modulus, Cauchy-threshold, finite-window, readback, dyadic, Real-seal, transport, replay, provenance, and naming rows.

For modulus compatibility, the only tolerance rows are B, M, and D. A consumer must therefore read the dyadic request through D and then expose both the completion-facing modulus row and the Cauchy-threshold row before it can inspect any StreamName window.

Readback comparison is downstream of the same rows. The row W supplies the finite observations, and R repacks those observations as regular rational data under the displayed threshold and tolerance discipline.

Finally E is the terminal Real-facing row, while H, C, P, N preserve the same packet. Since no quotient stream, selected limit, host equality, choice schedule, or ambient completeness coordinate occurs in the carrier, those objects cannot be exported by the local certificate. □

Theorem 7213.3 (Regular Cauchy modulus comparison stability)**.** *Let $K = (B, M, W, R, D, E, H, C, P, N)$ be an accepted* RegularCauchyModulusComparison$^{\uparrow}$ *carrier. If a later tolerance request is discharged by the same displayed* BishopCompletionModulus$^{\uparrow}$ *row B and* CauchyModulus$^{\uparrow}$ *row M with a refined* DyadicRatCore$^{\uparrow}$ *ledger still recorded in D, then every accepted Real-facing read factors through the same* StreamName$^{\uparrow}$ *window route, the same* RegSeqRat$^{\uparrow}$ *readback row, and the same terminal* Real$^{\uparrow}$ *seal row. Thus refinement preserves the comparison between the completion modulus and the regular Cauchy readback.*

Proof. Start with the refined tolerance request. By the NameCert obligations of Definition 7213.2, the request is still read through D and must expose the same completion-modulus and Cauchy-threshold rows B and M.

The finite window row is downstream of those rows. Hence the refined request reaches observations only through W, and the regular rational readback can only be the displayed row R attached to those windows.

The terminal Real-facing consumer then reads E after B, M, W, R, D. Componentwise transport, replay, provenance, and local naming preserve the same packet, so the refined request stays on the original comparison route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyModulusComparison}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first displaying $\mathsf{BishopCompletionModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows refutes the carrier.

Independence witness: bishopcompletionmodulus, cauchymodulus, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective with $\mathsf{RegularCauchyModulusComparison}^{\uparrow}$ because this packet jointly carries completion-modulus reuse, Cauchy-threshold exposure, finite windows, regular readback, dyadic tolerance comparison, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7213.1, Definition 7213.2, and Definition 7213.3 seed the finite comparison route tying completion moduli to regular Cauchy readback over displayed tolerance, window, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient streams, host real equality, countable choice, ambient completion, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus compatibility, readback comparison, Real-seal nonescape, and stability for BEDC.Derived.RegularCauchyModulusComparisonUp.

Constructive story: A $\mathsf{RegularCauchyModulusComparison}^{\uparrow}$ packet is generated from BishopCompletionModulus, CauchyModulus, StreamName, RegSeqRat, DyadicRatCore, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7214

A Concrete Naming Certificate for $\mathsf{ClopenAlgebra}^{\uparrow}$

Following Stone and Birkhoff on Boolean algebras of clopen sets, the $\mathsf{ClopenAlgebra}^{\uparrow}$ packet records the finite BEDC surface by which a displayed topology row supplies clopen rows together with Boolean operations on those rows. It sits beside the topology carrier of chapter 88, the Boolean algebra carrier of chapter 3733, the Stone-duality clopen ledger of chapter 261, the connectedness refusal surface of chapter 2353, and the total-disconnectedness separation surface of chapter 2271. The packet names a local finite clopen algebra ledger; it does not assert a global powerset algebra, selected clopen basis, ultrafilter representation, host subset extensionality, or excluded-middle separation.

Definition 7214.1 (Clopen algebra carrier)**.** *A* $\mathsf{ClopenAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, O, \bar{O}, B, L, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row. It records the open-set classifier, displayed empty and whole opens, and finite inclusion requests inspected by the packet.*
2. *O is the displayed open row for each clopen candidate under inspection.*
3. *$\bar{O}$ is the displayed complement-open row attached to the same candidate. A row is admitted as clopen only when both O and $\bar{O}$ are present over the same T.*
4. *B is the* $\mathsf{BooleanAlgebra}^{\uparrow}$ *operation row. It records finite union, intersection, complement, zero, one, and order reads on the admitted clopen rows.*
5. *L is the* $\mathsf{StoneDuality}^{\uparrow}$ *clopen ledger row. It records the same clopen observations as the Stone-duality surface of chapter 261 without adding ultrafilter points or a completed Stone space.*
6. *H records componentwise* hsame *transport for the topology row, open row, complement-open row, Boolean operation row, Stone ledger row, replay, provenance, and local name.*
7. *C records displayed* Cont *replay for the route*

$$T, O, \bar{O} \longmapsto B, L.$$

8. *P is the* Pkg *provenance over* $\mathsf{ClopenAlgebra}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{BooleanAlgebra}^{\uparrow}$, $\mathsf{StoneDuality}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{ClopenAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, O, \bar{O}, B, L, H, C, P, N$. It has no coordinate for arbitrary subsets, a selected clopen basis, ultrafilter choice, quotient topology equality, or host powerset Boolean operations.

Theorem 7214.2 (Clopen algebra NameCert obligations)**.** *For the carrier of Definition 7214.1, the local* $\mathsf{NameCert}_{\mathsf{ClopenAlgebra}^{\uparrow}}$ *surface consists exactly of topology-source exposure through T, displayed open-row exposure through O, displayed complement-open exposure through $\bar{O}$, Boolean operation exposure through B, Stone-duality clopen-ledger exposure through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every connectedness or total-disconnectedness consumer reads the clopen algebra only through those rows and receives no excluded-middle split, selected clopen basis, host subset equality, arbitrary powerset algebra, or ultrafilter representation.*

Proof. Carrier admission is projection from Definition 7214.1. The packet displays exactly the topology source, open row, complement-open row, Boolean operation row, Stone clopen ledger, transport, replay, provenance, and local naming row.

The clopen condition is local to $T, O, \bar{O}$. A consumer may call a row clopen only after both the open row and its complement-open row have been displayed over the same topology classifier.

The Boolean operations are then read through B. Union, intersection, complement, zero, one, and order requests are operations on the displayed clopen rows, not on an ambient powerset.

Finally L, H, C, P, N preserve and name the same route. The Stone-duality ledger records the clopen observations already visible in the packet, while transport and replay cannot create a selected basis, ultrafilter point, host subset equality, or external Boolean algebra. □

Theorem 7214.3 (Clopen algebra Boolean-topology handoff)**.** *Every Boolean-topology consumer of an accepted* $\mathsf{ClopenAlgebra}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Topology}^{\uparrow} \longrightarrow O, \bar{O} \longrightarrow \mathsf{BooleanAlgebra}^{\uparrow} \longrightarrow \mathsf{StoneDuality}^{\uparrow} \longrightarrow H, C, P, N.$$

The handoff gives connectedness consumers the displayed clopen-refusal boundary used by $\mathsf{ConnectedSpace}^{\uparrow}$ *and gives total-disconnectedness consumers the displayed clopen-separation ledger used by* $\mathsf{TotallyDisconnectedSpace}^{\uparrow}$ *It gives neither open-cover compactness, nor host subset extensionality, nor an ultrafilter representation, nor a selected global clopen basis.*

Proof. Start with the NameCert obligations of Definition 7214.2. They require every clopen read to expose the topology source together with both the open row and the complement-open row before the Boolean operation row is consumed.

The Boolean handoff is finite. The row B supplies only the displayed operations on admitted clopen rows, and L identifies those rows with the Stone-duality clopen ledger rather than with a completed point space.

Connectedness and total-disconnectedness consume different faces of the same packet. The connectedness side reads clopen attempts as refusal rows, while the total-disconnectedness side reads clopen separations as displayed separation rows.

Since H, C, P, N only transport, replay, source, and name the displayed rows, every Boolean-topology consumer remains inside the route shown above. The excluded powerset, basis-selection, ultrafilter, and host-extensionality objects are absent from the carrier. □

Lean4 (statement) `BEDC.Derived.ClopenAlgebraUp`

Closure status for $\mathsf{NameCert}_{\mathsf{ClopenAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{ClopenAlgebra}^{\uparrow}$ packet is generated from a Topology source row, displayed open and complement-open rows, BooleanAlgebra operation rows, a StoneDuality clopen ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClopenAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7214.1, Definition 7214.2, and Definition 7214.3 seed the finite Boolean-topology clopen algebra ledger over displayed topology rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClopenAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.ClopenAlgebraUp`

Bridge status: none

Not claimed: This chapter does not close arbitrary powerset Boolean algebras, selected clopen bases, ultrafilter representations, host subset extensionality, open-cover compactness, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open and complement-open exposure, Boolean operation exactness, Stone clopen-ledger compatibility, transport, replay, provenance, and local naming for BEDC.Derived.ClopenAlgebraUp.

Chapter 7215

A Concrete Naming Certificate for $\mathsf{DoobMaximalInequality}^{\uparrow}$

Following Doob, the $\mathsf{DoobMaximalInequality}^{\uparrow}$ packet records the finite maximal-window inequality surface used when a bounded martingale prefix is read before any convergence or almost-sure quotient consumer sees it. It sits after the finite martingale carrier of chapter 190, the bounded stopped-window route of chapter 383, the Doob upcrossing ledger of chapter 1630, the convergence-preparation packet of chapter 2246, and the terminal real-name seal of chapter 38. The certificate names only finite probability, martingale, maximal-window, stopping, inequality-bound, Real-boundary, transport, replay, provenance, and local naming rows.

Definition 7215.1 (Doob maximal inequality carrier)**.** *A* $\mathsf{DoobMaximalInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\Omega, M, W, A, S, U, B, R, H, C, P, N)$$

with the following visible rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *probability row, carrying only the finite event and expectation observations used by the bound.*
2. M *is the* $\mathsf{Martingale}^{\uparrow}$ *source row, exposing the adapted finite prefix and conditional-expectation faces.*
3. W *is the maximal-window row, recording the displayed finite horizon and the inspected prefix maximum.*
4. A *is the threshold row, naming the positive* $\mathsf{Real}^{\uparrow}$ *boundary at which the maximal event is queried.*
5. S *is the bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *route used to read first-hit and terminal stopped values inside the displayed horizon.*
6. U *is the* $\mathsf{DoobUpcrossing}^{\uparrow}$ *sibling row, recording that crossing-count control is available through the same martingale and stopped-window surface.*
7. B *is the finite Doob-bound row, relating the maximal event and threshold to the endpoint expectation read.*
8. R *is the* $\mathsf{Real}^{\uparrow}$ *boundary row sealing threshold, expectation, and bound comparisons after the finite rows have been replayed.*

9. *H records componentwise* hsame *transport for the probability, martingale, maximal-window, threshold, optional-stopping, upcrossing, bound, Real-boundary, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through*

$$\Omega, M, W, A, S, U, B, R \longmapsto \mathsf{NameCert}_{\mathsf{DoobMaximalInequality}^{\uparrow}}.$$

11. *P is the* Pkg *provenance over* $\mathsf{DoobMaximalInequality}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, $\mathsf{MartingaleConvergence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DoobMaximalInequality}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows and their displayed transports. It has no coordinate for a completed filtration, an unbounded stopping time, almost-sure quotient equality, a selected exceptional set, ambient measure completion, or host L^p maximal theorem.

Theorem 7215.2 (Doob maximal inequality NameCert obligations)**.** *For every accepted* $\mathsf{DoobMaximalInequality}^{\uparrow}$ *carrier $D = (\Omega, M, W, A, S, U, B, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DoobMaximalInequality}^{\uparrow}}$ *surface consists exactly of probability exposure, finite martingale-prefix exposure, maximal-window admission, threshold-boundary admission, bounded optional-stopping handoff, Doob-upcrossing compatibility, finite Doob-bound admission,* $\mathsf{Real}^{\uparrow}$ *boundary sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. No obligation is discharged by a completed filtration, an unbounded stopping theorem, almost-sure quotient equality, a selected exceptional set, ambient measure completion, or a host L^p maximal theorem.*

Proof. Project the accepted carrier of Definition 7215.1. The analytic-facing rows are exactly $\Omega, M, W, A, S, U, B, R$, and the structural rows H, C, P, N only transport, replay, source, and name those rows.

The maximal-window row W and threshold row A determine the finite event being bounded. The bounded optional-stopping row S keeps first-hit and terminal reads inside the displayed horizon, while U records that the same martingale surface is compatible with the Doob-upcrossing ledger.

The bound row B and Real-boundary row R are then terminal for the inequality read. Since every comparison passes through R after the finite rows have been replayed, the certificate cannot import completed filtrations, unbounded stopping, almost-sure quotient equality, selected exceptional sets, ambient measure completion, or host maximal theorems. □

Theorem 7215.3 (Doob maximal inequality convergence handoff)**.** *Every accepted* $\mathsf{DoobMaximalInequality}^{\uparrow}$ *carrier routes a convergence-facing maximal read through the finite dependency chain*

$$\mathsf{Martingale}^{\uparrow} \longmapsto \mathsf{OptionalStopping}^{\uparrow} \longmapsto \mathsf{DoobUpcrossing}^{\uparrow} \longmapsto \mathsf{DoobMaximalInequality}^{\uparrow} \longmapsto \mathsf{MartingaleConvergence}^{\uparrow}$$

The exported object is only the displayed maximal-bound row B together with its $\mathsf{Real}^{\uparrow}$ *boundary seal R; it is not a martingale convergence theorem, not an almost-sure maximal process, and not a completed measure-space argument.*

Proof. Begin with the martingale source row M. It supplies the finite adapted prefix and conditional-expectation faces consumed by the maximal-window row W.

Next read the bounded optional-stopping row S and the Doob-upcrossing sibling row U. These rows keep first-hit, terminal, and crossing-control reads inside the same displayed horizon and prevent the maximal event from becoming an unbounded stopping assertion.

Finally expose the bound row B and the Real-boundary row R. A convergence-facing consumer may cite this finite maximal-bound surface before reading chapter 2246, but receives no convergence theorem or almost-sure quotient from this chapter. □

Falsifiable prediction: Every accepted $\mathsf{DoobMaximalInequality}^{\uparrow}$ consumer that reads a maximal-event bound without displaying the probability source, finite martingale prefix, maximal-window row, threshold boundary, bounded $\mathsf{OptionalStopping}^{\uparrow}$ route, $\mathsf{DoobUpcrossing}^{\uparrow}$ compatibility row, finite bound row, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the packet surface.

Independence witness: martingale, optionalstopping, doob-upcrossing, martingale-convergence, real: none is bijective to $\mathsf{DoobMaximalInequality}^{\uparrow}$ because this packet jointly carries the finite maximal-window row, threshold boundary, bounded stopping route, upcrossing compatibility, Doob-bound row, Real seal, transport, replay, provenance, and local naming needed by maximal-inequality consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{DoobMaximalInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{DoobMaximalInequality}^{\uparrow}$ packet is generated from one probability row, one finite martingale row, one maximal-window row, one threshold row, one bounded optional-stopping row, one Doob-upcrossing compatibility row, one finite bound row, one RealUp boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoobMaximalInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7215.1, Definition 7215.2, and Definition 7215.3 seed the finite maximal-inequality packet over probability, martingale, bounded stopping, Doob-upcrossing, convergence-facing, Real-boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoobMaximalInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed filtrations, unbounded stopping, almost-sure quotient equality, selected exceptional sets, ambient measure completion, martingale convergence, host L^p maximal theorems, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, maximal-window exactness, bounded optional-stopping handoff, Doob-upcrossing compatibility, finite bound admission, Real-boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DoobMaximalInequalityUp.

Chapter 7216

A Concrete Naming Certificate for $\mathsf{BishopCompletionModulusStability}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompletionModulusStability}^{\uparrow}$ packet names the finite stability surface for the L10 completion-modulus chain. It sits after the displayed threshold route of chapter 1469 and the selection surface of chapter 7210, reads Cauchy thresholds through chapter 292, opens observation windows through chapter 126, records dyadic tolerance rows through chapter 291, repacks the window through chapter 301, and reaches only the terminal seal of chapter 38. The packet names stability of the displayed finite route; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, or host real equality.

Definition 7216.1 (Bishop completion modulus stability carrier)**.** *A* $\mathsf{BishopCompletionModulusStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, A, n, k, W, D, R, E, H, C, P, N)$$

with the following rows:

1. *M is the* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carrier row whose threshold route is being stabilized.*
2. *A is the* $\mathsf{CauchyModulus}^{\uparrow}$ *source row read by M for the displayed precision request.*
3. *n is the finite precision request and k is the selected threshold row.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window opened at k.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same threshold and window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff obtained from W and D.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after M, A, n, k, W, D, R are displayed.*
8. *H records componentwise* hsame *transport for the modulus, source, request, threshold, window, dyadic ledger, handoff, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay of the same route under accepted carrier comparison.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionModulusStability}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionModulusStability}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, countable choice, or host real equality.*

Theorem 7216.2 (Bishop completion modulus stability NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionModulusStability}^{\uparrow}$ *carrier* $T = (M, A, n, k, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionModulusStability}^{\uparrow}}$ *surface consists exactly of carrier admission, displayed* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *route exposure,* $\mathsf{CauchyModulus}^{\uparrow}$ *source exposure, finite precision and threshold exposure,* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *stability transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The analytic rows are M, A, n, k, W, D, R, E, while H, C, P, N are the structural rows that transport, replay, source, and name the same finite route.

Read the completion-modulus and Cauchy-modulus faces first. The selected threshold k is exposed as a row attached to the request n, and the stream window W is opened only after that threshold is visible.

The dyadic and regular rows are downstream from the same threshold. The ledger D records the tolerance data for W, and the handoff row R repacks W, D before the Real-facing seal E is consumed.

Finally the stability rows H, C, P, N preserve only the displayed coordinates. Since no other carrier row exists, $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, and host real equality cannot be local obligations of the packet. □

Theorem 7216.3 (Bishop completion modulus stability route)**.** *Every accepted* $\mathsf{BishopCompletionModulusStability}^{\uparrow}$ *read preserves the displayed L10 route*

$$\mathsf{BishopCompletionModulus}^{\uparrow}, \mathsf{CauchyModulus}^{\uparrow}, n \longmapsto k \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

If two accepted packets are compared by the classifier, their componentwise transport rows preserve the same threshold, window, dyadic ledger, regular rational handoff, and Real seal before any downstream completion-modulus consumer reads the packet.

Proof. Start with the NameCert obligations of Definition 7216.2. They expose the completion-modulus row, Cauchy-modulus source row, request, threshold, stream window, dyadic ledger, regular handoff, and Real seal as separate finite rows.

Use the scoped dependency surface of Definition 1469.10. It binds the underlying $\mathsf{BishopCompletionModulus}^{\uparrow}$ route to carrier admission, threshold coherence, heredity, Real seal ordering, and same-threshold transport.

Now replay that route inside the stability carrier. The rows H, C, P, N compare only the displayed carrier coordinates, so classifier-related packets keep the threshold, window, dyadic ledger, handoff, and seal aligned.

The excluded principles have no carrier coordinate and no route theorem in the packet. Thus a stability read cannot replace the finite L10 source chain by $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, or host real equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionModulusStability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCompletionModulusStability}^{\uparrow}$ packet is generated from a displayed BishopCompletionModulus row, a CauchyModulus source row, a finite precision request, a selected threshold, a StreamName window, a DyadicRatCore tolerance ledger, a RegSeqRat handoff, a RealUp seal, componentwise stability transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopCompletionModulusStability}^{\uparrow}}$, seed)

Scope closed: Definition 7216.1, Definition 7216.2, and Definition 7216.3 seed the finite stability surface for the L10 completion-modulus chain.

Formal verification: FormalStatus(NameCert$_{\text{BishopCompletionModulusStability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real$^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold stability, StreamName window readback, DyadicRatCore tolerance routing, RegSeqRat handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionModulusStabilityUp.

Chapter 7217

A Concrete Naming Certificate for $\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive analysis, the $\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}$ packet records the finite route by which one displayed point defect is repaired before an integration or completion-facing consumer reads the function. It sits beside the terminal real-name seal of chapter 38, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, the continuous-map carrier of chapter 130, the finite integrability witness of chapter 1960, and the Cauchy-sum completion boundary of chapter 5903. The packet repairs only the named finite defect; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, select hidden limits, identify quotient functions, use real trichotomy, invoke countable choice, or prove a full integration theorem.

Definition 7217.1 (Riemann removable-discontinuity carrier)**.** *A* $\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, F, A, W, R, E, J, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite defect row, naming the single point or finite displayed defect window at which the source function is not read through the ordinary continuous-map route.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *off-defect row, exposing the continuous-map evidence on the displayed punctured window or finite complement route.*
3. *A is the approach ledger, recording the visible two-sided or one-sided approximation windows by which the repaired value is compared with nearby off-defect reads.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing exactly the samples, punctured-neighbourhood observations, and requested precisions inspected before the repaired value is sealed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, so every numeric comparison has a regular rational source before the terminal real-name seal is read.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed replacement value and the repaired function values visible to downstream consumers.*
7. *J is the integration and completion handoff row, allowing* $\mathsf{RiemannIntegrable}^{\uparrow}$ *and* $\mathsf{RiemannIntegrationCompletion}^{\uparrow}$ *consumers to read the repaired packet only after D, F, A, W, R, E have been displayed.*

8. *H records componentwise* hsame *transport for the defect, off-defect continuity, approach ledger, finite windows, regular readback, Real seal, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a repair request through $D, F, A, W, R, E, J, H, P, N$.*
10. *P is the* Pkg *provenance over* RiemannRemovableDiscontinuity$^\uparrow$, ContinuousMap$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, RiemannIntegrable$^\uparrow$, RiemannIntegrationCompletion$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{RiemannRemovableDiscontinuity}^\uparrow}$ *row.*

The classifier compares accepted packets only through $D, F, A, W, R, E, J, H, C, P, N$. It has no coordinate for ambient Real$^\uparrow$ *completeness, selected limits, quotient function equality, real trichotomy, countable choice, a host integration functional, or a full Riemann integration theorem.*

Lean4 (statement) `BEDC.Derived.RiemannRemovableDiscontinuityUp`

Theorem 7217.2 (Riemann removable-discontinuity NameCert obligations)**.** *For every accepted* RiemannRemovableDiscontinuity$^\uparrow$ *carrier*

$$M = (D, F, A, W, R, E, J, H, C, P, N),$$

the local NameCert$_{\text{RiemannRemovableDiscontinuity}^\uparrow}$ *surface consists exactly of carrier admission for the displayed defect row, off-defect continuous-map row, approach ledger, finite StreamName windows, RegSeqRat readback, terminal Real seal, integration and completion handoff, componentwise transport, displayed replay, provenance, and local naming rows.*

The obligation surface requires the defect to be named before the off-defect continuity row is consumed, the approach ledger to expose only finite comparison windows, the StreamName$^\uparrow$ *and* RegSeqRat$^\uparrow$ *rows to precede any terminal* Real$^\uparrow$ *seal, and the handoff row J to export only the repaired finite route to* RiemannIntegrable$^\uparrow$ *or* RiemannIntegrationCompletion$^\uparrow$ *consumers.*

Proof. Project the carrier of Definition 7217.1. The analytic rows are D, F, A, W, R, E, J, and the structural rows are H, C, P, N.

The defect row D fixes the only place where the ordinary continuous-map route is not read directly. The off-defect row F supplies the continuous-map evidence away from that displayed window, while the approach ledger A records the finite comparisons used to justify the replacement value.

The numeric readback is W, R, E. The stream row W lists the inspected windows, the regular rational row R supplies the readback for those windows, and the Real row E seals the displayed replacement value only after those rows are present.

Finally J, H, C, P, N preserve the same finite route for integration and completion consumers. Since no excluded principle is a carrier coordinate, none is a local NameCert obligation of the packet. □

Theorem 7217.3 (Riemann removable-discontinuity completion handoff)**.** *Every* RiemannIntegrable$^\uparrow$ *or* RiemannIntegrationCompletion$^\uparrow$ *consumer of an accepted* RiemannRemovableDiscontinuity$^\uparrow$ *carrier must first read the finite route*

$$D, F, A \longmapsto W, R, E \longmapsto J \longmapsto H, C, P, N.$$

The consumer receives a displayed repaired-function boundary with one named removable defect, finite off-defect continuity evidence, finite approach windows, regular rational readback, and a terminal Real seal. It receives no ambient Real$^\uparrow$ *completeness theorem, no selected limiting value,*

no quotient equality of functions, no real trichotomy, no countable-choice schedule, and no full integration theorem.

Proof. Use Definition 7217.2. It places the defect row, off-defect continuity row, and approach ledger before any consumer-facing handoff.

The completion-facing readback is forced through W, R, E. Thus a requested repaired value is seen through finite StreamName observations and RegSeqRat data before the Real seal is public.

The handoff row J can then be read by $\mathsf{RiemannIntegrable}^{\uparrow}$ or $\mathsf{RiemannIntegrationCompletion}^{\uparrow}$ consumers, but only as a boundary row attached to the already displayed repair packet. It does not supply a separate proof of integrability, a Cauchy-sum convergence theorem, or a host integral.

The rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no coordinate for the excluded principles, the completion handoff cannot export them. □

Falsifiable prediction: Every accepted $\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}$ read must expose a finite defect row, an off-defect $\mathsf{ContinuousMap}^{\uparrow}$ row, an approach ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, an integration and completion handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: continuousmap, streamname, regseqrat, real, riemann-integrable, riemann-integration-completion: $\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}$ is not bijective to any listed sibling because it binds a named removable defect, off-defect continuity, finite approach readback, and the integration-completion handoff in one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}$ packet is generated from a finite defect row, an off-defect ContinuousMap row, an approach ledger, StreamName finite windows, RegSeqRat readback, a Real seal row, a RiemannIntegrable and RiemannIntegrationCompletion handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7217.1, Definition 7217.2, and Definition 7217.3 seed the finite removable-discontinuity repair surface over $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{RiemannIntegrationCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannRemovableDiscontinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient equality of functions, real trichotomy, countable choice, or a full integration theorem.

Upgrade path: Obligation closure requires checked carrier admission, defect exposure, off-defect continuity, approach-ledger exactness, StreamName and RegSeqRat readback, Real-seal nonescape, integration-completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.RiemannRemovableDiscontinuityUp.

Chapter 7218

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$ packet records the finite domination route by which one regular-Cauchy modulus may be replaced by a cofinal dominating modulus without changing the displayed tail-window readback. It sits after the completion-modulus packet of chapter 1469, the Cauchy threshold surface of chapter 292, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational handoff of chapter 301, and the terminal real-name boundary of chapter 38. The packet names a finite L10 route for changing modulus representatives along a displayed tail comparison; it does not select limits, quotient regular Cauchy names, countable-choice schedules, host real equality, or ambient completeness.

Definition 7218.1 (Regular Cauchy modulus domination carrier)**.** *A* $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M_0, M_1, D, W_0, W_1, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. M_0 *is the source* $\mathsf{CauchyModulus}^{\uparrow}$ *row attached to the original regular-Cauchy tail request.*
2. M_1 *is the dominating* $\mathsf{CauchyModulus}^{\uparrow}$ *row whose displayed threshold is used by the replacement route.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, certifying that* M_1 *dominates* M_0 *on the displayed tail and tolerance scale.*
4. W_0 *and* W_1 *are the corresponding* $\mathsf{StreamName}^{\uparrow}$ *finite windows read from the source modulus and the dominating modulus.*
5. T *is the cofinal tail comparison row, recording that every source-tail read used by* M_0 *is met by a dominating-tail read through* M_1*.*
6. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the dominated window comparison and the dyadic ledger.*
7. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the two moduli, the domination ledger, both windows, the cofinal tail row, and the regular readback have been displayed.*

8. *H stores componentwise* hsame *transport for the two modulus rows, domination ledger, windows, cofinal tail comparison, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay of the route*

$$M_0, M_1, D \longmapsto W_0, W_1, T \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusDomination}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M_0, M_1, D, W_0, W_1, T, R, E, H, C, P, N$. It has no coordinate for an infinite modulus choice function, selected limit, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 (statement) `BEDC.Derived.RegularCauchyModulusDominationUp`

Theorem 7218.2 (Regular Cauchy modulus domination NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$ *carrier $K = (M_0, M_1, D, W_0, W_1, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusDomination}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; source and dominating modulus exposure; dyadic domination through D; paired StreamName window exposure through W_0, W_1; cofinal tail comparison through T; RegSeqRat handoff through R; RealUp seal non-escape through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Proof. Project the carrier. The tuple in Definition 7218.1 lists exactly the two modulus rows, the dyadic domination ledger, the two window rows, the cofinal tail comparison, the regular readback, the Real seal, and the structural rows.

The domination obligation is forced by the order of the rows. A consumer first reads M_0 and M_1, then reads D as the finite certificate that the displayed M_1 threshold dominates the displayed M_0 threshold on the inspected tail.

The handoff rows are downstream. The windows W_0, W_1 and the cofinal comparison T supply the only route to R, and E is available only after R. Transport, replay, provenance, and naming preserve the same packet, so no unlisted modulus selector or completion principle can be exported. □

Theorem 7218.3 (Regular Cauchy modulus domination tail stability)**.** *Let $K = (M_0, M_1, D, W_0, W_1, T, R, E, H, C$ be an accepted* $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$ *carrier. Any later tail request transported by the displayed* hsame *rows and still certified by the domination ledger D reads the same cofinal comparison row T, the same dominating window route W_1, and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R. Thus replacing M_0 by the dominating modulus M_1 is stable for every Real-facing read that remains inside the displayed tail.*

Proof. Start with the transported tail request. Componentwise hsame transport preserves the visible modulus, ledger, window, cofinal comparison, readback, and seal rows rather than creating a second tail source.

Read the dyadic domination ledger next. Since D is still the certificate for the transported request, the route from the source window to the dominating window must pass through T and then through W_1.

Finally replay the continuation route. The row R is downstream from the two windows and T, and the Real seal E is downstream from R. Hence every transported Real-facing read stays on the original dominated tail route. □

Theorem 7218.4 (Regular Cauchy modulus domination Real seal route)**.** *Every accepted* RegularCauchyModulusDo *carrier routes a Real-completion consumer through the finite chain*

$$M_0, M_1, D \longmapsto W_0, W_1, T \longmapsto R \longmapsto E.$$

The terminal $\mathsf{Real}^{\uparrow}$ *seal records that the dominated cofinal tail window has already been repacked as a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff. It exports no selected real limit, quotient regular Cauchy equality, hidden modulus choice function, countable choice, host real equality, or ambient completeness principle.*

Proof. The displayed Cont row supplies the chain. A Real-completion consumer must first expose the two modulus rows and the domination ledger, then the paired windows and cofinal tail comparison.

The regular rational handoff is the next visible row. By the carrier definition, R is obtained only after W_0, W_1, T have been displayed, so the handoff cannot be read from an unregistered modulus or a hidden tail selector.

The Real seal is terminal. Since E appears after R and the carrier contains no selected limit, quotient equality, choice schedule, host equality, or completeness coordinate, the seal exports only the finite dominated-tail route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying M_0, M_1, the dyadic domination ledger D, both $\mathsf{StreamName}^{\uparrow}$ windows, the cofinal tail comparison T, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows refutes the packet.

Independence witness: bishopcompletionmodulus, cauchymodulus, streamname, dyadicratcore, regseqrat, real: no listed sibling is bijective with $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$ because this packet jointly carries two modulus rows, a domination ledger, paired windows, cofinal tail comparison, regular readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusDomination}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyModulusDomination}^{\uparrow}$ packet is generated from two CauchyModulus rows, a DyadicRatCore domination ledger, paired StreamName windows, a cofinal tail comparison row, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusDomination}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7218.1, Definition 7218.2, Definition 7218.3, and Definition 7218.4 seed the finite domination route between source and dominating regular-Cauchy moduli over displayed tail windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusDomination}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient regular Cauchy equality, infinite modulus choice, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic domination, paired window exposure, cofinal tail comparison, RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyModulusDominationUp.

Chapter 7219

A Concrete Naming Certificate for $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$

The $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$ packet realizes one bounded MetaCIC confluence frontier from section 9386.3 as finite residual-pair local-diamond data. It sits after the residual-substitution boundary of chapter 2181, the bounded residual-substitution frontier of chapter 3808, the residual-checker packet of chapter 3827, the typed residual-budget packet of chapter 7088, and the closed parallel-diamond obstruction of chapter 6169. The packet names a bounded local-diamond witness for a displayed residual pair; it does not claim full closed confluence, arbitrary parallel diamond, unrestricted substitution compatibility, global subject reduction, or a completed Church–Rosser theorem.

Definition 7219.1 (MetaCIC residual diamond witness carrier)**.** *A* $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (T, F, L, S, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, recording the bounded closed MetaCIC source, type window, and residual-pair observation range.*
2. *F is the residual-frontier row, naming the two residual steps whose local join is being checked.*
3. *L is the bounded local-join checker row, recording the finite local-diamond search and its accepted join endpoint for this residual pair.*
4. *S is the substitution-boundary row, exposing the exact residual-substitution interface consumed by the checker.*
5. *O is the obstruction-retention row, recording the remaining frontier outside this bounded residual pair.*
6. *H stores componentwise* hsame *transport for the typed window, residual frontier, local checker, substitution boundary, obstruction row, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the route*

$$T, F, S \longmapsto L \longmapsto O.$$

8. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$*, residual-substitution boundary data, bounded checker data, typed-window data,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, F, L, S, O, H, C, P, N$. It has no coordinate for full confluence, arbitrary residual closure, unrestricted substitution compatibility, subject-reduction discharge, hidden evaluator state, or host syntax quotienting.

Lean4 (statement) `BEDC.Derived.MetaCICResidualDiamondWitnessUp`

Theorem 7219.2 (MetaCIC residual diamond witness obligations)**.** *For every accepted* MetaCICResidualDiamondW *carrier $J = (T, F, L, S, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}}$ *surface consists exactly of typed-window exposure, residual-frontier exposure, bounded local-join checking, substitution-boundary exposure, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is discharged by full confluence, arbitrary parallel diamond, global substitution compatibility, subject reduction, hidden evaluator state, or host syntax quotienting.*

Proof. Project the carrier. The analytic rows are T, F, L, S, O, and the structural rows H, C, P, N only transport, replay, source, and name those rows.

The local-diamond witness is bounded. The residual frontier F and typed window T determine the residual pair under inspection, while S exposes the substitution boundary available to the checker.

The checker row L records only the finite local join for that pair. The obstruction row O remains visible, so the packet cannot be read as an arbitrary confluence theorem or as unrestricted substitution compatibility. □

Theorem 7219.3 (MetaCIC residual diamond witness local join route)**.** *Every accepted* MetaCICResidualDiamondW *carrier routes its bounded local join through*

$$T, F, S \longmapsto L \longmapsto O.$$

The row L is available only after the typed window, residual frontier, and substitution boundary have been displayed, and the row O records that the surrounding confluence frontier remains outside this bounded witness.

Proof. Read the typed window and residual frontier first. These rows fix the source, the observed residual pair, and the finite range over which the checker may operate.

Next read the substitution boundary. The checker receives exactly the boundary row S and no hidden substitution theorem, evaluator state, or subject-reduction discharge.

Finally expose the local checker and obstruction rows. The row L supplies the bounded join for the displayed pair, while O retains the unclosed frontier beyond that pair. □

Theorem 7219.4 (MetaCIC residual diamond witness transport stability)**.** *Componentwise* hsame *transport of an accepted* $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$ *carrier preserves the typed window, residual frontier, substitution boundary, bounded local-join checker, and obstruction-retention rows as one finite witness packet. A transported consumer may replay the local diamond route, but it cannot strengthen the packet into full confluence or erase the retained obstruction boundary.*

Proof. Transport acts componentwise on the displayed rows. Hence the typed window, residual pair, substitution boundary, checker result, obstruction row, replay, provenance, and local naming remain the classifier-visible coordinates.

Replay then follows the same continuation route. The transported checker row is still downstream from the typed window, residual frontier, and substitution boundary, and the obstruction row is still downstream from the checker.

The excluded endpoints are absent from the carrier. Since there is no row for arbitrary confluence, unrestricted substitution compatibility, subject reduction, hidden evaluator state, or host quotienting, transport cannot manufacture one. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$ consumer that reads a bounded local join without displaying the typed window, residual frontier, substitution boundary, bounded checker, obstruction-retention row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the packet surface.

Independence witness: metacic-residual-substitution-boundary, bounded-residual-substitution-frontier, metacic-confluence-residual-checker, metacic-typed-residual-budget, closed-parallel-diamond-obstruction: no listed sibling is bijective with $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$ because this packet jointly carries a typed window, residual pair, bounded local-join checker, substitution boundary, retained obstruction, transport, replay, provenance, and local naming.

The Lean TasteGate for $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$ will include Nontrivial and Field-Faithful instances for the typed-window row, residual-frontier row, substitution-boundary row, bounded local-join checker, and obstruction-retention row, so a future checked surface can distinguish a genuine local witness from a carrier-only smoke packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$ packet is generated from a typed-window row, a residual-frontier row, a bounded local-join checker, a substitution-boundary row, an obstruction-retention row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7219.1, Definition 7219.2, Definition 7219.3, and Definition 7219.4 seed one bounded residual-pair local-diamond witness for the MetaCIC confluence frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full closed confluence, arbitrary parallel diamond, unrestricted substitution compatibility, subject reduction, hidden evaluator state, host syntax quotienting, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window exposure, residual-frontier exposure, bounded local-join checking, substitution-boundary exposure, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualDiamondWitnessUp.

Chapter 7220

A Concrete Naming Certificate for MetaCICCriticalOverlapEnvelope$^{\uparrow}$

The MetaCICCriticalOverlapEnvelope$^{\uparrow}$ packet realizes the confluence audit map of chapter 9378 as finite candidate-overlap envelope data. It sits beside the parallel-diamond frontier of chapter 4238, the confluence diamond ledger of chapter 6547, the residual-substitution boundary packets cited in the same audit map, the normalization frontier of chapter 892, and the critical-path packet of chapter 765. The envelope names bounded local overlap rows only; it does not promote those rows to full confluence, kernel consistency, decidable conversion, or closed-normal completeness.

Definition 7220.1 (MetaCIC critical overlap envelope carrier)**.** *A* MetaCICCriticalOverlapEnvelope$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, K, J, R, C, B, N, O, H, Q, P, L)$$

with the following displayed rows:

1. *T is the typed-window row, recording the bounded context, source term, target term window, and typing side conditions under inspection.*
2. *K is the critical-pair row, recording the two local reduction choices and the overlap cell where they compete.*
3. *J is the candidate-join row, recording the proposed common reducts and the finite route by which each branch reaches them.*
4. *R is the residual-frontier row, recording the substitution-sensitive residual data that remains visible after the candidate join is proposed.*
5. *C is the closed-checker row, recording whether the bounded window is closed enough for the closed normal and atom fragments cited by the confluence audit map.*
6. *B is the bounded normal/check row, recording finite fuel, normal-form comparison, and local conversion checks for the candidate envelope.*
7. *N is the bounded normal endpoint row, recording any finished-normal or atom-fragment endpoint used by the checker.*
8. *O is the obstruction row, retaining the residual-substitution, closed-diamond, or local-check failure when the candidate envelope cannot discharge the overlap.*

9. *H records componentwise* hsame *transport for typed windows, critical pairs, candidate joins, residual frontiers, closed checks, bounded normal rows, obstruction rows, replay, provenance, and local naming.*
10. *Q records displayed* Cont *replay from a confluence-overlap request through $T, K, J, R, C, B, N, O, H, P, L$.*
11. *P is the* Pkg *provenance over* MetaCICCriticalOverlapEnvelope$^{\uparrow}$, MetaCICRedexFrontier$^{\uparrow}$, MetaCICNormalizationFr MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalOverlapEnvelope}^{\uparrow}}$ *row.*

Accepted carriers are compared only through $T, K, J, R, C, B, N, O, H, Q, P, L$. No coordinate stores full confluence, subject reduction, kernel consistency, unbounded proof search, decidable conversion, or a hidden substitution oracle.

Theorem 7220.2 (MetaCIC critical overlap envelope obligations)**.** *For every accepted* MetaCICCriticalOverlapEnvel *carrier $E = (T, K, J, R, C, B, N, O, H, Q, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalOverlapEnvelope}^{\uparrow}}$ *surface consists exactly of typed-window admission through T; critical-pair visibility through K; candidate-join exposure through J; residual-frontier retention through R; closed-checker visibility through C; bounded normal and check rows through B, N; obstruction retention through O; and componentwise transport, replay, provenance, and local naming through H, Q, P, L.*

Proof. Project the carrier of Definition 7220.1. The typed window T, critical pair K, candidate join J, and residual frontier R are the only rows that describe the local overlap geometry.

Read the checker rows next. The closed-checker row C and bounded normal/check rows B, N record finite inspection of the proposed envelope, while the obstruction row O keeps any residual-substitution or closed-diamond failure visible rather than erasing it.

Finally use the structural rows H, Q, P, L. They transport, replay, source, and name the same bounded envelope, so the accepted packet exports only the listed finite rows and not full confluence, kernel consistency, unbounded proof search, decidable conversion, or a hidden substitution oracle. □

Falsifiable prediction: Any confluence consumer omitting typed-window, candidate-join, residual-frontier, obstruction, transport, replay, provenance, or local naming rows is not an accepted MetaCICCriticalOverlapEnvelope$^{\uparrow}$ packet.

Independence witness: metacic-parallel-diamond-frontier, metacicconfluenceauditpacket, metacicnormalizationfrontier, metaciccriticalpath: the parallel-diamond frontier records a broader premise frontier without this packet's typed-window candidate envelope, the confluence audit packet records map-level boundary status without bounded overlap rows, the normalization frontier records candidate evidence and closed-normal use without confluence critical pairs, and the critical-path packet records programme routing without local candidate joins. None is bijective to MetaCICCriticalOverlapEnvelope$^{\uparrow}$.

The Lean follow-up must provide Nontrivial MetaCICCriticalOverlapEnvelope$^{\uparrow}$ and FieldFaithful MetaCICCriticalOv instances in `BEDC.Derived.MetaCICCriticalOverlapEnvelopeUp.TasteGate`. Those instances must preserve $T, K, J, R, C, B, N, O, H, Q, P, L$ as distinct finite rows before a checked carrier-alignment theorem can serve as the public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCriticalOverlapEnvelope}^{\uparrow}}$.

Constructive story: A MetaCICCriticalOverlapEnvelope$^{\uparrow}$ packet is generated from typed-window, critical-pair, candidate-join, residual-frontier, closed-checker, bounded normal/check, endpoint, obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICCriticalOverlapEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 7220.1 and Definition 7220.2 seed the finite bounded-overlap envelope over typed windows, critical pairs, candidate joins, residual frontiers, check rows, obstruction retention, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICCriticalOverlapEnvelope}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full MetaCIC confluence, subject reduction, kernel consistency, unbounded proof search, decidable conversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window admission, critical-pair visibility, candidate-join exposure, residual-frontier retention, checker rows, obstruction retention, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.MetaCICCriticalOverlapEnvelopeUp.

Chapter 7221

A Concrete Naming Certificate for $\mathsf{SuslinLine}^{\uparrow}$

Following Kelley and Engelking's treatment of ordered spaces and separability, the $\mathsf{SuslinLine}^{\uparrow}$ packet records the traditional Suslin-line boundary as finite order-topology NameCert data. It reads the total-order source of chapter 54, the topology surface of chapter 88, the ordered-real comparison of chapter 6850, and the separability boundary of chapter 5718. The packet names a dense linear order without endpoints, the order-topology base read, a countable-chain-condition row, a nonseparability boundary row, transport, replay, provenance, and local naming; it does not construct a host Suslin line, decide Suslin's hypothesis, import a choice-selected dense set, or identify the line with the Real carrier.

Definition 7221.1 (Suslin line carrier)**.** *A* $\mathsf{SuslinLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O, T, C, B, H, K, P, N)$$

with the following displayed rows:

1. *O is the total-order source row, naming a dense linear order without endpoints and exposing the comparison ledger inherited from chapter 54.*
2. *T is the topology row, recording the order-topology base and its local open-interval read through chapter 88.*
3. *C is the countable-chain-condition row, stating that pairwise-disjoint nonempty open intervals are admitted only through the displayed countability ledger.*
4. *B is the separability-boundary row, recording that no countable dense subset is exported by the packet.*
5. *H stores componentwise* hsame *transport for the order source, topology row, countable-chain-condition row, separability-boundary row, continuation, provenance, and local naming rows.*
6. *K records displayed* Cont *replay from order and topology requests through O, T, C, B.*
7. *P is the* Pkg *provenance over* $\mathsf{SuslinLine}^{\uparrow}$*, the total-order, topology, ordered-real, separability,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SuslinLine}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through O, T, C, B, H, K, P, N. It has no coordinate for host set-theoretic existence, a forcing extension, a selected dense enumeration, quotient Real equality, or a proof or refutation of Suslin's hypothesis.

Theorem 7221.2 (Suslin line NameCert obligations)**.** *For every accepted* $\mathsf{SuslinLine}^{\uparrow}$ *carrier* $S = (O, T, C, B, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SuslinLine}^{\uparrow}}$ *surface consists exactly of carrier admission for the total-order source, order-topology base, countable-chain-condition row, separability-boundary row, transport, replay, provenance, and local naming rows; order visibility through O; topology visibility through T; countable-chain-condition visibility through C; nonseparability-boundary visibility through B; componentwise transport through H; displayed continuation through K; package provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7221.1. The accepted inventory is exactly O, T, C, B, H, K, P, N, so every consumer must read the order source, topology row, countable-chain-condition row, and separability-boundary row before the local name is available.

The sibling anchors supply only their displayed surfaces. The total-order and topology chapters provide comparison and open-interval data, the ordered-real chapter supplies a comparison reference rather than an identification with $\mathsf{Real}^{\uparrow}$, and the separable-space chapter provides the boundary against a displayed countable dense subset.

Rows H, K, P, N preserve and replay that same finite route. Since no carrier coordinate names a host construction, forcing extension, selected dense enumeration, quotient Real equality, or set-theoretic decision principle, none of those endpoints can be exported by the NameCert obligations. □

Theorem 7221.3 (Suslin line separability boundary)**.** *Every topology, total-order, or ordered-real consumer of an accepted* $\mathsf{SuslinLine}^{\uparrow}$ *carrier must read the separability-boundary row B after the displayed order, topology, and countable-chain-condition rows O, T, C. The packet therefore records the Suslin-line boundary as a finite order-topology naming certificate: countable-chain-condition data may be consumed as a displayed row, but no countable dense subset, selected dense enumeration, quotient Real equality, host Suslin-line construction, or decision of Suslin's hypothesis is exported.*

Proof. Start with Definition 7221.2. It requires the order row O, topology row T, and countable-chain-condition row C before the separability-boundary row can be consumed.

Now compare with the separable-space anchor. The row B records the absence of an exported countable dense subset in the same finite packet that carries the order topology and countable-chain-condition rows, so a consumer cannot replace the boundary by a selected dense enumeration.

Finally apply the structural rows of Definition 7221.1. Transport, replay, provenance, and local naming preserve only the displayed order-topology packet, and they add no host construction, quotient Real equality, forcing decision, or ambient choice principle. □

Falsifiable prediction: Every accepted $\mathsf{SuslinLine}^{\uparrow}$ topology-facing read factors through a total-order source row, topology row, countable-chain-condition row, separability-boundary row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: totalorder, topology, linearly-ordered-real, separable-space: $\mathsf{SuslinLine}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a dense linear-order source, order-topology base, countable-chain-condition row, nonseparability-boundary row, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SuslinLine}^{\uparrow}}$.

Constructive story: A SuslinLine$^{\uparrow}$ packet is generated from a displayed total-order source, order-topology row, countable-chain-condition row, separability-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SuslinLine}\uparrow}$, seed)

Scope closed: Definition 7221.1, Definition 7221.2, and Definition 7221.3 seed the finite Suslin-line order-topology packet.

Formal verification: FormalStatus(NameCert$_{\mathsf{SuslinLine}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, Suslin's hypothesis, host construction of a Suslin line, forcing independence, a choice-selected dense subset, quotient Real equality, or ambient set-theoretic completeness.

Upgrade path: Obligation closure requires checked carrier admission, order-source discipline, topology-base exactness, countable-chain-condition visibility, separability-boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SuslinLineUp.

Chapter 7222

A Concrete Naming Certificate for $\mathsf{DyadicBracketing}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{DyadicBracketing}^{\uparrow}$ packet records the finite bracket data that feeds L10 real names before any completion-facing consumer reads a $\mathsf{Real}^{\uparrow}$ seal. It sits after the dyadic arithmetic surface of chapter 291, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, the located interval surface of chapter 1709, and the terminal real-name seal of chapter 38. The packet names finite lower and upper dyadic brackets with tolerance and nesting rows; it is not a quotient real construction, a selected completed limit, trichotomy on arbitrary reals, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 7222.1 (Dyadic bracketing carrier)**.** *A* $\mathsf{DyadicBracketing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, G, S, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row.*
2. *U is the upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row.*
3. *G is the finite gap and tolerance ledger, recording $L \leq U$ and the dyadic scale at which the bracket is accepted.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row whose observations request and replay the bracket.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed endpoints, gap ledger, and stream window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback row R is visible.*
7. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *source row that packages the same bracket as a located endpoint interval.*
8. *H records componentwise* hsame *transport for endpoint, gap, stream, readback, seal, interval, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a tolerance request through L, U, G, S, I to R and then to E.*

10. *P is the* Pkg *provenance over* $\mathsf{DyadicBracketing}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicBracketing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, a chosen real representative, arbitrary real trichotomy, countable choice, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.DyadicBracketingUp.DyadicBracketingTasteGate single carrier alignment`

Theorem 7222.2 (Dyadic bracketing NameCert obligations)**.** *For every accepted* $\mathsf{DyadicBracketing}^{\uparrow}$ *carrier*

$$B = (L, U, G, S, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicBracketing}^{\uparrow}}$ *surface consists exactly of lower endpoint exposure, upper endpoint exposure, dyadic gap and tolerance compatibility, finite stream-window readback, located-interval packaging, regular rational handoff, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every Real or Completion consumer must read the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows before treating the bracket as a real-name object.*

Proof. Project the carrier of Definition 7222.1. The endpoint rows L, U and the gap ledger G are the only dyadic data visible to the local classifier.

Read the observation and interval rows next. The stream window S requests the bracket at a finite tolerance, and the located interval row I repackages the same displayed endpoints without introducing a host interval object.

The consumer-facing handoff is downstream. The row R is the regular rational readback from L, U, G, S, I, and the $\mathsf{Real}^{\uparrow}$ seal E is exposed only after R.

Finally the structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the excluded quotient, selected-limit, trichotomy, choice, and completeness data are not carrier coordinates, the listed obligations exhaust the local NameCert surface. □

Theorem 7222.3 (Dyadic bracketing finite-bracket induction)**.** *Let* $B = (L, U, G, S, R, E, I, H, C, P, N)$ *be an accepted* $\mathsf{DyadicBracketing}^{\uparrow}$ *carrier. Any finite refinement history of the displayed bracket preserves the same route*

$$L, U, G, S, I \longmapsto R \longmapsto E$$

by induction on the bracket ledger. The base bracket reads the displayed lower and upper dyadic endpoints; each successor refinement tightens the gap ledger through $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, replays the finite* $\mathsf{StreamName}^{\uparrow}$ *window, preserves the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *packaging, and leaves the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the accepted carrier. The rows L, U, G, S, I are visible before the regular rational readback and the Real seal, so the initial bracket is a finite dyadic object rather than a completed real.

Induct on the finite bracket ledger recorded by G. In the base case the ledger contains the displayed endpoint order and tolerance scale, and the stream window S reads that bracket directly.

For a successor refinement, the new endpoint rows are obtained through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ comparisons in G. The stream window is replayed through S, and the located interval row I records the same refined endpoints as a finite interval package.

Apply Definition 7222.2 to the consumer-facing rows. The $\mathsf{RegSeqRat}^{\uparrow}$ readback R remains downstream of the bracket ledger, and E remains downstream of R, so the induction cannot export quotient real equality, selected limits, trichotomy, countable choice, or ambient completeness. □

Theorem 7222.4 (Dyadic bracketing L10 real-name handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{DyadicBracketing}^{\uparrow}$ *carrier must pass through the finite dyadic bracket rows before reading the regular rational handoff and terminal real-name seal. In carrier notation, the dependency order is* L, U, G, S, I *before* R*, and* R *before* E*, with* H, C, P, N *preserving the same route under transport, replay, provenance, and local naming.*

Proof. Start from the finite-bracket induction of Definition 7222.3. It keeps every accepted refinement inside the displayed dyadic endpoint, gap, stream-window, and located-interval rows.

Use the obligation theorem Definition 7222.2. It identifies the regular rational readback as a handoff from those rows rather than as a hidden Cauchy quotient or selected limit.

The terminal row is therefore ordered after R. Componentwise transport and continuation replay preserve this order, and the provenance and local naming rows do not add any alternate Real-facing coordinate. □

Falsifiable prediction: Every accepted $\mathsf{DyadicBracketing}^{\uparrow}$ Real-facing read factors through lower and upper $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, a finite gap ledger, a $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{LocatedRealInterval}^{\uparrow}$ package, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, locatedrealinterval, real: $\mathsf{DyadicBracketing}^{\uparrow}$ is not bijective to any listed sibling because it binds two dyadic endpoints, one finite gap ledger, a stream window, located interval packaging, regular readback, Real seal, transport, replay, provenance, and local naming as one bracket certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBracketing}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicBracketing}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint rows, a finite gap and tolerance ledger, StreamName windows, LocatedRealInterval packaging, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBracketing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7222.1, Definition 7222.2, Definition 7222.3, and Definition 7222.4 seed the finite dyadic bracketing route feeding L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBracketing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected completed limits, arbitrary real trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint exposure, dyadic gap compatibility, stream-window readback, located-interval packaging, RegSeqRat handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicBracketingUp.

Chapter 7223

A Concrete Naming Certificate for $\mathsf{CompactOscillationEnvelope}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Heine–Cantor finite-net reading of compact uniform continuity, the $\mathsf{CompactOscillationEnvelope}^{\uparrow}$ packet records a finite oscillation envelope before any uniform-modulus consumer reads its tolerance output. It sits after compact finite-net data from chapter 60, metric distance rows from chapter 57, pointwise continuity rows from chapter 59, rational and dyadic tolerance ledgers from chapter 291, Real-facing bounds from chapter 38, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369. The packet is a finite envelope over displayed compact-net cells and oscillation bounds; it is not open-cover compactness, semantic continuity, an external modulus selector, quotient point equality, countable choice, or ambient completeness.

Definition 7223.1 (Compact oscillation envelope carrier)**.** *A* $\mathsf{CompactOscillationEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, M, F, D, R, B, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row, displaying finitely many source cells and coverage witnesses.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to compare source points, centers, and target values.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise oscillation row attached to each displayed net cell.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested oscillation scale and cell radii.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for Real-facing distance and oscillation reads.*
6. *B is the finite envelope row, recording the maximum displayed cell oscillation and the lower-bound fold used by the packet.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exported only after K, M, F, D, R, B have been read.*
8. *H records componentwise* hsame *transport for compact-net, metric, continuity, dyadic, Real, envelope, uniform-modulus, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a tolerance request through the finite net, local oscillation rows, metric estimates, dyadic ledger, Real seals, and envelope fold to the uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactOscillationEnvelope}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host compactness, semantic continuity outside the displayed pointwise rows, an external selector for a modulus, quotient point equality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompactOscillationEnvelopeUp.CompactOscillationEnvelopeTasteGate single carrier alignment`

Theorem 7223.2 (Compact oscillation envelope NameCert obligations)**.** *For every accepted* CompactOscillationEnv *carrier*

$$O = (K, M, F, D, R, B, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOscillationEnvelope}^{\uparrow}}$ *surface consists exactly of compact finite-net admission, metric distance-read admission, pointwise oscillation admission, dyadic tolerance compatibility, Real-seal nonescape, finite envelope fold exactness, UniformModulus handoff ordering, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7223.1. The analytic rows K, M, F, D, R, B, U and the structural rows H, C, P, N are the only classifier-visible data.

The compact and continuity faces are finite. The row K supplies the displayed net cells, while F supplies pointwise oscillation rows on those cells and M supplies the metric reads used by the triangle estimates.

The tolerance and envelope rows are also displayed. The dyadic ledger D records the requested scale, the Real row R seals only the exposed distance and oscillation reads, and B folds those finitely many cell bounds into one envelope.

Finally U is downstream of the envelope. The rows H, C, P, N transport, replay, source, and name the same packet, and no excluded host compactness, semantic continuity, selector, quotient equality, choice, or completeness object is a carrier coordinate. □

Theorem 7223.3 (Compact oscillation envelope uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactOscillationEnvelope}^{\uparrow}$ *carrier must first read the finite route*

$$K, M, F, D, R, B \longmapsto U.$$

Thus compact finite-net rows, metric reads, pointwise oscillation rows, dyadic tolerance ledgers, Real-facing bounds, and the finite envelope fold are visible before any uniform-modulus row is exported. The handoff supplies a tolerance-only modulus packet and not host compactness, semantic continuity, quotient point equality, countable choice, or ambient completeness.

Proof. Start with the carrier inventory. The row K exposes finite compact-source coverage, and the rows M, F expose only displayed metric and pointwise oscillation data on that source.

Read the tolerance and bound rows next. The dyadic ledger D names the requested oscillation scale, while R seals the Real-facing distance and oscillation reads used by the envelope.

The finite envelope row B folds those displayed bounds before any uniform-modulus handoff is available. Hence U is downstream of K, M, F, D, R, B.

Apply the nonescape part of Definition 7223.2. Transport and replay preserve the finite route, and the packet has no row for the refused host or choice principles. □

Theorem 7223.4 (Compact oscillation envelope finite-cell stability)**.** *Let $O = (K, M, F, D, R, B, U, H, C, P, N)$ be an accepted* $\mathsf{CompactOscillationEnvelope}^{\uparrow}$ *carrier. Restricting to any displayed finite subfamily of the compact-net cells preserves the same oscillation-envelope route through M, F, D, R, B before the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row U is consumed. Componentwise transport may compare the restricted route, but it cannot introduce a second modulus source or an external compactness theorem.*

Proof. Project the finite net row K. A displayed subfamily is still a finite list of cells from the same compact-source packet.

Restrict the pointwise and metric rows to that subfamily. The rows M and F supply exactly the metric reads and local oscillation rows attached to those cells, while D keeps the same tolerance scale.

The envelope row B is then read on the restricted finite family, and the Real row R seals only those displayed bounds. The handoff theorem Definition 7223.3 keeps U downstream of that envelope route.

The structural rows H, C, P, N preserve, replay, source, and name the same finite data. Since no carrier coordinate stores a second selector or host compactness theorem, finite-cell restriction remains internal to the packet. □

Falsifiable prediction: Every accepted $\mathsf{CompactOscillationEnvelope}^{\uparrow}$ UniformModulus-facing read factors through CompactUp finite-net rows, MetricUp distance reads, ContinuousUp pointwise oscillation rows, DyadicRatCoreUp tolerance data, RealUp bounds, a finite envelope fold, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compact, metric, continuous, uniformmodulus, real, dyadicratcore: $\mathsf{CompactOscillationEnvelope}^{\uparrow}$ is not bijective to any listed sibling because it binds compact finite-net cells, metric reads, pointwise oscillation rows, dyadic tolerances, Real bounds, one finite envelope fold, UniformModulus handoff, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationEnvelope}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactOscillationEnvelope}^{\uparrow}$ packet is generated from CompactUp finite-net rows, MetricUp distance reads, ContinuousUp pointwise oscillation rows, DyadicRatCoreUp tolerance ledgers, RealUp bounds, a finite envelope fold, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOscillationEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7223.1, Definition 7223.2, Definition 7223.3, and Definition 7223.4 seed the finite oscillation-envelope route for compact uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOscillationEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host open-cover compactness, semantic continuity, external modulus selection, quotient point equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net admission, metric reads, pointwise oscillation rows, dyadic tolerance compatibility, Real-seal nonescape, finite envelope fold exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactOscillationEnvelopeUp.

Chapter 7224

A Concrete Naming Certificate for BishopIntervalNestingMetricCompletion$^{\uparrow}$

Following Bishop and Bridges on nested intervals and constructive metric completion, the BishopIntervalNestingMetr packet records the handoff from displayed interval nesting to a metric-completion-facing real name as finite BEDC data. It sits after the located nested-interval route of chapter 1713, the dyadic arithmetic core of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the metric completion boundary of chapter 1506, and the terminal real-name seal of chapter 38. The packet names only the displayed nesting-to-completion carrier; it does not assert ambient Real$^{\uparrow}$ completeness, choose an interval intersection point, quotient endpoint names, or select a metric-completion representative.

Definition 7224.1 (Bishop interval nesting metric-completion carrier)**.** *A* BishopIntervalNestingMetricCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, S, N, W, R, M, E, H, C, P, L)$$

with the following visible rows:

1. *I is the located interval row, displaying lower and upper endpoint witnesses and the locatedness comparison needed for retained windows.*
2. *D is the dyadic bisection and midpoint row, read through* DyadicRatCore$^{\uparrow}$ *and carrying the parent-to-child radius-halving ledger.*
3. *S is the shrinking-diameter budget row recording the finite request-to-radius schedule.*
4. *N is the nested containment ledger, including the retained child relation and the proof that later windows remain inside earlier windows.*
5. *W is the* StreamName$^{\uparrow}$ *finite-window row for the retained interval sequence.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row exposed after the stream window and dyadic tolerance data have been displayed.*
7. *M is the* MetricCompletion$^{\uparrow}$ *handoff row through which completion-facing consumers read the same regular Cauchy route without choosing a quotient representative.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row, downstream of W, R, M.*
9. *H records componentwise* hsame *transport for the interval, bisection, diameter, nesting, stream, readback, completion, and seal rows.*

10. *C records displayed* Cont *replay from a precision request through retained windows and into completion-facing readback.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}$, $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *L is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an ambient completeness theorem, a selected interval-intersection point, quotient equality of endpoint names, countable choice, trichotomy, or a detached real seal.

Theorem 7224.2 (Bishop interval nesting metric-completion obligations)**.** *For every accepted* $\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}$ *carrier* $K = (I, D, S, N, W, R, M, E, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for the displayed located interval, dyadic midpoint, shrinking-diameter, containment, stream, readback, completion, real-seal, transport, replay, provenance, and local naming rows;*

2. *dyadic contraction, requiring each retained child interval to read the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint and radius-halving ledger before the next window is admitted;*

3. *nested containment, requiring the row N to display that every later retained interval remains inside the earlier window named by the same stream prefix;*

4. *regular readback, requiring W and R to expose the retained windows as a* $\mathsf{RegSeqRat}^{\uparrow}$ *route before M or E is read;*

5. *metric-completion handoff, requiring every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer to read I, D, S, N, W, R on the same packet before using M;*

6. *real-seal non-escape, requiring E to be downstream of the displayed stream, regular-readback, and completion rows and excluding all hidden completeness or quotient coordinates.*

Proof. Project the carrier of Definition 7224.1. This exposes exactly the rows $I, D, S, N, W, R, M, E, H, C, P, L$ and no additional host-level interval intersection, quotient representative, choice functional, trichotomy, or completeness coordinate.

The dyadic contraction obligation is read from D and S. The midpoint and radius-halving data are carried as dyadic rows, while the shrinking schedule tells which finite budget is attached to the retained child interval.

The nesting and readback obligations are then rowwise. The containment ledger N records inclusion between retained windows, W names the finite stream windows, and R repacks those windows as regular rational readbacks.

Finally, M and E are downstream rows on the same packet. The transport, replay, provenance, and local naming rows H, C, P, L preserve the route, so every completion-facing or real-seal read is forced through the displayed finite obligations and cannot export an excluded host object. □

Theorem 7224.3 (Bishop interval nesting metric-completion point seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or* $\mathsf{MetricCompletion}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}$ *carrier factors through*

$$I, D, S, N, W, R, M, E, H, C, P, L.$$

In particular, the point seal is the displayed route from located nested intervals through $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff before the terminal* $\mathsf{Real}^{\uparrow}$ *row is exposed; it is not an ambient intersection theorem or a selected completed point.*

Proof. Begin with the accepted carrier and read its located interval row I. The dyadic row D supplies midpoint and child-window data, while S supplies the shrinking diameter budget that controls the requested precision.

The retained windows cannot be consumed until the nested containment ledger N is displayed. Once N is present, the stream row W names the finite window sequence and the regular row R provides the $\mathsf{RegSeqRat}^{\uparrow}$ readback seen by downstream real and completion consumers.

The metric-completion handoff M is therefore not a selected quotient representative; it is the same finite regular route repackaged for $\mathsf{MetricCompletion}^{\uparrow}$. The real seal E is downstream of that handoff and remains transported by H, C, P, L.

Since the carrier has no field for an ambient completeness theorem, selected intersection point, quotient endpoint equality, countable choice, or detached real seal, every point-seal read is exactly the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}$ packet is generated from located interval rows, dyadic midpoint and bisection rows, shrinking diameter budgets, nested containment ledgers, StreamName windows, RegSeqRat readback, a MetricCompletion handoff, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7224.1, Definition 7224.2, and Definition 7224.3 seed the finite handoff from Bishop-style interval nesting to MetricCompletion and Real consumers through displayed dyadic, stream, and regular-readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalNestingMetricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, selected interval intersections, quotient equality of endpoint names, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, dyadic contraction, nested containment, StreamName window exposure, RegSeqRat readback, MetricCompletion handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalNestingMetricCompletionUp.

Chapter 7225

A Concrete Naming Certificate for $\mathsf{CauchyCriterionForFunctions}^{\uparrow}$

Following Bishop–Bridges on the uniform Cauchy criterion for functions, the $\mathsf{CauchyCriterionForFunctions}^{\uparrow}$ packet records the finite function-window data by which a real-valued function family is read as uniformly Cauchy before any completed function object is available. It sits beside the already named $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ packet of chapter 1830, the continuous-map rows of chapter 130, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the criterion as BEDC rows for later uniform-convergence and continuous-map consumers; it is not host function equality, quotient equality of streams, countable choice, selected pointwise limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7225.1 (Cauchy criterion for functions carrier)**.** *A* $\mathsf{CauchyCriterionForFunctions}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, T, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the source function-window ledger. It lists the accepted finite argument windows, the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *rows available on those windows, and the paired value rows whose tails are compared.*

2. *T is the uniform tolerance request row. It records one displayed precision request and the single tail threshold demanded for all windows in W.*

3. *L is the pairwise tail-comparison ledger. For every pair of function indices beyond the threshold in T and every displayed source window in W, it stores the finite comparison row witnessing that the two value observations are within the requested dyadic tolerance.*

4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every rational observation exposed by the value comparisons in L.*

5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the function windows, tolerance request, comparison ledger, and regular rational readback have been displayed.*

6. *H records componentwise* hsame *transport for the function-window ledger, tolerance request, pairwise comparison ledger, readback row, real seal, replay, provenance, and local naming row.*

7. *C records displayed* Cont *replay from a uniform Cauchy request through W, T, L, R, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchyCriterionForFunctions}^{\uparrow}$, $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionForFunctions}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $W, T, L, R, E, H, C, P, N$. The carrier has no coordinate for host function equality, completed function-space equality, quotient streams, selected pointwise limits, countable-choice schedules, ambient real completeness, Lean verification, or bridge checking.

Theorem 7225.2 (Cauchy criterion for functions NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCriterionForFunctions}^{\uparrow}$ *carrier*

$$K = (W, T, L, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCriterionForFunctions}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed function-window ledger, uniform tolerance request, pairwise tail-comparison ledger, regular rational readback, terminal real seal, transport, replay, provenance, and local name;*
2. *source-window exposure, requiring every function value used by the criterion to be read from the finite windows listed in W;*
3. *uniform threshold accountability, requiring the threshold row in T to serve all accepted source windows and all compared function-index pairs beyond that threshold;*
4. *pairwise tail-comparison coverage, requiring every comparison consumed by the criterion to appear in L with its requested dyadic tolerance;*
5. *regular rational readback, requiring each numeric observation in L to pass through R before the terminal real seal is inspected;*
6. *Real-seal non-escape, requiring E to remain downstream of W, T, L, R and the structural rows;*
7. *componentwise stability, requiring replacement along* hsame *and displayed* Cont *replay to preserve the same finite criterion surface;*
8. *provenance exhaustion, requiring P to source only the listed rows and to export no host function equality, quotient stream, selected pointwise limit, countable-choice schedule, or ambient real-completeness principle;*
9. *local naming, requiring N to name exactly this finite criterion surface and no external function-space object.*

No local NameCert obligation is stored outside these rows.

Theorem 7225.3 (Cauchy criterion for functions uniform-window handoff)**.** *Let $K = (W, T, L, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCriterionForFunctions}^{\uparrow}$ *carrier. Every* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$*, uniform-convergence, or continuous-map consumer that reads the criterion must first expose the finite route*

$$\mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the source function windows W, the uniform tolerance request T, the pairwise tail-comparison ledger L, the readback row R, and the terminal seal E. Thus the consumer receives a uniform

Cauchy criterion only as displayed function-window data with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It cannot replace the hand-off by host function equality, quotient stream equality, countable choice, selected pointwise limits, completed function-space equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionForFunctions}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCriterionForFunctions}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7225.1, Definition 7225.2, and Definition 7225.3 seed the finite function-window route from the uniform Cauchy criterion to RealFunctionUniformCauchy, ContinuousMap, StreamName, RegSeqRat, DyadicRatCore, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCriterionForFunctions}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, completed function-space equality, quotient streams, countable choice, selected pointwise limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exposure, uniform threshold accountability, pairwise tail-comparison coverage, regular rational readback, Real-seal non-escape, componentwise stability, provenance exhaustion, and local naming for BEDC.Derived.CauchyCriterionForFunctionsUp.

Constructive story: A $\mathsf{CauchyCriterionForFunctions}^{\uparrow}$ packet is generated from finite function-window rows, one uniform tolerance request, a pairwise tail-comparison ledger, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7226

A Concrete Naming Certificate for $\mathsf{WhitneyApproximation}^{\uparrow}$

Following Whitney and standard smooth approximation theory, the $\mathsf{WhitneyApproximation}^{\uparrow}$ packet records a finite NameCert route for replacing a displayed continuous map on a finite manifold window by a smooth-row handoff at named tolerances. It sits over the finite-atlas source of chapter 96, the continuous-map source of chapter 130, the local smoothing cover of chapter 3369, smooth-row consumers such as chapter 4291 or chapter 136, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only the finite approximation certificate; it does not assert a host smooth-function space, select a smoothing operator, identify quotient maps, or use ambient completeness.

Definition 7226.1 (Whitney approximation carrier)**.** *A* $\mathsf{WhitneyApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, F, U, L, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *finite-atlas source row, exposing only the displayed chart domains, overlap rows, and local coordinate names.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *source map row to be approximated on the displayed finite window.*
3. *U is the* $\mathsf{PartitionOfUnity}^{\uparrow}$ *local cover and weight row used to assemble chartwise smooth pieces.*
4. *L is the smooth-row ledger, naming the local* $\mathsf{SmoothManifold}^{\uparrow}$ *handoff or* $\mathsf{DiffForm}^{\uparrow}$ *consumer-facing row reached after the partitioned construction.*
5. *S is the finite approximation schedule, listing the chart windows, requested tolerances, and overlap checks inspected by the packet.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the displayed tolerances and chartwise comparison data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the finite error bounds visible to downstream consumers.*
8. *H records componentwise* hsame *transport for the manifold, source map, partition, smooth ledger, schedule, readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the continuous source through the finite cover, local smooth rows, rational readback, and terminal Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{WhitneyApproximation}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{PartitionOfUnity}^{\uparrow}$, $\mathsf{SmoothManifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{WhitneyApproximation}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host smooth-function space, a choice-selected smoothing operator, quotient map equality, a global approximation theorem, or ambient completeness.

Theorem 7226.2 (Whitney approximation NameCert obligations)**.** *For every accepted* $\mathsf{WhitneyApproximation}^{\uparrow}$ *carrier* $W = (M, F, U, L, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WhitneyApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed manifold, continuous-map, partition, smooth-ledger, schedule, regular-readback, Real-seal, transport, replay, provenance, and local naming rows; finite-atlas exposure through M; source-map exposure through F; local smoothing cover exposure through U and L; tolerance readback through S, R, E; componentwise stability through H; displayed replay through C; and ledger exhaustion through P, N.*

Proof. Project the carrier of Definition 7226.1. The only analytic rows are the finite-atlas source, continuous source map, partition-of-unity cover, smooth ledger, approximation schedule, regular rational readback, and Real seal.

The local smoothing cover is visible before any smooth handoff is public. The partition row U and smooth ledger L name the chartwise route, while S, R, E record the finite tolerance checks that a downstream smooth-row consumer may inspect.

The structural rows H, C, P, N then transport, replay, source, and name the same finite packet. Since no host smooth-function space, selected smoothing operator, quotient map equality, global theorem, or ambient completeness row is present, the listed rows exhaust the local NameCert obligations. □

Theorem 7226.3 (Whitney approximation smooth handoff)**.** *Every* $\mathsf{SmoothManifold}^{\uparrow}$ *or* $\mathsf{DiffForm}^{\uparrow}$ *consumer of an accepted* $\mathsf{WhitneyApproximation}^{\uparrow}$ *packet must first read*

$$M, F, U, L, S, R, E$$

before it receives a smooth-row handoff. The consumer receives a finite atlas, a displayed continuous source map, a partition-of-unity assembly row, local smooth rows, finite tolerance windows, regular rational readback, and a terminal Real seal; it receives no host smooth-function space, selected smoothing operator, quotient map equality, global Whitney theorem, or ambient completeness principle.

Proof. Start with Definition 7226.2. It requires carrier admission and finite-atlas exposure before any approximation-facing consumer can inspect the packet.

The smooth handoff is downstream of U and L. These rows display the partitioned local construction and the smooth-row ledger, so a $\mathsf{SmoothManifold}^{\uparrow}$ or $\mathsf{DiffForm}^{\uparrow}$ consumer cannot enter through an untracked host smoothing operator.

The tolerance read is S, R, E. The finite schedule lists the inspected windows, the regular rational row supplies the readback, and the Real seal records the displayed error bound. The remaining rows H, C, P, N only transport, replay, source, and name this route, leaving no coordinate for quotient equality, a global theorem, or ambient completeness. □

Theorem 7226.4 (Whitney approximation nonescape)**.** *Every accepted* $\mathsf{WhitneyApproximation}^{\uparrow}$ *public read factors through the displayed rows*

$$M, F, U, L, S, R, E, H, C, P, N.$$

Thus the packet can expose only a finite NameCert approximation route over $\mathsf{Manifold}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{PartitionOfUnity}^{\uparrow}$, $\mathsf{SmoothManifold}^{\uparrow}$ *or* $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. It cannot export a host smooth-function space, a choice-selected smoothing operator, quotient map equality, ambient completeness, or a completed global approximation theorem.*

Proof. Use Definition 7226.1. The carrier displays exactly the eleven rows $M, F, U, L, S, R, E, H, C, P, N$.

Apply Definition 7226.2 and Definition 7226.3. They force every smooth-facing read to pass through the finite-atlas, continuous-map, partition, smooth-ledger, tolerance, readback, and Real-seal rows before structural transport and provenance are consumed.

The excluded host objects are not coordinates of the carrier and are not introduced by the structural rows. Therefore every public read remains inside the displayed finite NameCert route. □

Closure status for $\mathsf{NameCert}_{\mathsf{WhitneyApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{WhitneyApproximation}^{\uparrow}$ packet is generated from a finite ManifoldUp atlas row, a ContinuousMap source row, a PartitionOfUnity local cover, SmoothManifold or DiffForm handoff rows, a finite approximation schedule, RegSeqRat readback, a RealUp error seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WhitneyApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7226.1, Definition 7226.2, Definition 7226.3, and Definition 7226.4 seed the finite smooth-approximation route over manifold, continuous-map, partition, smooth-row, regular-readback, and Real-seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WhitneyApproximation}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a host smooth-function space, choice-selected smoothing operator, quotient map equality, ambient completeness, or a completed global Whitney approximation theorem.

Upgrade path: Obligation closure requires checked carrier admission, local cover exposure, smooth-row handoff, tolerance readback, transport, replay, provenance, and local naming for BEDC.Derived.WhitneyApproximationUp.

Chapter 7227

A Concrete Naming Certificate for $\mathsf{CompactCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges on compact metric sequence arguments, the $\mathsf{CompactCauchySubsequence}^{\uparrow}$ packet records the finite subsequence-window route by which compact-metric data can be consumed as a Cauchy subsequence surface. It sits beside the sequential compactness window packet of chapter 2372, the compact metric source of chapter 129, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet supplies RegSeqRat and Real seal arguments with a finite subsequence-window carrier, not host subsequence choice, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7227.1 (Compact Cauchy subsequence carrier)**.** *A* $\mathsf{CompactCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, J, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the compact metric carrier and the finite cover or total-bounded window that bounds the inspected sequence.*
2. *J is the* $\mathsf{SequentialCompact}^{\uparrow}$ *subsequence-window row, recording the finite increasing index windows supplied to the compact source.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row for the original sequence observations.*
4. *W is the selected finite subsequence-window ledger, displaying the inspected indices and their monotonicity evidence.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for pairwise tail comparisons inside W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the subsequence observations after the stream and dyadic rows have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, J, S, W, D, R have been exposed.*
8. *H records componentwise* hsame *transport for the compact source, sequential window, stream window, subsequence window, dyadic tolerance, regular readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact Cauchy-subsequence request through* $K, J, S, W, D, R, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{CompactCauchySubsequence}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $K, J, S, W, D, R, E, H, C, P, N$. It has no coordinate for host subsequence choice, quotient stream equality, selected limits, countable-choice schedules, open-cover compactness as a hidden theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7227.2 (Compact Cauchy subsequence obligation surface)**.** *For every accepted* CompactCauchySubsequen *carrier $Q = (K, J, S, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactCauchySubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, sequential compactness window, stream observation window, selected finite subsequence window, dyadic tolerance ledger, regular rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming rows.*

Consequently every $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the packet must read the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{SequentialCompact}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through $K, J, S, W, D, R, E, H, C, P, N$ and cannot replace it by host subsequence choice, quotient stream equality, countable choice, selected real limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7227.1. The displayed rows expose the compact metric source, the sequential compactness window, the original stream observations, the selected finite subsequence window, the dyadic tolerance ledger, the regular readback, and the terminal real seal.

The compact and sequential rows are finite. The $\mathsf{CompactMetric}^{\uparrow}$ source supplies only compact-metric carrier and finite cover data, while the $\mathsf{SequentialCompact}^{\uparrow}$ row supplies only the subsequence-window surface already named by the sibling chapter.

The Cauchy readback rows are downstream. The stream row S opens the inspected observations, the window row W records the selected finite indices, D records the dyadic comparison budget, and R is the regular rational readback available to later consumers.

Finally the Real seal E and the structural rows H, C, P, N preserve the same route. Since the carrier contains no field for host subsequence selection, quotient stream equality, selected limits, countable choice, or ambient completeness, the listed rows exhaust the local obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactCauchySubsequence}^{\uparrow}$ packet is generated from compact metric source rows, SequentialCompact finite subsequence-window rows, StreamName observations, DyadicRatCore tolerance comparisons, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactCauchySubsequence}^{\uparrow}}$, seed)

Scope closed: Definition 7227.1 and Definition 7227.2 seed the finite compact Cauchy subsequence route through compact metric, sequential-window, StreamName, dyadic tolerance, RegSeqRat, and Real seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactCauchySubsequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host subsequence choice, quotient stream equality, selected real limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, subsequence-window monotonicity, stream-window exactness, dyadic Cauchy comparison, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CompactCauchySubsequenceUp.

Chapter 7228

A Concrete Naming Certificate for $\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}$

Following Bishop and Bridges on compact uniform continuity and Cauchy convergence, the CompactUniformCauchyT packet records the finite route that turns compact finite-net modulus data into a Cauchy-tail handoff for regular real-name consumers. It realizes the compact-uniform-continuity route of chapter 9237 through the compact metric source of chapter 129, the compact uniform modulus packet of chapter 2299, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The router is a displayed finite tail packet; it is not a host uniform-continuity theorem, selected global modulus, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7228.1 (Compact uniform Cauchy-tail router carrier)**.** *A* $\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, M, S, D, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row.*
2. *M is the* $\mathsf{CompactUniformModulus}^{\uparrow}$ *row that converts compact finite-net and pointwise-modulus data into a tolerance-only modulus ledger.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row for the source and target Cauchy windows opened by the router.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested tail precision and compact-net radius budget.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream and dyadic rows.*
6. *L is the Cauchy-tail ledger, recording the finite threshold and the pairwise tail comparisons consumed by downstream regular real-name readers.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, M, S, D, R, L have been exposed.*
8. *H records componentwise* hsame *transport for the compact source, modulus, stream windows, dyadic ledger, regular readback, tail ledger, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a compact-uniform Cauchy-tail request through $K, M, S, D, R, L, E, H, P, N$*

10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, S, D, R, L, E, H, C, P, N$. It has no coordinate for a host uniform-continuity theorem, selected global modulus, quotient stream equality, selected limits, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7228.2 (Compact uniform Cauchy-tail router obligation surface)**.** *For every accepted* $\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}$ *carrier $T = (K, M, S, D, R, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCa}}$ *surface consists exactly of carrier admission for the compact metric source, compact uniform modulus row, stream windows, dyadic tolerance ledger, regular rational readback, Cauchy-tail ledger, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming.*

Consequently every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the router must read*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CompactUniformModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through $K, M, S, D, R, L, E, H, C, P, N$ and cannot replace the route by a selected global modulus, quotient stream equality, selected real limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7228.1. The compact source and uniform-modulus rows are exactly K and M, so no host compactness theorem or external modulus is available to the consumer.

The tail route is then finite. The row S names the inspected stream windows, D records the dyadic tolerance budget for the same request, R provides the regular rational readback, and L records the threshold and pairwise tail comparisons read by downstream consumers.

The terminal seal E is downstream of those rows. Componentwise transport, displayed replay, provenance, and local naming preserve the same finite packet, and the carrier has no additional coordinate for quotient stream equality, selected limits, countable choice, or ambient Real completeness. Thus the listed rows exhaust the obligation surface. □

Theorem 7228.3 (Compact uniform Cauchy-tail router obligation package)**.** *For the carrier of Definition 7228.1, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}}$ *route assembles one obligation package consisting of carrier admission, compact finite-net exposure, uniform-modulus handoff, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, Cauchy-tail ledger coverage,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, provenance, and local naming.*

Every consumer of the package must therefore read the finite route

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CompactUniformModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $K, M, S, D, R, L, E, H, C, P, N$ and cannot replace it by a host compactness theorem, selected global modulus, quotient stream equality, selected real limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7228.1. The rows $K, M, S, D, R, L, E, H, C, P, N$ are exactly the compact source, uniform-modulus handoff, stream-window, dyadic-tolerance, regular-readback, tail-ledger, Real-seal, transport, replay, provenance, and local naming fields available to the certificate.

Apply Definition 7228.2. It identifies those same rows as the whole local obligation surface and orders every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer through the displayed finite route.

Since no carrier coordinate stores a host compactness theorem, selected global modulus, quotient stream equality, selected real limit, choice schedule, or ambient completeness oracle, the projected rows and the obligation-surface theorem compose as one obligation package for the local $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}}$ route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}$ packet is generated from compact metric finite-net rows, CompactUniformModulus rows, StreamName windows, DyadicRatCore tolerance budgets, RegSeqRat readback, a Cauchy-tail ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7228.1 and Definition 7228.2 seed the compact-uniform Cauchy-tail route through compact metric, uniform-modulus, StreamName, dyadic tolerance, RegSeqRat, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyTailRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host uniform-continuity semantics, selected global moduli, quotient stream equality, selected real limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, uniform-modulus handoff, stream-window exactness, dyadic tail-budget exposure, RegSeqRat readback, Cauchy-tail threshold coverage, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformCauchyTailRouterUp.

Chapter 7229

A Concrete Naming Certificate for $\mathsf{RegularCauchyLimitTheorem}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{RegularCauchyLimitTheorem}^{\uparrow}$ packet records the finite route by which regular Cauchy evidence is admitted as a Real-facing limit theorem without importing a global completeness principle. It sits after the finite observation discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a theorem-facing carrier for the displayed tail-window route; it is not a selected limit, quotient equality of regular names, arbitrary trichotomy, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 7229.1 (Regular Cauchy limit theorem carrier)**.** *A* $\mathsf{RegularCauchyLimitTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the tail-modulus row, displaying the finite threshold schedule used by the accepted regular Cauchy evidence.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row whose observations request the tail after the displayed threshold.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic scale at which the tail comparison is read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the tail modulus, stream window, and dyadic tolerance rows are visible.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular rational readback row R.*
6. *H records componentwise* hsame *transport for modulus, window, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$M, S, D \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLimitTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitTheorem}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $M, S, D, R, E, H, C, P, N$. It has no coordinate for selecting a completed limit, quotienting regular Cauchy names, arbitrary real trichotomy, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) `BEDC.Derived.RegularCauchyLimitTheoremUp`

Theorem 7229.2 (Regular Cauchy limit theorem obligations)**.** *For every accepted* $\mathsf{RegularCauchyLimitTheorem}^{\uparrow}$ *carrier $L = (M, S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission; tail-modulus visibility through M; finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window visibility through S;* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure through D;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R;* $\mathsf{Real}^{\uparrow}$ *seal handoff through E; componentwise stability under* hsame *through H; displayed* Cont *replay through C;* Pkg *provenance through P; local naming through N; and ledger non-escape for all Real-facing reads.*

Proof. Project the carrier. The rows M, S, D are the only source rows visible before the regular rational readback, so tail-modulus visibility, window visibility, and dyadic tolerance exposure are all finite carrier clauses.

Read the handoff rows next. The row R is downstream of M, S, D, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is downstream of R.

The structural rows H, C, P, N transport, replay, source, and name the same displayed route. Since no excluded selected-limit, quotient-equality, trichotomy, choice, or completeness coordinate occurs in the carrier, ledger non-escape follows for every Real-facing read. □

Theorem 7229.3 (Regular Cauchy limit theorem tail-seal handoff)**.** *Every Real-facing read of an accepted* $\mathsf{RegularCauchyLimitTheorem}^{\uparrow}$ *carrier factors through the displayed route*

$$M, S, D \longmapsto R \longmapsto E$$

before the terminal seal is consumed. Transport, replay, provenance, and local naming preserve this route and do not add an alternate limit selector or completeness-facing coordinate.

Proof. Start with the obligation theorem Definition 7229.2. It identifies M, S, D as the complete finite source surface for the theorem-facing tail read.

The regular readback row is next in the carrier order. A Real-facing consumer therefore reaches R only after the tail modulus, stream window, and dyadic tolerance rows have been displayed.

Finally consume the seal row E. The rows H, C, P, N preserve the same dependency order under transport, replay, provenance, and naming, so no consumer can bypass the tail-window, readback, and tolerance route before reading the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLimitTheorem}^{\uparrow}$ packet is generated from a tail-modulus row, a StreamName tail-window row, a DyadicRatCore tolerance row, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyLimitTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 7229.1, Definition 7229.2, and Definition 7229.3 seed the finite theorem-facing tail-window route from regular Cauchy evidence to the RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyLimitTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, selected limits, quotient regular Cauchy equality, arbitrary trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-modulus visibility, StreamName window exposure, DyadicRatCore tolerance exposure, RegSeqRat readback, RealUp seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLimitTheoremUp.

Chapter 7230

A Concrete Naming Certificate for $\mathsf{RemovableDiscontinuity}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RemovableDiscontinuity}^{\uparrow}$ packet records the finite pointwise repair route by which a function value at one displayed puncture is replaced by a displayed limiting value before a continuity-facing consumer reads the repaired function. It sits beside the terminal real-name seal of chapter 38, the regular rational readback route of chapter 301, the finite limiting surface of $\mathsf{Limit}^{\uparrow}$, the continuous-function surfaces $\mathsf{Continuous}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$, and the Riemann-specific repair packet of chapter 7217. The packet repairs only the named local defect; it does not select global functions, identify quotient real functions, invoke countable choice, assume ambient $\mathsf{Real}^{\uparrow}$ completeness, or prove a host extensionality principle.

Definition 7230.1 (Removable-discontinuity carrier)**.** *A* $\mathsf{RemovableDiscontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (P, W, L, V, E, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the punctured point row, naming the source point, the displayed domain side, and the fact that the ordinary value at the point is not the row read by the repair certificate.*
2. *W is the punctured-window row, listing the finite neighbourhood windows and exclusions used to inspect the source function away from P.*
3. *L is the limiting-value row, read through* $\mathsf{Limit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *data attached to the punctured windows.*
4. *V is the repaired-value row, inserting the displayed limiting value as the value assigned at the puncture.*
5. *E is the continuous-extension row, recording the repaired local function surface through* $\mathsf{Continuous}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *after P, W, L, V have been displayed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback route for all numeric observations used by W, L, V, E.*
7. *H records componentwise* hsame *transport for the puncture, punctured windows, limiting value, repaired value, extension row, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a repair request through $P, W, L, V, E, R, H, Q, N$.*
9. *Q is the* Pkg *provenance over* $\mathsf{RemovableDiscontinuity}^{\uparrow}$, $\mathsf{Limit}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RemovableDiscontinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, W, L, V, E, R, H, C, Q, N$. It has no coordinate for host function extensionality, selected global functions, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7230.2 (Removable-discontinuity NameCert obligations)**.** *For every accepted* $\mathsf{RemovableDiscontinuity}^{\uparrow}$ *carrier*

$$M = (P, W, L, V, E, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{RemovableDiscontinuity}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier admission for the displayed packet M;*
2. *punctured-window exposure, requiring the source read to pass through P and W before any repair value is consumed;*
3. *limit-value readback, requiring L and R to expose the* $\mathsf{Limit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route used for the replacement value;*
4. *repaired-value insertion and continuous-extension handoff, requiring V to be inserted before E is exported to* $\mathsf{Continuous}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumers;*
5. *ledger nonescape, meaning every consumer-visible repair claim is projected from $P, W, L, V, E, R, H, C, Q, N$ and from no host extensionality, selected global function, quotient real equality, choice principle, or ambient completeness datum.*

Proof. Project the carrier of Definition 7230.1. The pointwise repair rows are P, W, L, V, E, and the structural rows are R, H, C, Q, N.

The puncture row P fixes the only point at which the ordinary source value is not read directly. The punctured-window row W lists the finite neighbourhood observations away from that point, so a consumer cannot infer a global function extension before the local windows are displayed.

The limiting value is read through L together with the numeric route R. These rows bind the $\mathsf{Limit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ data used for the replacement value, while V records that this displayed value is inserted at the puncture.

The handoff row E is therefore available only after P, W, L, V, R have been displayed. Transport and replay use H and C, and provenance and local naming use Q and N.

Since no excluded principle is a coordinate of the carrier, none can be exported by the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{RemovableDiscontinuity}^{\uparrow}$ read must expose a punctured point row, a punctured-window row, a limiting-value row, a repaired-value row, a continuous-extension row, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, limit, continuous, continuousmap, riemann-removable-discontinuity: $\mathsf{RemovableDiscontinuity}^{\uparrow}$ is not bijective to any listed sibling because it binds the punctured point, punctured-window route, limiting-value readback, repaired-value insertion, and continuous-extension handoff in one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RemovableDiscontinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RemovableDiscontinuity}^{\uparrow}$ packet is generated from a punctured point row, a punctured-window row, a limiting-value row, a repaired-value row, a continuous-extension row, regular rational and Real readback, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RemovableDiscontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7230.1 and Definition 7230.2 seed the finite pointwise repair surface over $\mathsf{Limit}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RemovableDiscontinuity}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, selected global functions, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, punctured-window exposure, limit-value readback, repaired-value insertion, continuous-extension handoff, transport, replay, provenance, and ledger nonescape for BEDC.Derived.RemovableDiscontinuityUp.

Chapter 7231

A Concrete Naming Certificate for $\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}$

The $\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}$ packet realizes the boundary-distortion budget route of chapter 9463 as finite NameCert data. It sits after the finite disk-map rows of chapter 6776, the boundary-shadow rows of chapter 6678, the visual-metric rows of chapter 3866, and the cross-ratio rows of chapter 3948. The budget row consumes those finite disk-map, boundary-shadow, visual-metric, and cross-ratio rows before the Real-facing distortion seal is exposed. The packet is not a completed hyperbolic plane, a selected ideal endpoint, quotient boundary equality, an external quasi-isometry theorem, or an ambient completeness principle.

Definition 7231.1 (Hyperbolic boundary-distortion budget carrier)**.** *A* $\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, V, X, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk-map row, displaying the Poincare disk map whose boundary distortion is being read.*
2. *S is the boundary-shadow row, recording the finite boundary arc or endpoint shadow consumed by the observer-expansion route.*
3. *V is the visual-metric row attached to the same boundary shadow.*
4. *X is the cross-ratio or metric-comparison row that compares the displayed before-and-after boundary shadows.*
5. *M is the metric-comparison budget row, recording the finite distortion allowance for the displayed disk map.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for the distortion threshold.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after disk-map, boundary-shadow, visual-metric, cross-ratio or metric-comparison, dyadic tolerance, and budget rows are visible.*
8. *H records componentwise* hsame *transport for disk-map, boundary-shadow, visual-metric, comparison, tolerance, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$D, S, V, X, M, Q \longmapsto E.$$

10. *P is the* Pkg *provenance over* HyperbolicBoundaryDistortionBudget$^{\uparrow}$, PoincareDiskAutomorphism$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicCrossRatio$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{HyperbolicBoundaryDistortionBudget}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, V, X, M, Q, E, H, C, P, N$. It has no coordinate for a completed hyperbolic surface, selected boundary endpoint, quotient boundary equality, hidden global distortion theorem, or ambient completeness principle.

Lean4 (statement) `BEDC.Derived.HyperbolicBoundaryDistortionBudgetUp`

Theorem 7231.2 (Hyperbolic boundary-distortion budget obligations)**.** *For every accepted* HyperbolicBoundaryDis *carrier $B = (D, S, V, X, M, Q, E, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicBoundaryDistortionBudget}^{\uparrow}}$ *surface consists exactly of disk-map admission through D; boundary-shadow exposure through S; visual-metric exposure through V; cross-ratio or metric-comparison exposure through X; finite distortion-budget exposure through M; dyadic tolerance exposure through Q;* Real$^{\uparrow}$ *seal non-escape through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Proof. Project the carrier. The rows D, S, V, X, M, Q are the complete boundary-distortion source surface: a disk map, its boundary shadow, the visual metric, the comparison read, the finite budget, and the dyadic tolerance.

The Real-facing row is downstream. The seal E is exposed only after the displayed source rows have been read, so a boundary-distortion consumer cannot reach a Real value from an unregistered disk map or hidden comparison theorem.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no completed surface, selected endpoint, quotient boundary equality, hidden global distortion theorem, or ambient completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7231.3 (Hyperbolic boundary-distortion budget nonescape)**.** *Every accepted* HyperbolicBoundaryDistorti *Real-facing read factors through the displayed disk-map, boundary-shadow, visual-metric, cross-ratio or metric-comparison, dyadic tolerance, transport, replay, provenance, and local NameCert rows before it consumes the seal. No consumer may export boundary distortion from a hidden hyperbolic metric, an unstated cross-ratio, a selected ideal endpoint, quotient boundary equality, or ambient completeness.*

Proof. Start from Definition 7231.2. It places the disk map D, boundary shadow S, visual metric V, comparison row X, distortion budget M, and dyadic tolerance Q before the Real seal.

Transport and replay preserve the displayed order. The rows H and C may replace the packet by componentwise same rows and replay the route, but neither adds a new source for distortion.

Provenance and local naming close the finite route. Since P and N name only the displayed rows, the refused hidden metric, unstated comparison, selected endpoint, quotient equality, and completeness principles have no export coordinate. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}$ boundary-distortion read is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying disk-map, boundary-shadow, visual-metric, cross-ratio or metric-comparison, dyadic tolerance, transport, replay, provenance, and local NameCert rows.

Independence witness: hyperbolic-metric, hyperbolic-visual-metric, hyperbolic-cross-ratio, hyperbolic-boundary-shadow, poincare-disk-automorphism: no listed sibling is bijective to HyperbolicBoundaryDistortionBudget because the budget packet binds disk-map, boundary-shadow, visual-metric, comparison, dyadic tolerance, Real seal, transport, replay, provenance, and local naming as one finite distortion certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}$ packet is generated from disk-map rows, boundary-shadow rows, visual-metric rows, cross-ratio or metric-comparison rows, dyadic tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7231.1, Definition 7231.2, and Definition 7231.3 seed the finite boundary-distortion budget route for observer-expansion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryDistortionBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic surfaces, selected ideal endpoints, quotient boundary equality, hidden global distortion theorems, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-map admission, boundary-shadow exposure, visual-metric exposure, cross-ratio or metric-comparison exposure, dyadic tolerance, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicBoundaryDistortionBudgetUp.

Chapter 7232

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverHorizon}^{\uparrow}$

The $\mathsf{HyperbolicObserverHorizon}^{\uparrow}$ packet realizes the observer-horizon branch of chapter 9463 as finite NameCert data. It sits over the visual boundary surface of chapter 4181, the Gromov-product comparison route of chapter 6073, the Busemann cocycle route of chapter 4134, the horoball-shadow row of chapter 6569, observer-window sources such as chapter 4154, and the terminal real-name seal of chapter 38. The packet names the finite horizon-facing route; it does not assert a global boundary compactification, a completed spacetime horizon, a selected geodesic ray, quotient boundary equality, or ambient hyperbolic completeness.

Definition 7232.1 (Hyperbolic observer-horizon carrier)**.** *A* $\mathsf{HyperbolicObserverHorizon}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, G, U, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row naming the visible boundary window under inspection.*
2. *G is the* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ *comparison row for the same observer-side basepoint and boundary window.*
3. *U is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *cocycle row used to orient the boundary-facing displacement read.*
4. *S is the* $\mathsf{HyperbolicHoroballShadow}^{\uparrow}$ *row naming the horoball-shadow window that a horizon consumer may inspect.*
5. *W is the observer-window row, read through the observer-shadow or observer-expansion surface, listing the finite records visible to the focused observer.*
6. *R is the regular readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal row for horizon depth, shadow threshold, or visual-radius comparisons.*
7. *E is the refusal row excluding interior far-end selection, quotient boundary equality, global compactification, and completed spacetime-horizon semantics.*
8. *H records componentwise* hsame *transport for the boundary, product, cocycle, horoball-shadow, observer-window, Real-seal, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from observer-window inspection through boundary, product, cocycle, horoball-shadow, Real-seal, and refusal rows.*

10. *P is the* Pkg *provenance over* HyperbolicObserverHorizon$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicGromovProduct HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicHoroballShadow$^{\uparrow}$, *observer-window rows,* Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{HyperbolicObserverHorizon}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global compactification object, selected geodesic ray, quotient boundary equality, completed spacetime horizon, hidden observer synchronization, or ambient hyperbolic completeness.

Theorem 7232.2 (Hyperbolic observer-horizon NameCert obligations)**.** *For every accepted* HyperbolicObserverHori *carrier $O = (B, G, U, S, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicObserverHorizon}^{\uparrow}}$ *surface consists exactly of carrier admission for the visual boundary, Gromov-product, Busemann-cocycle, horoball-shadow, observer-window, Real-seal, refusal, transport, replay, provenance, and local naming rows; boundary exposure through B; product comparison through G; cocycle orientation through U; shadow exposure through S; observer-window accountability through W; Real-seal readback through R; refusal exactness through E; and componentwise stability through H, C, P, N.*

Proof. Project the carrier of Definition 7232.1. The horizon-facing rows are exactly B, G, U, S, W, R, E, and the structural rows are H, C, P, N.

The boundary route is visible before any observer-horizon read is public. The visual boundary row B, Gromov product row G, Busemann cocycle row U, and horoball-shadow row S fix the boundary, comparison, orientation, and shadow data.

The observer and Real-facing rows are then W, R, E. They expose the finite observer window, seal the requested real comparison, and refuse the excluded global or quotient objects. The structural rows transport and replay only those displayed rows, so the listed obligations exhaust the local NameCert surface. □

Theorem 7232.3 (Hyperbolic observer-horizon boundary handoff)**.** *Every horizon-facing consumer of an accepted* HyperbolicObserverHorizon$^{\uparrow}$ *packet must first read*

$$B, G, U, S \longmapsto W, R, E \longmapsto H, C, P, N.$$

The consumer receives visual boundary, Gromov-product, Busemann-cocycle, horoball-shadow, observer-window, Real-seal, refusal, transport, replay, provenance, and local naming rows. It receives no selected geodesic ray, quotient boundary equality, global boundary compactification, completed spacetime-horizon object, hidden synchronized observer coordinate, or ambient hyperbolic completeness principle.

Proof. Use Definition 7232.2. It places the visual boundary, product comparison, Busemann cocycle, and horoball-shadow rows before any observer-window or Real-seal consumer can read the horizon packet.

The observer read is finite. The row W lists the inspected observer records, R seals the real comparison requested by that read, and E records the refusal of interior far-end selection and quotient boundary equality.

Finally H, C, P, N preserve the same finite route. Since the carrier contains no global compactification, selected ray, quotient equality, synchronized observer coordinate, completed horizon, or ambient completeness row, no consumer can obtain one from the packet. □

Falsifiable prediction: Every accepted HyperbolicObserverHorizon$^{\uparrow}$ read must expose HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicGromovProduct$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicHoroballShadow$^{\uparrow}$, observer-window,

terminal $\mathsf{Real}^{\uparrow}$ seal, refusal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any horizon-facing conclusion is visible.

Independence witness: hyperbolic-visual-boundary, hyperbolic-gromov-product, hyperbolic-busemann-cocycle, hyperbolic-horoball-shadow, hyperbolic-observer-shadow-metric: none is bijective to $\mathsf{HyperbolicObserverHorizon}^{\uparrow}$ because the horizon packet jointly binds boundary readback, product comparison, Busemann orientation, horoball-shadow exposure, observer-window accountability, Real sealing, refusal, transport, replay, provenance, and local naming.

The Lean follow-up for this packet must provide explicit Nontrivial $\mathsf{HyperbolicObserverHorizon}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicObserverHorizon}^{\uparrow}$ TasteGate instances. Those instances must keep $B, G, U, S, W, R, E, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizon}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicObserverHorizon}^{\uparrow}$ packet is generated from a HyperbolicVisualBoundary row, a HyperbolicGromovProduct comparison row, a HyperbolicBusemannCocycle orientation row, a HyperbolicHoroballShadow window, an observer-window row, a RealUp seal, a refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizon}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7232.1, Definition 7232.2, and Definition 7232.3 seed the finite observer-horizon route over visual boundary, Gromov product, Busemann cocycle, horoball shadow, observer-window, Real-seal, and refusal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizon}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global boundary compactification, selected geodesic rays, quotient boundary equality, completed spacetime horizons, synchronized observer coordinates, or ambient hyperbolic completeness.

Upgrade path: Obligation closure requires checked carrier admission, boundary exposure, product comparison, Busemann orientation, horoball-shadow exposure, observer-window accountability, Real-seal readback, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicObserverHorizonUp.

Chapter 7233

A Concrete Naming Certificate for $\mathsf{CompactNetSelection}^{\uparrow}$

Following Bishop and Bridges on compact metric finite nets, the $\mathsf{CompactNetSelection}^{\uparrow}$ packet records the displayed finite center list and hit ledger that Real-and-Completion consumers may read from a compact metric source. It sits after the compact finite-net surface of chapter 129, the metric-distance classifier of chapter 57, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet selects no host point and invokes no open-cover compactness principle; it only names the finite rows already displayed by the compact metric source.

Definition 7233.1 (CompactNetSelection carrier)**.** *A* $\mathsf{CompactNetSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (K_0, M, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. K_0 *is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, carrying the compact metric source, the displayed center list, the net radius, and the finite coverage witness table.*
2. M *is the* $\mathsf{Met}^{\uparrow}$ *distance and hit row, recording the inspected point names, center names, distance comparisons, and hit witnesses used by the selected net.*
3. S *is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing exactly the finite observations of source points and centers read by the compact-net query.*
4. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational distance and tolerance data opened by* M *and* S*.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for distance or tolerance comparisons, visible only after* K_0, M, S, Q *have been displayed.*
6. H *records componentwise* hsame *transport for the compact source, metric hit ledger, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a requested finite-net read through the center list, hit witnesses, StreamName windows, RegSeqRat readback, and Real seal.*
8. P *is the* Pkg *provenance over* $\mathsf{CompactNetSelection}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CompactNetSelection}^{\uparrow}}$ *row.*
The classifier accepts a packet only when the center list is displayed in K_0, every hit row is read through M, every observation window is exposed by S, every rational tolerance readback factors through Q, and every Real-facing comparison reaches E after the finite rows are visible. It has no coordinate for a host selector, an open-cover compactness theorem, a choice-selected center, quotient metric equality, selected Cauchy limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7233.2 (CompactNetSelection NameCert obligations)**.** *For every accepted* $\mathsf{CompactNetSelection}^{\uparrow}$ *carrier $K = (K_0, M, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactNetSelection}^{\uparrow}}$ *obligations consist exactly of carrier admission for the compact finite-net source, metric distance and hit ledger, StreamName windows, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming rows; center-list visibility through K_0; hit-row exactness through M; finite-window exactness through S; rational readback through Q; Real-seal nonescape through E; and preservation of the same route through H, C, P, N.*

Proof. Project the carrier of Definition 7233.1. Its visible rows are precisely $K_0, M, S, Q, E, H, C, P, N$, so every local obligation must be read from one of those rows.

The compact finite-net source row K_0 displays the center list and coverage table before the metric hit row is inspected. The metric row M then records the distance comparisons and hit witnesses attached to those displayed centers.

The Real-facing side is downstream. StreamName windows S expose the finite observations, RegSeqRat readback Q records the rational tolerance data, and the Real seal E is terminal.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since no further carrier coordinate exists, host selectors, open-cover compactness, choice-selected centers, quotient equality, selected limits, and ambient Real completeness cannot be local NameCert obligations. □

Theorem 7233.3 (CompactNetSelection Real-and-Completion handoff)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{CompactNetSelection}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $K_0, M, S, Q, E, H, C, P, N$ before it consumes a compact-net center, hit witness, rational tolerance, or Real seal. The handoff exports a finite selected-net packet only; it does not export a host selector, an open-cover compactness theorem, quotient metric equality, a selected Cauchy limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with K_0. The compact metric source supplies the finite center list and coverage witnesses as displayed BEDC data, not as a host compactness principle.

Read M next. It ties every selected center use to a metric distance comparison and hit witness, so a downstream consumer cannot detach the selected-net row from the source metric classifier.

The readback rows S, Q, E then expose the finite observation windows, regular rational tolerance data, and terminal Real seal. These rows are the only route by which the selected net becomes visible to Real or Completion consumers.

The structural rows H, C, P, N preserve that route under transport and replay. Therefore every accepted handoff is the finite packet displayed in the carrier, with no coordinate for the excluded host selector, compactness, quotient, selected-limit, or ambient-completeness data. □

Falsifiable prediction: Every accepted $\mathsf{CompactNetSelection}^{\uparrow}$ Real-and-Completion read factors through CompactMetric finite-net source data, Metric distance and hit rows, StreamName windows, RegSeqRat readback, RealUp seals, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: compactmetric, metric, streamname, regseqrat, real: no listed sibling is bijective with $\mathsf{CompactNetSelection}^{\uparrow}$ because this packet alone binds the displayed finite center list and hit ledger to downstream Real-and-Completion readback through transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactNetSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactNetSelection}^{\uparrow}$ packet is generated from a CompactMetric finite-net source row, Metric distance and hit rows, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactNetSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7233.1, Definition 7233.2, and Definition 7233.3 seed the finite selected-net route for compact metric Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactNetSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host selector extraction, open-cover compactness, choice-selected centers, quotient metric equality, selected Cauchy limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CompactNetSelection}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, center-list visibility, hit-row exactness, finite-window exactness, rational readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactNetSelec

Chapter 7234

A Concrete Naming Certificate for $\mathsf{FiniteSubcoverExtraction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteSubcoverExtraction}^{\uparrow}$ packet records the finite subcover extraction step only after the cover has already been presented as displayed compact-metric, interval, dyadic, stream, regular-rational, and real-seal data. It sits beside the finite Lebesgue-number route of chapter 452, the compact source certificate of chapter 129, the closed interval carrier of chapter 1591, the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names an extraction certificate for a displayed finite cover candidate; it does not assert general open-cover compactness, choose from an arbitrary cover family, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7234.1 (Finite subcover extraction carrier)**.** *A* $\mathsf{FiniteSubcoverExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, read only through finite-net and coverage data already admitted by the compact-metric packet.*
2. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *interval row when the cover is interval-facing; otherwise it records the absence of an interval specialization.*
3. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius ledger tying the displayed cover candidates to a finite lower-bound row.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and radius-comparison ledger used to compare cover radii with requested windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly which cover candidates are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every rational endpoint, center, or radius consumed by the extraction.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, downstream of W, R, D and never a source of cover selection.*
8. *H records componentwise* hsame *transport for the compact, interval, radius, dyadic, stream, readback, and seal rows.*

9. *C records displayed* Cont *replay from a finite cover request through the extracted subcover rows.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteSubcoverExtraction}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSubcoverExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple S. The carrier has no coordinate for an arbitrary open cover, selected infinite family, countable choice, host compactness theorem, quotient real equality, ambient completeness, Lean verification, or bridge checking.

Theorem 7234.2 (Finite subcover extraction NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSubcoverExtraction}^{\uparrow}$ *carrier $S = (K, I, L, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteSubcoverExtraction}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-metric source exposure through K, interval specialization through I when present, finite Lebesgue-number ledger exposure through L, dyadic tolerance comparison through D, finite-window inspection through W, regular rational readback through R, terminal Real-seal discipline through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7234.1. The accepted packet exposes exactly the rows $K, I, L, D, W, R, E, H, C, P, N$.

The extraction rows are finite before any consumer reads the result. The compact-metric row supplies the source coverage data, the interval row supplies the optional closed-bounded specialization, the finite Lebesgue-number row supplies a positive-radius ledger, and the dyadic row compares those radii with the requested windows.

The stream and readback rows then name the inspected cover candidates and rational observations. The terminal Real seal and structural rows preserve the same finite route, so no arbitrary open cover, countable-choice selector, host compactness theorem, quotient real equality, or ambient completeness coordinate is introduced. □

Theorem 7234.3 (Finite subcover extraction finite-cover route)**.** *Every finite-cover consumer of an accepted* $\mathsf{FiniteSubcoverExtraction}^{\uparrow}$ *packet must first read*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, RegSe

through the displayed rows $K, I, L, D, W, R, E, H, C, P, N$. The resulting subcover is therefore an extraction from already displayed finite rows, not a general open-cover compactness principle or a selected family outside the packet.

Proof. Start from the NameCert obligations of Definition 7234.2. They force every accepted read through the compact source, optional interval, finite-radius, dyadic comparison, finite-window, readback, and real-seal rows.

The finite-cover consumer can use only the rows named by the carrier. Thus the extracted list of cover candidates is read from W and checked against K, L, D, R before the seal row E is available.

Transport, replay, provenance, and local naming preserve that route for downstream compact-metric and interval consumers. Since no excluded compactness or choice object is a carrier coordinate, the route cannot be read as arbitrary open-cover compactness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSubcoverExtraction}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSubcoverExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7234.1, Definition 7234.2, and Definition 7234.3 seed the finite subcover extraction certificate over compact-metric, closed-interval, finite-radius, dyadic, stream, regular-rational, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteSubcoverExtraction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, arbitrary cover selection, countable choice, quotient Real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric source exposure, interval specialization, finite-radius ledger exposure, dyadic tolerance comparison, finite-window inspection, regular rational readback, Real-seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSubcoverExtractionUp.

Constructive story: A FiniteSubcoverExtraction$^{\uparrow}$ packet is generated from compact-metric coverage data, an optional closed-bounded interval row, a finite Lebesgue-number radius ledger, dyadic tolerance comparisons, StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7235

A Concrete Naming Certificate for $\mathsf{MazurLemma}^{\uparrow}$

Following Mazur's lemma in the standard Banach-space literature, the $\mathsf{MazurLemma}^{\uparrow}$ packet records the finite convex-combination ledger by which a weakly convergent sequence yields strong norm approximants in the convex hull of a tail. It sits over the vector-space source of chapter 47, the norm carrier of chapter 89, the convex-set rows of chapter 208, the bounded-linear-observer surface of chapter 1644, and the finite separation witness of chapter 3905. The certificate names only finite convex weights, tail windows, observer comparisons, separation-refusal rows, transport, replay, provenance, and local naming; it does not import a host weak topology, a selected subsequence, quotient equality of vectors, or a choice principle over all tails.

Definition 7235.1 (Mazur lemma finite convex-combination carrier)**.** *A* $\mathsf{MazurLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, N, C, T, W, O, S, A, R, H, Q, P, L)$$

with the following displayed rows:

1. *X is the normed vector-space source row, read through* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Norm}^{\uparrow}$*.*
2. *N is the weakly convergent sequence row, exposed only through finite bounded-linear-observer tests.*
3. *C is the convex target row, read through* $\mathsf{ConvexSet}^{\uparrow}$ *as the finite convex hull generated by a displayed tail window.*
4. *T is the tail-window row specifying the finite source terms available for one convex approximant.*
5. *W is the convex-weight ledger, listing rational nonnegative weights and the displayed sum-one certificate for the window T.*
6. *O is the bounded-linear-observer ledger, read through* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *for the finite family of observer tests used by the weak comparison.*
7. *S is the finite-dimensional separation row, routed through* $\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}$ *to refute a displayed norm ball separation from the convex hull window.*
8. *A is the strong norm-approximation row, recording the norm bound obtained after the separation refusal.*
9. *R is the readback row that exposes the convex combination as a normed vector-space element.*

10. *H stores componentwise* hsame *transport for the source, sequence, convex, tail, weight, observer, separation, approximation, readback, replay, provenance, and local naming rows.*
11. *Q stores displayed* Cont *replay from a weak-to-strong request through $X, N, C, T, W, O, S, A, R, H, P, L$.*
12. *P is the* Pkg *provenance over* $\mathsf{MazurLemma}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
13. *L is the local* $\mathsf{NameCert}_{\mathsf{MazurLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for a host weak topology, an infinite convex hull, a selected subsequence, quotient vector equality, countable choice, or ambient Banach-space completeness.

Theorem 7235.2 (Mazur lemma NameCert obligations)**.** *For every accepted* $\mathsf{MazurLemma}^{\uparrow}$ *carrier*

$$M = (X, N, C, T, W, O, S, A, R, H, Q, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MazurLemma}^{\uparrow}}$ *surface consists exactly of normed vector-space admission through X, weak sequence exposure through the bounded-linear-observer ledger N, O, convex-hull admission through C, T, W, finite separation refusal through S, strong norm-approximation readback through A, R, componentwise transport through H, displayed replay through Q, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 7235.1. The normed source X, sequence row N, convex row C, tail row T, and weight ledger W are the only rows from which a convex approximant can be built.

The weak information is finite. The observer ledger O lists exactly the bounded-linear tests read from the sequence row, and the separation row S is the only route that turns the failure of those finite tests to separate the convex hull from a norm ball into an admissible approximation claim.

The strong side is downstream of that refusal. The row A records the norm estimate and R records the convex-combination readback, while H, Q, P, L transport, replay, source, and name the same packet. Since the excluded host objects are not carrier coordinates, the listed rows exhaust the local certificate. □

Theorem 7235.3 (Mazur lemma weak-to-strong convex handoff)**.** *Every strong approximation exported by an accepted* $\mathsf{MazurLemma}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{VecSpace}^{\uparrow}, \mathsf{Norm}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{BoundedLinearOperator}^{\uparrow} \longmapsto \mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow} \longmapsto$$

Thus a consumer may read a norm-close convex combination only after the finite tail window, convex-weight ledger, bounded-linear observer tests, separation-refusal row, readback row, and norm-approximation row have all been displayed.

Proof. Start with a strong-approximation request. The carrier first exposes the normed vector-space row X, the weak sequence row N, the convex set row C, and the finite tail window T.

The convex combination is then determined by W. Because W records only finitely many rational nonnegative weights and their displayed sum-one certificate, the approximant is internal to the finite convex hull named by C and T.

Weak convergence is used only through the observer ledger O. The separation row S turns the finite observer comparison into a refusal of a displayed norm-ball separation, and only after that refusal may the readback row R and approximation row A be inspected.

The structural rows H, Q, P, L keep the handoff inside the same BHist packet. No host weak topology, infinite convex hull, selected subsequence, quotient equality, countable choice, or ambient completeness row is exported. □

Falsifiable prediction: Every accepted $\mathsf{MazurLemma}^{\uparrow}$ strong-approximation read factors through a displayed normed vector-space source, convex tail window, finite rational weight ledger, bounded-linear observer ledger, finite separation-refusal row, convex-combination readback, norm-approximation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: vecspace, norm, convexset, boundedlinearoperator, finite-dimensional-hahn-banach-separation: none is bijective with $\mathsf{MazurLemma}^{\uparrow}$ because this packet binds weak observer data, finite convex-combination ledgers, separation refusal, strong norm readback, transport, replay, provenance, and local naming as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MazurLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{MazurLemma}^{\uparrow}$ packet is generated from a normed vector-space source, weak sequence row, convex tail window, rational weight ledger, bounded-linear observer ledger, finite separation-refusal row, convex-combination readback, norm-approximation row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MazurLemma}^{\uparrow}}$, seed)

Scope closed: Definition 7235.1, Definition 7235.2, and Definition 7235.3 seed the finite convex-combination ledger route from weak observer rows to strong norm approximants.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MazurLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close a host weak topology, an infinite convex hull, selected subsequences, quotient vector equality, countable choice, ambient Banach-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite convex-weight ledger exactness, bounded-linear observer exposure, finite separation-refusal replay, strong norm readback, transport, provenance, and local naming for BEDC.Derived.MazurLemmaUp.

Chapter 7236

A Concrete Naming Certificate for $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$

Following Adams–Fournier and Evans on Sobolev trace theorems, the $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ packet records the finite boundary-read window through which a Sobolev-class object on a compact metric domain exposes trace data to Real-facing consumers. It sits after the compact source of chapter 129, the continuous representative route of chapter 130, the finite observation schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names only a compact-window trace carrier; it does not assert a full Sobolev embedding theorem, a measure-theoretic trace space, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7236.1 (Sobolev trace compact-window carrier)**.** *A* $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, B, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-window domain row, carrying the* $\mathsf{CompactMetric}^{\uparrow}$ *source, the finite boundary neighbourhoods inspected by the trace request, and the compact metric window in which all reads occur.*
2. *B is the boundary trace row, recording the finite side of the trace request, the boundary labels, and the local restriction data consumed by the packet.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the domain and boundary observations opened before trace data is read.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational approximations attached to the interior and boundary observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing the dyadic precision requests and comparisons used by the trace window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the trace values and tolerance comparisons visible after K, B, S, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for the compact window, trace row, stream windows, rational readback, dyadic tolerances, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a trace-window request through the same compact, boundary, stream, rational, dyadic, and Real rows.*
9. *P is the* Pkg *provenance over* $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SobolevTraceCompactWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, S, Q, D, E, H, C, P, N$. It has no coordinate for a measure-theoretic trace space, Sobolev embedding, quotient function equality, open-cover compactness, selected representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SobolevTraceCompactWindowUp.SobolevTraceCompactWindowTasteGate single carrier alignment`

Theorem 7236.2 (Sobolev trace compact-window NameCert obligations)**.** *For every accepted* $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ *carrier $T = (K, B, S, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SobolevTraceCompactWindow}}$ *surface consists exactly of carrier admission for the compact-window domain, boundary trace row, StreamName observations, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise transport, displayed replay, provenance, and local naming rows; compact-window exposure through K; boundary-row exposure through B; finite-window and rational readback through S, Q; dyadic tolerance accounting through D; Real-seal nonescape through E; and preservation of the same route through H, C, P, N.*

Proof. Project the carrier of Definition 7236.1. Its visible rows are exactly $K, B, S, Q, D, E, H, C, P, N$, so every local obligation is read from one of those rows.

The analytic boundary side is finite. The compact metric window K and boundary trace row B are exposed before any rational or Real-facing consumer reads trace values.

The readback side is downstream. Stream windows S, regular rational readback Q, dyadic tolerances D, and the Real seal E supply the only numerical data available to the trace request.

Finally H, C, P, N transport, replay, source, and name the same route. Because the carrier stores no measure-theoretic trace space, Sobolev embedding theorem, quotient function equality, open-cover compactness principle, selected representative, or ambient completeness row, the listed rows exhaust the local NameCert obligations. □

Theorem 7236.3 (Sobolev trace compact-window trace route)**.** *Every boundary trace read accepted by a* $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ *packet must first expose*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $K, B, S, Q, D, E, H, C, P, N$. The trace consumer receives a compact metric domain window, a boundary trace row, finite StreamName observations, regular rational readback, dyadic tolerance comparisons, and a terminal Real seal; it receives no measure-theoretic trace space, global Sobolev embedding, quotient function equality, selected representative, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 7236.2. It requires carrier admission and compact-window exposure before any boundary trace read can inspect the packet.

The boundary side is the pair K, B. These rows bind the trace request to the displayed compact metric source and to the finite boundary labels, so a consumer cannot enter through an untracked host trace operator.

The numerical side is S, Q, D, E. These rows expose finite windows, rational readback, dyadic tolerances, and the terminal Real seal in that order. The remaining rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. □

Theorem 7236.4 (Sobolev trace compact-window compact handoff)**.** *Every compact-metric or Real-facing consumer of an accepted* $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ *packet reads the compact-window route*

$$K, B, S, Q, D, E$$

before consuming a boundary trace value. The handoff remains a finite NameCert route over $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows; it does not open an ambient compactness theorem, a measure-theoretic trace construction, quotient equality of representatives, countable choice, or ambient Real completeness.*

Proof. Use Definition 7236.1. The compact-facing side is the displayed domain window K together with the boundary trace row B.

Apply Definition 7236.3. It orders the finite StreamName observations, RegSeqRat readback, dyadic tolerance row, and Real seal after the compact and boundary rows.

The structural rows H, C, P, N do not add analytic content; they only preserve the already displayed packet. Hence every compact handoff remains inside the named finite route and cannot import the excluded host objects. □

Theorem 7236.5 (Sobolev trace compact-window nonescape)**.** *Every accepted* $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ *public read factors through the displayed rows*

$$K, B, S, Q, D, E, H, C, P, N.$$

Thus the packet exposes only a compact-window trace NameCert over $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. It cannot export a full Sobolev embedding theorem, a measure-theoretic trace space, open-cover compactness, quotient function equality, countable choice, a selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7236.1. The public packet has exactly the ten displayed rows $K, B, S, Q, D, E, H, C, P, N$.

Apply Definition 7236.2 and Definition 7236.4. They force every trace-facing read to pass through the compact, boundary, finite-window, rational-readback, dyadic-tolerance, and Real-seal rows before structural transport and provenance are consumed.

The excluded analytic objects are not carrier coordinates and are not introduced by the structural rows. Therefore every public read remains inside the displayed compact-window trace route. □

Falsifiable prediction: Every accepted $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ consumer displays a CompactMetric domain window, a boundary trace row, StreamName finite observations, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any boundary trace value is consumed.

Independence witness: compactmetric, continuousmap, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective with $\mathsf{SobolevTraceCompactWindow}^{\uparrow}$ because this packet alone binds a compact-window boundary trace row to the finite Real-facing readback route.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevTraceCompactWindow}^{\uparrow}}$.

Constructive story: A SobolevTraceCompactWindow$^{\uparrow}$ packet is generated from a compact metric domain window, a boundary trace row, finite StreamName observations, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SobolevTraceCompactWindow}^{\uparrow}}$, seed)

Scope closed: Definition 7236.1, Definition 7236.2, Definition 7236.3, Definition 7236.4, and Definition 7236.5 seed the finite compact-window trace route over compact, continuous-map, stream, rational-readback, dyadic-tolerance, and Real-seal data.

Formal verification: FormalStatus(NameCert$_{\mathsf{SobolevTraceCompactWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, full Sobolev embedding, measure-theoretic trace theory, open-cover compactness, quotient function equality, countable choice, selected representatives, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-window exposure, boundary trace exactness, finite-window readback, dyadic tolerance accounting, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SobolevTraceCompactWindowUp.

Chapter 7237

A Concrete Naming Certificate for $\mathsf{DarstSelection}^{\uparrow}$

Following Darst and Bishop–Bridges constructive analysis, the $\mathsf{DarstSelection}^{\uparrow}$ packet records regulated bounded-variation compactness selection as finite NameCert data. It sits over the regulated source surface of chapter 1554, the bounded-variation budget of chapter 5933, the compact oscillation handoff of chapter 6818, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a sibling of $\mathsf{HellySelection}^{\uparrow}$ and $\mathsf{HellySelectionCompactVariation}^{\uparrow}$: it uses the same finite selection discipline, but its public route is regulated-function oscillation plus bounded real variation rather than a free host compactness theorem.

Definition 7237.1 (Darst selection carrier)**.** *A* $\mathsf{DarstSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (G, V, O, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the regulated source row, read through* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *and exposing only displayed step-window and endpoint-control data.*
2. *V is the* $\mathsf{BoundedRealVariation}^{\uparrow}$ *budget row, carrying the finite partition variation bound consumed by the selection route.*
3. *O is the* $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$ *handoff row, recording the compact oscillation windows that bind the regulated source to the bounded-variation budget.*
4. *W is the selector-window row. It stores the finite retained windows used by the Darst selection read, not a host-selected subsequence.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained selector windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the selected real-name windows.*
7. *H records componentwise* hsame *transport for G, V, O, W, Q, E.*
8. *C records displayed* Cont *replay from regulated source exposure through bounded-variation budgeting, compact oscillation handoff, selector windows, regular readback, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{DarstSelection}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{BoundedRealVariation}^{\uparrow}$, $\mathsf{RegulatedFunctionCompactOscillation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DarstSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, V, O, W, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, a host-selected subsequence, a completed function-space quotient, detached real equality, or an ambient compactness principle.

Theorem 7237.2 (Darst selection NameCert obligations)**.** *For every accepted* $\mathsf{DarstSelection}^{\uparrow}$ *carrier*

$$D = (G, V, O, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DarstSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, regulated source exposure through G, bounded-variation budget exposure through V, compact oscillation handoff through O, selector-window exposure through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7237.1. The regulated input row G, variation budget row V, compact oscillation row O, selector window row W, regular readback row Q, and Real seal row E are the only analytic rows visible to the classifier.

The structural rows then close the certificate surface. The row H transports the displayed coordinates componentwise, C replays the route in the same order, P records the package provenance, and N names the local packet.

Since no carrier coordinate stores an open cover, a choice-selected subsequence, a host function-space compactness theorem, detached equality of real functions, or an ambient compactness principle, the listed rows exhaust the NameCert obligations. □

Theorem 7237.3 (Darst selection regulated compact handoff)**.** *Every compact selection read from an accepted* $\mathsf{DarstSelection}^{\uparrow}$ *packet factors through the ordered route*

$$\mathsf{RegulatedRealFunction}^{\uparrow} \longmapsto \mathsf{BoundedRealVariation}^{\uparrow} \longmapsto \mathsf{RegulatedFunctionCompactOscillation}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

Concretely, the consumer must first expose the regulated source row G, then the bounded-variation budget V, then the compact oscillation handoff O, then the selector windows W, then the regular rational readback Q, and only then the terminal $\mathsf{Real}^{\uparrow}$ *seal E with H, C, P, N attached.*

Proof. Begin with the source side. The regulated source row G supplies finite step-window and endpoint-control data, while the bounded-variation budget V supplies only the displayed partition budget needed by the selection route.

The compactness handoff is the row O. It binds the regulated source and variation budget to compact oscillation windows before any selector window can be consumed.

The selected output is then read through W, Q, E in order. The selector row W records retained finite windows, Q gives the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and E seals the corresponding $\mathsf{Real}^{\uparrow}$ windows.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Because the carrier has no additional analytic coordinate, every compact selection read stays inside the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{DarstSelection}^{\uparrow}$ consumer must expose the regulated source row, bounded-variation budget, compact oscillation handoff, selector window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal before reading a Darst selection output.

Independence witness: helly-selection, helly-selection-compact-variation, bounded-real-variation, regulated-real-function, regulated-function-compact-oscillation: $\mathsf{DarstSelection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries regulated source data, bounded-variation budgeting,

compact oscillation handoff, selector windows, regular readback, Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DarstSelection}\uparrow}$.

Constructive story: A $\mathsf{DarstSelection}^{\uparrow}$ packet is generated from a RegulatedRealFunction source row, a BoundedRealVariation budget row, a RegulatedFunctionCompactOscillation handoff row, selector windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarstSelection}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7237.1, Definition 7237.2, and Definition 7237.3 seed the finite regulated bounded-variation selection packet over compact oscillation handoff, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarstSelection}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subsequence choice, host function-space compactness, quotient equality of functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated source exposure, bounded-variation budget exposure, compact oscillation handoff, selector-window exactness, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.DarstSelectionUp.

Chapter 7238

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusNormalForm}^{\uparrow}$

Following the Bishop–Bridges finite-net proof of compact uniform continuity, the CompactUniformModulusNormalFo packet records the normal-form route that turns compact coverage, local continuity rows, and a rational lower-bound fold into a tolerance-only uniform-modulus handoff. It realizes the compact-uniform-continuity route of chapter 9237 through the metric source of chapter 57, the compact carrier of chapter 60, the continuous-map rows of chapter 130, the rational fold substrate of chapter 37, and the consumer handoff of chapter 369. The certificate is finite NameCert data; it is not an open-cover compactness theorem, a host Heine–Cantor principle, a selected global minimum outside the fold, quotient equality of functions, or a hidden modulus function.

Definition 7238.1 (Compact uniform modulus normal-form carrier)**.** *A* $\mathsf{CompactUniformModulusNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, K, G, N, L, R, E, U, H, C, P, A)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row for the displayed domain and codomain distances.*
2. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row, exposing a finite* ProbeBundle *coverage window.*
3. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, read only through local pointwise-modulus data at the bundled centers.*
4. *N is the finite-net normal-form row, pairing each bundled center with a local radius and target tolerance row.*
5. *L is the local-radius ledger indexed by the same finite net.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row over the nonzero local-radius ledger.*
7. *E is the metric-triangle error-budget row that moves from an arbitrary point to its displayed center.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced by R and E.*
9. *H stores componentwise* hsame *transport for metric, compact, continuous, finite-net, local-radius, rational-fold, error-budget, uniform-modulus, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from a compact-uniform request through $M, K, G, N, L, R, E, U, H, P, A$.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusNormalForm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, ProbeBundle, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *A is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an open-cover proof, countable choice, a host-selected minimum, quotient function equality, an ambient compactness predicate, or a hidden modulus.

Theorem 7238.2 (Compact uniform modulus normal-form obligations)**.** *For every accepted* CompactUniformModu *carrier*

$$F = (M, K, G, N, L, R, E, U, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformModulusNormalForm}^{\uparrow}}$ *surface consists exactly of metric admission through M, compact finite-net admission through K, continuous-map local-modulus exposure through G, finite-net normal-form alignment through N, L, rational lower-bound exactness through R, metric error-budget transport through E, uniform-modulus export through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through A.*

Proof. Project the carrier of Definition 7238.1. The metric and compact rows M, K supply the finite net, while the continuous-map row G supplies only pointwise local-modulus data at the displayed centers.

The normal-form rows are N, L, R. They align the centers with local radii, keep the radius ledger finite, and fold the displayed positive rational radii to one global lower-bound row. No selected minimum outside the fold is present.

The consumer handoff is then forced through E and U. The error-budget row transports the center estimates to arbitrary points, and the uniform-modulus row records the tolerance-only output. Rows H, C, P, A only transport, replay, source, and name the same packet, so the listed obligations exhaust the certificate. □

Theorem 7238.3 (Compact uniform finite-net normal-form exhaustion)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read exported by an accepted* $\mathsf{CompactUniformModulusNormalForm}^{\uparrow}$ *packet factors through the finite normal-form route*

$$\mathsf{Met}^{\uparrow}, \mathsf{Compact}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The route exposes a finite net, local pointwise moduli at the net centers, a rational lower-bound fold, metric-triangle transport, and a tolerance-only uniform-modulus row before any consumer may read the output.

Proof. Begin with a compact-uniform request. The metric row M fixes the distance comparisons, and the compact row K exposes the finite ProbeBundle coverage window.

Read the continuous-map row G only at the bundled centers. The normal-form rows N and L pair those center reads with local-radius data, so every local modulus request has a visible finite-net index.

Apply the rational fold row R. It is the only row that turns the finite list of local radii into a global lower bound, and it is still a $\mathsf{Rat}^{\uparrow}$ ledger rather than a host minimum.

Finally use the error-budget row E and the uniform-modulus row U. The structural rows H, C, P, A preserve this route, so no open-cover compactness, selected minimum, quotient equality, ambient compactness theorem, or hidden modulus can be exported. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformModulusNormalForm}^{\uparrow}$ uniform-modulus read factors through displayed Metric, Compact, ContinuousMap, Rat lower-bound fold, UniformModulus, ProbeBundle, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: metric, compact, continuousmap, rat, uniformmodulus: none is bijective with $\mathsf{CompactUniformModulusNormalForm}^{\uparrow}$ because this packet binds finite-net coverage, center-local modulus rows, rational lower-bound folding, metric error-budget transport, uniform-modulus export, replay, provenance, and local naming as one normal-form certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusNormalForm}^{\uparrow}$ packet is generated from Metric source rows, Compact finite-net rows, ContinuousMap local-modulus rows, finite-net normal-form ledgers, Rat lower-bound folds, metric error-budget transport, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7238.1, Definition 7238.2, and Definition 7238.3 seed the finite-net lower-bound fold normal form for compact uniform modulus extraction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, host Heine–Cantor semantics, selected minima outside the fold, quotient function equality, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net normal-form alignment, local-modulus exposure, rational lower-bound fold exactness, metric error-budget transport, uniform-modulus export, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusNormalFormUp.

Chapter 7239

A Concrete Naming Certificate for $\mathsf{RationalDenseEmbedding}^{\uparrow}$

Following Bishop and Bridges, the rational dense embedding into the constructive real line is read through rational source data, finite tolerance windows, and regular Cauchy handoff rows rather than through an ambient density theorem. The $\mathsf{RationalDenseEmbedding}^{\uparrow}$ packet sits between the rational carrier of chapter 37, the dyadic tolerance ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the equality discipline of chapter 1820. It supplies the finite connector by which rational approximation data are consumed by $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ without importing host real equality, quotient representatives, selected limits, or ambient completeness.

Definition 7239.1 (Rational dense embedding carrier)**.** *A* $\mathsf{RationalDenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, D, W, S, R, H, T, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source row, recording the rational candidate and the rational order data visible to the embedding read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic budget used to compare the rational source against a requested real window.*
3. *W is the dense-witness window row, recording the finite interval request and the displayed rational candidate admitted inside that window.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row through which the finite window is inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attaching the rational and dyadic observations to a regular rational name surface.*
6. *H is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, D, W, S, R have been displayed.*
7. *T is the componentwise* hsame *transport row for the rational source, dyadic tolerance, witness window, stream observation, regular readback, real seal, and structural rows.*
8. *C is the displayed* Cont *replay route by which a consumer rereads the same dense-embedding packet through the same rows.*
9. *P is the* Pkg *provenance row over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalDenseEmbedding}^{\uparrow}}$ *row.*

The carrier exports no host real equality, no quotient representative, no trichotomy branch, no selected limit, no countable-choice schedule, and no ambient completeness coordinate.

Theorem 7239.2 (Rational dense embedding NameCert obligations)**.** *For an accepted* $\mathsf{RationalDenseEmbedding}^{\uparrow}$ *carrier* $E = (Q, D, W, S, R, H, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RationalDenseEmbedding}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the* $\mathsf{Rat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, dense-witness window,* $\mathsf{StreamName}^{\uparrow}$ *observation row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming data;*
2. *dense-window exactness, stating that each accepted rational candidate is read inside the displayed finite request window and not from a hidden density oracle;*
3. *regular-rational handoff, stating that each accepted read reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *only through the displayed rational, dyadic, witness-window, and stream-observation rows;*
4. *real-seal ordering, stating that the* $\mathsf{Real}^{\uparrow}$ *seal is consumed only after* Q, D, W, S, R *have been displayed;*
5. *nonescape, stating that the packet contains no host real equality, quotient representative, trichotomy branch, selected limit, countable-choice schedule, or ambient completeness row.*

Proof. Carrier admission is the tuple displayed in Definition 7239.1. Its rows name one rational source, one dyadic tolerance, one dense-witness window, one finite stream observation, one regular rational handoff, one Real seal, and the structural rows for transport, replay, provenance, and local naming.

Dense-window exactness is read from W together with Q and D. The rational candidate and dyadic tolerance are displayed before the finite request window is certified, so the packet has no hidden density oracle or host completeness row.

Regular-rational handoff and real-seal ordering are the roles of S, R, H. The stream observation exposes the finite window, the RegSeqRat row records the regular rational readback, and only then may the Real seal be consumed.

The nonescape clause follows from row exhaustion. The provenance may cite $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ as an equality-discipline boundary, but no row stores host real equality, quotient representatives, trichotomy, selected limits, countable choice, or ambient completeness. □

Theorem 7239.3 (Rational dense embedding RegSeqRat handoff)**.** *Every accepted dense-embedding read into* $\mathsf{Real}^{\uparrow}$ *factors through the displayed* $\mathsf{Rat}^{\uparrow}$ *source row* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, dense-witness window* W*,* $\mathsf{StreamName}^{\uparrow}$ *observation row* S*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *before the* $\mathsf{Real}^{\uparrow}$ *seal* H *is consumed. The exported route is finite certificate data for* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers; it exports no host real equality, quotient representative, trichotomy branch, selected limit, countable-choice schedule, or ambient completeness principle.*

Proof. Project the accepted carrier. The first available source data are the rational candidate in Q and the dyadic tolerance budget in D.

Next read the dense witness through W and S. The window row records the finite interval request and accepted rational candidate, while the StreamName observation exposes only the displayed finite window.

Now pass through R before consuming H. This records the regular rational name surface used by $\mathsf{RegSeqRat}^{\uparrow}$ and makes the terminal $\mathsf{Real}^{\uparrow}$ seal a consequence of the displayed certificate route rather than of an external density theorem.

The remaining rows transport, replay, source, and name the same route. Since the carrier has no host equality, quotient, trichotomy, selected-limit, choice, or completeness coordinate, every accepted dense-embedding read remains inside the Rat/DyadicRatCore/StreamName/RegSeqRat/Real corridor. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalDenseEmbedding}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalDenseEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7239.1, Definition 7239.2, and Definition 7239.3 seed the rational dense embedding route through Rat, DyadicRatCore, StreamName, RegSeqRat, Real, CauchyEquivalenceSetoid, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalDenseEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host real equality, quotient real representatives, trichotomy, selected limits, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-window exactness, RegSeqRat handoff, Real seal ordering, and local NameCert registration for BEDC.Derived.RationalDenseEmbeddingUp.

Constructive story: A $\mathsf{RationalDenseEmbedding}^{\uparrow}$ packet is generated from a Rat source row, a DyadicRatCore tolerance row, a dense-witness window, a StreamName observation row, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7240

A Concrete Naming Certificate for $\mathsf{ProofEntropyLedger}^{\uparrow}$

The $\mathsf{ProofEntropyLedger}^{\uparrow}$ packet realizes the theorem-DNA scoring surface of chapter 9460 as finite ledger data. It sits beside the score carrier of chapter 6243, the theorem-genome evolution packet of chapter 6358, the proof trace normal form of chapter 5157, the audit-gate boundary of chapter 526, and the certificate audit gate of chapter 1002. The packet exists so scalar theorem quality reads cannot detach from theorem-flow locus masses, recognizer mass, a public weight profile, and a displayed score-bound ledger.

Definition 7240.1 (Proof entropy ledger carrier)**.** *A* $\mathsf{ProofEntropyLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, R, W, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the theorem-flow source row, exposing the canonical theorem candidate and its site before any scalar read is public.*
2. *M is the theorem-DNA locus-mass row, recording the eight displayed masses for statement, dependencies, proof, certificates, ledger, status, canonical site, and closing seal.*
3. *R is the recognizer-mass row attached to the generated theorem recognizer.*
4. *W is the public weight-profile row, a nine-coordinate profile for the eight theorem-DNA loci together with recognizer mass.*
5. *S is the score-profile row, recording the componentwise products and the displayed scalar total.*
6. *A is the score-bound audit row, exposing the accepted bound, comparison result, and refusal of any scalar read that omits M, R, W, S.*
7. *E is the closing seal row, tying the score-bound ledger to the theorem-DNA closing seal and audit status.*
8. *H records componentwise* hsame *transport for T, M, R, W, S, A, E.*
9. *C records displayed* Cont *replay from theorem-flow exposure through locus masses, recognizer mass, public weights, score profile, score-bound audit, and closing seal.*

10. *P is the* Pkg *provenance over* ProofEntropyLedger$^{\uparrow}$, TheoremDnaScore$^{\uparrow}$, TheoremGenomeEvolution$^{\uparrow}$, ProofTraceNormalForm$^{\uparrow}$, AuditGateBoundary$^{\uparrow}$, CertificateAuditGate$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofEntropyLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, R, W, S, A, E, H, C, P, N$. It has no coordinate for a private weight profile, hidden recognizer mass, score-only theorem quality, unledgered audit acceptance, or an external theorem-value oracle.

Theorem 7240.2 (Proof entropy ledger NameCert obligations)**.** *For every accepted* ProofEntropyLedger$^{\uparrow}$ *carrier*

$$L = (T, M, R, W, S, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ProofEntropyLedger}^{\uparrow}}$ *surface consists exactly of theorem-flow exposure through T, theorem-DNA locus masses through M, recognizer mass through R, public weight profile through W, score profile through S, score-bound audit through A, closing seal through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7240.1. The theorem-flow source T, locus-mass row M, recognizer-mass row R, public weight profile W, score profile S, score-bound audit A, and closing seal E are the only scoring rows.

The support rows then preserve the same route. Componentwise transport is H, displayed replay is C, provenance is P, and local naming is N.

Since the carrier has no private-weight, score-only, hidden-recognizer, or external theorem-value coordinate, every certified scalar read must expose the listed rows. □

Theorem 7240.3 (Proof entropy ledger weight-profile nonescape)**.** *Every scalar score read from an accepted* ProofEntropyLedger$^{\uparrow}$ *packet must factor through the ordered ledger route*

$$T, M, R, W \longmapsto S \longmapsto A \longmapsto E.$$

In particular, the score profile S is public only together with the theorem-DNA locus masses M, recognizer mass R, and public weight profile W, and the score-bound audit A cannot be replayed as a scalar theorem-quality judgment after erasing the weight profile.

Proof. Start with the theorem-flow source row T. It fixes the theorem candidate whose locus masses are being read, so the score cannot float free of a canonical theorem site.

Next expose M, R, W. These rows give the eight theorem-DNA masses, the recognizer mass, and the public nine-coordinate weight profile before the scalar score profile is formed.

The row S is therefore downstream from the mass and weight rows. The audit row A can compare the displayed total with the displayed bound only after that downstream score profile is present, and the seal row E closes the same ledger.

Transport, replay, provenance, and local naming preserve this order through H, C, P, N. A consumer that erases W no longer has the row required to reconstruct or audit the scalar score, so no weight-detached score read escapes the packet. □

Falsifiable prediction: Every accepted ProofEntropyLedger$^{\uparrow}$ read must expose theorem-flow locus masses, recognizer mass, public weight profile, score bound, audit status, closing seal, transport, replay, provenance, and local naming before any scalar quality read is public.

Independence witness: theorem-dna-score, theorem-genome-evolution, proof-trace-normal-form, auditgateboundary, certificateauditgate: $\mathsf{ProofEntropyLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a public weight profile and score-bound ledger as first-class rows.

The Lean follow-up must provide `Nontrivial` and `FieldFaithful` instances in `lean4/BEDC/Derived/ProofEnt` preserving the theorem-flow source, locus-mass profile, recognizer-mass profile, public weight profile, score-profile row, score-bound audit row, and closing seal as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofEntropyLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofEntropyLedger}^{\uparrow}$ packet is generated from theorem-flow source data, theorem-DNA locus masses, recognizer mass, a public weight profile, a score profile, a score-bound audit row, a closing seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofEntropyLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7240.1, Definition 7240.2, and Definition 7240.3 seed the finite theorem-DNA score ledger whose scalar read remains attached to public mass and weight rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofEntropyLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close theorem-DNA scoring optimality, classifier-shift discovery, hidden recognizer soundness, global theorem quality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, theorem-flow exposure, locus-mass exactness, recognizer-mass exactness, public weight-profile exactness, score-bound nonescape, audit status, closing seal, transport, replay, provenance, local naming, and TasteGate instances for BEDC.Derived.ProofEntropyLedgerUp.

Chapter 7241

A Concrete Naming Certificate for $\mathsf{CompactIntervalIntermediateValue}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactIntervalIntermediateValue}^{\uparrow}$ packet records the constructive intermediate-value bisection route over a closed real interval as finite NameCert data. It consumes the compact interval finite-net surface of chapter 3969, the dyadic sign-change route of chapter 2203, the finite sign ledger of chapter 1422, the located real interval bisection route of chapter 5546, the displayed graph surface of chapter 130, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite bisection certificate; it does not assert classical Heine–Borel compactness, selected roots, quotient equality of real names, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7241.1 (Compact interval intermediate-value carrier)**.** *A* $\mathsf{CompactIntervalIntermediateValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, F, B, D, R, E, H, C, P, N)$$

with the following rows:

1. *I is the closed bounded interval source row, read through* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *and located endpoint data;*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, exposing only finite graph windows and a displayed continuity budget;*
3. *B is the sign-bracket and bisection row, consuming* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *and* $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ *branch data;*
4. *D is the dyadic tolerance row, recording the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh and sign-read budget;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained midpoint and interval-window schedule;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed limiting name;*
7. *H records componentwise* hsame *transport of I, F, B, D, R, E;*
8. *C records displayed* Cont *replay of the same bisection route;*
9. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalIntermediateValue}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{DyadicIntermediateValue}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactIntervalIntermediateValue}^{\uparrow}}$ *row.*

The carrier has no coordinate for an open-cover compactness principle, a selected root, quotient real equality, excluded middle over signs of arbitrary reals, or an ambient completeness theorem.

Lean4 (statement) `BEDC.Derived.CompactIntervalIntermediateValueUp`

Theorem 7241.2 (Compact interval intermediate-value NameCert obligations)**.** *For the carrier of Definition 7241.1, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalIntermediateValue}^{\uparrow}}$ *surface consists exactly of carrier admission for $V = (I, F, B, D, R, E, H, C, P, N)$, interval-source admission through I, continuous graph admission through F, bracket stability through B, dyadic descent and tolerance control through D, regular rational readback through R,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the finite packet. The interval row I supplies only the closed bounded interval and its finite compactness-facing data, while the graph row F supplies the displayed continuity budget needed to interpret finite sign reads.

Read the bisection rows next. The sign-bracket row B keeps the lower and upper sign entries attached to the retained subinterval, and the dyadic row D records the mesh, midpoint, and tolerance descent used by the branch ledger. These rows are finite and do not select an unbounded branch outside the displayed schedule.

The readback and seal rows then close the real-facing surface. Row R turns the retained windows into a $\mathsf{RegSeqRat}^{\uparrow}$ schedule, and row E seals only the resulting displayed real name. Finally H, C, P, N transport, replay, source, and name the same packet, so no excluded host principle can be introduced after the finite bisection route has been named. □

Falsifiable prediction: Every accepted compact-interval intermediate-value read must display a closed interval source, continuous graph row, sign-bracket bisection row, dyadic tolerance row, regular rational readback, Real seal, transport, replay, provenance, and local NameCert evidence before any zero-facing real name is exported.

Independence witness: closed-bounded-interval-compact, dyadic-intermediate-value, intermediate-value-bisection, located-real-interval-bisection, continuousmap, regseqrat, real, dyadicratcore: CompactIntervalInter is not bijective to any listed sibling because it jointly carries interval source, graph, bracket, dyadic descent, readback, seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalIntermediateValue}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalIntermediateValue}^{\uparrow}$ packet is generated from a closed interval source, continuous graph row, sign-bracket bisection row, dyadic tolerance row, regular rational readback, Real seal, componentwise transport, displayed continuation replay, provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactIntervalIntermediateValue}^{\uparrow}}$, seed)

Scope closed: Definition 7241.1 and Definition 7241.2 seed the finite compact-interval bisection certificate.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactIntervalIntermediateValue}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.CompactIntervalIntermediateValueUp`

Bridge status: none

Not claimed: This chapter does not close classical Heine–Borel compactness, selected roots, quotient equality of real names, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or theorem-level Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, bracket stability, bisection descent, dyadic readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalIntermediateValueUp.

Chapter 7242

A Concrete Naming Certificate for MetaCICNormalizationSubstitutionBoundary$^{\uparrow}$

The MetaCICNormalizationSubstitutionBoundary$^{\uparrow}$ packet realizes the substitution edge of the MetaCIC normalization audit map as finite NameCert rows. It sits at the conditional boundary of chapter 9383, beside the normalization frontier of chapter 892, the candidate-mediated strong-normalization route of chapter 5163, the substitution audit map of chapter 9380, the confluence diamond ledger of chapter 6547, and the subject-reduction obstruction of chapter 9377. The packet names the visible substitution-boundary row that must be consumed before candidate-mediated normalization can be read as a closed-term route; it does not assert evidence-free normalization, unrestricted subject reduction, global confluence, quotient syntax equality, or host evaluator soundness.

Definition 7242.1 (MetaCIC normalization substitution-boundary carrier)**.** *A* MetaCICNormalizationSubstitutionB *carrier is a finite* BHist *packet*

$$S = (F, C, S_b, D, O, H, R, P, N)$$

with the following rows:

1. *F is the normalization frontier row, retaining the candidate-mediated strong-normalization guard;*
2. *C is the candidate-evidence row, recording the candidate, closed-candidate, or candidate-set interface being consumed;*
3. *S_b is the visible substitution-boundary row, recording the substitution audit data that cannot be erased;*
4. *D is the confluence diamond ledger row, exposing the residual-substitution and local-join data used at the boundary;*
5. *O is the subject-reduction obstruction row, retaining the dependent-codomain and closedness-preservation obstruction data;*
6. *H records componentwise* hsame *transport of F, C, S_b, D, O;*
7. *R records displayed* Cont *replay of the same boundary route;*
8. *P is the* Pkg *provenance over* MetaCICNormalizationSubstitutionBoundary$^{\uparrow}$*, chapter 9383, chapter 9380,* MetaCICNormalizationFrontier$^{\uparrow}$*,* CandidateMediatedSN$^{\uparrow}$*,* MetaCICConfluenceDiamondLedger$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}}$ *row.*
The carrier has no coordinate for unconditional normalization, evidence-free closed-term strong normalization, unrestricted substitution compatibility, completed subject reduction, global confluence, or host quotient equality.

Lean4 (statement) `BEDC.Derived.MetaCICNormalizationSubstitutionBoundaryUp`

Theorem 7242.2 (MetaCIC normalization substitution-boundary NameCert obligations)**.** *For the carrier of Definition 7242.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for* $S = (F, C, S_b, D, O, H, R, P, N)$*, normalization-frontier retention through* F*, candidate-interface admission through* C*, visible substitution-boundary admission through* S_b*, confluence-diamond ledger exposure through* D*, subject-reduction obstruction retention through* O*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* R*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The frontier row F and candidate row C keep the normalization read inside the candidate-mediated interface recorded by the audit map.

Read the boundary rows next. The substitution row S_b is visible before the confluence row D or obstruction row O can be consumed, so residual-substitution and subject-reduction data cannot be hidden behind a global normalization statement.

The structural rows H, R, P, N then transport, replay, source, and name the same finite packet. Since no carrier coordinate supplies evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, or host evaluator soundness, the NameCert surface remains exactly the displayed substitution-boundary route. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}$ read must expose the visible substitution-boundary row S_b before candidate-mediated normalization can consume confluence or subject-reduction obstruction data.

Independence witness: metacicnormalizationfrontier, candidate-mediated-sn, metacic-substitution-audit-map, metacic-confluence-diamond-ledger, metacic-subject-reduction-obstruction: MetaCICNormalizationSubs is not bijective to any listed sibling because it jointly carries frontier, candidate, substitution-boundary, confluence-ledger, subject-reduction-obstruction, transport, replay, provenance, and local naming rows.

The Lean boundary must eventually provide $\mathsf{Nontrivial}\ \mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}$ instances. These instances must keep $F, C, S_b, D, O, H, R, P, N$ as separate displayed fields before a checked theorem may replace the statement marker.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}$ packet is generated from normalization frontier, candidate evidence, visible substitution-boundary, confluence diamond ledger, subject-reduction obstruction, componentwise transport, displayed continuation replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7242.1 and Definition 7242.2 seed the finite substitution-boundary packet for candidate-mediated normalization reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationSubstitutionBoundary}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.MetaCICNormalizationSubstitutionBoundaryUp`

Bridge status: none

Not claimed: This chapter does not close evidence-free normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or theorem-level Lean verification.

Upgrade path: Obligation closure requires checked frontier retention, candidate-interface admission, substitution-boundary visibility, confluence-ledger exposure, subject-reduction obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICNormalizationSubstitutionBoundaryUp.

Chapter 7243

A Concrete Naming Certificate for $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$

Following Bishop and Bridges on constructive compact spaces and located subsets, the $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$ packet records Cantor space as a prefix-located binary stream object whose finite cylinders can be inspected before any compactness consumer reads a cover. It sits beside the finite stream-window interface of chapter 126, the binary prefix carrier of chapter 1475, the Baire prefix route of chapter 334, and the Cantor compactness surface of chapter 6999. The packet names a traditional constructive Cantor-space object; it is not an ambient powerset, a selected infinite branch, a quotient stream equality, an open-cover compactness theorem outside displayed cylinders, or a countable-choice principle.

Definition 7243.1 (Bishop located Cantor space carrier)**.** *A* $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, S, C, L, V, R, H, Q, P, N)$$

with the following displayed rows:

1. *B is the binary-prefix row, naming the finite words in* $\mathsf{Bool}^{<\omega}$ *inspected by the packet.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, recording the finite stream windows whose prefixes are being compared.*
3. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *cylinder row, recording the basic clopen cylinder determined by each displayed prefix.*
4. *L is the located-decision row, exposing finite evidence that a queried prefix cylinder is inside, outside, or still separated from the displayed located subobject.*
5. *V is the prefix-stability row, requiring the located answer to be preserved by every displayed extension of the queried prefix.*
6. *R is the located cylinder-coverage row, listing the finite cylinder cover visible at the current precision request.*
7. *H records componentwise* hsame *transport for binary prefixes, stream windows, cylinder rows, located decisions, prefix stability, coverage, replay, provenance, and local naming.*
8. *Q records displayed* Cont *replay of the route*

$$B, S, C, L, V \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCantorSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, C, L, V, R, H, Q, P, N$. It has no coordinate for host stream equality, selected branches, open-cover compactness, powerset membership, quotient cylinders, or countable choice.

Theorem 7243.2 (Bishop located Cantor space NameCert obligations)**.** *For every accepted* BishopLocatedCantorSp *carrier $K = (B, S, C, L, V, R, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCantorSpace}^{\uparrow}}$ *surface consists exactly of binary-prefix admission, finite stream-window exposure, Cantor cylinder exposure, located-decision display, prefix-stability display, located cylinder coverage, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7243.1. The rows $B, S, C, L, V, R, H, Q, P, N$ are the complete local inventory.

The located decision is prefix-local. The binary row B, stream row S, and cylinder row C fix the finite prefix window before L is read, and V keeps the answer stable under displayed prefix extensions.

The coverage row R is downstream of the same finite route. The structural rows H, Q, P, N transport, replay, source, and name that route, and none supplies selected branches, quotient stream equality, powerset membership, open-cover compactness outside the displayed cylinders, or countable choice. □

Theorem 7243.3 (Bishop located Cantor space prefix stability)**.** *Every located-cylinder read of an accepted* $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$ *packet factors through*

$$B, S, C, L, V.$$

If two displayed stream windows have the same queried prefix, then the located answer is transported only by the prefix-stability row V and the componentwise row H. The read cannot appeal to host stream equality, a selected infinite branch, or quotient equality of cylinders.

Proof. Start from the accepted carrier. The queried prefix is named in B, the finite stream window is named in S, and the corresponding cylinder is named in C before any located answer is available.

The row L supplies the located decision for that displayed cylinder. Prefix stability V then records the permitted transport along displayed extensions of the same prefix.

Finally H preserves the same rows componentwise. Since the carrier has no coordinate for host stream equality, selected branches, or quotient cylinder equality, the located-cylinder read remains prefix-local. □

Theorem 7243.4 (Bishop located Cantor space located cylinder coverage)**.** *Every compactness-facing consumer of an accepted* $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$ *packet receives only the finite located cylinder route*

$$B, S, C, L, V \longmapsto R \longmapsto H, Q, P, N.$$

The consumer may read the displayed CantorSpace and StreamName rows, the located decision, the prefix-stability row, and the finite coverage row. It receives no arbitrary open cover, selected subcover outside the displayed prefixes, host powerset, quotient stream equality, or countable-choice schedule.

Proof. Use Definition 7243.3. It places every located-cylinder read through the displayed binary prefix, stream window, Cantor cylinder, located decision, and stability rows.

The coverage row R is formed only after those rows are visible. Thus a compactness-facing consumer can inspect a finite cylinder list at the current precision request, but cannot replace it by an arbitrary open cover or a selected subcover supplied externally.

The replay, provenance, and local naming rows preserve the same finite packet. Therefore the public read remains a located cylinder coverage route over $\mathsf{CantorSpace}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$, with no hidden branch selector or quotient stream equality. □

Theorem 7243.5 (Bishop located Cantor space ledger refusal)**.** *No accepted* $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$ *packet exports host stream equality, arbitrary powerset membership, selected infinite branches, open-cover compactness detached from displayed cylinders, quotient equality of cylinders, or countable choice. Every exported read is confined to the rows* $B, S, C, L, V, R, H, Q, P, N$.

Proof. Project the carrier. Its rows are the binary prefix, stream window, Cantor cylinder, located decision, prefix-stability, located coverage, transport, replay, provenance, and local naming rows.

Apply the located cylinder coverage theorem. It exhausts compactness-facing reads by the displayed finite cylinder route, so none of the refused host principles has an export coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCantorSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCantorSpace}^{\uparrow}$ packet is generated from binary prefixes, StreamName windows, CantorSpace cylinders, located-decision rows, prefix-stability rows, finite located cylinder coverage, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCantorSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7243.1, Definition 7243.2, Definition 7243.3, Definition 7243.4, and Definition 7243.5 seed the finite located Cantor-space cylinder route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCantorSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host stream equality, arbitrary powerset membership, selected branches, open-cover compactness outside displayed cylinders, quotient stream equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, prefix stability, located cylinder coverage, refusal exactness, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCantorSpaceUp.

Chapter 7244

A Concrete Naming Certificate for $\mathsf{PoincareHorocycleTransport}^{\uparrow}$

The $\mathsf{PoincareHorocycleTransport}^{\uparrow}$ packet realizes the horocycle transport branch of chapter 9463 as finite disk, boundary-shadow, horocycle, transport, Real-seal, provenance, and NameCert rows. It sits after the disk automorphism surface of chapter 6776, the horocycle carrier of chapter 3534, the boundary-shadow route of chapter 3813, the visual-boundary readout of chapter 4181, and the observer-expansion packet of chapter 4167. The packet names finite horocycle transport; it is not a completed hyperbolic plane, quotient ideal boundary, selected geodesic ray, physical observer trajectory, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7244.1 (Poincare horocycle transport carrier)**.** *A* $\mathsf{PoincareHorocycleTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, B, O, Y, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ *disk-transport row.*
2. *B is the boundary-shadow row, read through* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *and the visible boundary packet.*
3. *O is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *row, recording the boundary-tangent horocycle being transported.*
4. *Y is the observer-expansion row that records the finite observer-facing read of the transported horocycle.*
5. *M is the metric or visual-shadow comparison row that binds the disk transport, boundary shadow, and horocycle rows to one finite budget.*
6. *R is the refusal row excluding quotient boundary equality, selected rays, unlogged physical observer trajectories, host isometry semantics, and hidden completeness.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed comparison budget.*
8. *H records componentwise* hsame *transport for disk, boundary-shadow, horocycle, observer-expansion, comparison, refusal, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through*

$$D, B, O, Y, M, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* PoincareHorocycleTransport$^{\uparrow}$, PoincareDiskAutomorphism$^{\uparrow}$, HyperbolicBoundaryShad HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicHorocycle$^{\uparrow}$, HyperbolicObserverExpansion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{PoincareHorocycleTransport}^{\uparrow}}$ *row.*

The classifier accepts only packets whose rows $D, B, O, Y, M, R, E, H, C, P, N$ remain visible on the same finite route.

Theorem 7244.2 (Poincare horocycle transport NameCert obligations)**.** *For every accepted* PoincareHorocycleTran *carrier $T = (D, B, O, Y, M, R, E, H, C, P, N)$, the local* NameCert$_{\text{PoincareHorocycleTransport}^{\uparrow}}$ *surface consists exactly of disk-transport admission, boundary-shadow exposure, horocycle exposure, observer-expansion exposure, comparison-budget exposure, refusal exactness, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7244.1. The rows $D, B, O, Y, M, R, E, H, C, P, N$ are the whole local inventory.

The geometric source rows are D, B, O, Y, M. They bind the Poincare disk transport, boundary shadow, horocycle, observer-facing read, and comparison budget before the Real-facing seal can be inspected.

The refusal row R blocks quotient boundary equality, selected rays, physical observer trajectories, host isometry semantics, and hidden completeness. The structural rows H, C, P, N preserve the same finite route, so the listed obligations exhaust the certificate. □

Theorem 7244.3 (Poincare horocycle transport boundary-shadow handoff)**.** *Every accepted* PoincareHorocycleTran *Real-facing read factors through*

$$D, B, O, Y, M, R \longmapsto E \longmapsto H, C, P, N.$$

The boundary-shadow row B and horocycle row O must be displayed before the comparison budget M and the seal E are read. A consumer missing either row is outside the accepted horocycle transport packet.

Proof. Start from the carrier. The disk row D supplies the Poincare transport, but it does not by itself identify the boundary-shadow or horocycle data.

Read the rows B and O before M. These rows attach the visible boundary shadow and the boundary-tangent horocycle to the same transport budget, while Y records the observer-facing read.

The refusal and Real-seal rows are downstream. Transport, replay, provenance, and local naming preserve the same route, so omitting B or O leaves the carrier rather than producing a weaker accepted packet. □

Theorem 7244.4 (Poincare horocycle transport nonescape)**.** *No accepted* PoincareHorocycleTransport$^{\uparrow}$ *packet exports a completed hyperbolic plane, quotient ideal boundary, selected geodesic ray, physical observer trajectory, host isometry semantics, or ambient* Real$^{\uparrow}$ *completeness. Every exported read is confined to $D, B, O, Y, M, R, E, H, C, P, N$.*

Proof. Project the accepted carrier. Its rows are exactly the disk transport, boundary shadow, horocycle, observer expansion, comparison budget, refusal, Real seal, transport, replay, provenance, and local naming rows.

Apply the boundary-shadow handoff theorem. It forces every Real-facing consumer through the displayed finite route before the seal is read, so the refused host objects have no carrier coordinate and cannot be exported. □

Falsifiable prediction: A claimed $\mathsf{PoincareHorocycleTransport}^{\uparrow}$ packet that reaches the $\mathsf{Real}^{\uparrow}$ seal without displaying both the boundary-shadow row B and the horocycle row O is rejected as a horocycle transport packet.

Independence witness: poincare-disk-automorphism, hyperbolic-horocycle, hyperbolic-boundary-shadow, hyperbolic-visual-boundary, hyperbolic-observer-expansion: none is bijective to PoincareHorocycleTranspor because the transport packet binds disk transport, boundary shadow, horocycle, observer-expansion read, comparison budget, refusal, Real seal, transport, replay, provenance, and local NameCert rows as one finite route.

The Lean TasteGate route must provide explicit $\mathsf{Nontrivial\ PoincareHorocycleTransport}^{\uparrow}$ and $\mathsf{FieldFaithful\ PoincareHorocycleTransport}^{\uparrow}$ instances before the chapter can be treated as a checked discovery-facing surface. The nontrivial witness separates a packet with both B and O from a refused disk-only transport, and field faithfulness compares exactly $D, B, O, Y, M, R, E, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareHorocycleTransport}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareHorocycleTransport}^{\uparrow}$ packet is generated from Poincare disk transport, boundary-shadow rows, horocycle rows, observer-expansion rows, comparison-budget rows, refusal exactness, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareHorocycleTransport}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7244.1, Definition 7244.2, Definition 7244.3, and Definition 7244.4 seed the finite Poincare horocycle transport route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareHorocycleTransport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic planes, quotient ideal boundaries, selected geodesic rays, physical observer trajectories, host isometry semantics, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-transport admission, boundary-shadow exposure, horocycle exposure, observer-expansion exposure, comparison-budget exactness, refusal, RealUp sealing, TasteGate nontriviality, field faithfulness, replay, provenance, and local naming for BEDC.Derived.PoincareHorocycleTransportUp.

Chapter 7245

A Concrete Naming Certificate for $\mathsf{LocallyFiniteCover}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{LocallyFiniteCover}^{\uparrow}$ packet records the finite BEDC ledger by which a displayed open-cover family is read through local finite windows. It sits over the topology carrier of chapter 88, the open-cover request surface of chapter 6731, the finite refinement comparison of chapter 3430, the paracompact refinement carrier of chapter 1963, and the partition-of-unity consumer of chapter 3369. The packet names only displayed cover cells, local neighbourhood windows, finite incidence reads, refinement assignments, transport, replay, provenance, and local naming; it does not choose an arbitrary cover, infer paracompactness, assert compactness of open covers, or export partition-of-unity weights.

Definition 7245.1 (Locally finite cover carrier)**.** *A* $\mathsf{LocallyFiniteCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, A, U, W, I, R, F, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the open-row operations and finite neighbourhood reads on which the cover ledger is interpreted.*
2. *A is the* $\mathsf{OpenCover}^{\uparrow}$ *request row, listing the displayed cover cells and the source region they are meant to cover.*
3. *U is the neighbourhood-window row. For each displayed point or source window it records an open neighbourhood row over T before any local incidence check is read.*
4. *W is the finite-window row, listing the finitely many cover cells from A allowed to meet the neighbourhood row in U.*
5. *I is the incidence ledger, recording the displayed nonempty-meet checks between the neighbourhood windows and the cover cells named by W.*
6. *R is the refinement-assignment row, tying the local finite ledger either to the original cover request A or to a displayed refinement route read through* $\mathsf{Paracompact}^{\uparrow}$*.*
7. *F is the finite-refinement handoff row consumed by* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *when a compact or completion-facing argument needs a finite comparison window.*

8. *H records componentwise* hsame *transport for the topology source, open-cover request, neighbourhood windows, finite windows, incidence ledger, refinement assignments, finite-refinement handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a cover request through $T, A, U, W, I, R, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocallyFiniteCover}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{OpenCover}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, $\mathsf{Paracompact}^{\uparrow}$, $\mathsf{PartitionOfUnity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyFiniteCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host-indexed cover family, a selected infinite refinement, arbitrary subcover choice, open-cover compactness, partition-of-unity weights, quotient open equality, or ambient point-set topology.

Lean4 (statement) `BEDC.Derived.LocallyFiniteCoverUp`

Theorem 7245.2 (Locally finite cover NameCert obligations)**.** *For every accepted* $\mathsf{LocallyFiniteCover}^{\uparrow}$ *carrier*

$$L = (T, A, U, W, I, R, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocallyFiniteCover}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, open-cover request, neighbourhood windows, finite windows, incidence ledger, refinement assignment, finite-refinement handoff, transport, replay, provenance, and local naming;*
2. *open-cover exposure, requiring every local finiteness read to start with the displayed cover request A over the topology row T;*
3. *neighbourhood-window exactness, requiring every finite incidence claim to be read through a displayed open neighbourhood row U;*
4. *finite-window locality, requiring W to list all and only the cover cells inspected by the local incidence ledger I for the corresponding neighbourhood window;*
5. *refinement handoff exactness, requiring R and F to expose only assignments back to A, paracompact refinement rows, or finite refinement comparison rows already displayed in the packet;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve exactly the listed rows.*

No local locally-finite-cover obligation is stored outside these six rows.

Proof. Carrier admission is projection from Definition 7245.1. The accepted tuple displays exactly the topology source, open-cover request, neighbourhood windows, finite windows, incidence ledger, refinement assignment, finite-refinement handoff, transport, replay, provenance, and local naming.

Open-cover exposure is forced by row order. A local finiteness request first reads T and then the displayed cover row A, so the packet never begins from an unlogged host-indexed family.

Neighbourhood-window exactness is the projection to U. The finite incidence row cannot be inspected until the corresponding open neighbourhood has been displayed over the same topology source.

Finite-window locality is the projection to W and I. The row W lists the finite cells allowed to meet the displayed neighbourhood, and I records only the incidence checks for that finite list.

The handoff rows R and F keep the ledger usable by the neighbouring refinement packets. They expose assignments back to A, paracompact refinement rows when present, and finite comparison windows for compact or completion-facing consumers.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores host-indexed covers, selected infinite refinements, arbitrary subcover choice, open-cover compactness, partition-of-unity weights, quotient open equality, or ambient point-set topology, no such obligation can be exported by the local certificate. □

Theorem 7245.3 (Locally finite cover finite-window locality)**.** *Every accepted* $\mathsf{LocallyFiniteCover}^{\uparrow}$ *carrier exports each local incidence read through the finite route*

$$\mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{OpenCover}^{\uparrow} \longrightarrow U \longrightarrow W \longrightarrow I.$$

Thus a point-neighbourhood consumer sees only the displayed neighbourhood row, the finite list of cover cells meeting that neighbourhood, and the recorded incidence checks for those cells. It does not receive an arbitrary host-indexed cover, a selected infinite subfamily, or an open-cover compactness theorem.

Proof. Project the carrier of Definition 7245.1. The rows T and A expose the topology and cover request before any local window is available.

The local window is U, and the finite list attached to it is W. The incidence ledger I is meaningful only after both rows have been displayed.

The structural rows H, C, P, N only transport, replay, source, and name this same route. The excluded host data are absent from the carrier, so every point-neighbourhood consumer receives exactly the finite route above. □

Theorem 7245.4 (Locally finite cover refinement handoff)**.** *Every refinement-facing consumer of an accepted* $\mathsf{LocallyFiniteCover}^{\uparrow}$ *packet must read the assignment rows*

$$A,\ U,\ W,\ I,\ R,\ F$$

before citing the ledger as a paracompact refinement source, a finite cover comparison source, or a partition-of-unity support source. The handoff records displayed local finite windows and assignments only; it does not create paracompactness, finite subcover extraction, or partition-of-unity weights.

Proof. Begin with the local route from Definition 7245.3. It exposes the source cover, neighbourhood windows, finite visible cells, and incidence checks.

The assignment row R ties those local windows back to the cover request or to a paracompact refinement row already present in the packet. The finite-refinement row F exports only the finite comparison surface needed by compact or completion-facing consumers.

A partition-of-unity consumer may therefore cite the locally finite ledger as support data, but only after the finite windows and assignments have been displayed. Since no row stores paracompactness as an external theorem, finite subcover extraction, or weights, the handoff cannot export those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyFiniteCover}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyFiniteCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7245.1, Definition 7245.2, Definition 7245.3, and Definition 7245.4 seed the finite topology, open-cover, neighbourhood-window, incidence, refinement-assignment, finite-handoff, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyFiniteCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host-indexed covers, selected infinite refinements, arbitrary subcover choice, open-cover compactness, partition-of-unity weights, quotient open equality, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-cover exposure, neighbourhood-window exactness, finite-window locality, refinement handoff exactness, transport stability, replay stability, and non-escape proofs for BEDC.Derived.LocallyFiniteCoverUp.

Constructive story: A LocallyFiniteCover$^{\uparrow}$ packet is generated from a Topology$^{\uparrow}$ source row, an OpenCover$^{\uparrow}$ request row, displayed neighbourhood windows, finite visible-cell windows, an incidence ledger, refinement-assignment rows, a FiniteCoverRefinement$^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7246

A Concrete Naming Certificate for $\mathsf{KannanContractionFixedPoint}^{\uparrow}$

Following Kannan's fixed point theorem and Bishop–Bridges constructive metric analysis, the $\mathsf{KannanContractionFixedPoint}^{\uparrow}$ packet records a non-Lipschitz contraction endpoint route as finite NameCert data. It sits next to the complete-metric carrier of chapter 128, the ordinary contraction-map packet of chapter 1418, the Picard orbit ledger of chapter 2359, the fixed-point endpoint discipline of chapter 396, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names the finite Kannan adjacent-distance handoff; it does not select a host fixed point, identify quotient orbit tails, use countable choice, assume trichotomy, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7246.1 (Kannan contraction fixed-point carrier)**.** *A* $\mathsf{KannanContractionFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, F, A, O, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the pointed complete metric source, displaying the carrier, metric comparison rows, chosen starting point, and complete-metric handoff.*
2. *F is the self-map row, recording the displayed endomap whose Picard orbit is inspected.*
3. *A is the Kannan adjacent-distance inequality row, exposing a rational coefficient below one half and the comparison*
$$d(Fx, Fy) \leq a \cdot (d(x, Fx) + d(y, Fy))$$
only through displayed metric rows.
4. *O is the Picard orbit window row, displaying the finite orbit windows generated by repeatedly reading F from the chosen point.*
5. *U is the Cauchy modulus row obtained from the adjacent-distance ledger and the visible Picard windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational tail estimates consumed by the completion-facing route.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the complete-metric source, self-map row, adjacent-distance inequality, orbit windows, Cauchy modulus, and regular-rational readback are visible.*

8. *H records componentwise* hsame *transport for source, map, inequality, orbit, modulus, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$M, F, A, O, U, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* KannanContractionFixedPoint$^{\uparrow}$, CompleteMetric$^{\uparrow}$, ContractionMapping$^{\uparrow}$, PicardIteration$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{KannanContractionFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, F, A, O, U, R, E, H, C, P, N$. It has no coordinate for selected host fixed points, quotient orbit equality, countable choice, trichotomy, or ambient real completeness.

Theorem 7246.2 (Kannan contraction fixed-point obligations)**.** *For every accepted* KannanContractionFixedPoint$^{\uparrow}$ *carrier $K = (M, F, A, O, U, R, E, H, C, P, N)$, the local* NameCert$_{\text{KannanContractionFixedPoint}^{\uparrow}}$ *surface consists exactly of pointed complete-metric source exposure through M; self-map admission through F; Kannan adjacent-distance inequality exposure through A; finite Picard orbit windows through O; Cauchy modulus extraction through U;* RegSeqRat$^{\uparrow}$ *readback through R;* Real$^{\uparrow}$ *seal non-escape through E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

Proof. Project the carrier. The rows M, F, A, O are the complete source surface: a pointed complete metric object, the self-map, the Kannan adjacent-distance inequality, and the finite Picard windows.

The Cauchy handoff is displayed rather than chosen. The row U records the modulus obtained from the adjacent-distance ledger, and R reads it as regular rational tail data before the terminal seal E is available.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no selected host fixed point, quotient orbit equality, countable-choice selector, trichotomy principle, or ambient real completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7246.3 (Kannan Picard-to-Cauchy handoff)**.** *Every accepted* KannanContractionFixedPoint$^{\uparrow}$ *endpoint read factors through the displayed Picard orbit windows, the adjacent-distance Kannan ledger, the Cauchy modulus row, the* RegSeqRat$^{\uparrow}$ *readback row, and the* Real$^{\uparrow}$ *seal before it can be consumed by a fixed-point endpoint discipline. The route is adjacent to chapter 2359 and chapter 396, but its contraction evidence is the Kannan inequality row rather than a Lipschitz ratio row.*

Proof. Start from Definition 7246.2. It orders the complete-metric source, self-map, adjacent-distance inequality, and finite Picard windows before the modulus and regular-rational readback rows.

The endpoint read is therefore completion-facing only after U and R are visible. Transport and replay preserve this order, and provenance names the route as a KannanContractionFixedPoint$^{\uparrow}$ packet rather than as an ordinary ContractionMapping$^{\uparrow}$ packet.

Thus any consumer of the seal must pass through the displayed Picard-to-Cauchy handoff. The refused selected fixed point, quotient orbit equality, countable-choice selector, trichotomy principle, and ambient completeness principle have no export coordinate. □

Falsifiable prediction: An accepted $\mathsf{KannanContractionFixedPoint}^{\uparrow}$ endpoint read is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the pointed complete-metric source, self-map row, Kannan adjacent-distance inequality, Picard windows, Cauchy modulus, $\mathsf{RegSeqRat}^{\uparrow}$ readback, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: complete-metric, contractionmapping, picard-iteration, banach-fixed-point, regseqrat, real: no listed sibling is bijective to $\mathsf{KannanContractionFixedPoint}^{\uparrow}$ because the Kannan packet binds the adjacent-distance inequality, Picard orbit windows, Cauchy modulus handoff, regular-rational readback, Real seal, transport, replay, provenance, and local naming as one fixed-point certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{KannanContractionFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{KannanContractionFixedPoint}^{\uparrow}$ packet is generated from a pointed complete metric source, a self-map row, a Kannan adjacent-distance inequality row, Picard orbit windows, a Cauchy modulus row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KannanContractionFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7246.1, Definition 7246.2, and Definition 7246.3 seed the finite Kannan fixed-point handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KannanContractionFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected host fixed points, quotient orbit equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked complete-metric source exposure, self-map admission, Kannan adjacent-distance inequality, Picard orbit windows, Cauchy modulus extraction, RegSeqRat readback, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.KannanContractionFixedPointUp.

Chapter 7247

A Concrete Naming Certificate for $\mathsf{FiniteOpenCover}^{\uparrow}$

Following Bourbaki and Kelley on finite open covers, the $\mathsf{FiniteOpenCover}^{\uparrow}$ packet records a cover whose indexing family is already finite before any compactness or subcover-selection consumer inspects it. It sits between the general open-cover surface of chapter 6731, the open-set rows of chapter 88, the compact-metric source rows of chapter 129, the finite-subcover criterion of chapter 3503, and the dyadic interval cover carrier of chapter 1428. The packet is not a selected subcover and not an open-cover compactness theorem; it is the finite carrier row through which already finite cover data is named.

Definition 7247.1 (Finite open-cover carrier)**.** *A* $\mathsf{FiniteOpenCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, U, M, R, K, D, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row, listing exactly the cover indices available to the current consumer.*
2. *U is the* $\mathsf{Topology}^{\uparrow}$ *open-set row, assigning an open certificate to each displayed index of I.*
3. *M is the membership and coverage row, tying each covered point read to one displayed index and one open row.*
4. *R is the finite refinement row, comparing finite cover windows by finite index maps and inclusion witnesses.*
5. *K is the compact-source compatibility row, read only when a* $\mathsf{CompactMetric}^{\uparrow}$ *consumer supplies a compact metric source.*
6. *D is the dyadic-interval handoff row, present only when the finite cover is displayed through a* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *endpoint, mesh, or membership ledger.*
7. *H records componentwise* hsame *transport for index, open-set, membership, refinement, compact-source, dyadic-handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite cover request through $I, U, M, R, K, D, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteOpenCover}^{\uparrow}$, $\mathsf{OpenCover}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteSubcoverCriterion}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, U, M, R, K, D, H, C, P, N$. It has no coordinate for an arbitrary open-cover compactness theorem, a selected finite subcover, a host powerset of opens, quotient cover equality, countable choice, or ambient compactness outside the displayed finite rows.

Theorem 7247.2 (Finite open-cover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOpenCover}^{\uparrow}$ *carrier* $F = (I, U, M, R, K, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCover}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index, topology open-set, membership, refinement, compact-source, dyadic-handoff, transport, replay, provenance, and local naming rows; finite-index exactness through I; open-set exactness through U; coverage and refinement exactness through M and R; compact-metric compatibility through K; dyadic-interval handoff through D; and non-escape through H, C, P, N.*

Proof. Project the carrier of Definition 7247.1. The rows I, U, M, R expose the only finite cover window, open predicates, coverage witnesses, and refinement data available to the packet.

The compatibility rows are downstream. A compact-metric consumer reads K only after the finite cover rows are displayed, while a dyadic-interval consumer reads D only as the finite endpoint, mesh, or membership handoff already named by $\mathsf{DyadicIntervalCover}^{\uparrow}$.

Finally H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no coordinate for arbitrary open-cover compactness, selected subcovers, host powersets, quotient cover equality, countable choice, or ambient compactness, the listed rows exhaust the local NameCert obligations. □

Theorem 7247.3 (Finite open-cover dyadic interval handoff)**.** *Every* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *consumer that reads a* $\mathsf{FiniteOpenCover}^{\uparrow}$ *packet must display the finite index row I, the* $\mathsf{Topology}^{\uparrow}$ *open row U, the membership row M, the refinement row R, and the dyadic handoff row D before any interval-cover endpoint, mesh, or membership read is exported. The handoff factors through the finite route*

$$\mathsf{FiniteOpenCover}^{\uparrow} \longrightarrow \mathsf{DyadicIntervalCover}^{\uparrow} \longrightarrow \mathsf{FiniteSubcoverCriterion}^{\uparrow}$$

only as displayed cover data. It exports no selected finite subcover, open-cover compactness theorem, host compactness principle, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite cover rows of Definition 7247.1. The interval consumer first sees I, U, M, R, so the cover window is finite before any dyadic endpoint or mesh information is consulted.

Read the dyadic handoff through D. This row may point to the $\mathsf{DyadicIntervalCover}^{\uparrow}$ endpoint, mesh, or membership ledger, but it does so only after the finite open-cover rows have been displayed and transported by H.

The finite-subcover criterion can then consume the displayed cover data as a finite route. The packet contains no selector row and no compactness theorem row, so the handoff cannot export selected subcovers, host compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOpenCover}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteOpenCover}^{\uparrow}$ packet is generated from finite index rows, Topology open-set rows, membership and refinement rows, compact-source compatibility, dyadic interval handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteOpenCover}^{\uparrow}}$, seed)

Scope closed: Definition 7247.1, Definition 7247.2, and Definition 7247.3 seed the finite open-cover carrier and its dyadic interval handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteOpenCover}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, host compactness, quotient cover equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-index exactness, open-set exactness, coverage and refinement exactness, compact-metric compatibility, dyadic-interval handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteOpenCoverUp.

Chapter 7248

A Concrete Naming Certificate for $\mathsf{DyadicBarycentricSubdivision}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicBarycentricSubdivision}^{\uparrow}$ packet records the finite midpoint subdivision route for a displayed dyadic interval before regular-Cauchy, finite-net, and real-completion consumers may inspect a smaller mesh. It sits over the dyadic arithmetic core of chapter 291, the dyadic subdivision ledger of chapter 366, the dyadic interval tree route of **??**, the dyadic interval net of chapter 5966, the finite-net mesh refinement of chapter 6168, and the terminal real-name boundary of chapter 38. The packet is a finite L10 mesh-refinement certificate; it is not open-cover compactness, a selected infinite refinement path, quotient real equality, a host barycentric subdivision theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7248.1 (Dyadic barycentric subdivision carrier)**.** *A* $\mathsf{DyadicBarycentricSubdivision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, M, L, R, D, T, C, P, N)$$

with the following displayed rows:

1. *I is the parent dyadic interval row, exposing the lower endpoint, upper endpoint, endpoint order, and dyadic denominator budget through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *M is the midpoint row, recording the common-denominator normalization and the displayed barycentric midpoint of the two endpoint rows.*
3. *L and R are the left-child and right-child interval rows, with L using the lower endpoint and midpoint, and R using the midpoint and upper endpoint.*
4. *D is the mesh-decay row, recording that each child mesh bound is at most one half of the parent bound through the same dyadic denominator ledger.*
5. *T is the finite-net transport row, exposing the handoff from the two child intervals to* $\mathsf{DyadicIntervalNet}^{\uparrow}$*,* $\mathsf{DyadicSubdivision}^{\uparrow}$*, and* $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$ *consumers.*
6. *C records displayed* Cont *replay from a parent interval request through the midpoint, child intervals, mesh-decay, finite-net transport, provenance, and local naming rows.*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicBarycentricSubdivision}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicSubdivision}^{\uparrow}$*,* $\mathsf{DyadicIntervalTree}^{\uparrow}$*,* $\mathsf{DyadicIntervalNet}^{\uparrow}$*,* $\mathsf{RealIntervalTotalBoundedness}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicBarycentricSubdivision}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, L, R, D, T, C, P, N$ and their componentwise hsame *transports. The carrier has no coordinate for an infinite subdivision sequence, selected limiting point, arbitrary open cover, quotient real equality, host interval compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7248.2 (Dyadic barycentric subdivision NameCert obligations)**.** *For every accepted* $\mathsf{DyadicBarycentricSubdivision}^{\uparrow}$ *carrier $B = (I, M, L, R, D, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicBarycentricSubdivision}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the parent dyadic interval, midpoint row, two child intervals, mesh-decay row, finite-net transport, replay, provenance, and local naming;*
2. *midpoint closure, requiring M to compute the displayed midpoint by* $\mathsf{DyadicRatCore}^{\uparrow}$ *common-denominator arithmetic from the endpoints of I;*
3. *parent-cover exactness, requiring L and R to share the midpoint boundary and to cover exactly the parent interval row I;*
4. *mesh shrinkage, requiring D to bind the two child mesh bounds to the parent mesh by the displayed halving comparison;*
5. *finite-net handoff, requiring T to expose the two child intervals to the same dyadic subdivision, dyadic interval net, and total-boundedness mesh consumers;*
6. *transport, requiring componentwise* hsame *to preserve $I, M, L, R, D, T, C, P, N$ and no further interval object;*
7. *ledger, requiring C, P, N to replay, source, and name exactly the displayed packet; and*
8. *non-escape, requiring every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer to pass through the finite rows before reading any real-name seal.*

No barycentric-subdivision obligation is stored outside these rows, and the packet refuses open-cover compactness, quotient real equality, selected infinite refinement, host barycentric-subdivision semantics, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness as local data.*

Proof. Project the carrier of Definition 7248.1. The visible analytic rows are the parent interval I, midpoint row M, child intervals L, R, mesh-decay row D, and finite-net transport row T.

Midpoint closure is read from M. The row exposes the common denominator and the dyadic arithmetic ledger inherited from $\mathsf{DyadicRatCore}^{\uparrow}$, so the midpoint is not a host real midpoint or a selected point of a completed interval.

Parent-cover exactness is then a finite endpoint check. The left child reuses the lower endpoint and midpoint, the right child reuses the midpoint and upper endpoint, and the only shared boundary is the displayed midpoint row.

Mesh shrinkage is the row D. It records the halving comparison for the two children against the parent mesh bound, while T hands those children to the existing finite dyadic subdivision and finite-net routes.

Finally replay the structural rows C, P, N and transport componentwise. Since the packet has no additional coordinate for compactness, quotient equality, infinite refinement, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7248.3 (Dyadic barycentric subdivision mesh stability)**.** *Let $B = (I, M, L, R, D, T, C, P, N)$ and $B' = (I', M', L', R', D', T', C', P', N')$ be accepted* $\mathsf{DyadicBarycentricSubdivision}^{\uparrow}$ *carriers related componentwise by* hsame*. If B displays a midpoint choice, parent-cover exactness, and a mesh*

bound through M, L, R, D, then B' displays the transported midpoint choice, transported parent-cover exactness, and transported child mesh bound through M', L', R', D'.

Proof. Read the componentwise hsame transport between the two accepted carriers. The transport relates the parent interval rows, midpoint rows, child interval rows, mesh-decay rows, finite-net transport rows, replay rows, provenance rows, and local naming rows in the same order.

The midpoint choice is preserved first. Since the midpoint is named only by the row M, the transported carrier can read it only through M', with the same common-denominator dyadic arithmetic transported from the endpoint rows.

The coverage rows are preserved next. The left and right children of B share the midpoint boundary and cover the parent row; componentwise transport sends these endpoint incidences to L' and R' over the transported parent I'.

The mesh comparison is preserved by the transported decay row. Row D' is the image of D, so the halving bound attached to the children remains the child mesh bound available to any dyadic subdivision, interval-net, or total-boundedness consumer.

Thus B' exposes exactly the transported midpoint, coverage, and mesh data. It gains no selected limiting point, open-cover compactness, quotient real equality, or ambient completeness row. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBarycentricSubdivision}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBarycentricSubdivision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7248.1, Definition 7248.2, and Definition 7248.3 seed the finite barycentric mesh-refinement route over parent dyadic intervals, midpoint rows, child intervals, mesh-decay rows, finite-net handoff, componentwise transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBarycentricSubdivision}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite refinement paths, quotient real equality, host barycentric-subdivision semantics, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint closure, parent-cover exactness, mesh shrinkage, finite-net handoff, transport, ledger, non-escape, and local naming for BEDC.Derived.DyadicBarycentricSubdivisionUp.

Constructive story: A $\mathsf{DyadicBarycentricSubdivision}^{\uparrow}$ packet is generated from a parent dyadic interval row, a DyadicRatCore midpoint row, two child interval rows, a mesh-decay row, finite-net transport toward DyadicSubdivision, DyadicIntervalNet, and RealIntervalTotalBoundedness consumers, displayed Cont replay, Pkg provenance, componentwise hsame transport, and a local NameCert row.

Chapter 7249

A Concrete Naming Certificate for CantorSpaceBaireCategory$^{\uparrow}$

Following Baire and Bishop–Bridges constructive analysis, the CantorSpaceBaireCategory$^{\uparrow}$ packet records the finite-cylinder face of the Baire-category argument on Cantor space. It sits beside the Cantor-space carrier of chapter 1475, the Baire-category theorem packet of chapter 3570, the choice-free Baire route of chapter 4123, the finite stream-window discipline of chapter 126, and the complete metric surface of chapter 128. The chapter names only the finite cylinder and dense-window handoff; it does not import countable choice, open-cover compactness, quotient equality, or ambient Real completeness.

Definition 7249.1 (CantorSpaceBaireCategory carrier)**.** *A* CantorSpaceBaireCategory$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, T, F, S, M, H, A, P, N)$$

with the following displayed rows:

1. *C is the* CantorSpace$^{\uparrow}$ *cylinder row, exposing finite Boolean prefixes, prefix projection, and cylinder stability;*
2. *T is the* BaireCategoryTheorem$^{\uparrow}$ *dense-open theorem row, exposing only the dense-window rows consumed by the category argument;*
3. *F is the* BaireCategoryChoiceFree$^{\uparrow}$ *refusal row, recording that the route is read without a countable-choice selector or chosen generic point;*
4. *S is the* StreamName$^{\uparrow}$ *finite-window row used to list exactly the Cantor coordinates and dense-open requests inspected by a consumer;*
5. *M is the* CompleteMetric$^{\uparrow}$ *service row for the Cantor metric surface, available only as the displayed complete-metric handoff used by T;*
6. *H records componentwise* hsame *transport for the cylinder, dense-window, choice-free, stream-window, complete-metric, replay, provenance, and local naming rows;*
7. *A records displayed* Cont *replay from cylinder admission through dense-window inspection and terminal NameCert publication;*
8. *P is the* Pkg *provenance over* CantorSpaceBaireCategory$^{\uparrow}$, CantorSpace$^{\uparrow}$, BaireCategoryTheorem$^{\uparrow}$, BaireCategoryChoiceFree$^{\uparrow}$, StreamName$^{\uparrow}$, CompleteMetric$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{CantorSpaceBaireCategory}^{\uparrow}}$ *row.*
The carrier has no coordinate for a selected generic point, a countable-choice schedule, an open-cover compactness theorem, quotient equality of streams, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7249.2 (CantorSpaceBaireCategory NameCert obligations)**.** *For every accepted* CantorSpaceBaireCatego *carrier $K = (C, T, F, S, M, H, A, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorSpaceBaireCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cantor cylinder row, Baire-category dense-open row, choice-free refusal row, finite stream-window row, complete-metric service row, componentwise transport, displayed replay, provenance, and local naming. Every dense-window read must expose the finite cylinder row C, the theorem row T, the refusal row F, and the window row S before it can publish a Baire-category conclusion.*

Proof. Project the carrier of Definition 7249.1. The accepted packet displays exactly the rows $C, T, F, S, M, H, A, P, N$, so the local NameCert surface can read only those coordinates.

The analytic obligations are the first five rows. The Cantor cylinder row supplies finite Boolean prefixes, the Baire-category theorem row supplies dense-window evidence, the choice-free row refuses a generic-point selector, the StreamName row records inspected coordinates, and the complete-metric row supplies the service handoff consumed by the theorem route.

The structural obligations are H, A, P, N. They transport, replay, source, and name the same finite packet. Since no coordinate stores countable choice, open-cover compactness, quotient equality, or ambient Real completeness, those principles cannot discharge a local obligation. □

Theorem 7249.3 (CantorSpaceBaireCategory cylinder route)**.** *Every accepted* $\mathsf{CantorSpaceBaireCategory}^{\uparrow}$ *packet routes a Baire-category dense-window read through the finite path*

$$\mathsf{CantorSpace}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{CompleteMetric}^{\uparrow},\quad \mathsf{BaireCategoryTheorem}^{\uparrow},\quad \mathsf{BaireCategoryChoiceFree}^{\uparrow},\quad \mathsf{Name}$$

The route may shrink Cantor cylinders and inspect dense-open rows along the finite window S, but it cannot export countable choice, open-cover compactness, quotient equality, selected generic points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Cantor cylinder row C. A consumer sees only finite Boolean prefix data, prefix projection, and cylinder stability inherited from the $\mathsf{CantorSpace}^{\uparrow}$ surface.

Next read the StreamName window S and the complete-metric service row M. The window records the coordinates and dense-open requests inspected by the consumer, while M provides only the complete-metric handoff used by the Baire-category theorem row.

Finally apply the theorem row T together with the choice-free row F. The Baire-category conclusion is published through H, A, P, N only after the finite cylinder, stream window, and complete-metric handoff remain visible. The refused principles are absent from the route, so the packet exports a finite-cylinder Baire-category handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{CantorSpaceBaireCategory}^{\uparrow}$ dense-window read factors through one $\mathsf{CantorSpace}^{\uparrow}$ finite cylinder row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{CompleteMetric}^{\uparrow}$ service row, one $\mathsf{BaireCategoryTheorem}^{\uparrow}$ dense-open row, one $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cantorspace, bairecategorytheorem, bairecategorychoicefree, streamname, completemetric: $\mathsf{CantorSpaceBaireCategory}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Cantor finite-cylinder row, the dense-open theorem row, the choice-free refusal row, the finite StreamName window, the complete-metric service handoff, transport, replay, provenance, and local NameCert row as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorSpaceBaireCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorSpaceBaireCategory}^{\uparrow}$ packet is generated from CantorSpace finite cylinders, BaireCategoryTheorem dense-open rows, BaireCategoryChoiceFree refusal evidence, StreamName finite windows, CompleteMetric service rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorSpaceBaireCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7249.1, Definition 7249.2, and Definition 7249.3 seed the finite-cylinder Baire-category route from CantorSpace cylinders to dense-open Baire rows without choice or compactness imports.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorSpaceBaireCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close a public Cantor-space category theorem, Lean verification, a standard bridge, countable choice, open-cover compactness, quotient equality, selected generic points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, dense-window exposure, cylinder-route determinacy, choice-free refusal, transport, replay, provenance, and local naming for BEDC.Derived.CantorSpaceBaireCategoryUp.

Chapter 7250

A Concrete Naming Certificate for BishopHeineBorelInterval$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the BishopHeineBorelInterval$^{\uparrow}$ packet records the finite-net interval compactness read that is available for a located real interval when the endpoints, tolerance rows, and net witnesses are all displayed. It sits on the finite route through DyadicRatCore$^{\uparrow}$ of chapter 291, RegSeqRat$^{\uparrow}$ of chapter 301, Real$^{\uparrow}$ of chapter 38, LocatedCompact$^{\uparrow}$ of chapter 1488, and TotallyBounded$^{\uparrow}$ of chapter 127: dyadic tolerances name the requested mesh, regular rational rows read endpoint and distance windows, the Real seal closes the endpoint names, located compactness supplies the inside-or-apart boundary, and total boundedness supplies the finite net. The packet is not the general open-cover Heine–Borel theorem; it exports no countable choice, quotient real equality, selected finite subcover, or ambient Real$^{\uparrow}$ completeness.

Definition 7250.1 (Located compactness finite-net extraction carrier)**.** *A* BishopHeineBorelInterval$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, D, R, L, T, F, H, C, P, N)$$

with the following displayed rows:

1. *E is the located interval endpoint row, naming the two* Real$^{\uparrow}$ *endpoint seals and the interval orientation check;*
2. *D is the positive* DyadicRatCore$^{\uparrow}$ *tolerance and mesh ledger used to request a finite net;*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row for endpoint windows, mesh comparisons, and distance estimates;*
4. *L is the* LocatedCompact$^{\uparrow}$ *locatedness row, exposing the finite inside-or-apart tests for the interval boundary;*
5. *T is the* TotallyBounded$^{\uparrow}$ *finite-net row, exposing a closed* ProbeBundle *of interval centers,* InBundle *membership evidence, and coverage radii;*
6. *F is the extraction row pairing each displayed tolerance request with the corresponding finite list of centers and the coverage comparison read through D, R, L, T;*
7. *H records componentwise* hsame *transports for endpoints, dyadic tolerances, regular rational readbacks, locatedness, finite nets, extraction, replay, provenance, and naming;*

8. *C records displayed* Cont *replay from a mesh request through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, *and* $\mathsf{TotallyBounded}^{\uparrow}$ *before the extraction row is consumed;*
9. *P is the* Pkg *provenance over* $\mathsf{BishopHeineBorelInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopHeineBorelInterval}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten displayed rows. It has no coordinate for an arbitrary open cover, a choice-selected subcover, quotient real equality, a host compact interval, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7250.2 (Located compactness finite-net extraction obligations)**.** *For every accepted* $\mathsf{BishopHeineBorelInterval}^{\uparrow}$ *carrier* $I = (E, D, R, L, T, F, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{BishopHeineBorelInterval}^{\uparrow}}$ *surface consists exactly of finite endpoint admission, dyadic mesh admission, regular rational readback, located-boundary testing, total-bounded finite-net exposure, extraction exactness, componentwise transport, displayed replay, provenance, and local naming. Thus the interval compactness read available to Real and Completion consumers is the finite-net extraction surface over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, *and* $\mathsf{TotallyBounded}^{\uparrow}$, *not an open-cover compactness principle, countable-choice schedule, quotient real equality, selected finite subcover, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted packet $I = (E, D, R, L, T, F, H, C, P, N)$. The endpoint row E, dyadic ledger D, and regular rational readback R name the interval and the requested mesh before any compactness consumer reads data from the packet.

Use the locatedness row L and finite-net row T. The located boundary is inspected by finite inside-or-apart comparisons, and the total-bounded surface supplies only closed ProbeBundle centers, InBundle membership rows, and coverage radii.

The extraction row F pairs those displayed requests with finite center data. Componentwise transport in H and displayed replay in C preserve the same route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, and $\mathsf{TotallyBounded}^{\uparrow}$.

Finally, P and N record provenance and local naming for exactly that route. Since the carrier contains no open-cover, choice, quotient-equality, selected-subcover, or ambient-completeness coordinate, the listed obligations exhaust the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopHeineBorelInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopHeineBorelInterval}^{\uparrow}$ packet is generated from displayed Real endpoint seals, a DyadicRatCoreUp mesh ledger, RegSeqRatUp readbacks, a LocatedCompactUp located-boundary row, a TotallyBoundedUp finite-net row, an extraction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopHeineBorelInterval}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 7250.1 and Definition 7250.2 close the paper-side finite-net extraction surface for located real intervals over the displayed Real, RegSeqRat, DyadicRatCore, LocatedCompact, and TotallyBounded route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopHeineBorelInterval}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general open-cover Heine–Borel compactness, countable choice, quotient real equality, selected finite subcovers, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite-net extraction obligation theorem.

Chapter 7251

A Concrete Naming Certificate for $\mathsf{FiniteShiftAverage}^{\uparrow}$

Following Banach, Lorentz, and Bishop–Bridges finite averaging practice, the $\mathsf{FiniteShiftAverage}^{\uparrow}$ packet records a finite shift-window average over L10 real-name data as one NameCert carrier. It consumes the stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the Cauchy-name route of chapter 3413. The packet names only the finite averaging route for a displayed window; it does not select a Banach limit, quotient sequence class, ultrafilter, countable-choice subsequence, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness.

Definition 7251.1 (Finite shift average carrier)**.** *A* $\mathsf{FiniteShiftAverage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, A, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the finite stream windows whose shifted entries are inspected.*
2. *W is the finite shift-window row, recording the window length, shift offsets, and local inclusion of every sampled entry.*
3. *A is the average ledger, storing the finite rational sum and denominator schedule before any real seal is consumed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic precision and rounding budget for the average readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the average ledger into a regular rational name.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed averaged name.*
7. *H records componentwise* hsame *transport for S, W, A, D, R, E.*
8. *C records displayed* Cont *replay from stream windows through finite averaging, dyadic tolerance, regular readback, and real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteShiftAverage}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteShiftAverage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for an invariant mean, a Banach-limit value, quotient equality of sequences, an ultrafilter, a choice-selected subsequence, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.FiniteShiftAverageUp.FiniteShiftAverageTasteGate single carrier alignment`

Theorem 7251.2 (Finite shift average NameCert obligations)**.** *For every accepted* $\mathsf{FiniteShiftAverage}^{\uparrow}$ *carrier* $F = (S, W, A, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteShiftAverage}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *source row, finite shift-window admission through* W*, finite average ledger exactness through* A*, dyadic tolerance control through* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal discipline through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7251.1. The stream source S and shift-window row W list the only entries that can be sampled, so every average is finite before any real-facing read is available.

Read the average ledger next. Row A records the rational sum and denominator schedule, while D supplies the dyadic tolerance budget used to compare the finite sum with the requested precision.

The readback and seal rows then expose the L10 real-name route. Row R turns the finite ledger into a regular rational name, and E seals only that displayed name. Transport, replay, provenance, and local naming through H, C, P, N preserve the same rows, so no invariant mean or completion principle can enter after the finite average has been named. □

Theorem 7251.3 (Finite shift average Banach-limit boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteShiftAverage}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{StreamName}^{\uparrow},\ W,\ A,\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the rows $S, W, A, D, R, E, H, C, P, N$ *of Definition 7251.1. The consumer may use the finite shift-window average as L10 real-name data, but it cannot replace that route by a Banach limit, quotient sequence class, ultrafilter, countable-choice subsequence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.FiniteShiftAverageUp.FiniteShiftAverageCarrier banach limit boundary`

Proof. Start with the NameCert obligations of Definition 7251.2. They require the stream window, shift window, finite average ledger, dyadic tolerance row, regular rational readback, and real seal to be displayed before any consumer reads the averaged name.

The finite route is already closed under the sibling readbacks. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{Cauchy}^{\uparrow}$ source rows expose the sampled entries, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the tolerance budget, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal.

Since the carrier has no coordinate for an invariant mean, quotient sequence class, ultrafilter, selected subsequence, or ambient completeness witness, none of those objects can be substituted for the finite ledger. The boundary is therefore a finite shift-window average route rather than a Banach-limit selection principle. □

Falsifiable prediction: Every accepted $\mathsf{FiniteShiftAverage}^{\uparrow}$ consumer must expose StreamName windows, the finite shift-window row, average ledger, DyadicRatCore tolerance row, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert evidence before any averaged real-name read is public.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy: $\mathsf{FiniteShiftAverage}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds source windows, finite shifts, averaging, dyadic tolerance, regular readback, real sealing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteShiftAverage}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteShiftAverage}^{\uparrow}$ packet is generated from StreamName source windows, a finite shift-window row, a finite average ledger, a DyadicRatCore tolerance row, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteShiftAverage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7251.1, Definition 7251.2, and Definition 7251.3 seed the finite shift-average certificate for L10 real-name consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteShiftAverage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Banach-limit existence, quotient sequence equality, ultrafilters, countable-choice subsequences, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exactness, average-ledger exactness, dyadic tolerance control, regular readback, Real-seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.FiniteShiftAverageUp.

Chapter 7252

A Concrete Naming Certificate for $\mathsf{DarbouxOscillationCriterion}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxOscillationCriterion}^{\uparrow}$ packet names the finite oscillation criterion that a Darboux-integral consumer reads before accepting an integrability boundary. It sits next to the Darboux integral route of chapter 1460, the finite sum interfaces $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{LowerDarbouxSum}^{\uparrow}$, and **??** of chapter 1880, chapter 5858, and chapter 4083, the oscillation packet of chapter 7161, and the regular rational and real-name endpoints $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ of chapter 301 and chapter 38. The packet records finite partition oscillation ledgers; it does not choose partitions by host choice, identify functions by quotient equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7252.1 (DarbouxOscillationCriterion carrier)**.** *A* $\mathsf{DarbouxOscillationCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, S, L, U, O, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{DarbouxIntegral}^{\uparrow}$ *consumer row that requests a finite upper-minus-lower gap before reading an integral seal;*
2. *S is the common* $\mathsf{DarbouxSum}^{\uparrow}$ *row over the displayed partition surface;*
3. *L and U are the* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *and* ***??*** *rows, both tied to the same cells and interval source;*
4. *O is the finite oscillation ledger, read through* $\mathsf{DarbouxOscillation}^{\uparrow}$*, that records the displayed cellwise upper-minus-lower bounds;*
5. *M is the finite partition and refinement row, naming the cells on which S, L, U, O are compared;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the tolerance and gap windows;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the Darboux rows and regular rational readback have been displayed;*
8. *H records componentwise* hsame *transports for integral, sum, lower, upper, oscillation, partition, readback, seal, continuation, provenance, and naming rows;*
9. *C records displayed* Cont *replay for the same ordered route;*
10. *P is the* Pkg *provenance over* $\mathsf{DarbouxOscillationCriterion}^{\uparrow}$*,* $\mathsf{DarbouxIntegral}^{\uparrow}$*,* $\mathsf{DarbouxSum}^{\uparrow}$*,* $\mathsf{LowerDarbouxSum}^{\uparrow}$*,* ***??****,* $\mathsf{DarbouxOscillation}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxOscillationCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host suprema, quotient function equality, selected refining partitions, countable choice, or ambient real completeness.

Lean4 (statement) `BEDC.Derived.DarbouxOscillationCriterionUp`

Theorem 7252.2 (DarbouxOscillationCriterion NameCert obligations)**.** *For every accepted* DarbouxOscillationCrit *carrier $K = (I, S, L, U, O, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxOscillationCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Darboux integral, common sum, lower-sum, upper-sum, oscillation, partition, regular readback, Real seal, transport, replay, provenance, and naming rows; lower-and-upper coherence over the same partition row M; oscillation-ledger exactness for O; regular tolerance readback through R; terminal Real-seal nonescape through E; and provenance exactness through P, N.*

Lean4 (definition) `BEDC.Derived.DarbouxOscillationCriterionUp.darbouxOscillationCriterionToEventFlow`

Proof. Project the carrier of Definition 7252.1. The displayed tuple is the whole certificate surface, so every obligation begins with one of $I, S, L, U, O, M, R, E, H, C, P, N$.

The Darboux rows are coherent because S, L, U, O are all read over the same partition and refinement row M. The lower and upper sum rows therefore produce a finite upper-minus-lower comparison before the integral row I may consume the criterion.

The readback and seal obligations are terminal. The row R supplies the regular rational tolerance windows, and E supplies the $\mathsf{Real}^{\uparrow}$ seal only after the Darboux and oscillation rows have been displayed.

Finally, H, C, P, N preserve, replay, source, and name the same route. Since no host supremum, selected refinement, quotient function equality, countable choice, or ambient completeness coordinate appears in the carrier, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{DarbouxOscillationCriterion}^{\uparrow}}$ surface. □

Theorem 7252.3 (DarbouxOscillationCriterion partition route)**.** *Every* $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{LowerDarbouxSum}^{\uparrow}$, *or ?? consumer of an accepted* $\mathsf{DarbouxOscillationCriterion}^{\uparrow}$ *packet must read the finite route*

$$M \longmapsto (S, L, U, O) \longmapsto R \longmapsto E$$

with structural support H, C, P, N before it uses the criterion. Thus the criterion exposes a finite partition oscillation ledger and regular rational gap readback, not a selected mesh sequence, host supremum, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.DarbouxOscillationCriterionUp.DarbouxOscillationCriterionPartitionRoute`

Proof. Start with the displayed partition row M. It is the only row that names the cells and refinements on which the Darboux rows can be compared.

Read the sum and oscillation data next. The rows S, L, U, O expose the common Darboux sum boundary, the lower and upper sides, and the upper-minus-lower oscillation ledger over that same finite partition surface.

Then pass through R and E. The regular rational readback supplies the finite tolerance windows, and the Real seal is reached only after those windows and Darboux rows have been consumed.

The structural rows H, C, P, N transport, replay, source, and name this route without adding any hidden analytic object. Therefore the partition route is a finite BEDC criterion surface rather than a host-level compactness, choice, supremum, or quotient principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxOscillationCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxOscillationCriterion}^{\uparrow}$ packet is generated from DarbouxIntegral, DarbouxSum, LowerDarbouxSum, UpperDarbouxSum, DarbouxOscillation, finite partition, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxOscillationCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7252.1, Definition 7252.2, and Definition 7252.3 seed the finite Darboux oscillation criterion over displayed partition, sum, oscillation, regular rational, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxOscillationCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host Darboux integrability theorem, selected refining partition sequence, quotient equality of functions, countable choice, ambient RealUp completeness, Lean verification of the obligation rows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-upper coherence, oscillation-ledger exactness, partition-route nonescape, regular readback, Real-seal nonescape, replay, provenance, and local naming for BEDC.Derived.DarbouxOscillationCriterionUp.

Chapter 7253

A Concrete Naming Certificate for $\mathsf{FinitePrefixStream}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FinitePrefixStream}^{\uparrow}$ packet records the finite prefix of a countable name inspected at a displayed unary depth. It sits between the countable-name surface of chapter 126 and the regular rational readback of chapter 301, while keeping its dyadic tolerance row anchored in chapter 291, its terminal real-facing seal anchored in chapter 38, and its completion-facing use anchored in chapter 1639. The diagonal-selection corridor of chapter 4080 consumes these prefix windows before selecting a regular Cauchy diagonal readback, so the diagonal handoff is fed by displayed finite observations rather than by a detached tail selector. The packet gives the Real and Completion route a named finite observation-prefix object, not quotient stream equality, selected limits, countable choice, host real equality, or ambient real completeness.

Definition 7253.1 (Finite prefix stream certificate carrier)**.** *A* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (k, W, D, R, H, C, P, N)$$

with the following displayed rows:

1. *k is the unary depth row. It fixes the largest inspected index and contains only the finite successor spine needed to reach that depth.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It displays exactly the stream-name observations at indices $0, \ldots, k$ and no infinite representative.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the finite dyadic radii, slack bounds, and comparison budgets used by the displayed windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It reads the same finite windows and dyadic budgets as regular rational data before any real-facing seal can be consumed.*
5. *H records componentwise* hsame *transport for the unary-depth, stream-window, dyadic, regular-rational, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a finite prefix request through k, W, D, R, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{FinitePrefixStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePrefixStream}^{\uparrow}}$ *row naming exactly this finite prefix certificate.*

The classifier compares accepted packets only through k, W, D, R, H, C, P, N. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.TasteGate.FinitePrefixStreamTasteGate single carrier alignment`

Theorem 7253.2 (Finite prefix stream NameCert obligations)**.** *For every accepted* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier $F = (k, W, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FinitePrefixStream}^{\uparrow}}$ *surface consists exactly of carrier admission for the unary depth, finite StreamName windows, dyadic tolerance rows, RegSeqRat handoff, componentwise transport, displayed replay, provenance, and local naming. The obligation surface may cite the StreamName source of chapter 126, the RegSeqRat source of chapter 301, and the dyadic arithmetic core of chapter 291; it cannot add quotient stream equality, a selected limit, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a bridge certificate.*

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCarrier obligation surface`

Proof. Project the carrier of Definition 7253.1. The visible analytic rows are exactly the unary depth k, finite stream window W, dyadic tolerance ledger D, and regular rational handoff R.

Induct on the finite successor spine displayed by k. At depth 0, the certificate reads only the initial window cell, its dyadic budget, and the matching regular rational observation. In the successor step, append one displayed window row and one matching dyadic budget, then transport the already-read prefix through H and replay it through C.

The rows P and N source and name only that finite packet. Since the excluded principles are not fields of the carrier and are not produced by the induction, no local NameCert obligation can export quotient stream equality, a selected limit, countable choice, host real equality, ambient real completeness, or bridge checking. □

Theorem 7253.3 (Finite prefix stream window readback)**.** *Every RegSeqRat-facing consumer of an accepted* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier reads the displayed prefix by the finite route*

$$k \longmapsto W \longmapsto D \longmapsto R \longmapsto H, C, P, N.$$

The exported read is a prefix-bounded regular-rational handoff, not an equality class of streams, not a chosen infinite tail, not a countable-choice schedule, not host equality of real names, and not ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCarrier window readback`

Proof. Fix a consumer of the accepted carrier. The first row available to the consumer is the unary depth k, so the consumer receives a finite bound before any stream observation is inspected.

The window read is then bounded by W. For each displayed index at or below k, the consumer reads the corresponding dyadic budget from D and the matching regular rational row from R.

The structural rows H, C, P, N preserve this same finite route under transport, replay, provenance, and naming. They do not add an infinite tail, an equality class of streams, a choice schedule, host equality of real names, or completeness data. □

Theorem 7253.4 (Finite prefix stream observation induction)**.** *Let $F = (k, W, D, R, H, C, P, N)$ be an accepted* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier. For every displayed unary index $i \leq k$, the observation at i is obtained by induction on the successor spine of k: the route reads exactly the corresponding*

StreamName$^{\uparrow}$ *window row in* W*, the matching* DyadicRatCore$^{\uparrow}$ *tolerance row in* D*, the* RegSeqRat$^{\uparrow}$ *handoff row in* R*, and the structural* H, C, P, N *rows. The induction exports a finite observation proof only; it does not export quotient stream equality, a selected tail, countable choice, host real equality, ambient* Real$^{\uparrow}$ *completeness, or a bridge certificate.*

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCarrier observation induction`

Proof. Use Definition 7253.1 to project the unary depth row k and the finite rows W, D, R, H, C, P, N.

The base depth reads the initial window entry from W, the matching dyadic tolerance entry from D, and the corresponding regular-rational handoff from R. The structural rows then record the displayed transport, replay, provenance, and local naming for that initial observation.

For the successor step, extend the already-read finite route by one displayed observation. Apply Definition 7253.3 to force the new observation to pass through the same W, D, R rows before it reaches the structural rows H, C, P, N.

Thus every index $i \leq k$ is read by finite induction on the displayed spine. Since no excluded object is a carrier coordinate or a product of the induction, the observation proof remains a finite StreamName-to-RegSeqRat handoff. □

Definition 7253.5 (Finite prefix stream observation cut)**.** *Let* $F = (k, W, D, R, H, C, P, N)$ *be an accepted* FinitePrefixStream$^{\uparrow}$ *carrier and let* $j \leq k$ *be a displayed unary cut. The observation cut is the restricted packet*

$$F_{\leq j} = (j, W_{\leq j}, D_{\leq j}, R_{\leq j}, H, C, P, N)$$

where $W_{\leq j}$ *is the first* j *StreamName window row segment,* $D_{\leq j}$ *is the first* j *DyadicRatCore tolerance row segment, and* $R_{\leq j}$ *is the first* j *RegSeqRat handoff row segment read from the same finite prefix carrier. The cut preserves only the displayed unary prefix, not any omitted tail coordinate.*

Lean4 (definition) `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCertificateObservationCut`

Theorem 7253.6 (Finite prefix stream observation cut stability)**.** *Let* $F = (k, W, D, R, H, C, P, N)$ *be an accepted* FinitePrefixStream$^{\uparrow}$ *carrier and let* $j \leq k$ *be a displayed unary cut. Then the cut packet* $F_{\leq j}$ *of Definition 7253.5 is again an accepted* FinitePrefixStream$^{\uparrow}$ *carrier, and every RegSeqRat or Real-facing consumer of* $F_{\leq j}$ *factors through the same route*

$$j \longmapsto W_{\leq j} \longmapsto D_{\leq j} \longmapsto R_{\leq j} \longmapsto H, C, P, N.$$

The cut exposes only the displayed finite prefix route; it does not export a selected tail, quotient stream equality, countable choice, host real equality, ambient Real$^{\uparrow}$ *completeness, or bridge checking.*

Proof. Project the accepted carrier of Definition 7253.1. The unary cut $j \leq k$ simply shortens the displayed prefix window, dyadic tolerance, and RegSeqRat handoff rows to the visible initial segment.

Now apply Definition 7253.4. The proof already reads each displayed index by induction on the successor spine of k, so the same finite induction reruns on the truncated prefix without exposing any omitted tail coordinate.

Finally replay Definition 7253.3. The RegSeqRat and Real-facing consumers still see the same finite route through $W_{\leq j}, D_{\leq j}, R_{\leq j}$ before the structural rows H, C, P, N can be read. Since the omitted tail is not a carrier coordinate, the cut remains a finite observation prefix and nothing more. □

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCarrier observation cut stability`

Theorem 7253.7 (Finite prefix stream cofinal reindex stability)**.** *Let $F = (k, W, D, R, H, C, P, N)$ be an accepted* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier. Suppose a displayed monotone cofinal reindex route sends a target prefix request m to a source cut $j \leq k$ and exposes that route through the cofinal and stream-reindexing rows of chapter 7209 and chapter 7081. Then every visible prefix observation in the reindexed request still factors through the same* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff after the unary depth k is replaced by the displayed reindexed prefix m. The exported route is finite reindex data followed by finite prefix data; it does not use quotient stream equality, selected tails, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCofinalReindexStability`

Proof. Project the carrier by Definition 7253.1. The source-side prefix observations available to the reindex route are exactly the displayed rows k, W, D, R, H, C, P, N.

Apply Definition 7253.4. Each source observation at or below k is read by finite induction through the matching $\mathsf{StreamName}^{\uparrow}$ window row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff row.

The displayed cofinal route supplies the target prefix m and the source cut $j \leq k$. By Definition 7253.6, the source-side read may be restricted to $F_{\leq j}$ without exposing any omitted tail coordinate.

Finally use the sibling reindexing surfaces of chapter 7209 and chapter 7081. They place the monotone cofinal route and the stream schedule before any regular-rational or real-facing read, so replacing the visible unary depth by m changes only the displayed prefix request. The downstream StreamName window, DyadicRatCore tolerance row, and RegSeqRat handoff remain the same finite rows. □

Theorem 7253.8 (Finite prefix stream regular Cauchy reindex handoff)**.** *Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that reads a reindexed* $\mathsf{FinitePrefixStream}^{\uparrow}$ *prefix must pass first through the displayed cofinal reindex route, then through the finite prefix rows*

$$m \longmapsto W_{\leq j} \longmapsto D_{\leq j} \longmapsto R_{\leq j} \longmapsto H, C, P, N,$$

and only after that route may it consume the terminal $\mathsf{Real}^{\uparrow}$ *seal or Bishop regular Cauchy completion seal. Thus a regular Cauchy or Real handoff from a reindexed prefix is a composed finite route, not quotient stream equality, a selected subsequence limit, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Begin with the cofinal reindex route and apply Definition 7253.7. This forces the reindexed prefix request to expose the finite StreamName window, dyadic tolerance, and RegSeqRat handoff rows before any downstream consumer reads the packet.

Next apply Definition 7253.11. The Real-facing or completion-facing budget can inspect only the prefix rows $W_{\leq j}, D_{\leq j}, R_{\leq j}$ and the structural rows H, C, P, N before it reaches a terminal seal.

Finally use Definition 7253.12. Any completion-facing section is pulled back to that same finite route, so the Bishop regular Cauchy or Real consumer receives a composed reindex-and-prefix handoff rather than a host-level equality or selected limiting object. □

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCarrier regular cauchy reindex handoff`

Theorem 7253.9 (Finite prefix stream certificate prefix concatenation)**.** *Let*

$$F_0 = (k_0, W_0, D_0, R_0, H_0, C_0, P_0, N_0)$$

and

$$F_1 = (k_1, W_1, D_1, R_1, H_1, C_1, P_1, N_1)$$

be accepted $\mathsf{FinitePrefixStream}^{\uparrow}$ *carriers whose unary-depth rows are adjacent. Suppose the shared boundary observation is classified by the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, and suppose both prefixes use the same displayed dyadic tolerance ledger shape and compatible structural rows. Then the two prefixes concatenate to a larger finite prefix certificate whose visible rows are exactly the merged* W, D, R, H, C, P, N *rows. The concatenated certificate exports no infinite tail, selected limit, quotient stream equality, host real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCertificatePrefixConcatenation`

Proof. Project both carriers using Definition 7253.1. The only analytic rows available for concatenation are the unary depths, StreamName windows, dyadic ledgers, and RegSeqRat handoff rows.

Apply observation induction on the left prefix. This reads every displayed observation up to the boundary through W_0, D_0, R_0 and the structural rows H_0, C_0, P_0, N_0.

Use one successor step for the right boundary. The shared boundary hypothesis identifies the boundary observation through the same $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows, so the first row of the right prefix attaches to the already-read left prefix without changing the classifier route.

Merge only the displayed window, dyadic, regular-rational, transport, replay, provenance, and local naming rows. Because both carriers expose the same ledger shape and compatible structural rows, the merged packet is again a finite prefix certificate.

No carrier coordinate in either prefix stores an infinite tail, selected limit, quotient stream equality, host real equality, choice schedule, or ambient completeness. The concatenation therefore preserves the finite StreamName-to-RegSeqRat boundary and exports none of the excluded objects. □

Theorem 7253.10 (Finite prefix stream nonescape)**.** *Every Real or Completion-facing use of an accepted* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier remains downstream of the displayed prefix window and the RegSeqRat handoff. Thus the packet may be used by the real-name and Bishop regular Cauchy completion routes only as finite prefix evidence; it does not export quotient stream equality, selected limits, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCarrier nonescape`

Proof. Start with a Real or Completion-facing use of F. By Definition 7253.1, the only analytic route into such a use is through k, W, D, R.

Apply Definition 7253.3. The consumer obtains only prefix-bounded regular rational readback, and the structural rows keep the same prefix route visible.

Consequently any downstream $\mathsf{Real}^{\uparrow}$ or Bishop regular Cauchy completion argument can cite this packet only as finite observation evidence. The missing objects are absent from the route, so no quotient stream equality, selected limit, countable-choice schedule, host real equality, ambient real completeness, or checked bridge can escape from the certificate. □

Theorem 7253.11 (Finite prefix stream real-completion budget route)**.** *Any completion-facing use of an accepted* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier must expose the unary depth row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and structural* H, C, P, N *rows before reading a* $\mathsf{Real}^{\uparrow}$ *seal or a Bishop regular Cauchy completion seal. The route is the finite budget*

$$k \longmapsto W \longmapsto D \longmapsto R \longmapsto H, C, P, N,$$

not quotient stream equality, selected tails, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier using Definition 7253.1. The only analytic rows available before a completion-facing handoff are the unary depth k, the finite window row W, the dyadic tolerance row D, and the regular rational handoff R.

Apply Definition 7253.3. It forces the consumer to read the prefix route through k, W, D, R before the structural rows can replay, transport, source, and name the packet.

Now use Definition 7253.10. Any $\mathsf{Real}^{\uparrow}$ or Bishop regular Cauchy completion read remains downstream of that prefix route, so the completion budget is exactly the displayed finite window and tolerance budget.

Since no carrier coordinate stores quotient stream equality, a selected tail, countable choice, host real equality, or ambient Real completeness, none of those principles can be read by the completion-facing consumer. □

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCarrier real completion budget route`

Theorem 7253.12 (Finite prefix stream completion-section pullback)**.** *Let* $F = (k, W, D, R, H, C, P, N)$ *be an accepted* $\mathsf{FinitePrefixStream}^{\uparrow}$ *carrier. Any completion-facing section that consumes* F *factors through the same finite route*

$$k \longmapsto W \longmapsto D \longmapsto R \longmapsto H, C, P, N.$$

The four visible analytic faces of this pullback are $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*: the stream window is read from* W*, its dyadic tolerance budget is read from* D*, the regular-rational handoff is read from* R*, and every real-facing seal remains downstream of those finite rows. The pullback exports no quotient stream equality, selected tail, countable-choice schedule, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Project the accepted carrier by Definition 7253.1. The completion-facing section can inspect only the displayed unary depth k, window row W, dyadic row D, regular-rational row R, and structural rows H, C, P, N.

Apply Definition 7253.3 to force every stream observation used by the section through k, W, D, R. Then apply Definition 7253.4 to see that each displayed index is obtained by finite induction on the successor spine of k, with no appeal to an infinite representative or selected tail.

Finally use Definition 7253.11. The real and completion-facing read is therefore pulled back to the same finite budget route before any $\mathsf{Real}^{\uparrow}$ seal is consumed. Since quotient stream equality, countable choice, host real equality, ambient Real completeness, and bridge checking are absent from the carrier coordinates and from the cited finite route, none of them is exported by the section. □

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamCompletionSectionPullback`

Theorem 7253.13 (Finite prefix stream L10 exit observation route)**.** *Every accepted Real-and-Completion observation route served by a* $\mathsf{FinitePrefixStream}^{\uparrow}$ *packet factors through the displayed finite prefix rows*

$$k, W, D, R, H, C, P, N.$$

The four analytic faces of the route are $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*: the StreamName prefix is read from* W*, the dyadic tolerance budget is read from* D*, the regular rational handoff is read from* R*, and the Real-facing seal remains downstream of those finite rows.*

The exit observation route exports no quotient stream equality, selected tail, countable-choice schedule, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Apply finite prefix window readback, Definition 7253.3. Any RegSeqRat-facing consumer first reads the displayed route through k, W, D, R and only then uses the structural rows H, C, P, N.

Use observation induction, Definition 7253.4, to identify each displayed prefix index with the corresponding StreamName row, dyadic tolerance row, and regular rational handoff row. This supplies the finite observation route for the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ faces.

Next apply the real-completion budget route, Definition 7253.11, and the completion-section pullback, Definition 7253.12. Together they force every Real or Completion-facing use to pass through the same finite prefix budget before a $\mathsf{Real}^{\uparrow}$ seal can be consumed.

All cited routes use only the displayed rows k, W, D, R, H, C, P, N. Since none of those rows stores quotient stream equality, a selected tail, countable choice, host real equality, ambient Real completeness, or bridge checking, the L10 exit route exports none of those objects. □

Lean4 ✓ `BEDC.Derived.FinitePrefixStreamUp.FinitePrefixStreamL10ExitObservationRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePrefixStream}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePrefixStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7253.1, Definition 7253.2, Definition 7253.3, and Definition 7253.10 seed the finite observation-prefix certificate between StreamName and RegSeqRat real-name reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePrefixStream}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unary-depth prefix induction, finite StreamName window readback, DyadicRatCore tolerance exactness, RegSeqRat handoff, transport, replay, provenance, and local naming for BEDC.Derived.FinitePrefixStreamUp.

Constructive story: A $\mathsf{FinitePrefixStream}^{\uparrow}$ packet is generated from a unary depth, finite StreamName windows, DyadicRatCore tolerance rows, a RegSeqRat handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7254

A Concrete Naming Certificate for $\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}$ packet records the finite route from an explicit-modulus Cauchy rational name to a sealed $\mathsf{Real}^{\uparrow}$ boundary. It sits over the dyadic tolerance core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the seal route of chapter 386. The packet names an effective completion surface for displayed Cauchy data; it does not quotient Cauchy classes, select host limits, use countable choice, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7254.1 (Effective Cauchy real completion carrier)**.** *An* $\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the explicit modulus row, assigning to each requested dyadic tolerance a finite stream window large enough for the Cauchy comparison.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing only the entries selected by M.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the selected rational entries inside each modulus window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from M, W, D after the Cauchy window comparison has been displayed.*
5. *S is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback row R is visible.*
6. *H records componentwise* hsame *transport for M, W, D, R, S, C, P, N.*
7. *C records displayed* Cont *replay from a Cauchy request through the modulus, window, dyadic, readback, seal, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, W, D, R, S, H, C, P, N$. It has no coordinate for quotient stream equality, a selected representative, host real equality, countable choice, an independent limit object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7254.2 (Effective Cauchy real completion obligation surface)**.** *For every accepted* EffectiveCauchyRealCo *carrier*

$$E = (M, W, D, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier admission for the displayed* BHist *packet E;*
2. *modulus-window exactness, requiring M to choose the same finite windows read by W and checked by D;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *readback discipline, requiring R to be produced only from the displayed M, W, D route;*
4. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *row S to be read only after R is visible;*
5. *ledger exhaustion through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Proof. Project the carrier of Definition 7254.1. The analytic rows are exactly the explicit modulus M, finite stream window W, dyadic tolerance ledger D, regular rational readback R, and terminal seal row S.

The modulus-window row is exact because W exposes only the entries selected by M, while D checks those entries against the requested dyadic tolerance. Thus no Cauchy comparison can be imported from an unlisted stream coordinate.

Next read the $\mathsf{RegSeqRat}^{\uparrow}$ handoff. The row R is downstream of M, W, D, so the regular rational readback discipline is the same finite route used in chapter 301 and cannot be replaced by host sequence equality.

The seal row is then consumed through chapter 386 and chapter 38. Since S appears only after R, the $\mathsf{Real}^{\uparrow}$ endpoint is a routed seal surface rather than a selected limit or a completeness theorem.

Finally H, C, P, N exhaust the ledger. They transport, replay, package, and name the same displayed rows, and the carrier has no coordinate for quotient streams, selected representatives, countable choice, host equality, independent limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7254.3 (Effective Cauchy real completion seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$M, W, D, R, S, H, C, P, N.$$

In particular, the read first displays the explicit modulus, selected $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *seal before the* $\mathsf{Real}^{\uparrow}$ *boundary is public. It exports no quotient completion, selected host limit, countable-choice schedule, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 7254.2. It places the modulus, window, dyadic, readback, and seal rows in the required order for every accepted packet.

Use the sibling routes named in the chapter introduction. $\mathsf{StreamName}^{\uparrow}$ supplies only finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies only displayed tolerance checks, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular rational readback, and $\mathsf{CauchyLimitSeal}^{\uparrow}$ supplies the routed seal consumed by $\mathsf{Real}^{\uparrow}$.

The structural rows H, C, P, N preserve that same route for downstream consumers. Because no row stores quotient classes, selected limits, countable choice, or ambient completeness, the exported completion read is exactly the displayed finite seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}$ packet is generated from an explicit modulus row, finite StreamName windows, DyadicRatCore tolerance ledgers, a RegSeqRat readback row, a CauchyLimitSeal and RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7254.1, Definition 7254.2, and Definition 7254.3 seed the explicit-modulus Cauchy-to-Real completion surface over displayed DyadicRatCore, StreamName, RegSeqRat, CauchyLimitSeal, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyRealCompletion}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected host limits, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-window exactness, RegSeqRat readback discipline, RealUp seal nonescape, ledger exhaustion, provenance, and local naming for BEDC.Derived.EffectiveCauchyRealCompletionUp.

Chapter 7255

A Concrete Naming Certificate for $\mathsf{CompactModulusSelection}^{\uparrow}$

Following Bishop and Bridges on constructive compactness and uniform continuity, the $\mathsf{CompactModulusSelection}^{\uparrow}$ packet records the finite-net route by which a compact metric source and a pointwise continuity ledger yield a displayed modulus-selection row. It sits over the compact-metric source of chapter 129, the uniform-modulus boundary of chapter 369, the finite stream window surface of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite compact-net and modulus-selection data only; it does not assert open-cover compactness, selected subsequence choice, quotient $\mathsf{Real}^{\uparrow}$ equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7255.1 (Compact modulus selection carrier)**.** *A* $\mathsf{CompactModulusSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, N, L, U, S, R, E, H, C, P, A)$$

with the following displayed rows:

1. *K is the compact-metric source row read from chapter 129.*
2. *N is the finite-net row, recording the displayed compact net, tolerance budget, and cover membership checks used by the selector.*
3. *L is the local pointwise continuity ledger, naming the inspected centers and local continuity budgets before any uniform row is exposed.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, available only after K, N, L have been displayed.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to replay center and tolerance requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row for the selected rational tolerance.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for Real-facing consumers.*
8. *H records componentwise* hsame *transport for compact source, finite net, continuity ledger, uniform handoff, stream, regular-rational, Real, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from compact-net requests through local continuity budgets into the uniform handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactModulusSelection}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *A is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, N, L, U, S, R, E, H, C, P, A$. It has no coordinate for an open-cover compactness theorem, selected subsequence functional, quotient Real representative, or ambient completeness principle.

Theorem 7255.2 (Compact modulus selection carrier boundary)**.** *Every accepted* $\mathsf{CompactModulusSelection}^{\uparrow}$ *carrier is read through the finite rows*

$$M = (K, N, L, U, S, R, E, H, C, P, A)$$

over BHist*, componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompactModulusSelecti}}$ *surface. Any consumer of the carrier sees compact-metric data, a finite-net selector, a pointwise continuity ledger, a* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, stream windows, regular-rational readback, Real sealing, and the structural rows, and it sees no open-cover compactness, selected subsequence choice, quotient* $\mathsf{Real}^{\uparrow}$ *equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7255.1. The displayed tuple lists exactly the compact source, finite-net, pointwise continuity, uniform-modulus, stream, regular-rational, Real, and structural rows.

The transport and replay rows preserve those coordinates componentwise. Thus a read of the carrier cannot introduce a host compactness proof, a selected subsequence object, a quotient representative, or an ambient completeness datum not already present in M. □

Theorem 7255.3 (Compact modulus selection finite-net selector)**.** *Let $M = (K, N, L, U, S, R, E, H, C, P, A)$ be an accepted* $\mathsf{CompactModulusSelection}^{\uparrow}$ *packet. The finite-net selector row N must be consumed before the* $\mathsf{UniformModulus}^{\uparrow}$ *row U is public: every modulus request first reads the compact-metric source K, the finite net N, the pointwise continuity ledger L, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. The selector does not choose a subsequence, infer open-cover compactness, identify quotient Real names, or use ambient Real completeness.*

Proof. Read the source side first. The compact-metric row K supplies the displayed compact source, while N supplies the finite net and tolerance ledger on that same source.

Next read the local continuity ledger L. The uniform handoff U is available only after the finite centers and local budgets have been replayed through C and transported through H.

Finally pass to the stream, regular-rational, and Real rows. They record finite request replay and readback only, so the selector remains a finite-net route rather than any of the refused choice, open-cover, quotient, or completeness principles. □

Theorem 7255.4 (Compact modulus selection NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusSelecti}$ *packet $M = (K, N, L, U, S, R, E, H, C, P, A)$, the local* $\mathsf{NameCert}_{\mathsf{CompactModulusSelection}^{\uparrow}}$ *surface consists of the following finite obligation rows:*

1. *carrier admission for compact-metric source, finite-net selector, pointwise continuity ledger, uniform-modulus handoff, stream windows, regular-rational readback, Real seal, transport, replay, provenance, and local naming;*
2. *finite-net coverage, requiring N to be read from the compact source row K before any uniform handoff is exported;*
3. *local-budget compatibility, requiring L to assign pointwise continuity budgets to the centers named by N;*

4. *modulus handoff exactness, requiring U to be computed only from K, N, L and the structural rows H, C, P, A;*
5. *terminal non-escape, requiring S, R, E to replay and seal the selected tolerance without adding selected subsequences, quotient Real equality, open-cover compactness, or ambient Real completeness.*

Thus the certificate packages compact finite-net modulus selection as displayed BEDC NameCert data.

Proof. Project the accepted packet through the carrier boundary. The first obligation records exactly the displayed rows in Definition 7255.1.

For coverage and compatibility, read K, N, L in order. The finite net is anchored in the compact source, and the local continuity budgets are attached to the centers displayed by that net.

For handoff and non-escape, read U, S, R, E, H, C, P, A. The uniform row is downstream of the finite net and local budgets, while stream replay, regular-rational readback, and Real sealing preserve the same route. Since no further coordinate remains, the certificate refuses the open-cover, subsequence, quotient, and completeness endpoints named in the statement. □

Falsifiable prediction: A $\mathsf{CompactModulusSelection}^{\uparrow}$ consumer that exports a $\mathsf{UniformModulus}^{\uparrow}$ handoff without displaying the compact-metric row K, finite-net row N, pointwise continuity ledger L, and structural BHist, hsame, Cont, Pkg, and NameCert rows refutes the carrier of Definition 7255.1.

Independence witness: compactmetric, uniformmodulus, streamname, regseqrat, real: CompactModulusSelectio is not bijective to any listed sibling because it jointly carries compact-metric source data, finite-net selector rows, pointwise continuity budgets, uniform-modulus handoff, stream replay, regular-rational readback, Real sealing, hsame transport, Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusSelection}^{\uparrow}$ packet is generated from compact-metric source data, finite-net selector rows, pointwise continuity budgets, a UniformModulus handoff, stream replay, regular-rational readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7255.1, Definition 7255.2, Definition 7255.3, and Definition 7255.4 seed the finite compact-net modulus-selection carrier and its NameCert route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter explicitly refuses open-cover compactness, selected subsequence choice, quotient $\mathsf{Real}^{\uparrow}$ equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, local-budget compatibility, modulus handoff exactness, terminal non-escape, hsame transport, Cont replay, provenance, and local naming for BEDC.Derived.CompactModulusSelectionUp.

Chapter 7256

A Concrete Naming Certificate for $\mathsf{LocatedDedekindCut}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers and Troelstra–van Dalen on located cuts, the $\mathsf{LocatedDedekindCut}^{\uparrow}$ packet records the traditional two-sided located Dedekind cut as finite NameCert data before any real-seal consumer reads it. It sits between the located supremum surface of chapter 1427, the located real boundary of **??**, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a narrow L10 carrier for Real and Completion consumers: it exposes cut location and readback rows without identifying cuts by quotient equality or asserting completeness of the ambient real surface.

Definition 7256.1 (Located Dedekind cut carrier)**.** *A* $\mathsf{LocatedDedekindCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, U, G, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower-cut row, carrying inhabited lower observations, downward closure witnesses, rounded lower-side requests, and the finite rational or dyadic cells actually inspected.*
2. *U is the upper-cut row, carrying inhabited upper observations, upward closure witnesses, rounded upper-side requests, and the matching finite comparison cells.*
3. *G is the located comparison row. For each displayed interval request $a < b$, it records either a lower-side observation below b or an upper-side observation above a inside the same finite packet.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by Real and Completion consumers that inspect the cut at a requested precision.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed lower, upper, locatedness, and window rows.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for endpoint comparison, gap narrowing, radius accounting, and lower-bound folds used by the readback route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, G, W, R, Q have been displayed.*
8. *H records componentwise* hsame *transport for lower-cut rows, upper-cut rows, located comparisons, windows, readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a cut request through the same ordered tuple $L, U, G, W, R, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedDedekindCut}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDedekindCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, G, W, R, Q, E, H, C, P, N$. It has no coordinate for quotient cuts, selected suprema, trichotomy, host Real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7256.2 (Located Dedekind cut NameCert obligations)**.** *For every accepted* $\mathsf{LocatedDedekindCut}^{\uparrow}$ *carrier $D = (L, U, G, W, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedDedekindCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower-cut row, upper-cut row, located comparison row, StreamName window row, RegSeqRat readback row, DyadicRatCore tolerance ledger, terminal Real seal, componentwise transport, displayed replay, package provenance, and local naming. Every Real, Completion, or* $\mathsf{LocatedSupremum}^{\uparrow}$ *consumer must read those rows before using the packet as located cut evidence.*

Proof. Project the accepted carrier. The lower and upper cut rows are the only cut data present, and the located comparison row G is the only answer to interval requests $a < b$.

The observation and readback rows are downstream of those cut rows. A consumer first opens finite windows through W, then reads regular rational data through R, and then checks dyadic tolerance and lower-bound accounting through Q.

The terminal Real seal E is reached only after this displayed route. The structural rows H, C, P, N transport, replay, source, and name the same finite packet, so they do not add quotient cuts, selected suprema, trichotomy, host equality, choice, or ambient completeness. □

Theorem 7256.3 (Located Dedekind cut Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{LocatedDedekindCut}^{\uparrow}$ *packet factors through*

$$L, U, G \longmapsto W \longmapsto R \longmapsto Q \longmapsto E.$$

The route exposes lower-cut observations, upper-cut observations, located comparison, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, and the terminal Real seal before any consumer may read real-name evidence.

Proof. Read the cut rows L, U, G from Definition 7256.1. They supply the lower side, upper side, and located comparison surface available to a Real-facing request.

Next pass through the finite observation rows. The window row W lists exactly the finite observations opened by the request, while R repacks those observations as regular rational readback and Q records the dyadic tolerance ledger used to compare them.

The seal row E is terminal for this route. Componentwise transport and continuation replay preserve only the displayed rows, so the seal cannot export quotient cut equality, selected suprema, host Real equality, countable choice, trichotomy, or ambient completeness. □

Theorem 7256.4 (Located Dedekind cut supremum handoff)**.** *Every* $\mathsf{LocatedSupremum}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedDedekindCut}^{\uparrow}$ *packet receives only the displayed lower row L, upper row U, located comparison row G, finite windows W, readback row R, tolerance ledger Q, Real seal E, and structural rows H, C, P, N. The handoff may use the packet as finite located-cut evidence, but it does not select a supremum, prove trichotomy, identify host Real equality, invoke countable choice, or assert ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7256.2. They force every consumer, including the located-supremum consumer, to read the lower, upper, locatedness, window, readback, tolerance, seal, and structural rows.

The handoff is therefore finite. The rows L, U, G provide the cut evidence, W, R, Q provide precision-facing readback, and E gives the terminal real-seal boundary.

Since no row contains a selected least upper bound, a quotient cut representative, a trichotomy branch, a choice schedule, or a host completeness proof, the $\mathsf{LocatedSupremum}^{\uparrow}$ consumer receives only the displayed finite located-cut packet. □

Falsifiable prediction: A $\mathsf{LocatedDedekindCut}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal or $\mathsf{LocatedSupremum}^{\uparrow}$ handoff while bypassing the lower-cut row, upper-cut row, located comparison row, finite windows, regular readback, or dyadic tolerance ledger refutes the carrier of Definition 7256.1.

Independence witness: locatedsupremum, locatedreal, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedDedekindCut}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries lower and upper cut rows, located comparison, finite windows, regular rational readback, dyadic tolerance accounting, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDedekindCut}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDedekindCut}^{\uparrow}$ packet is generated from lower-cut rows, upper-cut rows, located comparison rows, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedDedekindCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7256.1, Definition 7256.2, and Definition 7256.3 seed the narrow L10 located-Dedekind-cut carrier between located cut evidence and Real seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedDedekindCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter explicitly refuses quotient cuts, selected suprema, trichotomy, host Real equality, countable choice, ambient Real completeness, Lean verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-cut and upper-cut row exposure, located comparison exactness, StreamName window replay, RegSeqRat readback, DyadicRatCore tolerance accounting, Real-seal ordering, hsame transport, Cont replay, provenance, and local naming for BEDC.Derived.LocatedDedekindCutUp.

Chapter 7257

Shape Theory NameCert Construction

Following Borsuk and Mardesic–Segal, the $\mathsf{ShapeTheory}^{\uparrow}$ packet encodes compact-metric shape through finite pro-homotopy expansion rows. It sits beside the compact metric carrier of chapter 129, the hyperspace packet of chapter 1660, the absolute-neighborhood-retract packet of chapter 6562, and the homotopy carrier of chapter 156. The chapter records the finite expansion, comparison, and nonescape rows that a shape consumer may inspect, not a host pro-category, quotient compactum, selected inverse system, or ambient homotopy classifier.

Definition 7257.1 (Shape theory carrier)**.** *A* $\mathsf{ShapeTheory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, H, A, T, E, M, R, U, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *surface.*
2. *H is the hyperspace row recording finite compact-subset windows used by expansion stages.*
3. *A is the absolute-neighborhood-retract row naming the finite ANR approximants admitted by the packet.*
4. *T is the homotopy row recording finite homotopy comparisons between adjacent approximants.*
5. *E is the expansion-index row, listing the finite prefix of pro-homotopy stages visible to the consumer.*
6. *M is the bonding-map row, recording the displayed maps and homotopy commutation checks inside that prefix.*
7. *R is the refinement row, pairing later expansion prefixes with earlier displayed stages.*
8. *U records componentwise* hsame *transport for compact-metric, hyperspace, ANR, homotopy, expansion, bonding-map, refinement, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a compact-metric read through hyperspace, ANR, and homotopy rows before a shape comparison is exposed.*
10. *P is the* Pkg *provenance over* $\mathsf{ShapeTheory}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ShapeTheory}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an unbounded pro-object, host compactum quotient, arbitrary shape category, selected inverse-system representative, or ambient homotopy equivalence outside the displayed prefix.

Theorem 7257.2 (Shape theory NameCert obligations)**.** *For every accepted* $\mathsf{ShapeTheory}^{\uparrow}$ *carrier* $S = (K, H, A, T, E, M, R, U, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ShapeTheory}^{\uparrow}}$ *surface consists exactly of compact-metric admission, hyperspace-window admission, ANR approximant admission, finite homotopy comparison, expansion-prefix exposure, bonding-map exactness, refinement-row visibility, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming through the displayed rows.*

Proof. Project the carrier of Definition 7257.1. The compact metric row K and hyperspace row H name the compact source and finite compact-subset windows before any shape read is available.

The ANR row A and homotopy row T supply only displayed approximants and finite comparison data. The expansion row E, bonding row M, and refinement row R bind those comparisons into a finite pro-homotopy prefix.

Transport, replay, provenance, and naming through U, C, P, N preserve that same prefix. Since no carrier coordinate stores a host pro-category, quotient compactum, selected inverse system, or ambient homotopy classifier, the listed rows exhaust the local NameCert obligations. □

Theorem 7257.3 (Shape theory pro-homotopy handoff)**.** *Every shape comparison read from an accepted* $\mathsf{ShapeTheory}^{\uparrow}$ *packet factors through the compact-metric source, hyperspace windows, ANR approximant rows, homotopy comparison rows, expansion prefix, bonding-map row, refinement row, transport, replay, provenance, and local naming. The handoff is finite pro-homotopy NameCert data, not an ambient pro-category theorem or an unrestricted shape-equivalence principle.*

Proof. Read the source through K and H, then expose ANR approximants through A. Homotopy comparisons are visible only through T.

The expansion prefix E determines which stages are in scope. The bonding and refinement rows M, R then route every comparison through a displayed finite row before it reaches a consumer.

The structural rows U, C, P, N transport and replay the same data. Thus the exported handoff remains the finite pro-homotopy prefix named by the packet. □

Theorem 7257.4 (Shape theory nonescape)**.** *An accepted* $\mathsf{ShapeTheory}^{\uparrow}$ *carrier exports no host compactum quotient, selected inverse system, arbitrary pro-object equality, open-cover compactness theorem, or ambient homotopy classifier. Any consumer that cites a shape comparison must exhibit the rows* $K, H, A, T, E, M, R, U, C, P, N$ *of the same packet.*

Proof. The only comparison rows in Definition 7257.1 are T, E, M, R together with the compact, hyperspace, and ANR sources K, H, A.

No row stores a host quotient, selected inverse system, arbitrary pro-object equality, open-cover compactness proof, or ambient classifier. Therefore any such read is outside the carrier unless it is first reduced to the displayed rows and replayed through U, C, P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{ShapeTheory}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ShapeTheory}^{\uparrow}$ packet is generated from compact metric, hyperspace, absolute-neighborhood-retract, homotopy, expansion-prefix, bonding-map, refinement, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ShapeTheory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7257.1, Definition 7257.2, Definition 7257.3, and Definition 7257.4 seed the finite pro-homotopy expansion surface for compact-metric shape data.

Formal verification: FormalStatus(NameCert$_{\mathsf{ShapeTheory}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host pro-categories, quotient compacta, selected inverse systems, arbitrary shape equivalence, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove the finite pro-homotopy handoff and nonescape obligations.

Chapter 7258

A Concrete Naming Certificate for MetaCICResidualJoinGrid$^{\uparrow}$

The MetaCICResidualJoinGrid$^{\uparrow}$ packet realizes the confluence audit route of chapter 9378 as a finite residual-join-grid NameCert carrier. It sits beside the parallel-diamond frontier of chapter 4238, the closed parallel-diamond premise ledger of chapter 2325, and the residual handoff of chapter 5126. The packet records residual vertices, candidate joins, premise rows, and obstruction rows before any confluence handoff can be consumed; it does not assert global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Definition 7258.1 (MetaCIC residual join grid carrier)**.** *A* MetaCICResidualJoinGrid$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, L, R, V, J, D, O, H, C, P, N)$$

with the following displayed rows:

1. *F is the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *row retaining the conditional residual-substitution frontier.*
2. *L is the* ClosedParallelDiamondPremiseLedger$^{\uparrow}$ *row recording the closed premise ledger a confluence route must cite.*
3. *R is the* ParallelDiamondResidual$^{\uparrow}$ *row exposing the residual local-join packet.*
4. *V is the finite residual-vertex row, listing the bounded residual endpoints inspected by the grid.*
5. *J is the candidate-join row, pairing residual vertices with displayed local joins.*
6. *D is the diamond-cell row, recording which adjacent residual vertices share a displayed join cell.*
7. *O is the obstruction row retaining missing residual-substitution, subject-reduction, evaluator-equality, quotient-equality, and kernel-consistency endpoints.*
8. *H records componentwise* hsame *transport for frontier, ledger, residual, vertex, join, diamond-cell, obstruction, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a frontier read through premise ledger and residual rows before any join cell is consumed.*
10. *P is the* Pkg *provenance over* MetaCICResidualJoinGrid$^{\uparrow}$*,* MetaCICParallelDiamondFrontier$^{\uparrow}$*,* ClosedParallelDiamon ParallelDiamondResidual$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGrid}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for premise-free confluence, global normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Theorem 7258.2 (MetaCIC residual join grid NameCert obligations)**.** *For every accepted* MetaCICResidualJoinGric *carrier $G = (F, L, R, V, J, D, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGrid}^{\uparrow}}$ *surface consists exactly of frontier retention, premise-ledger exposure, residual-handoff exposure, finite residual-vertex exposure, candidate-join exposure, diamond-cell exactness, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming through the displayed rows.*

Proof. Project the carrier of Definition 7258.1. The rows F, L, R expose the conditional frontier, closed premise ledger, and residual handoff before any grid cell is visible.

The vertex row V, join row J, and diamond-cell row D record only finite residual endpoints and displayed local joins. The obstruction row O remains part of the same packet, so the grid cannot be read as premise-free confluence.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite row surface. Since no coordinate stores the refused global endpoints, the listed rows exhaust the local NameCert obligations. □

Theorem 7258.3 (MetaCIC residual join grid confluence handoff)**.** *Every confluence-audit consumer of an accepted* $\mathsf{MetaCICResidualJoinGrid}^{\uparrow}$ *packet receives a finite residual join grid only after the parallel-diamond frontier, closed premise ledger, residual handoff, residual vertices, candidate joins, diamond cells, obstruction row, transport, replay, provenance, and local naming have been displayed. The handoff can feed the audit route of chapter 9378, but it does not discharge residual-substitution compatibility, subject reduction, global confluence, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Begin with F, L, R. These rows retain the conditional frontier, premise ledger, and residual packet named by the sibling chapters.

The grid rows V, J, D then expose only bounded vertices, local joins, and finite diamond cells. The obstruction row O remains visible at the same handoff.

The structural rows H, C, P, N replay the route without adding any refused endpoint. Thus the consumer receives a finite residual join grid, not a completed confluence theorem. □

Theorem 7258.4 (MetaCIC residual join grid nonescape)**.** *An accepted* $\mathsf{MetaCICResidualJoinGrid}^{\uparrow}$ *carrier exports no premise-free parallel diamond, full Church–Rosser theorem, subject-reduction theorem, evaluator equality, quotient equality of terms, global normalization theorem, or kernel-consistency certificate. Any accepted residual-grid read must remain inside $F, L, R, V, J, D, O, H, C, P, N$.*

Proof. The grid carrier contains frontier, premise-ledger, residual, vertex, join, diamond-cell, and obstruction rows only. Each row is finite and replayed through the same structural route.

No coordinate removes O or supplies a global endpoint. Therefore a consumer that reads one of the refused endpoints has left the displayed $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGrid}^{\uparrow}}$ surface. □

Falsifiable prediction: Every closed $\mathsf{MetaCICResidualJoinGrid}^{\uparrow}$ residual join grid forces a finite confluence handoff row through the displayed frontier, premise ledger, residual, vertex, join, diamond-cell, obstruction, transport, replay, provenance, and local NameCert rows.

Independence witness: metacic-parallel-diamond-frontier, closed-parallel-diamond-premise-ledger, parallel-diamond-residual, metacic-residual-join-determinacy: none is bijective with $\mathsf{MetaCICResidualJoinGrid}^{\uparrow}$ because this packet simultaneously carries the frontier row, closed premise ledger, residual handoff, finite grid vertices, candidate joins, diamond cells, retained obstructions, transport, replay, provenance, and local naming.

The expected Lean TasteGate surface is that lean4/BEDC/Derived/MetaCICResidualJoinGridUp/TasteGate.lean supplies Nontrivial $\mathsf{MetaCICResidualJoinGrid}^{\uparrow}$ and FieldFaithful $\mathsf{MetaCICResidualJoinGrid}^{\uparrow}$ witnesses for the displayed rows $F, L, R, V, J, D, O, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGrid}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualJoinGrid}^{\uparrow}$ packet is generated from parallel-diamond frontier, closed premise ledger, residual handoff, residual-vertex, candidate-join, diamond-cell, obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGrid}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7258.1, Definition 7258.2, Definition 7258.3, and Definition 7258.4 seed the finite residual-join-grid route for the MetaCIC confluence audit map.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGrid}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close premise-free parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient term equality, global normalization, kernel consistency, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove the residual-grid obligation, confluence handoff, nonescape, nontriviality, and field-faithfulness rows.

Chapter 7259

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusSpace}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyModulusSpace}^{\uparrow}$ packet records the regular-Cauchy schedule surface used when a Cauchy modulus family is read back as rational windows and then sealed as a real-facing name. It refines the schedule route of chapter 5887 through the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The chapter names the finite handoff from abstract schedule rows to regular rational readback; it does not select a limit, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7259.1 (Regular-Cauchy modulus space carrier)**.** *A* $\mathsf{RegularCauchyModulusSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, S, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *schedule-family row that names the precision requests available to the packet.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger inspected by those schedules.*
3. *W is the regular-window alignment row, pairing each requested schedule entry with the stream window used for readback.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the aligned windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the dyadic bound compared against the regular readback.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after S, W, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for $M, S, W, Q, D, E, C, P, N$.*
8. *C records displayed* Cont *replay from a schedule request through the stream window, regular readback, dyadic tolerance, and terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusSpace}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for an unscheduled Cauchy oracle, quotient stream equality, a selected limit, countable choice, or an ambient completeness theorem.

Theorem 7259.2 (Regular-Cauchy modulus space NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusSpace}^{\uparrow}$ *carrier*

$$R = (M, S, W, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusSpace}^{\uparrow}}$ *surface consists exactly of CauchyModulusSpace schedule admission, finite StreamName window admission, regular-window alignment, RegSeqRat readback, DyadicRatCore tolerance compatibility, terminal Real seal compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. Thus the regular Cauchy schedule may be consumed by Real and Completion routes only as finite readback data over* $\mathsf{CauchyModulusSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 7259.1. The analytic rows are M, S, W, Q, D, E, and the structural rows are H, C, P, N.

The schedule row M names only the displayed requests already available from $\mathsf{CauchyModulusSpace}^{\uparrow}$. The stream row S and alignment row W attach each request to a finite window before any rational readback is inspected.

The readback and tolerance rows are then forced through Q and D. The real seal row E is available only after those regular and dyadic ledgers have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded host object is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7259.3 (Regular-Cauchy RegSeqRat handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyModulusSpace}^{\uparrow}$ *carrier receives the regular Cauchy schedule only through the finite handoff*

$$M, S, W, Q, D, E, H, C, P, N.$$

In particular, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row is consumed before the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance comparison and before the terminal* $\mathsf{Real}^{\uparrow}$ *seal, so the handoff exports no quotient stream equality, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a Real or Completion read of the accepted packet. The carrier definition exposes the CauchyModulusSpace schedule row M before the finite stream window row S and the regular-window alignment row W.

The regular rational readback Q is the only row from which the consumer may read the scheduled windows. The dyadic ledger D compares those readings with displayed tolerances, and the terminal seal E is consumed only after that comparison has been named.

Componentwise transport H and displayed replay C preserve the same order of rows, while P and N record provenance and local naming. Hence the consumer receives a finite regular readback handoff, not any quotient, choice, selected limit, or ambient completeness object. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusSpace}^{\uparrow}$ packet is generated from a CauchyModulusSpace schedule row, finite StreamName windows, regular-window alignment, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyModulusSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7259.1, Definition 7259.2, and Definition 7259.3 seed the regular-Cauchy schedule handoff from CauchyModulusSpace rows to RegSeqRat readback and Real-seal consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyModulusSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the schedule-admission and RegSeqRat-handoff obligations.

Chapter 7260

A Concrete Naming Certificate for $\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}$ packet records the last finite estimate in the compact-uniform-continuity route: source compact-net coverage, source metric triangle control, pointwise modulus rows at the selected center, and the target metric triangle are displayed as one ledger before the $\mathsf{UniformModulus}^{\uparrow}$ handoff is consumed. It is anchored in the compact finite net route of chapter 60, the source and target metric surfaces of chapter 4230, the rational tolerance rows of chapter 37, and the downstream uniform-modulus row of chapter 369. The packet does not claim host compactness, a selected center outside the finite bundle, semantic continuity, quotient point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7260.1 (Compact-uniform source-target triangle ledger carrier)**.** *A* CompactUniformSourceTargetTriang *carrier is a finite* BHist *packet*

$$T = (K, X, Y, C, R, A, S, U, H, G, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row, exposing the selected* ProbeBundle *center and the coverage witness for the source point.*
2. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the distance witness from the source point to the selected center and the source triangle witness for the second source point.*
3. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, including the triangle witness that combines the two pointwise target estimates.*
4. *C is the pointwise-modulus row at the selected compact-net center.*
5. *R is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance ledger, carrying the $\varepsilon/3$ target budgets and the source precision budget.*
6. *A is the center-alignment row, tying the compact-net center used by K to the center consumed by C, X, and Y.*
7. *S is the final source-triangle row, showing that the second source point lies inside the same pointwise-modulus window.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff row.*

9. *H records componentwise* hsame *transport for $K, X, Y, C, R, A, S, U, G, P, N$.*
10. *G records displayed* Cont *replay from compact-net coverage through source triangle control, pointwise modulus, target triangle control, and the uniform-modulus handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for host compactness, an external center selector, semantic continuity, quotient point equality, or ambient completeness.

Theorem 7260.2 (Compact-uniform triangle ledger NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}$ *carrier*

$$T = (K, X, Y, C, R, A, S, U, H, G, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}}$ *surface consists exactly of compact finite-net admission, source metric admission, target metric admission, pointwise-modulus admission, positive RatUp tolerance admission, center alignment, final source-triangle admissibility, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.*

Proof. Project the accepted carrier of Definition 7260.1. The estimate rows are K, X, Y, C, R, A, S, U, and the structural rows are H, G, P, N.

The compact finite-net row K supplies the selected center only as displayed bundle data. The alignment row A keeps that center identical to the one used by the source metric row X and the pointwise-modulus row C.

The source triangle row S is then forced through X and the RatUp ledger R. The target triangle row in Y can be consumed only after the two pointwise target estimates from C have been displayed.

Finally the handoff row U receives the same finite estimate by the displayed transport, replay, provenance, and naming rows. Since no excluded host object is a carrier coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 7260.3 (Compact-uniform final source-target estimate)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}$ *carrier receives the final compact-uniform estimate only through the finite route*

$$K, X, Y, C, R, A, S, U, H, G, P, N.$$

When K selects a center c, X displays source distances from x and x' to c, C displays the two pointwise target estimates at c, and Y displays the target triangle row, the handoff U certifies the tolerance-only uniform-modulus ledger without adding a host compactness theorem, a separate center selector, quotient point equality, semantic continuity, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the compact-net row K and the alignment row A. They give one displayed center for the whole route, so the source triangle and target triangle cannot choose different compact-net witnesses.

Use the source metric row X and the source-triangle row S. The source point x is covered by the compact net, and the displayed source distance from x to x' keeps x' inside the same pointwise-modulus window named by R.

Apply the pointwise-modulus row C at the selected center. It supplies the two target estimates from the center to the two source points, using only the positive RatUp tolerance ledger.

The target metric row Y composes those two target estimates by its triangle row. The continuation row G and provenance row P then deliver exactly this finite estimate to the $\mathsf{UniformModulus}^{\uparrow}$ handoff U, while H and N record classifier-stable transport and local naming. No absent host object can be read from the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}$ packet is generated from compact finite-net coverage, source MetricSpace triangle rows, target MetricSpace triangle rows, pointwise-modulus rows, positive RatUp tolerance ledgers, center alignment, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7260.1, Definition 7260.2, and Definition 7260.3 seed the finite source-and-target triangle ledger used by compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformSourceTargetTriangleLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host compactness, semantic continuity, quotient point equality, selected centers outside the finite bundle, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the twelve-row carrier and prove the NameCert obligation and final-estimate theorems.

Chapter 7261

A Concrete Naming Certificate for $\mathsf{TightProbabilityMeasure}^{\uparrow}$

Following Prokhorov and Billingsley, the $\mathsf{TightProbabilityMeasure}^{\uparrow}$ packet records the finite tightness surface of a probability measure before weak-convergence or compactness consumers inspect it. It starts from the probability source of chapter 184, the event-surface row of chapter 92, and the pushforward law row of chapter 186; it then hands the same finite outside-mass and compact-test route to the Prokhorov-facing surface of chapter 4008. The packet names tight probability-measure data through displayed certificates, not through measure completion, selected compact sets, countable choice, host weak compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7261.1 (Tight probability measure carrier)**.** *A* $\mathsf{TightProbabilityMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (P, M, D, K, E, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row carrying the total-mass and event-family surface.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *event-surface row through which the inspected outside event and its mass are read.*
3. *D is the* $\mathsf{Distribution}^{\uparrow}$ *pushforward row used when the same probability mass is consumed as a law on a target measurable surface.*
4. *K is the compact-test row naming the finite compactness request whose outside event is being measured.*
5. *E is the real-valued outside-mass error row, read through the displayed* $\mathsf{Real}^{\uparrow}$ *comparison surface.*
6. *R is the finite tolerance ledger aligning the compact-test request, the outside event in M, the pushforward row in D, and the error row E.*
7. *H records componentwise* hsame *transport for the probability source, measure event, distribution law, compact test, outside-mass row, tolerance ledger, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from probability-source admission to event-surface inspection, distribution readback, compact-test exposure, outside-mass comparison, and tolerance-ledger readback.*
9. *Q is the* Pkg *provenance over* $\mathsf{TightProbabilityMeasure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{ProkhorovTightProbability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{TightProbabilityMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, M, D, K, E, R, H, C, Q, N$. It has no coordinate for measure completion, selected compact subsets, countable choice, host weak compactness, quotient events, or ambient real completeness.

Theorem 7261.2 (Tight probability measure NameCert obligations)**.** *For every accepted* $\mathsf{TightProbabilityMeasure}^{\uparrow}$ *carrier*

$$T = (P, M, D, K, E, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{TightProbabilityMeasure}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the probability source, measure event surface, distribution law, compact-test request, outside-mass error row, tolerance ledger, transport, replay, provenance, and local naming;*
2. *probability-measure compatibility, requiring the* $\mathsf{ProbSpace}^{\uparrow}$ *row P and* $\mathsf{Measure}^{\uparrow}$ *row M to name the same mass surface before a tightness read is accepted;*
3. *distribution compatibility, requiring the* $\mathsf{Distribution}^{\uparrow}$ *row D to consume the same measured event through its pushforward law route rather than through a host law equality;*
4. *compact outside-mass exposure, requiring K, E, R to display the compact-test request, real outside-mass bound, and tolerance ledger before any Prokhorov-facing consumer inspects the packet;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through H, C, Q, N;*
6. *nonescape, excluding measure completion, selected compact subsets, countable choice, host weak compactness, quotient events, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No tight probability-measure obligation is stored outside these rows.

Proof. Project the accepted carrier. The probability source P, event-surface measure row M, and distribution law row D are the only probability-facing coordinates.

The compact side is finite. The compact-test request K, outside-mass row E, and tolerance ledger R must be displayed before a tightness consumer can inspect the packet.

Transport and replay preserve the same route through H and C. Provenance Q and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, the local NameCert surface cannot supply measure completion, selected compact subsets, countable choice, host weak compactness, quotient events, or ambient real completeness. □

Theorem 7261.3 (Tight probability measure Prokhorov handoff)**.** *Every Prokhorov-facing consumer of an accepted* $\mathsf{TightProbabilityMeasure}^{\uparrow}$ *carrier reads only the finite route*

$$\mathsf{ProbSpace}^{\uparrow} \longmapsto \mathsf{Measure}^{\uparrow} \longmapsto \mathsf{Distribution}^{\uparrow} \longmapsto K, E, R \longmapsto \mathsf{ProkhorovTightProbability}^{\uparrow}$$

together with H, C, Q, N. Thus the handoff to chapter 4008 is a displayed probability-source, measure-event, distribution-law, compact-test, outside-mass, tolerance-ledger, transport, replay, provenance, and local-naming route, with no measure completion, selected subsequence, countable-choice selector, host weak compactness theorem, quotient event, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the NameCert obligations of Definition 7261.2. They force the probability source, measure event surface, and distribution law to be displayed before the compact outside-mass route is consumed.

Next read the compact and tolerance rows. The rows K, E, R are the only compact-test, outside-mass, and tolerance coordinates available to the carrier, so the Prokhorov-facing consumer receives those rows rather than a host compactness theorem.

Finally pass the displayed route to the Prokhorov tight probability surface. The structural rows H, C, Q, N transport, replay, source, and name the same finite packet, and the carrier has no remaining coordinate from which a consumer could extract measure completion, selected subsequences, countable choice, weak compactness, quotient events, or ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{TightProbabilityMeasure}^{\uparrow}$ tightness read factors through $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, a displayed compact-test row, an outside-mass $\mathsf{Real}^{\uparrow}$ row, and a finite tolerance ledger before any $\mathsf{ProkhorovTightProbability}^{\uparrow}$ consumer can inspect it.

Independence witness: probspace, measure, distribution, prokhorov-tight-probability: $\mathsf{TightProbabilityMeasure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries probability-source admission, event-surface measure access, pushforward-law compatibility, compact outside-mass data, tolerance alignment, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TightProbabilityMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{TightProbabilityMeasure}^{\uparrow}$ packet is generated from ProbSpaceUp source rows, MeasureUp event-surface rows, DistributionUp pushforward rows, compact-test rows, outside-mass RealUp rows, a finite tolerance ledger, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TightProbabilityMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7261.1, Definition 7261.2, and Definition 7261.3 seed the finite tight probability-measure certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TightProbabilityMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, weak compactness, selected compact sets, selected subsequences, countable choice, quotient events, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, probability-measure compatibility, distribution compatibility, compact outside-mass exposure, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TightProbabilityMeasureU

Chapter 7262

A Concrete Naming Certificate for CauchyLimitUniquenessModulus$^{\uparrow}$

Following Bishop and Bridges, the CauchyLimitUniquenessModulus$^{\uparrow}$ packet records the finite modulus data used to compare two regular Cauchy real-limit routes without quotienting streams or appealing to host real equality. It sits after the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the regular Cauchy limit uniqueness packet of chapter 3942, and the real-limit uniqueness seal of chapter 1039. The packet names a displayed finite-means uniqueness modulus for Real and Completion consumers; it is not a completed-real equality theorem, a quotient-stream principle, a selected limit, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 7262.1 (Cauchy limit uniqueness modulus carrier)**.** *A* CauchyLimitUniquenessModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L_0, L_1, B, W, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. L_0 *and* L_1 *are the two regular Cauchy limit source rows whose terminal reads are being compared.*
2. B *is the* DyadicRatCore$^{\uparrow}$ *tail-budget row naming the requested dyadic radius and its common comparison scale.*
3. W *is the paired* StreamName$^{\uparrow}$ *finite tail-window row, including the two observations used after the displayed unary threshold.*
4. R *is the* RegSeqRat$^{\uparrow}$ *readback row for the two scheduled tails.*
5. U *is the* RegularCauchyLimitUniqueness$^{\uparrow}$ *route row binding the paired tails to one uniqueness read.*
6. E *is the terminal* Real$^{\uparrow}$ *seal row, available only after* B, W, R, U *have been displayed.*
7. H *records componentwise* hsame *transport for* $L_0, L_1, B, W, R, U, E, C, P, N$.
8. C *records displayed* Cont *replay through the tail-budget, window, readback, uniqueness, and terminal seal rows.*
9. P *is the* Pkg *provenance over* CauchyLimitUniquenessModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RegularCauchyLimitUniqueness$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}}$ *row.*
The carrier has no coordinate for host real equality, quotient stream equality, a selected limiting representative, a hidden modulus oracle, countable choice, trichotomy, or ambient completion.

Lean4 ✓ `BEDC.Derived.CauchyLimitUniquenessModulusUp.CauchyLimitUniquenessModulusTasteGate`
`single carrier alignment`

Definition 7262.2 (Cauchy limit uniqueness modulus classifier)**.** *The* $\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}$ *classifier identifies accepted packets only through displayed agreement of* $L_0, L_1, B, W, R, U, E, H, C, P, N$*. In particular, the classifier refuses equality that preserves the two source rows but changes the dyadic budget, the finite StreamName observations, the RegSeqRat readback, the uniqueness route, the terminal Real seal, or any structural transport, replay, provenance, or local naming row.*

Theorem 7262.3 (Cauchy limit uniqueness modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}$ *carrier* $M = (L_0, L_1, B, W, R, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyLimitUniquen}}$ *surface consists exactly of carrier admission, classifier exactness, dyadic tail-budget stability, finite StreamName window stability, RegSeqRat readback compatibility, regular Cauchy uniqueness routing, terminal Real-seal exposure, componentwise transport, displayed replay, package provenance, and local naming. Every uniqueness read for a requested dyadic radius factors through these rows.*

Proof. Project the carrier of Definition 7262.1. The analytic rows are the paired source rows L_0, L_1, dyadic tail budget B, finite window W, regular readback R, uniqueness route U, and terminal seal E.

Apply the classifier of Definition 7262.2. It makes the five NameCert obligations visible: carrier admission for the displayed tuple, exact comparison through the classifier row, stability of the dyadic and StreamName windows, ledger compatibility for the RegSeqRat and Real-seal route, and nonescape from the structural rows H, C, P, N.

The regular Cauchy uniqueness route is read through chapter 3942 and the terminal seal is read through chapter 1039. Since neither route supplies host real equality, quotient stream equality, a selected limit, or ambient completion, every requested dyadic radius remains inside the displayed finite modulus ledger. □

Falsifiable prediction: A Real-facing uniqueness consumer that identifies two regular Cauchy limit reads while omitting the dyadic budget row, the paired StreamName observations, the RegSeqRat readback, or the regular Cauchy uniqueness route is rejected by the $\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}$ classifier.

Independence witness: dyadicratcore, streamname, regseqrat, regular-cauchy-limit-uniqueness, real-limit-uniqueness-seal, real: no listed sibling is bijective to $\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}$ because this packet jointly carries two source rows, one dyadic tail budget, paired finite observations, regular readback, uniqueness routing, terminal Real sealing, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}$ packet is generated from paired regular Cauchy limit rows, a DyadicRatCore tail budget, finite StreamName observations, RegSeqRat readback, RegularCauchyLimitUniqueness routing, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7262.1, Definition 7262.2, and Definition 7262.3 seed the finite uniqueness-modulus route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyLimitUniquenessModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, host real equality, selected limits, countable choice, trichotomy, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic budget, paired finite observations, RegSeqRat readback, uniqueness route, terminal Real seal, transport, replay, provenance, and local naming for BEDC.Derived.CauchyLimitUniqueness

Chapter 7263

A Concrete Naming Certificate for $\mathsf{PoincareDiskIsometry}^{\uparrow}$

The $\mathsf{PoincareDiskIsometry}^{\uparrow}$ packet realizes the reversible disk-transport branch of chapter 9463 as finite Poincare-disk isometry data. It sits after the disk carrier of chapter 377, the metric rows of chapter 3474 and chapter 6209, the disk-automorphism route of chapter 6776, and the boundary-transport packet of chapter 6267. The packet names reversible hyperbolic disk transport; it is not a completed hyperbolic plane, a global automorphism group, quotient boundary equality, a non-invertible disk map, or a physical observer law.

Definition 7263.1 (Poincare disk isometry carrier)**.** *A* $\mathsf{PoincareDiskIsometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, F, G, A, B, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *source-and-target disk row for the displayed points under inspection.*
2. *F is the disk-map row naming the finite transport on those displayed points.*
3. *G is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *or* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *metric-preservation row for every displayed source-target pair.*
4. *A is the* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ *reversible-map row, including inverse and composition read-backs for F.*
5. *B is the* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *boundary row showing that ideal-boundary reads are transported only through displayed disk data.*
6. *Q is the refusal row for non-invertible disk maps, metric-changing maps, omitted boundary evidence, and host geometry shortcuts.*
7. *H records componentwise* hsame *transport for $D, F, G, A, B, Q, C, P, N$.*
8. *C records displayed* Cont *replay through disk coordinates, map rows, metric preservation, automorphism, boundary transport, and refusal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{PoincareDiskIsometry}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$, $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareDiskIsometry}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, F, G, A, B, Q, H, C, P, N$ and has no coordinate for a non-invertible transport, hidden metric-preservation proof, completed disk model, quotient boundary object, or physical observer trajectory.

Theorem 7263.2 (Poincare disk isometry NameCert obligations)**.** *For every accepted* $\mathsf{PoincareDiskIsometry}^{\uparrow}$ *carrier* $I = (D, F, G, A, B, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PoincareDiskIsometry}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, reversible map admission, metric-preservation exactness, boundary-transport compatibility, refusal of non-invertible or metric-changing witnesses, componentwise transport, displayed replay, package provenance, and local naming. A disk-map witness that lacks any one of F, G, A, B, Q is not an accepted isometry packet.*

Proof. Project the carrier of Definition 7263.1. The geometric rows are the disk observations D, disk-map row F, metric-preservation row G, automorphism row A, boundary-transport row B, and refusal row Q.

Metric preservation is read through the existing hyperbolic and Poincare disk metric packets, while reversibility is read through the disk-automorphism packet. The boundary row keeps ideal-end transport attached to the same displayed disk data rather than to a quotient boundary.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a non-invertible map, hidden metric proof, completed disk model, physical observer law, or quotient boundary object, every accepted isometry read remains inside the displayed NameCert surface. □

Falsifiable prediction: A disk-map witness that preserves the displayed point row but fails metric preservation, lacks an inverse, or omits the boundary-transport row is rejected by the $\mathsf{PoincareDiskIsometry}^{\uparrow}$ classifier.

Independence witness: unitdisk, hyperbolic-metric, poincare-disk-automorphism, hyperbolic-boundary-transport: no listed sibling is bijective to $\mathsf{PoincareDiskIsometry}^{\uparrow}$ because UnitDiskUp supplies disk coordinates without reversible metric preservation, HyperbolicMetricUp supplies metric reads without a disk-map inverse, PoincareDiskAutomorphismUp supplies reversible maps without the isometry refusal row, and boundary transport supplies boundary routing without the full disk-map, metric, inverse, refusal, transport, replay, provenance, and local NameCert surface.

The Lean `TasteGate.lean` boundary for $\mathsf{PoincareDiskIsometry}^{\uparrow}$ must provide explicit Nontrivial PoincareDiskIsom and FieldFaithful $\mathsf{PoincareDiskIsometry}^{\uparrow}$ instances preserving the displayed rows $D, F, G, A, B, Q, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskIsometry}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PoincareDiskIsometry}^{\uparrow}$ packet is generated from UnitDisk coordinates, a displayed disk map, HyperbolicMetric or PoincareDiskMetric preservation rows, PoincareDiskAutomorphism inverse rows, boundary transport, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PoincareDiskIsometry}^{\uparrow}}$, seed)

Scope closed: Definition 7263.1 and Definition 7263.2 seed the finite reversible hyperbolic disk-transport route over $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$, and $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PoincareDiskIsometry}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, completed hyperbolic disk geometry, global automorphism groups, quotient boundary equality, non-invertible disk maps, or physical observer dynamics.

Upgrade path: Obligation closure requires checked carrier admission, disk coordinates, reversible map rows, metric preservation, boundary transport, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.PoincareDiskIsometryUp

Chapter 7264

A Concrete Naming Certificate for $\mathsf{NewtonCotes}^{\uparrow}$

Following Newton–Cotes quadrature in classical numerical analysis, the $\mathsf{NewtonCotes}^{\uparrow}$ packet records a finite interpolation-node quadrature rule as BEDC NameCert data before any integration-facing consumer may read an approximate integral. It sits after the quadrature carrier of chapter 227, the Darboux-sum surface of chapter 1880, the polynomial source of chapter 50, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names only a finite node-and-weight rule with a displayed error budget; it does not import host integration, measure theory, selected limits, quotient function equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7264.1 (Newton–Cotes carrier)**.** *A* $\mathsf{NewtonCotes}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, N, W, S, A, D, R, E, H, C, P, L)$$

with the following displayed rows:

1. *I is the interval endpoint row, naming the displayed left and right endpoints and the orientation data used by the quadrature rule.*
2. *N is the finite node ledger. It records the node order, endpoint inclusion flags, and node positions inside the same interval row.*
3. *W is the rational weight ledger, assigning one rational weight to each displayed node and recording the finite denominator schedule.*
4. *S is the sample row, exposing the inspected function values only at the nodes listed by N.*
5. *A is the finite weighted-sum row that combines S with W before any regular-rational or Real-facing readback is opened.*
6. *D is the dyadic error-budget row, recording the tolerance request, mesh width, and finite remainder budget available to the rule.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the weighted-sum row and the dyadic budget.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, N, W, S, A, D, R have been displayed.*
9. *H records componentwise* hsame *transport for endpoint, node, weight, sample, weighted-sum, budget, handoff, seal, provenance, replay, and naming rows.*

10. *C records displayed* Cont *replay from an interval request through nodes, weights, samples, weighted sum, dyadic budget, regular-rational handoff, and Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{NewtonCotes}^{\uparrow}$, $\mathsf{Quadrature}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *L is the local* $\mathsf{NameCert}_{\mathsf{NewtonCotes}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, N, W, S, A, D, R, E, H, C, P, L$. It has no coordinate for a host integral, measure-theoretic completion, an unbounded function space, quotient function equality, selected limiting partitions, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7264.2 (Newton–Cotes NameCert obligations)**.** *For every accepted* $\mathsf{NewtonCotes}^{\uparrow}$ *carrier*

$$Q = (I, N, W, S, A, D, R, E, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{NewtonCotes}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the endpoint, node, weight, sample, weighted-sum, dyadic-budget, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming rows;*
2. *node-and-weight coverage, requiring N and W to list the same finite node positions and rational weights over the endpoint row I;*
3. *sample exactness, requiring each entry of S to be a displayed sample at a node named by N;*
4. *weighted-sum and dyadic-budget exactness, requiring A to use only the samples and rational weights in S, W and requiring D to bind the requested quadrature tolerance before readback;*
5. *RegSeqRat and Real-seal non-escape, requiring R and E to be exposed only after I, N, W, S, A, D and the structural rows H, C, P, L are visible.*

No Newton–Cotes obligation is stored outside these finite rows.

Proof. Project the accepted carrier. The tuple lists exactly the interval endpoint, finite node ledger, rational weight ledger, sample row, weighted-sum row, dyadic budget, regular-rational handoff, Real seal, and structural rows.

Node-and-weight coverage is read from N and W. The two rows have the same finite index surface over the endpoint row I, so there is no hidden node, extra weight, or external partition.

Sample exactness is the row S. Since S is indexed by N, every sampled value is attached to a displayed node before the weighted sum can be inspected.

The numerical handoff is then finite. Row A combines only S and W, row D binds the dyadic error request, and R, E expose the regular-rational and Real-facing readback only after those rows are visible. Transport, replay, provenance, and local naming through H, C, P, L preserve the same route and add no host integration or completeness principle. □

Theorem 7264.3 (Newton–Cotes RegSeqRat quadrature handoff)**.** *Every quadrature-facing read of an accepted* $\mathsf{NewtonCotes}^{\uparrow}$ *packet factors through the finite route*

$$I, N, W, S, A, D \longmapsto R \longmapsto E.$$

In particular, a consumer must expose the endpoint row, node ledger, rational weight ledger, sample row, finite weighted-sum row, and dyadic error-budget row before the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and terminal* $\mathsf{Real}^{\uparrow}$ *seal are available. The packet exports no host integral, measure-theoretic completion, selected limiting partition, quotient function equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 7264.2. They place every consumer read downstream of the carrier rows $I, N, W, S, A, D, R, E, H, C, P, L$.

Read the quadrature data in order. The endpoint row I fixes the interval, N lists the nodes, W lists the rational weights on those nodes, and S supplies only the corresponding samples.

The finite weighted sum and error budget are the last numerical rows before readback. Row A combines the displayed samples and weights, while D records the dyadic tolerance and finite remainder budget attached to the same rule.

Only then may the consumer inspect R and E. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff and $\mathsf{Real}^{\uparrow}$ seal are therefore exposed as a finite Newton–Cotes quadrature route, not as a host integration theorem, measure-theoretic limit, quotient function equality, compactness principle, or ambient completeness claim. □

Falsifiable prediction: A $\mathsf{NewtonCotes}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal without displaying the interval endpoint row, node ledger, rational weight ledger, sample row, weighted-sum row, and dyadic error-budget row refutes the carrier of Definition 7264.1.

Independence witness: quadrature, darbouxsum, polynomial, regseqrat, real: $\mathsf{NewtonCotes}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint rows, node rows, rational weights, sample rows, finite weighted sums, dyadic error budgets, regular-rational handoff, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{NewtonCotes}^{\uparrow}}$.

Constructive story: A $\mathsf{NewtonCotes}^{\uparrow}$ packet is generated from an interval endpoint row, finite node ledger, rational weight ledger, sample row, finite weighted-sum row, dyadic error-budget row, RegSeqRat handoff, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NewtonCotes}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7264.1, Definition 7264.2, and Definition 7264.3 seed the finite Newton–Cotes quadrature carrier and its RegSeqRat-to-Real handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NewtonCotes}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter explicitly refuses host integration, measure theory, selected limits, quotient function equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, node-and-weight coverage, sample exactness, finite weighted-sum exactness, dyadic error-budget exposure, RegSeqRat handoff, Real-seal ordering, hsame transport, Cont replay, provenance, and local naming for BEDC.Derived.NewtonCotesUp.

Chapter 7265

A Concrete Naming Certificate for $\mathsf{SimpsonRule}^{\uparrow}$

Following Simpson and the Newton–Cotes quadrature tradition, the $\mathsf{SimpsonRule}^{\uparrow}$ packet records the finite three-point closed quadrature rule as BEDC NameCert data before an integration-facing consumer may read its approximation or error row. It sits after the finite exactness interface of chapter 227, the Newton–Cotes node-and-weight packet of chapter 7264, the Taylor remainder packet of chapter 4732, the tagged integral route of chapter 1526, and the terminal real-name seal of chapter 38. The packet names only the midpoint/endpoints rule with displayed weights, a displayed Taylor or Peano error row, and the regular rational to Real handoff; it does not import host integration, measure theory, selected limits, quotient function equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7265.1 (Simpson rule carrier)**.** *A* $\mathsf{SimpsonRule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, M, E, W, Q, T, R, D, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact interval row, naming the displayed left and right endpoints, the orientation data, and the compact-interval source used by the rule.*
2. *M is the midpoint row, recording the finite construction of the midpoint between the two endpoint names and its membership in the same interval row.*
3. *E is the endpoint sample row, exposing the two endpoint samples and the midpoint sample as the only function reads used by the rule.*
4. *W is the Simpson weight row, recording the finite rational weights $1, 4, 1$ together with the common denominator and interval-width factor.*
5. *Q is the finite quadrature row, combining E and W into the displayed three-point weighted sum.*
6. *T is the Taylor or Peano error row, recording the displayed fourth-order remainder budget or Peano kernel budget used by the packet.*
7. *R is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *and Darboux handoff row, exposing the tagged-integral or Darboux-facing consumer route only after I, M, E, W, Q, T have been displayed.*
8. *D is the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal row, recording the regular-rational read-back, dyadic tolerance schedule, and terminal Real seal for the weighted sum and error row.*

9. *H records componentwise* hsame *transport for interval, midpoint, sample, weight, quadrature, error, handoff, seal, provenance, replay, and naming rows.*
10. *C records displayed* Cont *replay from the interval request through midpoint construction, endpoint and midpoint samples, Simpson weights, finite quadrature row, error row, integral handoff, regular-rational readback, dyadic tolerance, and Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{SimpsonRule}^{\uparrow}$, $\mathsf{Quadrature}^{\uparrow}$, $\mathsf{NewtonCotes}^{\uparrow}$, $\mathsf{TaylorRemainder}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SimpsonRule}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, E, W, Q, T, R, D, H, C, P, N$. It has no coordinate for a host integral, an undisplayed mesh limit, a selected antiderivative, quotient function equality, a hidden fourth derivative, an open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7265.2 (Simpson rule NameCert obligations)**.** *For every accepted* $\mathsf{SimpsonRule}^{\uparrow}$ *carrier*

$$S = (I, M, E, W, Q, T, R, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SimpsonRule}^{\uparrow}}$ *surface consists exactly of compact-interval admission, midpoint construction, endpoint and midpoint sample exposure, Simpson weight exposure, finite quadrature-row exactness, Taylor or Peano error-row exposure, Riemann and Darboux handoff, RegSeqRat/Dyadic/Real sealing, componentwise transport, displayed continuation replay, provenance, local naming, and non-escape from host integration, undisplayed mesh limits, selected antiderivatives, quotient function equality, hidden differentiability data, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7265.1. The interval row I and midpoint row M are the only source rows from which the three sampling sites can be read.

The numerical rule is then finite. Row E exposes exactly the two endpoint samples and the midpoint sample, while W exposes the rational weight pattern $1, 4, 1$ with its denominator and interval-width factor.

The quadrature and error rows are downstream of those displayed samples. Row Q combines only E and W, and row T records the Taylor or Peano error budget without adding a hidden derivative or host analytic function.

Finally, R, D, H, C, P, N transport, replay, source, seal, and name the same route. Since no carrier coordinate stores a host integral, selected limit, quotient function equality, compactness principle, or ambient real completeness, the listed rows exhaust the local certificate surface. □

Theorem 7265.3 (Simpson rule quadrature-error non-escape)**.** *Every Riemann-facing, Darboux-facing, or real-seal read of an accepted* $\mathsf{SimpsonRule}^{\uparrow}$ *packet factors through*

$$I, M, E, W, Q, T \longmapsto R \longmapsto D.$$

In particular, a consumer must expose the compact interval, midpoint row, endpoint and midpoint samples, Simpson weights, finite quadrature row, and Taylor or Peano error row before the integral handoff and RegSeqRat/Dyadic/Real seal are available. The packet exports no host integration theorem, undisplayed limiting partition, quotient function equality, hidden differentiability assumption, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a consumer read of the accepted packet. The NameCert obligations of Definition 7265.2 place every read downstream of $I, M, E, W, Q, T, R, D, H, C, P, N$.

The endpoint and midpoint data must be displayed first. The interval row fixes the endpoints, the midpoint row fixes the middle sample site, and the sample row exposes only those three function reads.

The Simpson weights and finite weighted sum are then the only quadrature rows. The error row is attached to that same three-point rule, so an integral-facing read cannot bypass Q or T.

Only after those rows are present may R and D be inspected. The Riemann/Darboux handoff and the RegSeqRat/Dyadic/Real seal are therefore finite readback rows, not host analytic integration, quotient function equality, selected limiting partitions, compactness, or ambient completeness. □

Falsifiable prediction: A $\mathsf{SimpsonRule}^{\uparrow}$ consumer that reaches a $\mathsf{RiemannIntegral}^{\uparrow}$ handoff, Darboux-facing read, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, or $\mathsf{Real}^{\uparrow}$ seal without displaying I, M, E, W, Q, T refutes the carrier of Definition 7265.1.

Independence witness: quadrature, newton-cotes, taylor-remainder, riemannintegral, real: none is bijective to $\mathsf{SimpsonRule}^{\uparrow}$ because this packet jointly carries the compact interval, midpoint, endpoint and midpoint samples, Simpson weights, finite quadrature row, Taylor or Peano error row, Riemann/Darboux handoff, RegSeqRat/Dyadic/Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SimpsonRule}^{\uparrow}}$.

Constructive story: A $\mathsf{SimpsonRule}^{\uparrow}$ packet is generated from a compact interval row, midpoint row, endpoint and midpoint sample row, Simpson weight row, finite quadrature row, Taylor or Peano error row, Riemann/Darboux handoff row, RegSeqRat/Dyadic/Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SimpsonRule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7265.1, Definition 7265.2, and Definition 7265.3 seed the finite three-point Simpson quadrature carrier and its error-to-readback route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SimpsonRule}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host integration, measure theory, selected limits, quotient function equality, hidden differentiability data, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint construction, three-sample exposure, Simpson weight exposure, quadrature-row exactness, Taylor or Peano error exposure, Riemann/Darboux handoff, RegSeqRat/Dyadic/Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.SimpsonRuleUp.

Chapter 7266

A Concrete Naming Certificate for $\mathsf{FiniteJacobian}^{\uparrow}$

Following Cartan and Spivak on finite-dimensional differential calculus, the $\mathsf{FiniteJacobian}^{\uparrow}$ packet records the derivative matrix of a finite coordinate-window presentation as BEDC NameCert data. It sits over the matrix surface of chapter 49, the linear-map handoff of chapter 48, the calculus route of chapter 3632, the real readback seal of chapter 38, and the metric neighbourhood discipline of chapter 57. The finite derivative table is consumed as a calculus-facing bridge from the $\mathsf{Mat}^{\uparrow}$ table through the $\mathsf{LinMap}^{\uparrow}$ handoff before $\mathsf{Real}^{\uparrow}$ error budgets and $\mathsf{Met}^{\uparrow}$ neighbourhood budgets are exposed. The packet is a finite derivative table and error-budget certificate; it does not import host differentiability, quotient function equality, selected limits, inverse-function data, implicit-function data, or countable choice.

Definition 7266.1 (FiniteJacobian carrier)**.** *A* $\mathsf{FiniteJacobian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (W, M, L, E, V, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite coordinate-window row: it records the source coordinate labels, target coordinate labels, base point window, and the finite list of directions inspected by the derivative read.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *derivative table row whose entries are the displayed coordinatewise linear coefficients for the window W.*
3. *L is the* $\mathsf{LinMap}^{\uparrow}$ *handoff row reading the same table as a finite linear map between the displayed coordinate windows.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *finite-difference error budget row: for each displayed direction it records the rational or dyadic tolerance by which the table M approximates the observed difference quotient.*
5. *V is the* $\mathsf{Met}^{\uparrow}$ *neighbourhood budget row that bounds the domain window on which the finite-difference observations may be replayed.*
6. *H records componentwise* hsame *transport for W, M, L, E, V, C, P, N.*
7. *C records displayed* Cont *replay from a coordinate-window read through the matrix table, linear-map handoff, real error budget, and metric neighbourhood budget.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteJacobian}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteJacobian}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient differentiability predicate, host function equality, selected limit, inverse map, implicit solver, quotient real equality, or countable-choice schedule.

Lean4 ✓ `BEDC.Derived.FiniteJacobianUp.FiniteJacobianTasteGate single carrier alignment`

Theorem 7266.2 (FiniteJacobian NameCert obligations)**.** *For every accepted* $\mathsf{FiniteJacobian}^{\uparrow}$ *carrier*

$$J = (W, M, L, E, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteJacobian}^{\uparrow}}$ *surface consists exactly of finite coordinate-window admission, Matrix derivative-table admission, LinearMap handoff, Real finite-difference error-budget compatibility, Metric neighbourhood-budget compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. Thus a derivative consumer may read the finite Jacobian only as displayed matrix and linear-map data over* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{Calculus}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Met}^{\uparrow}$*.*

Proof. Project the accepted carrier of Definition 7266.1. The analytic rows are W, M, L, E, V, and the structural rows are H, C, P, N.

The coordinate-window row W fixes the finite source and target faces before any derivative entry is inspected. The matrix row M is therefore a finite table over that window rather than an ambient derivative operator.

The linear-map row L reads the same table as a finite handoff. The real error row E records the finite-difference tolerance for each displayed direction, and the metric row V records the neighbourhood on which those observations may be replayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since every obligation is one of the displayed rows and none of the excluded host objects is a coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7266.3 (FiniteJacobian matrix derivative handoff)**.** *Every inverse-function, implicit-function, ODE, PDE, or linearisation consumer of an accepted* $\mathsf{FiniteJacobian}^{\uparrow}$ *carrier receives the derivative only through the finite handoff*

$$W, M, L, E, V, H, C, P, N.$$

In particular, the $\mathsf{Mat}^{\uparrow}$ *derivative table is consumed before the* $\mathsf{LinMap}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *finite-difference error budget, and the* $\mathsf{Met}^{\uparrow}$ *neighbourhood budget. The handoff exports no host differentiability theorem, selected derivative limit, quotient function equality, inverse-function conclusion, implicit-function conclusion, ODE solution, PDE solution, or countable choice.*

Proof. Begin with a downstream analytic consumer of the accepted packet. The carrier first exposes the coordinate-window row W, so every later derivative read is attached to the same finite list of source directions and target coordinates.

The consumer then reads the matrix table M and only afterward the linear-map handoff L. This order makes the linear map a replay of the displayed derivative table, not a hidden ambient derivative.

The finite-difference budget E and neighbourhood budget V bound the table as real and metric data before any consumer can reuse it in an inverse, implicit, evolution, or linearisation route.

Componentwise transport H and displayed replay C preserve this order, while P and N record provenance and local naming. Hence the consumer receives a finite matrix derivative packet and none of the stronger analytic endpoints refused in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteJacobian}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteJacobian}^{\uparrow}$ packet is generated from finite coordinate-window rows, a displayed MatrixUp derivative table, a LinearMapUp handoff, RealUp finite-difference error budgets, MetricUp neighbourhood budgets, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteJacobian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7266.1, Definition 7266.2, and Definition 7266.3 seed the finite matrix derivative packet over coordinate windows, Matrix, LinearMap, Real error budgets, and Metric neighbourhood budgets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteJacobian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host differentiability, selected derivative limits, quotient function equality, inverse-function results, implicit-function results, ODE or PDE solvability, countable choice, Lean verification, or a standard bridge.

Upgrade path: Scoped treatment asks for checked carrier admission, coordinate-window exactness, matrix-table compatibility, linear-map handoff, finite-difference error control, neighbourhood-budget compatibility, transport, replay, provenance, and local naming.

Chapter 7267

A Concrete Naming Certificate for $\mathsf{BishopRegularRealLocator}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopRegularRealLocator}^{\uparrow}$ packet records the locator surface carried by a regular Cauchy real name before any Real-facing approximation consumer reads it. It sits over the dyadic tolerance ledger of chapter 291, the finite window service of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies located approximation windows for regular Cauchy data; it is not quotient real equality, countable choice, trichotomy, host equality, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7267.1 (Bishop regular real locator carrier)**.** *A* $\mathsf{BishopRegularRealLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, A, E, H, C, P, N)$$

with the following visible rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and rational-probe ledger, carrying the requested dyadic radius, lower and upper rational guards, and comparison slack.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened from the regular Cauchy name at the requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the regular rational approximants attached to the same finite windows.*
4. *A is the located approximation-window row, recording the finite rational interval or apartness window accepted for the requested dyadic tolerance.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after D, S, R, A have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic tolerance, stream window, regular rational readback, approximation-window, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an approximation request through D, S, R, A, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularRealLocator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealLocator}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, A, E, H, C, P, N$. It has no coordinate for quotient real equality, countable-choice schedules, trichotomy of arbitrary real comparisons, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.BishopRegularRealLocatorUp.BishopRegularRealLocatorUp`

Theorem 7267.2 (Bishop regular real locator NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularRealLocato}$ *carrier $L = (D, S, R, A, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealLocator}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the dyadic tolerance ledger, finite stream window, regular rational readback, located approximation window, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *source agreement, requiring D, S, and R to refer to the same displayed regular Cauchy name before A is read;*
3. *locator exactness, requiring the approximation window in A to be bounded by the dyadic tolerance and rational guards named in D;*
4. *regular readback binding, requiring A to be justified by the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and not by a host real representative;*
5. *Real seal non-escape, requiring E to be downstream of the finite dyadic, stream, regular-rational, and approximation-window rows;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N;*
7. *refusal of quotient real equality, countable choice, trichotomy, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as certificate data.*

No locator obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 7267.1. The only analytic rows exposed before the Real seal are the dyadic tolerance ledger D, the finite stream window S, the regular rational readback R, and the approximation window A.

Source agreement is read from the shared route D, S, R. The locator row A can answer a rational approximation request only after the requested dyadic tolerance and the inspected regular-rational window have both been displayed.

The Real-facing row E is downstream of that finite route. Transport through H and replay through C preserve the same dyadic, stream, readback, and approximation coordinates, while P and N package the local certificate.

Since the carrier has no coordinate for quotient equality, choice, trichotomy, host equality, or ambient completeness, none of those principles can enter the NameCert surface. □

Theorem 7267.3 (Bishop regular real locator approximation handoff)**.** *Every approximation consumer reading an accepted* $\mathsf{BishopRegularRealLocator}^{\uparrow}$ *carrier factors through the finite route*

$$D, S, R \longmapsto A \longmapsto E \longmapsto H, C, P, N.$$

The consumer receives a displayed rational window over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *data. It receives no quotient real equality witness, no countable-choice schedule, no trichotomy oracle, no host equality comparison, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Begin with an approximation request for the accepted carrier. The request first reads D for the dyadic tolerance and rational guards, then opens the finite stream window S and the regular rational readback R attached to the same regular Cauchy name.

The located approximation window A is therefore a finite consequence of displayed regular-rational data. It is not a selected representative of a quotient real and does not require a comparison of completed host objects.

The final Real-facing handoff passes through E, H, C, P, N. These rows seal, transport, replay, source, and name the same route, so a downstream consumer can inspect the approximation window without importing countable choice, trichotomy, host equality, or ambient completeness. □

Theorem 7267.4 (Bishop regular real locator window composition)**.** *Suppose two accepted* BishopRegularRealLocat *reads expose the same* DyadicRatCore$^{\uparrow}$ *tolerance row and compatible* StreamName$^{\uparrow}$ *finite windows. Their locator-facing reads compose into a single finite route whose* RegSeqRat$^{\uparrow}$ *readback and terminal* Real$^{\uparrow}$ *seal remain downstream from the displayed windows. The composed route uses only* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows, and it exports no quotient real equality, countable-choice schedule, selected limit, trichotomy oracle, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 7267.1 for both reads. The visible analytic rows are the dyadic tolerance ledger, the finite stream windows, the regular rational readback, the located approximation window, and the terminal Real seal.

Apply the NameCert obligations of Definition 7267.2. They force source agreement and locator exactness through the displayed D, S, R, A rows before any Real-facing row can be consumed.

Use the approximation handoff of Definition 7267.3. Compatible stream windows over the same dyadic tolerance can be concatenated only at the finite-window level; the RegSeqRat$^{\uparrow}$ readback and the Real seal remain downstream from that display.

The structural rows then transport and replay the same composed route through H, C, P, N. Since no carrier coordinate stores quotient equality, choice, selected limits, trichotomy, or ambient completeness, the composition is only a locator-facing finite-window handoff. □

Falsifiable prediction: Every accepted BishopRegularRealLocator$^{\uparrow}$ packet exposing a Real-facing approximation handoff must display dyadic tolerance, StreamName window, RegSeqRat readback, located approximation, Real seal, hsame transport, Cont replay, Pkg provenance, and NameCert rows.

Independence witness: dyadicratcore, streamname, regseqrat, real: BishopRegularRealLocator$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a dyadic tolerance request, finite stream observation, regular rational readback, located approximation window, terminal Real seal, and local naming rows.

Closure status for NameCert$_{\text{BishopRegularRealLocator}^{\uparrow}}$.

Constructive story: A BishopRegularRealLocator$^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, a StreamName finite-window row, a RegSeqRat regular readback row, a located approximation-window row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopRegularRealLocator}^{\uparrow}}$, seed)

Scope closed: Definition 7267.1, Definition 7267.2, Definition 7267.3, and Definition 7267.4 seed the finite locator surface for regular Cauchy real names and Real-facing approximation consumers.

Formal verification: FormalStatus(NameCert$_{\text{BishopRegularRealLocator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, countable choice, trichotomy, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source agreement, locator exactness, regular readback binding, Real seal non-escape, transport, replay, provenance, local naming, and approximation handoff for BEDC.Derived.BishopRegularRealLocatorUp.

Chapter 7268

A Concrete Naming Certificate for $\mathsf{ConstructiveLocatedReal}^{\uparrow}$

From Bishop and Bridges, the $\mathsf{ConstructiveLocatedReal}^{\uparrow}$ packet records a located real as finite dyadic locator data tied to regular rational readback and a terminal real-name seal. It sits after the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Bishop regular real packet of chapter 4058, and the positive apartness witness of chapter 6450. The packet names the constructive located-real boundary needed by Real and Completion consumers; it does not claim quotient equality of Cauchy streams, ambient real completeness, real trichotomy, countable choice, selected representatives, or a chosen limit.

Definition 7268.1 (Constructive located real carrier)**.** *A* $\mathsf{ConstructiveLocatedReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, E, A, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *locator row, carrying the dyadic radius, comparison slack, and positive tolerance budget used by each located read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected at the dyadic addresses requested by D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite windows and tolerance ledger.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reachable only after the dyadic locator, stream window, and regular rational readback rows have been displayed.*
5. *A is the apartness and refusal row, recording either a displayed positive separation through* $\mathsf{LocatedRealApartness}^{\uparrow}$ *or a finite refusal to provide trichotomy, quotient equality, countable choice, selected representatives, or ambient completeness.*
6. *F is the Bishop regular row, binding the* $\mathsf{BishopRegularReal}^{\uparrow}$ *route to the same dyadic windows and regular rational readback.*
7. *H records componentwise* hsame *transport for the dyadic locator, stream window, regular readback, Real seal, apartness/refusal row, Bishop regular row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located-real request through D, S, R, E, A, F, H.*

9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveLocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealApartness}^{\uparrow}$, $\mathsf{BishopRegularReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveLocatedReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, E, A, F, H, C, P, N$. It has no coordinate for host real equality, quotient real equality, a trichotomy decision, a choice schedule, a selected Cauchy representative, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.ConstructiveLocatedRealUp`

Theorem 7268.2 (Constructive located real apartness stability)**.** *Let $L = (D, S, R, E, A, F, H, C, P, N)$ and $L' = (D', S', R', E', A', F', H', C', P', N')$ be accepted* $\mathsf{ConstructiveLocatedReal}^{\uparrow}$ *carriers. If H records componentwise* hsame *transport from each displayed row of L to the corresponding row of L', then every apartness or refusal read of L transports to L' only through*

$$D, S, R, E, A, F, H, C, P, N.$$

In particular, positive separation evidence remains attached to the same dyadic locator, finite StreamName window, RegSeqRat readback, and Real seal route, while refusal rows remain refusals of trichotomy, quotient equality, choice, selected representatives, selected limits, and ambient completeness.

Proof. Project the two accepted carriers. The analytic rows are the dyadic locator D, the finite stream window S, the regular rational readback R, and the terminal Real seal E; the apartness/refusal row A is downstream of those rows.

Componentwise transport through H carries D, S, R, E, A, F to the corresponding rows of L'. Since C only replays the displayed route and P, N only source and name the same packet, no new comparison principle or equality test is introduced during transport.

Therefore a positive separation witness remains a finite located-apartness witness, and a refusal row remains an explicit refusal of non-displayed real principles. The transported packet can be consumed as constructive located-real data only through the stated rows. □

Theorem 7268.3 (Constructive located real regular NameCert)**.** *For every accepted* $\mathsf{ConstructiveLocatedReal}^{\uparrow}$ *carrier $L = (D, S, R, E, A, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveLocatedReal}^{\uparrow}}$ *surface consists exactly of dyadic locator admission, finite StreamName window admission, RegSeqRat readback, Real seal admission, apartness/refusal admission, Bishop regular route admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the displayed rows $D, S, R, E, A, F, H, C, P, N$.*

Proof. Read the carrier of Definition 7268.1. The regular readback row R is available only after the dyadic locator D and finite stream window S have been displayed, and the terminal Real seal E is downstream of that readback.

The apartness/refusal row A is row-local: it records positive separation when such a finite witness is displayed, and otherwise records refusals of trichotomy, quotient equality, choice, selected representatives, selected limits, and ambient completeness. The Bishop regular row F binds the same dyadic-window and regular-readback route to the classical Bishop regular-real surface without adding a host real oracle.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Hence the local NameCert obligations are exhausted by the listed rows, and no unregistered equality, completeness, or selection principle can enter the constructive located-real boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveLocatedReal}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveLocatedReal}^{\uparrow}$ packet is generated from a DyadicRatCore locator row, StreamName finite windows, RegSeqRat readback, a RealUp seal, apartness and refusal rows, a BishopRegularReal route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveLocatedReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7268.1, Definition 7268.2, and Definition 7268.3 seed the finite constructive located-real boundary over DyadicRatCore, StreamName, RegSeqRat, Real, located-apartness, Bishop regular, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveLocatedReal}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.ConstructiveLocatedRealUp`

Bridge status: none

Not claimed: This chapter does not claim quotient equality of Cauchy streams, ambient real completeness, real trichotomy, countable choice, selected representatives, selected limits, theorem checking, axiom purity, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic locator exactness, StreamName window admission, RegSeqRat readback, Real seal non-escape, apartness and refusal stability, Bishop regular route admission, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveLocatedRealUp.

Chapter 7269

A Concrete Naming Certificate for $\mathsf{BarrelledSpace}^{\uparrow}$

Following Schaefer and Bourbaki on locally convex spaces, the $\mathsf{BarrelledSpace}^{\uparrow}$ packet records the traditional barrel condition as finite BEDC NameCert data. It sits after the locally convex carrier of chapter 3386, the finite seminorm-family surface of chapter 5868, the Banach-space boundary of **??**, and the theorem-level uniform boundedness route of chapter 3375. The packet gives Banach–Steinhaus and locally convex consumers a named barrelledness certificate without importing full Banach–Steinhaus, countable choice, Hahn–Banach separation, quotient dual equality, or bridge checking.

Definition 7269.1 (BarrelledSpace carrier)**.** *A* $\mathsf{BarrelledSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, S, A, D, V, C, K, F, U, H, T, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *source row supplying the topological-vector, convex-neighbourhood, and local-convexity surface.*
2. *S is the* $\mathsf{SeminormedSpace}^{\uparrow}$ *finite seminorm-family row through which boundedness probes and neighbourhood reads are inspected.*
3. *A is the absorbing test row for candidate barrels in the displayed locally convex source.*
4. *D is the balanced test row.*
5. *V is the convex test row.*
6. *C is the closed test row.*
7. *K is the barrel predicate row, admitting a candidate precisely when A, D, V, C are displayed for the same neighbourhood carrier.*
8. *F is the bounded-family test row, reading pointwise bounded operator-family windows through the same locally convex and seminorm rows.*
9. *U is the* $\mathsf{BanachSteinhaus}^{\uparrow}$ *consumer row that may receive a uniform-boundedness handoff only after the barrel predicate and bounded-family rows have been exposed.*
10. *H records componentwise* hsame *transport for $L, S, A, D, V, C, K, F, U$.*

11. *T records displayed* Cont *replay from barrel reads and bounded-family requests through the same rows.*
12. *P is the* Pkg *provenance over* $\mathsf{BarrelledSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{BanachSteinhaus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BarrelledSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host topological-vector-space equality, a selected dual, a quotient completion, a full Banach–Steinhaus theorem, a Hahn–Banach separator, or a choice-selected family of barrels.

Theorem 7269.2 (BarrelledSpace NameCert obligations)**.** *For every accepted* $\mathsf{BarrelledSpace}^{\uparrow}$ *carrier* $B = (L, S, A, D, V, C, K, F, U, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BarrelledSpace}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the locally convex source row L and finite seminorm-family row S;*
2. *barrel recognition through the absorbing, balanced, convex, and closed tests A, D, V, C and the predicate row K;*
3. *bounded-family compatibility through F, with all pointwise bounded windows read over the same L, S surface;*
4. *Banach–Steinhaus consumer routing through U, available only after K and F have been displayed;*
5. *nonescape through H, T, P, N, excluding host Banach–Steinhaus, countable choice, Hahn–Banach strong forms, selected duals, quotient completions, and bridge checking.*

Proof. Project the carrier of Definition 7269.1. The tuple $L, S, A, D, V, C, K, F, U, H, T, P, N$ is the whole accepted packet, so carrier admission and local naming are finite row reads.

The barrel predicate is not primitive. It is assembled from the absorbing, balanced, convex, and closed tests A, D, V, C over the locally convex source L and seminorm-family row S, so a consumer cannot detach barrelledness from the displayed locally convex carrier.

The bounded-family test F uses the same L, S surface. The $\mathsf{BanachSteinhaus}^{\uparrow}$ row U is therefore a downstream consumer of the barrel and bounded-family rows rather than a proof of the full Banach–Steinhaus theorem.

Finally the rows H, T, P, N transport, replay, source, and name the same packet. Since no row names choice, Hahn–Banach separation, quotient completion, selected dual data, or bridge checking, the five listed rows exhaust the NameCert obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{BarrelledSpace}^{\uparrow}$ packet must expose the locally convex source, finite seminorm-family row, absorbing, balanced, convex, and closed tests, barrel predicate, bounded-family test, and Banach–Steinhaus consumer row before any barrelledness read is public.

Independence witness: locally-convex-space, seminormed-space, banachspace, banach-steinhaus: $\mathsf{BarrelledSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the locally convex source, finite seminorm family, four barrel tests, barrel predicate, bounded-family test, Banach–Steinhaus consumer row, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BarrelledSpace}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BarrelledSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7269.1 and Definition 7269.2 seed the finite barrelled-space route over locally convex, seminormed-space, Banach-space, Banach–Steinhaus, barrel-test, bounded-family, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BarrelledSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full Banach–Steinhaus, countable choice, Hahn–Banach strong forms, selected duals, quotient completions, Lean verification, or bridge checking for BarrelledSpace$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, barrel-test compatibility, bounded-family exactness, Banach–Steinhaus consumer routing, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.BarrelledSpaceUp.

Constructive story: A BarrelledSpace$^{\uparrow}$ packet is generated from locally convex source rows, finite seminorm-family rows, absorbing, balanced, convex, closed, barrel-predicate, bounded-family, Banach–Steinhaus consumer, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 7270

A Concrete Naming Certificate for $\mathsf{RealApartnessLocator}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealApartnessLocator}^{\uparrow}$ packet records the finite located-apartness locator surface needed when Real and Completion consumers compare two displayed real names without asking for trichotomy. It sits after the apartness witness surface of chapter 304, the located-real boundary of **??**, the dyadic tolerance core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a locator interface for positive apartness evidence; it does not assert quotient real equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7270.1 (Real apartness locator carrier)**.** *A* $\mathsf{RealApartnessLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, A, D, S, R, O, G, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *request row, exposing the two real-name sides and the located comparison request read by the consumer.*
2. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *witness row, carrying the positive apartness evidence made available to the locator.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that fixes the positive dyadic gap scale used by the comparison.*
4. *S is the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the two real names.*
5. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row computed from the displayed windows and dyadic tolerance.*
6. *O is the located-observation row that records which finite read of L, A, D, S, R produces the positive locator answer.*
7. *G is the positive gap row; it records the witnessed dyadic separation without turning the packet into an exhaustive order decision.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached only after L, A, D, S, R, O, G are displayed.*

9. *H stores componentwise* hsame *transport for the located request, apartness witness, dyadic tolerance, stream windows, regular readback, locator observation, gap, seal, replay, provenance, and naming rows.*
10. *C stores displayed* Cont *replay from a locator request through $L, A, D, S, R, O, G, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{RealApartnessLocator}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealApartnessLocator}^{\uparrow}}$ *row.*

The carrier has no coordinate for total order trichotomy, quotient real equality, a selected representative of a real name, countable choice, an independent completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7270.2 (Real apartness locator NameCert obligations)**.** *For every accepted* $\mathsf{RealApartnessLocator}^{\uparrow}$ *carrier*

$$Q = (L, A, D, S, R, O, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealApartnessLocator}^{\uparrow}}$ *surface consists exactly of carrier admission, located-real request exposure, apartness-witness exposure, dyadic tolerance exactness, paired stream-window exposure, regular-rational readback, located-observation display, positive-gap display, Real-seal routing, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7270.1. The analytic rows are L, A, D, S, R, O, G, E, and the structural rows are H, C, P, N.

The located-real row L supplies only the comparison request. The apartness row A supplies positive evidence, while the dyadic row D fixes the tolerance at which that evidence is read.

The stream windows S and regular readback R make the inspected comparison finite. The observation row O and positive gap row G then display the locator answer without adding a global order branch.

Finally E, H, C, P, N route, transport, replay, source, and name the same finite packet. Since no excluded equality, representative choice, countable-choice schedule, trichotomy, independent completion object, or ambient-completeness coordinate appears in Q, the local certificate obligations are exhausted by the stated rows. □

Theorem 7270.3 (Real apartness locator window exactness)**.** *Every accepted* $\mathsf{RealApartnessLocator}^{\uparrow}$ *locator answer is read through the displayed finite window route*

$$L, A, D, S, R, O, G.$$

The $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used by O are exactly the rows recorded in the same carrier as the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and* $\mathsf{ApartnessReal}^{\uparrow}$ *witness. No consumer may replace them by a quotient real-name comparison, hidden representative, or external trichotomy test.*

Proof. Start from the NameCert obligations of Definition 7270.2. They require the located request, apartness witness, dyadic tolerance, stream windows, regular readback, observation, and gap rows to be displayed in one carrier.

The observation row O is downstream of L, A, D, S, R. Thus the window and readback consumed by the locator are the same S and R stored with the tolerance row D and apartness row A.

The positive gap row G records the finite result of that route. Because the carrier contains no separate equality or order oracle, a consumer cannot replace the route by quotient real comparison, a hidden representative, or trichotomy. □

Theorem 7270.4 (Real apartness locator Real-seal handoff)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing or Completion-facing consumer of an accepted* $\mathsf{RealApartnessLocator}^{\uparrow}$ *packet may read the seal-facing row* E *only after the located request, apartness witness, dyadic tolerance, stream windows, regular readback, observation row, and positive gap row are visible. The handoff therefore factors through*

$$L, A, D, S, R, O, G, E, H, C, P, N$$

before the consumer reaches the Real seal.

Proof. Use window exactness, Definition 7270.3. It places L, A, D, S, R, O, G before any locator answer is public.

The seal-facing row E is a downstream row of the same carrier. It is reached only after the located-apartness answer has been displayed, so the Real-facing read cannot skip the dyadic tolerance, window, readback, observation, or gap rows.

The structural rows H, C, P, N preserve the same route. They do not create a selected representative or a completion endpoint, and hence the Real-seal handoff remains a finite NameCert route rather than an assertion of $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7270.5 (Real apartness locator nonescape)**.** *No accepted* $\mathsf{RealApartnessLocator}^{\uparrow}$ *packet exports trichotomy, quotient real equality, selected representatives, countable choice, an independent completion object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every exported read remains confined to the displayed rows* $L, A, D, S, R, O, G, E, H, C, P, N$ *and to their* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *structure.*

Proof. Project the carrier. The only analytic rows are the located request, apartness witness, dyadic tolerance, stream windows, regular readback, observation, positive gap, and seal-facing row.

Apply the Real-seal handoff theorem. It shows that even Real-facing and Completion-facing consumers reach the endpoint only through the displayed locator route.

The remaining rows transport, replay, package, and name the same route. Since none of the refused objects is a carrier coordinate or a structural row, it cannot escape from an accepted packet. □

Lean4 (statement) `BEDC.Derived.RealApartnessLocatorUp`

Closure status for $\mathsf{NameCert}_{\mathsf{RealApartnessLocator}^{\uparrow}}$.

Constructive story: A $\mathsf{RealApartnessLocator}^{\uparrow}$ packet is generated from a LocatedReal request row, an ApartnessReal witness row, a DyadicRatCore tolerance row, paired StreamName windows, paired RegSeqRat readback, a located observation row, a positive gap row, a Real seal-facing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealApartnessLocator}^{\uparrow}}$, seed)

Scope closed: Definition 7270.1, Definition 7270.2, Definition 7270.3, Definition 7270.4, and Definition 7270.5 seed the finite located-apartness locator route over LocatedReal, ApartnessReal, DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealApartnessLocator}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, independent completion objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-real request exposure, apartness-witness exposure, dyadic tolerance exactness, paired stream-window exposure, regular-rational readback, located-observation display, positive-gap display, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RealApartnessLocatorUp.

Chapter 7271

A Concrete Naming Certificate for $\mathsf{KoopmanOperator}^{\uparrow}$

Following Koopman and von Neumann on operator-theoretic dynamics, the $\mathsf{KoopmanOperator}^{\uparrow}$ packet records the observable-side pullback of a displayed dynamical system as finite NameCert data. It sits after the routed flow carrier of chapter 195, the continuous-map graph surface of chapter 130, the transfer-operator and Perron–Frobenius density routes of chapter 456 and chapter 5123, the mean-ergodic averaging route of chapter 1840, and the finite StreamName-to-RegSeqRat-to-Real readback chain of chapter 126, chapter 301, and chapter 38. The packet names a finite observable pullback route; it is not a host Hilbert-space operator, an invariant measure theorem, a selected spectral decomposition, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7271.1 (Koopman operator carrier)**.** *A* $\mathsf{KoopmanOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, T, F, O, W, R, E, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{DynSystem}^{\uparrow}$ *state-evolution row, naming the displayed source states and the single-step or finite-step transition being inspected.*
2. *T is the* $\mathsf{ContinuousMap}^{\uparrow}$ *transition row attached to the same displayed dynamical system.*
3. *F is the observable row, recording the finite graph values of the displayed observable on the target of T.*
4. *O is the Koopman pullback row, whose displayed value at a source state is read as the observable row F after the transition row T.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row through which the pulled-back observable is inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to those finite windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after X, T, F, O, W, R have been displayed.*
8. *A is the averaging or transfer-neighbour row, recording which reads may be compared with* $\mathsf{TransferOperator}^{\uparrow}$, $\mathsf{PerronFrobenius}^{\uparrow}$, *and* $\mathsf{MeanErgodic}^{\uparrow}$ *consumers without identifying the packet with any one of them.*
9. *H records componentwise* hsame *transport for the dynamical-system, transition, observable, pullback, window, readback, seal, neighbour, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through*

$$X, T, F, O, W, R \longmapsto E$$

and through the neighbour row A when an averaging or density-facing consumer is present.

11. *P is the* Pkg *provenance over* $\mathsf{KoopmanOperator}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{TransferOperator}^{\uparrow}$, $\mathsf{PerronFrobenius}^{\uparrow}$, $\mathsf{MeanErgodic}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{KoopmanOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, F, O, W, R, E, A, H, C, P, N$. It has no coordinate for an ambient function space, selected invariant measure, spectral theorem, quotient observable equality, host integration, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KoopmanOperatorUp.KoopmanOperatorTasteGate single carrier alignment`

Theorem 7271.2 (Koopman operator NameCert obligations)**.** *For every accepted* $\mathsf{KoopmanOperator}^{\uparrow}$ *carrier*

$$K = (X, T, F, O, W, R, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KoopmanOperator}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dynamical-system row, continuous transition row, observable row, pullback row, observation windows, regular-rational readback, Real seal, neighbour route, transport, replay, provenance, and local naming;*
2. *pullback exactness, requiring each O read to be the displayed observable row F consumed after the transition row T on the same* $\mathsf{DynSystem}^{\uparrow}$ *state row X;*
3. *readback ordering, requiring W and R to be exposed before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is available;*
4. *neighbour separation, requiring the* $\mathsf{TransferOperator}^{\uparrow}$, $\mathsf{PerronFrobenius}^{\uparrow}$, *and* $\mathsf{MeanErgodic}^{\uparrow}$ *rows in A to remain comparison or averaging consumers rather than replacements for the observable pullback row;*
5. *structural stability under the displayed* hsame, Cont, Pkg, *and local* NameCert *rows.*

No Koopman-operator obligation is stored outside these rows.

Proof. Project the accepted carrier. The tuple lists the dynamical-system row, transition row, observable row, pullback row, observation-window and readback rows, terminal seal, neighbour row, and structural rows.

Pullback exactness is local. Row O is admitted only as the observable row F read after the displayed transition T on the same state-evolution row X, so the packet has no coordinate for an ambient function-space equality.

Readback ordering then follows the StreamName and RegSeqRat rows. The finite window W is inspected before the regular-rational row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is downstream of both.

Finally read the neighbour row A. It permits comparison with transfer, Perron–Frobenius, and mean-ergodic consumers while keeping the observable-side pullback distinct. Transport, replay, provenance, and local naming preserve that same finite route and add no invariant-measure theorem, spectral decomposition, host integration, or ambient completeness principle. □

Theorem 7271.3 (Koopman operator dynamics-observable route)**.** *Every observable-facing read of an accepted* $\mathsf{KoopmanOperator}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DynSystem}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

More explicitly, the consumer must expose the state-evolution row X, transition row T, observable row F, pullback row O, observation window W, and readback row R before the terminal seal E or any neighbour comparison row A is consumed. The packet exports no invariant measure, density pushforward, selected spectral datum, quotient observable equality, host integration theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 7271.2. They place every accepted consumer read inside the displayed carrier rows $X, T, F, O, W, R, E, A, H, C, P, N$.

Read the dynamics-to-observable route first. The $\mathsf{DynSystem}^{\uparrow}$ row X and $\mathsf{ContinuousMap}^{\uparrow}$ row T determine where the observable is sampled, and the row O records that the observable value is pulled back from F along that transition.

The numerical readback is downstream. The finite $\mathsf{StreamName}^{\uparrow}$ window W feeds the $\mathsf{RegSeqRat}^{\uparrow}$ row R, and only then can the terminal $\mathsf{Real}^{\uparrow}$ seal E be read.

The neighbour row A cannot reverse the route. It may point to transfer, Perron–Frobenius, or mean-ergodic consumers, but those rows do not replace X, T, F, O, W, R, E by a measure-theoretic, spectral, quotient, or host-completeness object. Therefore the displayed dynamics-observable route exhausts the accepted packet. □

Falsifiable prediction: A $\mathsf{KoopmanOperator}^{\uparrow}$ consumer that reads a RealUp seal or an averaging neighbour without displaying the DynSystem transition, ContinuousMap row, observable pullback row, StreamName window, and RegSeqRat readback refutes the carrier of Definition 7271.1.

Independence witness: dynsystem, continuousmap, transferoperator, perronfrobenius, mean-ergodic, streamname, regseqrat, real: $\mathsf{KoopmanOperator}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state evolution, transition, observable pullback, finite observation windows, regular-rational readback, Real sealing, neighbour separation, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KoopmanOperator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KoopmanOperator}^{\uparrow}$ packet is generated from DynSystem state-evolution rows, ContinuousMap transition rows, observable pullback rows, StreamName windows, RegSeqRat readback, a RealUp seal, transfer and mean-ergodic neighbour rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KoopmanOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7271.1, Definition 7271.2, and Definition 7271.3 seed the finite observable-side dynamics route over DynSystem, ContinuousMap, StreamName, RegSeqRat, Real, transfer, Perron–Frobenius, and mean-ergodic rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KoopmanOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close invariant measures, density pushforwards, spectral theory, quotient observable equality, host integration, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pullback exactness, readback ordering, neighbour separation, transport, replay, provenance, and local naming for BEDC.Derived.KoopmanOperatorUp.

Chapter 7272

A Concrete Naming Certificate for $\mathsf{LocatedUniformity}^{\uparrow}$

Following Bourbaki and Kelley on uniform structures, and Bishop–Bridges on located metric comparison and regular real names, the $\mathsf{LocatedUniformity}^{\uparrow}$ packet records the finite interface where metric locatedness is read as a uniform-entourage basis before any Cauchy-filter, stream-name, regular-rational, or real-seal consumer may use it. It sits between the ambient uniform-space surface of chapter 339, the real-entourage route of chapter 1624, the regular-Cauchy entourage route of chapter 1628, the Cauchy filter boundary of chapter 333, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located compact consumer surface of chapter 1488. The packet names a located uniformity as displayed finite data; it does not select a completion point, quotient filters, import an open-cover compactness principle, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7272.1 (Located uniformity carrier)**.** *A* $\mathsf{LocatedUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, A, E, F, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, naming the* $\mathsf{Met}^{\uparrow}$ *or real-facing metric source whose entourage reads are admitted by the packet.*
2. *A is the located comparison row, exposing finite inside-or-apart comparison data for point-pairs and positive rational radii.*
3. *E is the entourage-basis row, recording the displayed basis used by* $\mathsf{UniformSpace}^{\uparrow}$*,* $\mathsf{RealUniformStructure}^{\uparrow}$*, and* $\mathsf{RegularCauchyUniformity}^{\uparrow}$ *consumers.*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row, available only after M, A, E have been displayed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row read by filter and completion consumers.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the windows named by W.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located comparison, entourage basis, Cauchy-filter handoff, stream windows, and regular rational readback are visible.*
8. *H records componentwise* hsame *transport for $M, A, E, F, W, Q, R, C, P, N$.*

9. *C records displayed* Cont *replay from a metric locatedness request through the entourage basis, Cauchy-filter handoff, StreamName windows, RegSeqRat readback, Real seal, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{RegularCauchyUniformity}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCompact}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a hidden completion point, quotient filter equality, host uniform-space equality, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7272.2 (Located uniformity NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUniformity}^{\uparrow}$ *carrier*

$$L = (M, A, E, F, W, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedUniformity}^{\uparrow}}$ *surface consists exactly of metric source admission, located comparison admission, entourage-basis admission, Cauchy-filter handoff, StreamName window admission, RegSeqRat readback, Real seal nonescape, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.*

Proof. Project the carrier of Definition 7272.1. The analytic rows are exactly M, A, E, F, W, Q, R, and the structural rows are H, C, P, N.

The metric source and located comparison rows are read first. They expose the finite point-pair and rational-radius comparisons from which the entourage basis row E may be inspected by $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, and $\mathsf{RegularCauchyUniformity}^{\uparrow}$ consumers.

The Cauchy-filter and completion-facing rows are downstream. A consumer reaches F only after the located entourage basis is visible, then reads W as finite windows, Q as regular rational readback, and R as the terminal real seal.

Finally H, C, P, N transport, replay, package, and name the same route. Since no excluded host object is a carrier coordinate, these rows exhaust the local NameCert obligations. □

Theorem 7272.3 (Located uniformity Cauchy-filter handoff)**.** *Every Cauchy-filter or completion consumer of an accepted* $\mathsf{LocatedUniformity}^{\uparrow}$ *carrier receives the located uniformity only through the finite route*

$$M, A, E, F, W, Q, R, H, C, P, N.$$

In particular, the $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row is consumed after the metric located comparison and entourage basis rows, and before the StreamName, RegSeqRat, and Real-seal rows. The handoff exports no quotient filter equality, selected completion point, countable-choice schedule, or ambient completeness principle.*

Proof. Begin with a Cauchy-filter or completion read of the accepted packet. The carrier first exposes the metric source M, the located comparison row A, and the entourage-basis row E.

The handoff row F is the only Cauchy-filter coordinate of the carrier. The consumer may inspect F only along the route already displaying M, A, E.

The read then proceeds through W, Q, R: finite stream windows, regular rational readback, and the terminal real seal. Componentwise transport and continuation replay preserve the same order, while P and N record provenance and local naming.

Because no quotient filter, selected completion point, choice schedule, or ambient completeness coordinate occurs in the packet, the consumer receives exactly the displayed finite handoff. □

Theorem 7272.4 (Located uniformity Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedUniformity}^{\uparrow}$ *carrier factors through the displayed located-uniformity route*

$$M, A, E, F, W, Q, R, H, C, P, N.$$

Thus the terminal seal row R *is reached only after metric source admission, located comparison, entourage-basis admission, Cauchy-filter handoff, finite StreamName windows, and RegSeqRat readback. It does not export host real equality, quotient stream equality, quotient filter equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 7272.2 to identify the complete local obligation surface. The route to the real seal contains the source, comparison, entourage, filter, window, and rational-readback rows before R.

Next apply the handoff theorem Definition 7272.3. It fixes the order in which Cauchy-filter and completion consumers may read the packet, so the terminal real seal cannot be reached from an unlisted source.

The structural rows preserve this route without adding host data: H transports the displayed coordinates, C replays the same finite path, P records only the named sibling packets, and N names the local certificate. Hence the real-facing read is a finite seal boundary, not a quotient, selection, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedUniformity}^{\uparrow}$ packet is generated from a metric source row, located comparison row, entourage-basis row, CauchyFilter handoff row, StreamName finite windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7272.1, Definition 7272.2, Definition 7272.3, and Definition 7272.4 seed the located-uniformity interface from metric locatedness to uniform, Cauchy-filter, StreamName, RegSeqRat, and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected completion points, open-cover compactness, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove the located comparison, Cauchy-filter handoff, Real seal nonescape, transport, replay, provenance, and local naming obligations.

Chapter 7273

A Concrete Naming Certificate for $\mathsf{DyadicIntervalBisection}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicIntervalBisection}^{\uparrow}$ packet records the finite act of bisecting a dyadic interval before any infinite branch or real-completion argument is available. It sits between the dyadic midpoint arithmetic of chapter 445, the arithmetic carrier of chapter 291, the finite located-real interval route of chapter 5546, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite bisection ledger; it does not select an infinite branch, construct a Dedekind cut, assert trichotomy, quotient reals, or close ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7273.1 (Dyadic interval bisection carrier)**.** *A* $\mathsf{DyadicIntervalBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, R, M, S, W, J, H, C, P, N)$$

with the following displayed rows:

1. *L is the left dyadic endpoint row.*
2. *R is the right dyadic endpoint row.*
3. *M is the midpoint row consumed from the dyadic midpoint certificate and checked in* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
4. *S is the branch-choice row, recording whether the finite bisection retains the left half, the right half, or both halves as named subintervals.*
5. *W is the width-budget row, recording the dyadic width before and after the bisection.*
6. *J is the nestedness ledger, recording that every retained subinterval has endpoints between L and R and is read as a subinterval of the source packet.*
7. *H is the componentwise* hsame *transport row over L, R, M, S, W, J.*
8. *C is the displayed* Cont *replay row for the finite bisection step.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalBisection}^{\uparrow}$*, the dyadic midpoint certificate of chapter 445,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalBisection}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite branch selector, Dedekind cut, real trichotomy, quotient-real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Theorem 7273.2 (Dyadic interval bisection NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalBisection}^{\uparrow}$ *carrier* $B = (L, R, M, S, W, J, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalBisection}^{\uparrow}}$ *surface consists exactly of endpoint exposure through* L, R*, midpoint exposure through* M*, branch-choice exposure through* S*, width-budget exposure through* W*, nestedness exposure through* J*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Every downstream finite located-interval consumer must read those rows before it can hand bisection data to $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalBisectionUp.DyadicIntervalBisectionNamecertObligations`

Proof. Project the carrier of Definition 7273.1. Its rows are exactly $L, R, M, S, W, J, H, C, P, N$, so endpoint, midpoint, branch, width, and nestedness data are all displayed before any consumer can read the bisection.

The midpoint row is checked against the dyadic midpoint certificate and $\mathsf{DyadicRatCore}^{\uparrow}$, while S and J record which finite subintervals are retained. The transport row H and replay row C preserve those finite rows componentwise.

Finally read the provenance and local naming rows P, N. They identify the route into $\mathsf{LocatedRealIntervalBisectio}$ $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ without adding an infinite selector, cut object, quotient equality, trichotomy decision, or completeness witness. Hence the displayed rows exhaust the local NameCert obligations. □

Theorem 7273.3 (Dyadic interval bisection nested width)**.** *Every retained subinterval of an accepted* $\mathsf{DyadicIntervalBisection}^{\uparrow}$ *packet is nested inside the source interval and has dyadic width bounded by the width-budget row* W*. In the exact bisection case, the retained width row is read as one half of the source width through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint calculation.*

Proof. Use the endpoint rows L, R and midpoint row M from Definition 7273.1. The midpoint is a dyadic rational row, so the two candidate subintervals have dyadic endpoints already visible in the packet.

Read the branch-choice row S together with the nestedness ledger J. These rows say that a retained left or right half uses the source endpoint and the midpoint, hence every retained endpoint lies between the original endpoints.

The width-budget row W records the source width and the retained width. Since the midpoint row is checked in $\mathsf{DyadicRatCore}^{\uparrow}$, the exact bisection case reads the retained width as half the source width, while the structural rows H, C, P, N preserve and name that finite calculation for downstream consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalBisection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicIntervalBisection}^{\uparrow}$ packet is generated from left and right dyadic endpoint rows, a dyadic midpoint row, a branch-choice row, a width-budget row, a nestedness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7273.1, Definition 7273.2, and Definition 7273.3 seed the finite dyadic bisection carrier, local NameCert surface, and nested-width ledger used by located real interval and regular rational readback packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalBisection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, Dedekind cuts, trichotomy, quotient reals, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic midpoint exactness, branch-row stability, nested-width preservation, readback handoff, and nonescape for BEDC.Derived.DyadicIntervalBisectionUp.

Chapter 7274

A Concrete Naming Certificate for $\mathsf{BeltramiKleinDisk}^{\uparrow}$

Following Beltrami, Klein, and the projective disk model of hyperbolic geometry, the $\mathsf{BeltramiKleinDisk}^{\uparrow}$ packet records a chord-geodesic disk reading as finite NameCert data. It sits beside the disk carrier of chapter 377, the metric surfaces of chapter 6209 and chapter 3474, the boundary-geodesic route of chapter 3491, and the terminal real-name seal of chapter 38. The packet names the projective comparison surface of the disk model; it is not a completed hyperbolic plane, quotient ideal boundary, host projective space, selected geodesic family, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7274.1 (Beltrami–Klein disk carrier)**.** *A* $\mathsf{BeltramiKleinDisk}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, P, K, G, M, Q, R, H, C, S, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate row for the displayed interior disk points and boundary-facing observations.*
2. *P is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *comparison row on the same displayed disk observations.*
3. *K is the projective chord row, recording the finite chord segment through which the Beltrami–Klein reading treats geodesics as straight disk chords.*
4. *G is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *boundary-incidence row attached to the displayed chord endpoints.*
5. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row used to compare the chord reading with the Poincare-disk metric surface.*
6. *Q is the refusal row excluding a completed projective plane, quotient ideal-boundary equality, selected global geodesics, host cross-ratio semantics, and physical observer trajectories.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed metric or incidence comparison.*
8. *H records componentwise* hsame *transport for disk coordinates, Poincare comparison, chord rows, boundary incidence, metric reads, refusal rows, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay through*

$$D, P, K, G, M, Q \longmapsto R.$$

10. *S is the* Pkg *provenance over* $\mathsf{BeltramiKleinDisk}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BeltramiKleinDisk}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, P, K, G, M, Q, R, H, C, S, N$. It has no coordinate for a completed projective model, quotient boundary object, selected infinite geodesic family, host analytic cross-ratio, physical observer law, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7274.2 (Beltrami–Klein disk NameCert obligations)**.** *For every accepted* $\mathsf{BeltramiKleinDisk}^{\uparrow}$ *carrier*

$$B = (D, P, K, G, M, Q, R, H, C, S, N),$$

the local $\mathsf{NameCert}_{\mathsf{BeltramiKleinDisk}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for disk coordinates, Poincare metric comparison, projective chord rows, geodesic-boundary incidence, hyperbolic metric reads, refusal rows, Real seals, transport, replay, provenance, and local naming;*
2. *chord-geodesic exactness, requiring K to be read only over the displayed disk row D and boundary-incidence row G;*
3. *Poincare comparison exactness, requiring the Poincare metric row P and hyperbolic metric row M to be displayed before any Real-facing comparison R is consumed;*
4. *refusal preservation, requiring Q to stay visible whenever a consumer asks for completed projective geometry, quotient boundary equality, selected global geodesics, host cross-ratio semantics, or physical observer trajectories;*
5. *structural stability under H, C, S, N.*

No Beltrami–Klein disk obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 7274.1. The packet exposes the disk row D, Poincare comparison row P, chord row K, boundary-incidence row G, hyperbolic metric row M, refusal row Q, Real seal R, and structural rows H, C, S, N.

Chord-geodesic exactness is finite. The row K can be read only as a displayed chord over the disk observations in D and the boundary-incidence evidence in G, so no selected global geodesic family or host projective plane enters the packet.

The comparison with the Poincare disk model is downstream of the metric rows. Rows P and M must both be visible before R is read as a Real-facing metric or incidence comparison.

Finally the refusal row remains attached under transport and replay. The structural rows preserve the same finite route and add no completed hyperbolic plane, quotient ideal boundary, host cross-ratio semantics, physical observer law, or ambient completeness principle. □

Theorem 7274.3 (Beltrami–Klein disk Poincare comparison route)**.** *Every accepted* $\mathsf{BeltramiKleinDisk}^{\uparrow}$ *comparison with the Poincare disk model factors through the finite route*

$$\mathsf{UnitDisk}^{\uparrow},\ \mathsf{PoincareDiskMetric}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{HyperbolicGeodesicBoundary}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

More explicitly, the consumer must expose disk coordinates D, Poincare metric comparison P, chord row K, geodesic-boundary incidence G, hyperbolic metric read M, and refusal row Q before any terminal Real seal R is consumed. The packet exports no completed projective model, quotient ideal-boundary equality, selected global geodesics, host analytic cross-ratio, physical observer trajectory, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 7274.2. They keep every accepted comparison inside the displayed rows $D, P, K, G, M, Q, R, H, C, S, N$.

Read the disk-model data first. The $\mathsf{UnitDisk}^{\uparrow}$ row D supplies the displayed interior and boundary-facing observations, while K records the projective chord only over that finite disk surface.

The comparison rows then attach the Poincare and hyperbolic metric readings. Row P supplies the Poincare-disk metric surface, row M supplies the hyperbolic metric read, and row G keeps boundary incidence visible before the Real seal R is inspected.

The refusal row Q blocks the common overreadings of the projective model. Transport, replay, provenance, and local naming preserve the displayed route, so the comparison remains a finite disk-model packet rather than a completed projective, quotient-boundary, host analytic, physical, or completeness claim. □

Falsifiable prediction: A $\mathsf{BeltramiKleinDisk}^{\uparrow}$ consumer that reaches a RealUp comparison without displaying UnitDisk coordinates, the PoincareDiskMetric row, the chord-geodesic row, HyperbolicGeodesicBoundary incidence, HyperbolicMetric comparison, and the refusal row refutes the carrier of Definition 7274.1.

Independence witness: unitdisk, poincare-disk-metric, hyperbolic-metric, hyperbolic-geodesic-boundary, real: $\mathsf{BeltramiKleinDisk}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries disk coordinates, projective chord rows, Poincare comparison, hyperbolic metric reads, boundary incidence, refusal, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BeltramiKleinDisk}^{\uparrow}}$.

Constructive story: A $\mathsf{BeltramiKleinDisk}^{\uparrow}$ packet is generated from UnitDisk coordinates, PoincareDiskMetric comparison rows, projective chord rows, HyperbolicGeodesicBoundary incidence, HyperbolicMetric reads, refusal rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BeltramiKleinDisk}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7274.1, Definition 7274.2, and Definition 7274.3 seed the finite projective disk-model comparison route over UnitDisk, PoincareDiskMetric, HyperbolicMetric, HyperbolicGeodesicBoundary, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BeltramiKleinDisk}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed projective disk geometry, quotient ideal-boundary equality, selected global geodesics, host analytic cross-ratio semantics, physical observer trajectories, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, chord-geodesic exactness, Poincare comparison exactness, boundary-incidence exposure, refusal preservation, transport, replay, provenance, and local naming for BEDC.Derived.BeltramiKleinDiskUp.

Chapter 7275

A Concrete Naming Certificate for $\mathsf{MetricRetraction}^{\uparrow}$

Following Borsuk and Dugundji on retractions and constructive metric topology, the $\mathsf{MetricRetraction}^{\uparrow}$ packet records the finite BEDC surface for an idempotent retraction on a displayed metric carrier. It sits after the metric source of chapter 57, the continuous-map route of chapter 130, the complete-service surface of chapter 128, the terminal real comparison seal of chapter 38, and the stronger Lipschitz retraction packet of chapter 5915. The packet names the general idempotent continuous metric retraction route; it does not assert a Lipschitz constant, selected nearest point, quotient subspace equality, ambient completeness of the source, or host fixed-point theorem.

Definition 7275.1 (Metric retraction carrier)**.** *A* $\mathsf{MetricRetraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, A, G, I, T, M, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *source row supplying the finite distance witnesses used by the retraction request.*
2. *A is the displayed subcarrier row, recording membership, inclusion into X, and the inherited distance reads inspected by the packet.*
3. *G is the retraction graph row, whose source observations lie in X and whose values are admitted by A.*
4. *I is the identity-on-subcarrier row, requiring every displayed point already admitted by A to replay through G as the same subcarrier point.*
5. *T is the idempotence row, recording that a second read through the same graph contributes no new value row after the first retraction read.*
6. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row available only as a downstream consumer service for the displayed subcarrier route.*
7. *E is the* $\mathsf{ContinuousMap}^{\uparrow}$ *replay row tying the graph G to the finite continuity route used by metric consumers.*
8. *H records componentwise* hsame *transport for the metric source, subcarrier, graph, identity, idempotence, complete-service, continuous-map replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a retraction request through $X, A, G, I, T, M, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricRetraction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LipschitzRetraction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricRetraction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a Lipschitz constant, selected best approximation, quotient subspace equality, ambient source completeness theorem, host real equality, or global fixed-point theorem.

Theorem 7275.2 (Metric retraction NameCert obligations)**.** *For every accepted* $\mathsf{MetricRetraction}^{\uparrow}$ *carrier $R = (X, A, G, I, T, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricRetraction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, metric-source visibility through X, subcarrier admission and inherited-distance visibility through A, graph admission through G, identity-on-subcarrier replay through I, idempotent replay through T, complete-metric service access through M, continuous-map replay through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7275.1. The displayed tuple lists exactly the metric source, subcarrier, graph, identity, idempotence, complete-service, continuous-map, transport, replay, provenance, and naming rows.

The source-facing obligations are exhausted by X, A, G, I, T. The metric row supplies distance witnesses, the subcarrier row supplies admissible values, the graph row supplies finite retraction observations, the identity row fixes points already in the subcarrier, and the idempotence row prevents a repeated graph read from adding a second value.

The consumer-facing obligations are exhausted by M, E. A complete-space consumer can inspect only the displayed $\mathsf{CompleteMetric}^{\uparrow}$ service row, and a continuity consumer can inspect only the $\mathsf{ContinuousMap}^{\uparrow}$ replay attached to the same graph.

Finally H, C, P, N transport, replay, package, and name this same finite route. Since the carrier has no Lipschitz constant, selected nearest point, quotient equality, ambient source-completeness theorem, host real equality, or global fixed-point coordinate, no such obligation is present in the local certificate. □

Theorem 7275.3 (Metric retraction idempotent handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{MetricRetraction}^{\uparrow}$ *carrier factors through the finite route*

$$X, A \longmapsto G, I, T \longmapsto E, M \longmapsto H, C, P, N.$$

Thus source distances are read in the metric row X, subcarrier values are admitted through A, the retraction graph and identity rows are checked before any continuous-map or complete-service handoff, and idempotence is recorded by the displayed row T. The handoff is the general metric retraction surface; the stronger $\mathsf{LipschitzRetraction}^{\uparrow}$ *packet may consume it, but this packet exports no Lipschitz constant, selected projection, quotient subspace equality, or ambient completeness claim.*

Proof. Start with the NameCert obligations of Definition 7275.2. Any consumer first receives the metric source row X and the subcarrier row A, since these are the only rows that can supply source distances and admitted retraction values.

The retraction data then pass through G, I, T. The graph row records finite observations, the identity row verifies that subcarrier points replay as themselves, and the idempotence row records that replaying the graph again stays on the same displayed subcarrier value.

Only after those rows are displayed can a consumer read E, M. The continuous-map row is induced by the same graph route, and the complete-metric service row is a displayed downstream service rather than an ambient completeness theorem for the source.

Transport, replay, provenance, and local naming are then carried by H, C, P, N. These rows preserve the factorization but add no Lipschitz constant, selected projection, quotient equality, host equality, or classical branch. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricRetraction}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricRetraction}^{\uparrow}$ packet is generated from a Metric source row, a displayed subcarrier row, a retraction graph, an identity-on-subcarrier row, an idempotence row, a CompleteMetric service row, a ContinuousMap replay row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricRetraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7275.1, Definition 7275.2, and Definition 7275.3 seed the finite metric retraction route over source, subcarrier, graph, identity, idempotence, continuous-map replay, and complete-service rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricRetraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lipschitz constants, selected nearest points, quotient subspace equality, ambient source completeness, global fixed-point existence, Lean verification, bridge checking, or host real equality.

Upgrade path: Obligation closure requires checked carrier admission, metric-source visibility, subcarrier admission, graph admission, identity replay, idempotent replay, continuous-map replay, complete-metric service access, transport, replay, provenance, and local naming for BEDC.Derived.MetricRetractionUp.

Chapter 7276

A Concrete Naming Certificate for $\mathsf{DyadicCauchyApartness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicCauchyApartness}^{\uparrow}$ packet records a positive separation witness between regular Cauchy real names as finite BEDC NameCert data. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located real apartness boundary of chapter 6450. The packet supplies a constructive apartness boundary for Real and Completion consumers without importing quotient stream equality, trichotomy, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7276.1 (Dyadic Cauchy apartness carrier)**.** *A* $\mathsf{DyadicCauchyApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, W_X, W_Y, D, R_X, R_Y, A, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two regular Cauchy name rows whose observations are read only through displayed finite windows.*
2. *W_X and W_Y are the* $\mathsf{StreamName}^{\uparrow}$ *window rows inspected for the two names at the separating precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-bound row; it records the dyadic radius and strict positive gap used by the apartness witness.*
4. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from the two stream windows and the dyadic tolerance ledger.*
5. *A is the* $\mathsf{LocatedRealApartness}^{\uparrow}$ *handoff row reading the displayed positive gap as located apartness evidence.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the two readbacks and the positive dyadic gap have been displayed.*
7. *H records componentwise* hsame *transport for the two names, windows, dyadic gap, readbacks, apartness handoff, Real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a precision request through $W_X, W_Y, D, R_X, R_Y, A, E$.*

9. *P is the* Pkg *provenance over* $\mathsf{DyadicCauchyApartness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRealApartness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyApartness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these finite rows. It has no coordinate for quotient streams, a selected limit, real trichotomy, host real equality, or an ambient completeness principle.

Theorem 7276.2 (Dyadic Cauchy apartness NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyApartness}^{\uparrow}$ *carrier*

$$K = (X, Y, W_X, W_Y, D, R_X, R_Y, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCauchyApartness}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular Cauchy names, paired* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-gap exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback stability,* $\mathsf{LocatedRealApartness}^{\uparrow}$ *handoff compatibility,* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7276.1. The analytic rows are the two names X, Y, the two finite windows W_X, W_Y, the positive dyadic row D, the two readbacks R_X, R_Y, the apartness handoff A, and the Real seal E.

The positive witness is forced through D. Since D is the only row carrying a strict dyadic gap, no apartness consumer can read a separation assertion before the finite windows and dyadic positive-bound data have been displayed.

The regular readbacks R_X, R_Y attach the two inspected windows to the regular rational source surface, and A reads exactly that displayed gap as located real apartness evidence. The Real seal E is downstream of those rows rather than a source of equality or trichotomy.

Finally H, C, P, N transport, replay, source, and name the same route. No further coordinate is present in the carrier, so the listed rows exhaust the local NameCert obligations. □

Theorem 7276.3 (Dyadic Cauchy apartness located-comparison boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{DyadicCauchyApartness}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{LocatedRealApartness}^{\uparrow} \longmapsto \mathsf{Real}$$

The consumer may use the displayed positive dyadic gap as located apartness evidence, but it cannot extract quotient stream equality, trichotomy, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Begin with a Real or Completion consumer of the accepted packet. The carrier exposes no comparison row before the two finite stream windows and the positive dyadic ledger have been read.

The consumer then obtains R_X and R_Y from the displayed windows. These rows keep the comparison attached to regular rational readback rather than to a quotient of completed streams.

Next the row A turns the same positive dyadic separation into located apartness evidence, and the row E seals the route for Real-facing consumers. The seal is therefore reached only after the window, gap, and readback rows have been displayed.

The structural rows H, C, P, N preserve this ordering under transport, replay, provenance, and local naming. Since the carrier has no row for the excluded host objects, the consumer receives only the stated finite located-comparison boundary. □

Theorem 7276.4 (Dyadic Cauchy apartness window induction)**.** *Let*

$$K = (X, Y, W_X, W_Y, D, R_X, R_Y, A, E, H, C, P, N)$$

be an accepted $\mathsf{DyadicCauchyApartness}^{\uparrow}$ *carrier. If the paired finite windows* W_X, W_Y *are extended by one displayed* $\mathsf{StreamName}^{\uparrow}$ *observation and the positive dyadic gap row* D *transports through the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_X, R_Y*, then the same* $\mathsf{DyadicCauchyApartness}^{\uparrow}$ *packet remains accepted and the located-apartness handoff still reaches the* $\mathsf{Real}^{\uparrow}$ *seal row* E*.*

Proof. Proceed by finite induction on the displayed paired window extension. The base case is the accepted carrier itself, where $W_X, W_Y, D, R_X, R_Y, A, E$ already expose the positive dyadic gap, the two regular readbacks, the located-apartness handoff, and the Real seal.

For the successor step, append one displayed $\mathsf{StreamName}^{\uparrow}$ observation to each of W_X and W_Y. The transported positive dyadic gap remains the row D, and its two readbacks remain the corresponding R_X and R_Y rows after the window extension.

The handoff row A reads that same transported positive gap as located apartness evidence. Since the extension changes only displayed finite windows and their readbacks, A still feeds the terminal seal row E.

Finally H, C, P, N transport, replay, source, and name the enlarged finite route. Thus the accepted packet is stable under the displayed one-step window extension, and the Real-facing consumer still receives the located-apartness handoff only through E. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyApartness}^{\uparrow}$ packet is generated from two regular Cauchy name rows, paired StreamName windows, a DyadicRatCore positive-gap row, RegSeqRat readbacks, a LocatedRealApartness handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicCauchyApartness}^{\uparrow}}$, seed)

Scope closed: Definition 7276.1, Definition 7276.2, Definition 7276.3, and Definition 7276.4 seed the finite constructive apartness boundary over dyadic positive gaps, stream windows, regular rational readbacks, located apartness, window extension, and Real sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicCauchyApartness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, trichotomy, selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Scoped treatment asks for checked carrier admission, dyadic positive-gap exactness, paired window readback, located-apartness compatibility, Real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 7277

A Concrete Naming Certificate for $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$

Following Bishop and Bridges on separated constructive completions, the $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$ packet records the finite L10 surface where a located Cauchy-filter completion comparison is allowed to read uniqueness only after the separated completion route, completion uniqueness ledger, stream windows, regular rational readback, dyadic tolerance data, and terminal real seal have all been displayed. It sits over the located filter boundary of chapter 1661, the separated-completion boundary of chapter 1612, the completion-uniqueness ledger of chapter 1463, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the located uniqueness boundary; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient completion equality, selected limits, or host equality of completed points.

Definition 7277.1 (Located completion uniqueness carrier)**.** *A* $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, S, Q, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *source row, exposing the located tail and basis-refinement data that any completion comparison must first read.*
2. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row, recording that equality-facing completion reads pass through separated zero-distance evidence rather than host equality.*
3. *Q is the* $\mathsf{CompletionUniqueness}^{\uparrow}$ *comparison ledger for the two located completion presentations over the same displayed source route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by the comparison ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those windows.*
6. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the two located tails at the requested precision.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, S, Q, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for $F, S, Q, W, R, D, E, C, P, N$.*

9. *C records displayed* Cont *replay from a located completion uniqueness request back through the same filter, separated-completion, completion-uniqueness, window, readback, tolerance, and seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7277.2 (Located completion uniqueness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$ *carrier*

$$U = (F, S, Q, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompletionUniqueness}^{\uparrow}}$ *surface consists exactly of located Cauchy-filter source admission, separated-completion boundary admission, completion-uniqueness ledger exposure, StreamName window admission, RegSeqRat readback, DyadicRatCore tolerance comparison, Real seal nonescape, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.*

Proof. Project the carrier of Definition 7277.1. The analytic rows are exactly F, S, Q, W, R, D, E, and the structural rows are H, C, P, N.

The located source and separated boundary rows are read first. Row F exposes the located filter data, while row S forces equality-facing completion reads to pass through the separated completion boundary.

The uniqueness comparison is then a displayed finite ledger. Row Q records the completion-uniqueness comparison, and rows W, R, D provide the stream windows, regular rational readback, and dyadic tolerance data consumed by that ledger.

Only after those rows are visible may the route reach the real seal E. The rows H, C, P, N transport, replay, source, and name the same route, so the local certificate cannot export quotient completion equality, selected representatives, host equality, countable choice, or ambient completeness. □

Theorem 7277.3 (Located completion uniqueness Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{LocatedCauchyFilter}^{\uparrow},\ \mathsf{SeparatedCompletion}^{\uparrow},\ \mathsf{CompletionUniqueness}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow}$$

Thus located completion uniqueness is available only as a displayed NameCert route through located filter data, separated completion, the completion uniqueness ledger, finite windows, regular readback, and dyadic tolerances. The packet exports no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient completion equality, selected limit, host equality of completed points, or countable-choice schedule.*

Proof. Use Definition 7277.2 to identify the complete local obligation surface. A real-facing read must first consume F, S, Q, W, R, D before the seal row E is available.

The separated and uniqueness rows are both visible. Row S supplies the separated completion boundary, and row Q supplies the completion uniqueness ledger over the same located route rather than replacing it by a quotient object.

The window, readback, and tolerance rows make the comparison finite. Rows W, R, D expose the StreamName, RegSeqRat, and DyadicRatCore data used by the ledger, after which E is only a terminal seal.

Finally H, C, P, N preserve that route without adding host data. Since no excluded object is a carrier coordinate, every exported real-facing read remains inside the displayed located completion uniqueness boundary. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$ uniqueness read must expose a $\mathsf{LocatedCauchyFilter}^{\uparrow}$ source row, a $\mathsf{SeparatedCompletion}^{\uparrow}$ boundary row, a $\mathsf{CompletionUniqueness}^{\uparrow}$ ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: locatedcauchyfilter, separatedcompletion, completionuniqueness, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the located filter source, separated completion boundary, completion uniqueness ledger, finite windows, regular readback, dyadic tolerance comparison, Real seal, transport, replay, provenance, and local naming while refusing quotient completion equality and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletionUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$ packet is generated from a LocatedCauchyFilter row, SeparatedCompletion boundary, CompletionUniqueness ledger, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompletionUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7277.1, Definition 7277.2, and Definition 7277.3 seed the located uniqueness boundary over located Cauchy filters, separated completions, completion uniqueness, finite stream windows, regular rational readback, dyadic tolerances, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompletionUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient completion equality, selected limits, host equality of completed points, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located filter exposure, separated completion boundary, completion uniqueness ledger exactness, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance comparison, Real seal nonescape, transport, replay, provenance, and local naming.

Chapter 7278

A Concrete Naming Certificate for $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the uniform-completion practice of Bourbaki and Kelley, the $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$ packet records the finite unit-map modulus route used by L10 completion consumers. It sits over the uniform-completion carrier of chapter 1473, the completion universal-property route of chapter 397, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal Real seal of chapter 38. The packet names the displayed modulus by which the unit map enters completion; it does not quotient Cauchy names, select representatives, import countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7278.1 (Uniform completion unit modulus carrier)**.** *A* $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, I, M, D, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source uniform-space row whose unit map is being read by a completion consumer.*
2. *I is the unit-map row from X into the displayed* $\mathsf{UniformCompletion}^{\uparrow}$ *boundary.*
3. *M is the modulus ledger assigning each requested uniform tolerance a finite dyadic control row.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the ledger M.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by M and checked against D.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed window and tolerance data.*
7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the readback row R is visible.*
8. *H records componentwise* hsame *transport for $X, I, M, D, W, R, S, C, P, N$.*
9. *C records displayed* Cont *replay from a unit-map request through the modulus ledger, dyadic tolerance, finite window, readback, seal, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, CompletionUniversalProperty $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionUnitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient completion equality, selected representatives, host uniform-space equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7278.2 (Uniform completion unit modulus NameCert obligations)**.** *For every accepted* $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$ *carrier*

$$U = (X, I, M, D, W, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCompletionUnitModulus}^{\uparrow}}$ *surface consists exactly of source uniform admission, unit-map admission, modulus-ledger exactness, dyadic tolerance admission, StreamName window admission, RegSeqRat readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7278.1. The analytic rows are X, I, M, D, W, R, S, and the structural rows are H, C, P, N.

The source row X and unit-map row I place the read inside the $\mathsf{UniformCompletion}^{\uparrow}$ and $\mathsf{CompletionUniversalProperty}^{\uparrow}$ corridor. The modulus row M is the only coordinate that answers a tolerance request, and it answers only by displaying the dyadic row D and the finite window row W.

The readback row R is downstream of M, D, W. Thus a completion consumer may read regular rational data only after the finite tolerance and window ledger is visible.

Finally the seal row S is downstream of R, while H, C, P, N transport, replay, package, and name the same route. Since no excluded host object appears as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7278.3 (Uniform completion unit modulus RegSeqRat route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$ *carrier factors through the finite route*

$$X, I, M, D, W, R, H, C, P, N.$$

The route first displays the unit map, the modulus ledger, the dyadic tolerance row, and the StreamName window row; it exports no quotient stream equality, selected Cauchy representative, countable-choice schedule, or host equality of completion points.

Proof. Use Definition 7278.2 to identify the accepted obligation surface. The only row with regular rational readback content is R.

The rows M, D, W are ordered before R by the carrier itself. They provide the displayed modulus, dyadic tolerance, and finite window needed for the readback, so a consumer cannot reach R from an unlisted stream coordinate or selected representative.

The structural rows H, C, P, N preserve that same route for transport, replay, provenance, and naming. Hence the RegSeqRat-facing read is exactly the displayed finite unit-modulus route. □

Theorem 7278.4 (Uniform completion unit modulus Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$ *carrier factors through the finite route*

$$X, I, M, D, W, R, S, H, C, P, N.$$

Thus the Real seal is reached only after the unit map, modulus ledger, DyadicRatCore tolerance, StreamName window, and RegSeqRat readback rows are visible. It does not export host real equality, quotient completion equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the RegSeqRat route of Definition 7278.3. It places the readback row R after the displayed unit-map, modulus, tolerance, and window rows.

The seal row S is the only Real-facing coordinate in the carrier, and it is downstream of R. Therefore the Real read cannot bypass the finite unit-modulus ledger.

Componentwise transport, continuation replay, provenance, and local naming preserve the same finite chain. Since the carrier has no row for the excluded objects, the Real-facing endpoint is a seal boundary, not an ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionUnitModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCompletionUnitModulus}^{\uparrow}$ packet is generated from a source uniform-space row, unit-map row, modulus ledger, DyadicRatCore tolerance row, StreamName finite windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionUnitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7278.1, Definition 7278.2, Definition 7278.3, and Definition 7278.4 seed the finite unit-map modulus route from uniform completion to StreamName, RegSeqRat, and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionUnitModulus}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host uniform-space equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-map exactness, modulus-ledger exhaustion, RegSeqRat readback discipline, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformCompletionUni

Chapter 7279

A Concrete Naming Certificate for $\mathsf{DiscreteGronwall}^{\uparrow}$

Following Bellman, Gronwall, and Bishop–Bridges finite induction practice, the $\mathsf{DiscreteGronwall}^{\uparrow}$ packet records the stepwise inequality ledger used when a Cauchy-rate or Picard-style error estimate is bounded by a finite product-and-sum majorant. It sits beside the continuous envelope route of chapter 2034, the Picard iteration surfaces of chapter 2359, chapter 2233, and chapter 5794, the Cauchy-rate criteria of chapter 3343 and chapter 6981, the summable-tail ledger of chapter 1799, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite dyadic induction boundary; it is not a continuous differential inequality, not a selected infinite product, and not an ambient completeness principle.

Definition 7279.1 (DiscreteGronwall finite-step carrier)**.** *A* $\mathsf{DiscreteGronwall}^{\uparrow}$ *finite-step carrier is a finite* BHist *packet*

$$G = (I, U, A, B, T, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *I is a finite initial segment of step indices with a distinguished first step and successor relation;*
2. *U is the nonnegative error ledger recording the displayed value at each step of I;*
3. *A is the dyadic multiplicative coefficient ledger, with each coefficient read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *B is the dyadic additive inhomogeneity ledger;*
5. *T is the finite product-and-sum majorant row generated by primitive recursion along I;*
6. *Q is the* $\mathsf{SummableTailModulus}^{\uparrow}$ *row used when the additive ledger is read as a Cauchy tail;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the dyadic bounds;*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed to Real or Completion consumers;*
9. *H records componentwise* hsame *transport for the index, error, coefficient, tail, readback, seal, continuation, package, and local naming rows;*
10. *C records the displayed* Cont *replay of the finite induction;*
11. *P is the* Pkg *provenance over* $\mathsf{DiscreteGronwall}^{\uparrow}$, $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{SummableTailModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DiscreteGronwall}^{\uparrow}}$ *row.*

The local classifier compares two accepted carriers only through the finite index segment, displayed error ledger, dyadic coefficient rows, primitive-recursive majorant, summable-tail read, regular-rational readback, Real seal, transport, continuation replay, provenance, and local naming.

Theorem 7279.2 (DiscreteGronwall NameCert obligations)**.** *For a carrier $G = (I, U, A, B, T, Q, R, S, H, C, P, N)$ of Definition 7279.1, the local* $\mathsf{NameCert}_{\mathsf{DiscreteGronwall}^{\uparrow}}$ *surface has six obligations:*

1. *carrier exposure of the finite tuple $I, U, A, B, T, Q, R, S, H, C, P, N$;*
2. *step admission for the first step and successor reads in I;*
3. *dyadic coefficient admission for every row of A and B;*
4. *primitive induction exactness for the majorant row T;*
5. *Cauchy-rate handoff through Q, R, S when a consumer reads a tail estimate;*
6. *non-escape from continuous Gronwall arguments, selected infinite products, countable choice, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiscreteGronwallUp.DiscreteGronwallNamecertObligations`

Proof. Carrier exposure is coordinate projection from the displayed finite tuple. The classifier has no source outside $I, U, A, B, T, Q, R, S, H, C, P, N$.

Step admission and dyadic coefficient admission are read before the induction starts. The first-step row and successor relation bound the recursion to the finite segment I, while A and B force each multiplicative and additive coefficient through the dyadic ledger.

Primitive induction exactness is then obtained by induction over I. At the first step, T records the displayed initial bound. At a successor step, the previous majorant is multiplied by the visible coefficient row and then enlarged by the visible additive row, so the next error entry of U is bounded by the next entry of T.

For a Cauchy-rate consumer, the terminal read is through Q, R, S. The summable-tail row supplies the finite tail modulus, the regular-rational row repacks the dyadic estimates, and the Real seal exposes the same bound to Real and Completion consumers.

Since no other coordinate is present, the packet cannot export a continuous Gronwall theorem, a selected infinite product, countable choice, quotient real equality, or ambient Real completeness. □

Theorem 7279.3 (DiscreteGronwall finite induction boundary)**.** *Every accepted* $\mathsf{DiscreteGronwall}^{\uparrow}$ *packet bounds its displayed error ledger only by primitive induction over the finite step segment I. Picard-style iteration and L10 Cauchy-rate consumers must read the dyadic coefficient ledgers A, B, the recursive majorant T, the* $\mathsf{SummableTailModulus}^{\uparrow}$ *row Q, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the* $\mathsf{Real}^{\uparrow}$ *seal S before exporting a rate bound. The packet exports no continuous-time envelope, no hidden infinite product, no selected limit, and no ambient completeness theorem.*

Proof. Begin with the carrier. The only rows available to the consumer are the finite step segment, error ledger, dyadic coefficient ledgers, primitive-recursive majorant, tail modulus, readback, Real seal, transport, replay, provenance, and local naming rows.

Induct over the finite segment I. The base step reads the initial error row and the initial majorant entry. The successor step applies the displayed dyadic multiplicative row and additive row to the previous majorant entry, producing the next entry of T and bounding the corresponding entry of U.

Now route the bound to the downstream ledgers. Picard consumers read the same finite estimate as an iteration budget through $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, and $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, while Cauchy-rate consumers read the tail through $\mathsf{SummableTailModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The continuous $\mathsf{GronwallInequality}^{\uparrow}$ chapter remains a sibling reference rather than a source of this proof. Because the finite packet has no coordinate for a continuous envelope, hidden infinite product, selected limit, or ambient completeness theorem, every exported bound stays inside the displayed induction route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiscreteGronwall}^{\uparrow}}$.

Constructive story: A $\mathsf{DiscreteGronwall}^{\uparrow}$ packet is generated from a finite step segment, error ledger, dyadic multiplicative and additive coefficients, primitive-recursive majorant, summable-tail row, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiscreteGronwall}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7279.1, Definition 7279.2, and Definition 7279.3 seed the finite dyadic induction boundary for Cauchy-rate and Picard-style error ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiscreteGronwall}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close continuous Gronwall or Bihari inequalities, selected infinite products, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Further closure requires Lean encoding of the finite-step carrier and a checked primitive-induction theorem for the displayed dyadic majorant.

Chapter 7280

A Concrete Naming Certificate for $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$

The $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ packet realizes the refusal taxonomy of chapter 9412 as finite NameCert data. It sits after the generic refusal packet of chapter 6558, the pseudotheory-specific gate of chapter 6560, the discovery-certificate discipline of Definition 9410.5, and the TasteGate boundary of chapter 9459. The packet does not certify positive discovery; it records the finite countermodel rows that block an asserted positive payload when its evidence is unpaid.

Definition 7280.1 (Pseudotheory refutation countermodel carrier)**.** *A* $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, C, A, D, T, B, X, R, V, H, K, P, N)$$

with the following displayed rows:

1. *S is the structural-DNA collision row, naming the candidate payload, a prior payload, and the checked equality of their structural fingerprints.*
2. *C is the classifier-shift failure row, recording the asserted before and after classifiers together with the missing or neutral disagreement support.*
3. *A is the axiom-scan row, carrying the source-token and kernel-dependency evidence for forbidden axiom, sorry, or dependency exposure.*
4. *D is the certificate-debt row, recording unpaid semantic naming, row-evidence, ledger-membership, cost, debt, or scope-seal obligations.*
5. *T is the TasteGate admission-boundary row, marking the human-only value and stability judgment that is not computed by the cheap refusal gate.*
6. *B is the transport row carrying componentwise* hsame *comparisons for $S, C, A, D, T, X, R, V, K, P, N$.*
7. *X is the replay row, recording displayed* Cont *replay from the positiveDiscovery payload through the countermodel rows.*
8. *R is the provenance row tying the packet to the refutation-gate, pseudotheory-refutation-gate, discovery-certificate, theory-stability-taste-gate, and NameCert surfaces.*
9. *V is the verdict row, storing which of S, C, A, D is displayed against the asserted positive payload.*

10. *H is the admission-history row preserving the candidate's local chapter, carrier, classifier, and evidence ledger names.*
11. *K is the local audit-key row used to replay the refusal without reading unlisted corpus data.*
12. *P is the* Pkg *provenance over* $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$, $\mathsf{RefutationGate}^{\uparrow}$, PseudotheoryRefutationGat BHist, hsame, Cont, Pkg, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a positive-discovery witness, an automatic TasteGate admission, an unscanned axiom surface, or a hidden corpus oracle.

Theorem 7280.2 (Pseudotheory refutation countermodel NameCert obligations)**.** *For every accepted* $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ *carrier*

$$Q = (S, C, A, D, T, B, X, R, V, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}}$ *surface consists exactly of structural-DNA collision admission, classifier-shift failure admission, axiom-scan admission, certificate-debt admission, TasteGate boundary marking, componentwise* hsame *transport, displayed* Cont *replay, provenance, verdict selection, admission-history preservation, audit-key replay,* Pkg *source, and local naming.*

Proof. Project the carrier of Definition 7280.1. The refusal rows are S, C, A, D, the taste boundary is T, and the structural rows are B, X, R, V, H, K, P, N.

Rows S, C, A, D correspond to the finite countermodel classes: structural-DNA collision, classifier-shift failure, axiom exposure, and unpaid certificate debt. The verdict row V records which displayed row is being used against the asserted positive payload.

The TasteGate boundary T separates cheap refusal from human admission. It can mark where value and stability judgment is required, but it is not a positive discovery witness and does not convert the absence of a countermodel row into admission.

Finally B, X, R, H, K, P, N transport, replay, source, preserve, audit, package, and name the same finite refusal route. Since the carrier has no coordinate for the excluded host objects, these rows exhaust the local NameCert obligations. □

Theorem 7280.3 (Pseudotheory refutation countermodel audit route)**.** *Every audit read of an accepted* $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ *carrier factors through the finite route*

$$S, C, A, D, T, B, X, R, V, H, K, P, N.$$

If the verdict row displays a structural-DNA collision row, classifier-shift failure row, axiom-scan row, or certificate-debt row, then the audit blocks the asserted positive payload unless the payload supplies the corresponding paid evidence.

Proof. Begin with Definition 7280.2. It identifies S, C, A, D as the only rows that can carry a cheap finite refusal.

The verdict row V reads one of those rows against the asserted payload. The replay row X and audit-key row K make the read repeatable without importing unlisted corpus data or a hidden oracle.

The TasteGate boundary T is read separately from the cheap refusal rows. It marks human admission requirements and therefore cannot be used as automatic positive evidence.

Componentwise transport, provenance, admission history, package source, and local naming preserve the same finite route. Hence every accepted audit read is the displayed countermodel route, and a positive payload without the matching paid evidence is blocked by the displayed verdict. □

Falsifiable prediction: A positive discovery claim is refuted when a $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ packet displays a structural-DNA collision row, classifier-shift failure row, axiom-scan row, or certificate-debt row while the positiveDiscovery payload lacks the corresponding paid evidence.

Independence witness: refutation-gate, pseudotheory-refutation-gate, discovery-certificate, theory-stability-taste-gate, namecert: $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries concrete countermodel rows, TasteGate boundary marking, verdict replay, provenance, audit key, transport, and local naming as one packet.

The Lean TasteGate surface for this packet must later provide explicit Nontrivial PseudotheoryRefutationCounterm and FieldFaithful $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ instances. Those instances must keep $S, C, A, D, T, B, X, R,$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}}$.

Constructive story: A $\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}$ packet is generated from structural-DNA collision, classifier-shift failure, axiom-scan, certificate-debt, TasteGate boundary, transport, replay, provenance, verdict, admission-history, audit-key, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7280.1, Definition 7280.2, and Definition 7280.3 seed the finite countermodel route for pseudotheory refusal audits.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PseudotheoryRefutationCountermodel}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim positive discovery certification, automatic TasteGate admission, Lean verification, bridge checking, or a hidden corpus oracle.

Upgrade path: Obligation closure requires checked carrier admission, countermodel-row exactness, verdict replay, TasteGate boundary separation, transport, provenance, audit-key replay, and local naming for BEDC.Derived.PseudotheoryRefutationCounterm

Chapter 7281

A Concrete Naming Certificate for $\mathsf{RegularCauchyBishopLimit}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{RegularCauchyBishopLimit}^{\uparrow}$ packet records the finite operation row by which a regular Cauchy name is read as a Real-facing limit without importing an ambient completeness theorem. It sits after the dyadic tolerance ledger of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names an operation-facing carrier for the displayed limit route; it is not quotient equality of streams, a selected host limit, arbitrary trichotomy, countable choice, or completeness for $\mathsf{Real}^{\uparrow}$.

Definition 7281.1 (Regular Cauchy Bishop limit carrier)**.** *A* $\mathsf{RegularCauchyBishopLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular-Cauchy row, displaying the finite modulus and tail-comparison evidence accepted by the operation.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the source name is inspected at the requested precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the exact dyadic scale used by the window comparison.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the source row, stream window, and dyadic ledger are visible.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular-rational readback row R.*
6. *H records componentwise* hsame *transport for source, window, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S, W, D \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBishopLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyBishopLimit}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected host limit, arbitrary real trichotomy, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) `BEDC.Derived.RegularCauchyBishopLimitUp`

Theorem 7281.2 (Regular Cauchy Bishop limit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBishopLimit}^{\uparrow}$ *carrier $L = (S, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBishopLimit}^{\uparrow}}$ *surface consists exactly of carrier admission; source regular-Cauchy visibility through S; finite-window coverage through W; dyadic exactness through D;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R;* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N. A limit-operation witness missing any one of these rows is not an accepted packet.*

Proof. Project the carrier of Definition 7281.1. The rows S, W, D are the complete finite source surface for the regular-Cauchy operation, so carrier admission, finite-window coverage, and dyadic exactness are all visible before any Real-facing read.

Read the handoff rows next. The regular rational row R is downstream of S, W, D, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is downstream of R.

Finally the structural rows H, C, P, N transport, replay, source, and name the same displayed dependency route. Since no excluded quotient equality, selected limit, trichotomy, choice, or completeness row occurs in the carrier, every accepted obligation stays inside the listed NameCert surface. □

Theorem 7281.3 (Regular Cauchy Bishop limit Real-seal handoff)**.** *Every Real-facing limit read of an accepted* $\mathsf{RegularCauchyBishopLimit}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. The handoff exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, arbitrary trichotomy, countable choice, or selected host limit.*

Proof. Apply Definition 7281.2. It identifies the source row S, stream-window row W, and dyadic tolerance ledger D as the only finite input surface for the operation-facing limit read.

The readback row R is therefore available only through that finite input surface. A Real-facing consumer reaches the seal row E only after this $\mathsf{RegSeqRat}^{\uparrow}$ readback has been displayed.

The transport, replay, provenance, and local naming rows preserve the same dependency order. No carrier row can supply a host completeness theorem, quotient stream equality, trichotomy, countable choice, or selected limit, so the terminal handoff remains a finite seal rather than an ambient Real construction. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBishopLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyBishopLimit}^{\uparrow}$ packet is generated from a source regular-Cauchy row, a StreamName window row, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyBishopLimit}^{\uparrow}}$, seed)

Scope closed: Definition 7281.1, Definition 7281.2, and Definition 7281.3 seed the finite Bishop-style limit-operation route from regular Cauchy evidence to the RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyBishopLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient RealUp completeness, quotient stream equality, arbitrary trichotomy, countable choice, selected host limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window coverage, dyadic exactness, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyBishopLimitUp

Chapter 7282

A Concrete Naming Certificate for $\mathsf{FuchsianGroupAction}^{\uparrow}$

Following Poincare and Klein on discrete groups of hyperbolic disk transformations, the $\mathsf{FuchsianGroupAction}^{\uparrow}$ packet records a finite NameCert surface for a Fuchsian-style action on displayed Poincare disk data. It sits after the disk metric route of chapter 6209, the hyperbolic metric rows of chapter 3474, the reversible disk automorphism packet of chapter 6776, the boundary-shadow handoff of chapter 3813, and the visual-boundary readback of chapter 4181. The chapter names a finite action packet; it does not construct an orbit quotient, a global hyperbolic surface, a Kleinian boundary object, or a selected fundamental polygon.

Definition 7282.1 (Fuchsian group action carrier)**.** *A* $\mathsf{FuchsianGroupAction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, W, M, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite disk-point row, recording the displayed source and target points on the Poincare disk.*
2. *W is the Mobius-action word row, recording the finite generator word whose partial products are inspected.*
3. *M is the metric-preservation row over* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *and* $\mathsf{HyperbolicMetric}^{\uparrow}$*, attached to every displayed action step.*
4. *B is the boundary-handoff row through* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *and* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *for every boundary-facing read of the same action word.*
5. *H records componentwise* hsame *transport for disk points, action words, metric preservation, boundary handoff, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay through disk-point reads, word reads, metric-preservation checks, and boundary handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{FuchsianGroupAction}^{\uparrow}$*,* $\mathsf{PoincareDiskMetric}^{\uparrow}$*,* $\mathsf{HyperbolicMetric}^{\uparrow}$*,* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$*,* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*,* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FuchsianGroupAction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through D, W, M, B, H, C, P, N. It has no coordinate for a quotient orbit space, a global hyperbolic surface theorem, a chosen fundamental polygon, an ambient Kleinian group object, or host-level boundary equality.

Lean4 (statement) `BEDC.Derived.FuchsianGroupActionUp`

Theorem 7282.2 (Fuchsian group action NameCert obligations)**.** *For every accepted* $\mathsf{FuchsianGroupAction}^{\uparrow}$ *carrier* $A = (D, W, M, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FuchsianGroupAction}^{\uparrow}}$ *surface consists exactly of finite disk-point admission; finite Mobius-action word admission through the* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ *route; metric-preservation exactness through* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *and* $\mathsf{HyperbolicMetric}^{\uparrow}$*; boundary handoff through* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *and* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$*; componentwise transport; displayed replay; provenance; and local naming. An action witness missing any one of* D, W, M, B, H, C, P, N *is not an accepted packet.*

Proof. Project the carrier of Definition 7282.1. The disk row D and word row W are the only displayed action source rows, so admission of the finite action is scoped before any metric or boundary read.

The metric row M is then read through the existing Poincare disk and hyperbolic metric packets, while the action word is routed through the disk-automorphism packet. Boundary-facing reads pass through B, not through a quotient boundary object.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no orbit quotient, global surface theorem, chosen polygon, ambient Kleinian object, or host boundary equality row occurs in the carrier, the listed clauses exhaust the local NameCert surface. □

Theorem 7282.3 (Fuchsian group action boundary handoff)**.** *Every boundary-facing read of an accepted* $\mathsf{FuchsianGroupAction}^{\uparrow}$ *carrier factors through the finite disk-point row, the Mobius-action word row, the metric-preservation row, and the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *and* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *boundary rows. The handoff exports no quotient orbit space, global hyperbolic surface theorem, selected fundamental polygon, or host boundary equality.*

Proof. Apply Definition 7282.2. It identifies D, W, M, B as the complete geometric surface before any boundary-facing consumer can read the action.

The boundary row B is downstream of the same displayed disk points, action word, and metric-preservation evidence. Thus a boundary consumer cannot bypass the finite action packet and cannot replace it by an ambient quotient or surface construction.

The transport, replay, provenance, and local naming rows preserve this dependency order. Because the carrier has no row for a quotient orbit space, global surface theorem, selected polygon, or host boundary equality, the boundary handoff remains a finite NameCert route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FuchsianGroupAction}^{\uparrow}}$.

Constructive story: A $\mathsf{FuchsianGroupAction}^{\uparrow}$ packet is generated from finite disk-point rows, finite Mobius-action word rows, PoincareDiskMetric and HyperbolicMetric preservation rows, HyperbolicBoundaryShadow and HyperbolicVisualBoundary handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FuchsianGroupAction}^{\uparrow}}$, seed)

Scope closed: Definition 7282.1, Definition 7282.2, and Definition 7282.3 seed the finite Fuchsian-style action route over disk, metric, automorphism, and boundary rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FuchsianGroupAction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient orbit spaces, global hyperbolic surface theorems, selected fundamental polygons, Kleinian boundary theory, host boundary equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-point admission, Mobius-action word admission, metric-preservation exactness, boundary handoff, transport, replay, provenance, and local naming for BEDC.Derived.FuchsianGroupActionUp.

Chapter 7283

A Concrete Naming Certificate for $\mathsf{ProofNet}^{\uparrow}$

Following Girard proof nets, the $\mathsf{ProofNet}^{\uparrow}$ packet records proof objects as finite link-and-switching data rather than as host proof trees or quotient proof identities. It sits between the syntax and deduction rows of chapter 197, the proof-term corridor of chapter 200, the normalization-by-evaluation surface of chapter 6305, the logical-relation route of chapter 6767, and the MetaCIC critical path of chapter 765. The packet names finite link tables, switching choices, cut interfaces, transport, replay, provenance, and local naming rows; it does not assert full normalization, confluence, quotient proof equality, a completed semantic model, or a global cut-elimination theorem.

Definition 7283.1 (Proof-net carrier)**.** *A* $\mathsf{ProofNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (L, S, C, B, R, H, Q, N)$$

with the following displayed rows:

1. *L is the link table, listing axiom, tensor, par, unit, dereliction, contraction, weakening, and cut links only as finite syntax rows.*
2. *S is the switching row, recording the finite switching choices and connectedness checks exposed to a consumer.*
3. *C is the cut-interface row, naming the displayed cut pairs and the local redex boundary without collapsing proof nets by cut conversion.*
4. *B is the boundary row, tying conclusions, formula occurrences, and sequent-facing endpoints to the* $\mathsf{FirstOrder}^{\uparrow}$ *and* $\mathsf{LambdaCalc}^{\uparrow}$ *source surfaces.*
5. *R is the proof-net route row consumed by* $\mathsf{NormalizationByEvaluation}^{\uparrow}$*,* $\mathsf{LogicalRelation}^{\uparrow}$*, and* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *readers before they may cite proof-object data.*
6. *H records componentwise* hsame *transport for link tables, switching rows, cut interfaces, boundaries, routes, provenance, and local naming.*
7. *Q is the* Pkg *provenance over* $\mathsf{ProofNet}^{\uparrow}$*,* $\mathsf{FirstOrder}^{\uparrow}$*,* $\mathsf{LambdaCalc}^{\uparrow}$*,* $\mathsf{NormalizationByEvaluation}^{\uparrow}$*,* $\mathsf{LogicalRelation}^{\uparrow}$*,* $\mathsf{MetaCICCriticalPath}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofNet}^{\uparrow}}$ *row.*

The carrier has no coordinate for completed proof normalization, Church–Rosser confluence, quotient proof equality, a semantic completeness theorem, or a host evaluator.

Theorem 7283.2 (Proof-net NameCert obligations)**.** *For every accepted* $\mathsf{ProofNet}^{\uparrow}$ *carrier* $P = (L, S, C, B, R, H, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ProofNet}^{\uparrow}}$ *surface consists exactly of carrier admission for the link table, switching row, cut-interface row, boundary row, proof-net route row, componentwise* hsame *transport,* Pkg *provenance, and local naming. A consumer may read proof-net data only after the finite links, switchings, cuts, boundaries, and route rows are displayed in the same packet.*

Proof. Project the carrier of Definition 7283.1. The packet exposes only L, S, C, B, R, H, Q, N.

The proof-object obligations are exhausted by L, S, C, B, R. Link data are finite syntax rows, switching data are finite checks, cut data are local interfaces, and boundary data keep the proof-net endpoints attached to the $\mathsf{FirstOrder}^{\uparrow}$ and $\mathsf{LambdaCalc}^{\uparrow}$ surfaces.

The rows H, Q, N transport, source, and name the same finite packet. Since no carrier coordinate stores global normalization, confluence, quotient proof equality, semantic completeness, or a host evaluator, the listed rows are exactly the local certificate obligations. □

Theorem 7283.3 (Proof-net cut-elimination route)**.** *Every cut-elimination-facing read of an accepted* $\mathsf{ProofNet}^{\uparrow}$ *packet must first expose*

$$L, S, C, B, R, H, Q, N$$

and may then hand the displayed local cut-interface route to $\mathsf{NormalizationByEvaluation}^{\uparrow}$, $\mathsf{LogicalRelation}^{\uparrow}$, *or* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumers. The handoff is a finite proof-net carrier route over displayed links, switchings, and cut interfaces; it is not a proof of full normalization, unrestricted confluence, quotient proof equality, or a completed semantic model.*

Proof. Read the link and switching rows L, S first. They display the finite graph and switching data available to a proof-net consumer.

Next read the cut-interface row C and boundary row B. These rows identify the local redex boundary and the sequent or proof-term endpoints without quotienting proof nets by cut conversion.

Finally read the route and structural rows R, H, Q, N. They allow the normalization-by-evaluation, logical-relation, and MetaCIC critical-path consumers to cite the same finite route, while the carrier inventory excludes full normalization, confluence, quotient proof equality, and completed semantic-model coordinates. □

Falsifiable prediction: Every accepted $\mathsf{ProofNet}^{\uparrow}$ consumer displays finite link tables, switching rows, cut-interface rows, boundary rows, proof-net route rows, componentwise hsame transport, Pkg provenance, and a local NameCert row before citing proof-object data.

Independence witness: firstorder, lambdacalc, normalization-by-evaluation, logical-relation, metaciccriticalpath: $\mathsf{ProofNet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite link tables, switching rows, cut-interface rows, proof-object boundaries, proof-net route rows, transport, provenance, and local naming while refusing full normalization, confluence, quotient proof equality, and completed semantic-model claims.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofNet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ProofNet}^{\uparrow}$ packet is generated from finite link tables, switching rows, cut-interface rows, boundary endpoints, proof-net route rows, componentwise hsame transport, Pkg provenance, and local naming evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProofNet}^{\uparrow}}$, seed)

Scope closed: Definition 7283.1, Definition 7283.2, and Definition 7283.3 seed the finite proof-net carrier surface for proof-object consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProofNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, full normalization, unrestricted confluence, quotient proof equality, semantic completeness, or a completed MetaCIC model.

Upgrade path: Obligation closure requires checked carrier admission, switching exposure, cut-interface route preservation, boundary compatibility, transport, provenance, and local naming for BEDC.Derived.ProofNetUp.

Chapter 7284

A Concrete Naming Certificate for LocatedCauchyIntervalCompletion$^{\uparrow}$

Following Bishop and Bridges on located intervals and regular Cauchy completion, the LocatedCauchyIntervalComple packet records the finite BEDC route by which a located interval source produces a regular Cauchy interval-name surface and then reaches the Real-facing seal. It sits after the located interval carrier of chapter 1709, the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real$^{\uparrow}$ boundary of chapter 38, and the completion criterion of chapter 3404. The packet is a located interval completion certificate, not quotient real equality, open-cover compactness, countable choice, a selected limit, or ambient Real$^{\uparrow}$ completeness.

Definition 7284.1 (Located Cauchy interval completion carrier)**.** *A* LocatedCauchyIntervalCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, W, D, Q, S, A, H, C, P, N)$$

with the following rows:

1. *I is the* LocatedRealInterval$^{\uparrow}$ *source row, exposing endpoints, radius data, and locatedness probes as finite interval evidence.*
2. *W is the* StreamName$^{\uparrow}$ *finite-window row through which interval observations are requested.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for interval widths, endpoint comparison slack, and refinement budgets.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerances.*
5. *S is the* BishopCompletionCriterion$^{\uparrow}$ *row recording that the regular interval windows meet the displayed Cauchy completion criterion.*
6. *A is the terminal* Real$^{\uparrow}$ *seal row reached only after I, W, D, Q, S have been displayed.*
7. *H records componentwise* hsame *transport for the interval source, windows, dyadic ledger, regular readback, completion criterion, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion request through the same ordered rows.*
9. *P is the* Pkg *provenance over* LocatedCauchyIntervalCompletion$^{\uparrow}$, LocatedRealInterval$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, BishopCompletionCriterion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyIntervalCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these ten rows form one located Cauchy interval completion packet. It has no coordinate for quotient reals, selected representatives, host interval equality, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.LocatedCauchyIntervalCompletionUp.LocatedCauchyIntervalCompletionUp`
Lean4 ✓ `BEDC.Derived.LocatedCauchyIntervalCompletionUp.LocatedCauchyIntervalCompletionTasteGate`
`single carrier alignment`

Theorem 7284.2 (Located Cauchy interval completion NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchyIntervalCompletion}^{\uparrow}$ *carrier* $T = (I, W, D, Q, S, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyIr}}$ *surface consists exactly of carrier admission for the located interval source, finite windows, dyadic tolerance ledger, regular readback, Bishop completion criterion, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming rows. It also includes route exactness from I through W, D, Q, S, A and ledger exhaustion excluding quotient reals, selected limits, open-cover compactness, countable choice, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 7284.1. The projected rows are exactly the located interval source, finite window, dyadic ledger, regular readback, completion criterion, Real seal, and structural rows.

Route exactness follows from the tuple order. A public completion read begins with I, opens only the finite windows in W, measures them by the dyadic ledger D, reads them through Q, and then checks the displayed Bishop completion criterion S before A is available.

The transport, replay, provenance, and local naming obligations are the rows H, C, P, N. Since the carrier contains no further coordinate, the excluded quotient, choice, compactness, host equality, selected-limit, and ambient-completeness principles cannot be exported. □

Theorem 7284.3 (Located Cauchy interval completion Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{LocatedCauchyIntervalCompletion}^{\uparrow}$ *carrier is downstream of the displayed route*

$$\mathsf{LocatedRealInterval}^{\uparrow}(I) \longmapsto \mathsf{StreamName}^{\uparrow}(W) \longmapsto \mathsf{DyadicRatCore}^{\uparrow}(D) \longmapsto \mathsf{RegSeqRat}^{\uparrow}(Q) \longmapsto \mathsf{BishopCompletionC}$$

The seal therefore names only the finite located Cauchy interval completion read and exports no quotient stream equality, selected host limit, countable-choice schedule, open-cover compactness witness, host interval equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source interval row I. It supplies endpoint, radius, and locatedness data through the located real interval certificate rather than through a host closed interval.

Read the finite observation route. The stream row W schedules the inspected windows, the dyadic ledger D records the tolerance and refinement budget, and Q supplies the regular rational readback for the requested precision.

Apply the completion criterion row S. The Real seal A is public only after that displayed criterion has been read from the same finite route.

The structural rows H, C, P, N transport and replay this route without adding analytic data. Thus the listed quotient, choice, compactness, host, selected-limit, and ambient-completeness principles remain outside the packet. □

Theorem 7284.4 (Located Cauchy interval completion L10 handoff)**.** *Any Phase Real and Completion consumer of* $\mathsf{LocatedCauchyIntervalCompletion}^{\uparrow}$ *must consume the L10 handoff through the*

four displayed source faces DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *with the located interval row and Bishop completion criterion kept visible as source and acceptance rows. Agreement on a terminal Real seal alone cannot replace the displayed interval source, tolerance ledger, regular readback, or completion criterion.*

Proof. Project the L10 faces from Definition 7284.1. The rows W, D, Q, A are exactly the StreamName, DyadicRatCore, RegSeqRat, and Real faces available to a Real and Completion consumer.

Keep the source and acceptance rows visible. The located interval row I supplies the finite interval data, while S records the Bishop completion criterion that permits the terminal seal to be read as a completion handoff.

Use Definition 7284.2 and Definition 7284.3. Together they force every accepted handoff through $I, W, D, Q, S, A, H, C, P, N$ and rule out terminal-seal agreement as a substitute for the displayed route. □

Falsifiable prediction: Every accepted LocatedCauchyIntervalCompletion$^{\uparrow}$ read must expose a located interval source, StreamName finite windows, DyadicRatCore tolerance ledger, RegSeqRat readback, BishopCompletionCriterion acceptance, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: located-real-interval, streamname, dyadicratcore, regseqrat, bishop-completion-criterion, real: LocatedCauchyIntervalCompletion$^{\uparrow}$ is not bijective to any listed sibling because it binds located interval source data to the regular Cauchy completion handoff and terminal Real seal in one finite NameCert packet.

Closure status for NameCert$_{\text{LocatedCauchyIntervalCompletion}^{\uparrow}}$.

Constructive story: A LocatedCauchyIntervalCompletion$^{\uparrow}$ packet is generated from a located interval source row, finite StreamName windows, DyadicRatCore tolerance data, RegSeqRat readback, a BishopCompletionCriterion row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedCauchyIntervalCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 7284.1, Definition 7284.2, Definition 7284.3, and Definition 7284.4 seed the located Cauchy interval completion route through located interval, StreamName, DyadicRatCore, RegSeqRat, BishopCompletionCriterion, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedCauchyIntervalCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, open-cover compactness, countable choice, selected host limits, host interval equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, route exactness, Real-seal nonescape, L10 handoff, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchyIntervalCompletionUp.

Chapter 7285

A Concrete Naming Certificate for $\mathsf{PrincipalBundle}^{\uparrow}$

Following Steenrod and Kobayashi–Nomizu, the $\mathsf{PrincipalBundle}^{\uparrow}$ packet records principal-bundle data as finite BEDC NameCert rows. It sits over the displayed bundle carrier of chapter 97, the charted base surface of chapter 96, the smooth structure-group rows of chapter 140, the algebraic action boundary of chapter 41, and the continuous operation ledger of chapter 204. The packet names only the visible total space, base manifold, projection, local trivializations, transition cocycle, group action, transport, replay, provenance, and local certificate rows; it does not construct quotient bundle equality, choose a global section, assert a host smooth structure, or provide bridge checking.

Definition 7285.1 (Principal bundle carrier)**.** *A* $\mathsf{PrincipalBundle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (E, B, \pi, G, U, \tau, \gamma, \alpha, H, C, \rho, N)$$

with the following displayed rows:

1. *E is the total-space row, read through the upstream* $\mathsf{Bundle}^{\uparrow}$ *carrier surface.*
2. *B is the base-manifold row, read through the chart carrier of* $\mathsf{Manifold}^{\uparrow}$*.*
3. *π is the projection row from E to B, displayed as bundle data rather than as a host map equality.*
4. *G is the structure-group row, read through the* $\mathsf{LieGroup}^{\uparrow}$*,* $\mathsf{Group}^{\uparrow}$*, and* $\mathsf{TopGroup}^{\uparrow}$ *operation surfaces.*
5. *U is the finite local-trivialization cover row, including the displayed local product windows used by the bundle packet.*
6. *τ is the transition-cocycle row over overlapping local trivialization windows.*
7. *γ is the group-action row, naming the right action of the displayed structure group on the displayed total-space fibres.*
8. *α is the* hsame *transport row for the total space, base, projection, structure group, local trivializations, transition cocycle, and group action.*
9. *H is the displayed* Cont *replay row for reading the same local data after transport.*
10. *C is the* Pkg *provenance over* $\mathsf{PrincipalBundle}^{\uparrow}$*,* $\mathsf{Bundle}^{\uparrow}$*,* $\mathsf{Manifold}^{\uparrow}$*,* $\mathsf{LieGroup}^{\uparrow}$*,* $\mathsf{Group}^{\uparrow}$*,* $\mathsf{TopGroup}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

11. *ρ records the finite dependency order in which the upstream rows are exposed to a principal-bundle consumer.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PrincipalBundle}^\uparrow}$ *row.*

The carrier has no coordinate for quotient bundle equality, selected global sections, ambient smooth structures, external atlas maximality, or detached host principal-bundle objects.

Theorem 7285.2 (Principal bundle NameCert obligations)**.** *For the carrier of Definition 7285.1, the local* $\mathsf{NameCert}_{\mathsf{PrincipalBundle}^\uparrow}$ *surface consists exactly of the following displayed obligations:*

1. *carrier admission for the packet $P = (E, B, \pi, G, U, \tau, \gamma, \alpha, H, C, \rho, N)$;*
2. *bundle exposure through the total-space, projection, and local-trivialization rows E, π, U;*
3. *base exposure through the* $\mathsf{Manifold}^\uparrow$ *row B;*
4. *structure-group exposure through the* $\mathsf{LieGroup}^\uparrow$, $\mathsf{Group}^\uparrow$, *and* $\mathsf{TopGroup}^\uparrow$ *readings of G;*
5. *action and transition exposure through γ and τ;*
6. *componentwise transport, replay, dependency provenance, and local naming through α, H, C, ρ, N.*

Ledger exactness says that every accepted principal-bundle read exposes precisely these rows before a principal-bundle consumer may inspect the transition or action data. The obligations do not add quotient bundle equality, selected global sections, host smooth structures, atlas maximality, or bridge checking.

Theorem 7285.3 (Principal bundle transition cocycle)**.** *Let $P = (E, B, \pi, G, U, \tau, \gamma, \alpha, H, C, \rho, N)$ be an accepted* $\mathsf{PrincipalBundle}^\uparrow$ *carrier. Every transition-cocycle read from P factors through the displayed base-manifold row B, the local-trivialization row U, and the structure-group row G before the cocycle row τ is public:*

$$\mathsf{Manifold}^\uparrow,\ \mathsf{Bundle}^\uparrow,\ \mathsf{LieGroup}^\uparrow,\ \mathsf{Group}^\uparrow,\ \mathsf{TopGroup}^\uparrow \longrightarrow \tau.$$

On triple overlaps, the cocycle comparison is recorded only as finite NameCert data transported by α and replayed by H. It cannot identify quotient bundles, choose a section, import a maximal smooth atlas, or replace the displayed structure-group row by an ambient host group.

Closure status for $\mathsf{NameCert}_{\mathsf{PrincipalBundle}^\uparrow}$.

Constructive story: A $\mathsf{PrincipalBundle}^\uparrow$ packet is generated from total-space, base-manifold, projection, structure-group, local-trivialization, transition-cocycle, and group-action rows, together with componentwise hsame transport, displayed Cont replay, Pkg provenance, dependency ordering, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PrincipalBundle}^\uparrow}$, seed)

Scope closed: Definition 7285.1, Definition 7285.2, and Definition 7285.3 seed the finite principal-bundle NameCert surface over displayed bundle, manifold, Lie-group, group, topological-group, action, and transition-cocycle rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PrincipalBundle}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient bundle equality, selected global sections, host smooth structures, atlas maximality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-cocycle exposure, group-action exposure, dependency exactness, transport, replay, provenance, and local naming for BEDC.Derived.PrincipalBundleUp.

Chapter 7286

A Concrete Naming Certificate for $\mathsf{DyadicCauchyStaircase}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicCauchyStaircase}^{\uparrow}$ packet records the finite precision staircase by which dyadic tolerance rows are opened in monotone order before a regular rational name is read back and sealed as a Real-facing row. It sits between the finite stream windows of chapter 126, the dyadic tolerance core of chapter 291, the effective-rate schedule of chapter 415, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet is a finite precision-schedule certificate; it is not a quotient completion, a selected limit, a countable-choice operator, trichotomy, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7286.1 (Dyadic Cauchy staircase carrier)**.** *A* $\mathsf{DyadicCauchyStaircase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected windows of the source rational stream.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row ledger, listing the dyadic tolerance rows requested by the consumer.*
3. *L is the monotone staircase ledger, recording that later displayed rows of D refine earlier rows and that each read of S is attached to the current step.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed only after the relevant staircase step and stream window have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the staircase and regular readback route has been consumed.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic precision rows, staircase ledger, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through D, L, S, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicCauchyStaircase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCauchyStaircase}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, selected limits, countable choice, trichotomy, host real equality, hidden stream equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicCauchyStaircaseUp.DyadicCauchyStaircaseTasteGate single carrier alignment`

Theorem 7286.2 (Dyadic Cauchy staircase NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyStaircase}^{\uparrow}$ *carrier* $K = (S, D, L, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyStaircase}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger, monotone staircase ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *precision visibility, requiring each consumed tolerance request to appear as a displayed row of D before L advances the staircase;*
3. *monotone-step admission, requiring L to record that later displayed precision rows refine earlier displayed rows and that no step is skipped by the readback route;*
4. *window-readback routing, requiring S to be opened at the current staircase step before R is consumed;*
5. *real-seal order, requiring E to be read only after D, L, S, R have all been displayed in the same finite route;*
6. *transport and replay stability, requiring H and C to preserve the same precision, staircase, window, readback, and seal rows componentwise;*
7. *ledger nonescape from quotient completion, selected limits, countable choice, trichotomy, host real equality, hidden stream equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7286.1. The accepted packet displays exactly the rows $S, D, L, R, E, H, C, P, N$.

Precision visibility and monotone-step admission are the role of D and L. The dyadic rows in D name the requested tolerances, while L records their displayed refinement order and attaches each opened stream window to the current step.

Window-readback routing follows from the route order. A readback row R can be consumed only after the current dyadic precision row and its staircase step have opened the finite window S.

The real seal is downstream. The row E is read after D, L, S, R, and the structural rows H, C, P, N transport, replay, source, and name that same finite path.

The nonescape clause follows because none of the excluded objects is a coordinate of the carrier. The local certificate therefore exports only the displayed precision-staircase surface. □

Theorem 7286.3 (Dyadic Cauchy staircase L10 handoff)**.** *Every accepted* $\mathsf{DyadicCauchyStaircase}^{\uparrow}$ *carrier* $K = (S, D, L, R, E, H, C, P, N)$ *hands any L10 Real or Completion consumer the ordered finite route*

$$D \longrightarrow L \longrightarrow S \longrightarrow R \longrightarrow E.$$

The route first displays the $\mathsf{DyadicRatCore}^{\uparrow}$ *precision rows, then the monotone staircase ledger, then the* $\mathsf{StreamName}^{\uparrow}$ *window, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then the* $\mathsf{Real}^{\uparrow}$ *seal. A consumer*

receives no quotient completion, selected limit, countable-choice selector, trichotomy datum, host real equality, hidden stream equality, or ambient Real-completeness row.

Proof. Start with the accepted carrier $K = (S, D, L, R, E, H, C, P, N)$. Projection gives the dyadic precision ledger D, the staircase ledger L, the stream-window row S, the regular readback row R, and the terminal seal E.

The precision rows are consumed first. The staircase ledger L records their monotone refinement order and fixes which window of S is attached to each requested tolerance.

The regular readback R is then read through the opened window, and E is reached only after that readback has been displayed. The rows H, C, P, N preserve, replay, source, and name the same finite route.

Since the route has no carrier coordinate beyond $D, L, S, R, E, H, C, P, N$, the handoff cannot export quotient completion, selected limits, countable choice, trichotomy, host real equality, hidden stream equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: An accepted $\mathsf{DyadicCauchyStaircase}^{\uparrow}$ read is refuted if a Real or Completion consumer reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the DyadicRatCore precision rows, monotone staircase ledger, StreamName window, RegSeqRat readback, transport, replay, provenance, and local naming rows.

Independence witness: dyadicratcore, streamname, cauchy-rate, regseqrat, real: none alone is bijective with $\mathsf{DyadicCauchyStaircase}^{\uparrow}$ because the packet jointly records finite precision rows, a monotone staircase ledger, stream windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyStaircase}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyStaircase}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore precision rows, a monotone staircase ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyStaircase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7286.1, Definition 7286.2, and Definition 7286.3 seed the finite precision-staircase certificate between dyadic tolerance rows, stream windows, regular rational readback, and the Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchyStaircase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, trichotomy, host real equality, hidden stream equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, precision visibility, monotone-step admission, window-readback routing, real-seal order, transport and replay stability, and ledger nonescape for BEDC.Derived.DyadicCauchyStaircaseUp.

Chapter 7287

A Concrete Naming Certificate for $\mathsf{SobolevDual}^{\uparrow}$

Following Sobolev and Adams–Fournier, the $\mathsf{SobolevDual}^{\uparrow}$ packet records the finite dual-test-action surface over the Sobolev carrier of chapter 5911. It reads the weak-derivative rows of $\mathsf{WeakDerivative}^{\uparrow}$, the norm budgets of $\mathsf{Norm}^{\uparrow}$, the scalar seals of $\mathsf{Real}^{\uparrow}$, and the completion handoff of $\mathsf{MetricCompletion}^{\uparrow}$ before any dual-facing consumer can inspect a test action or a budgeted functional value. The packet gives PDE, variational, and weak-form consumers a displayed BEDC route rather than a host distribution-dual quotient, a Hahn–Banach extension, or a selected representative of a function class.

Definition 7287.1 (SobolevDual carrier)**.** *A* $\mathsf{SobolevDual}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D^* = (S, T, A, R, B, M, H, C, P, L)$$

with the following displayed rows:

1. *S is the source Sobolev carrier row, read from the* $\mathsf{SobolevSpace}^{\uparrow}$ *packet of chapter 5911 after its source-function,* $\mathsf{WeakDerivative}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, integrability,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows have been displayed.*
2. *T is the test-action family row. It records the finite test windows, derivative-coordinate tags, support tags, and admissible probe names on which the dual action may be evaluated.*
3. *A is the action ledger row. It binds each displayed test window in T to a finite action value request over the source Sobolev data in S.*
4. *R is the scalar* $\mathsf{Real}^{\uparrow}$ *readback row for action values, norm estimates, and dual-budget comparisons.*
5. *B is the norm and dual-budget row. It records the finite bound, tolerance, and comparison data by which the action ledger is admitted as a bounded dual-facing read.*
6. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row, available only after S, T, A, R, B have been displayed and only for the completion route named by this dual packet.*
7. *H stores componentwise* hsame *transport for Sobolev source, test-action family, action ledger, scalar readback, norm and dual budget, completion handoff, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from every dual-facing request through $S, T, A, R, B, M, H, P, L$.*

9. *P is the* Pkg *provenance over* $\mathsf{SobolevDual}^{\uparrow}$, $\mathsf{SobolevSpace}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *L is the local* $\mathsf{NameCert}_{\mathsf{SobolevDual}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, A, R, B, M, H, C, P, L$. It has no coordinate for host distribution-dual quotients, quotient equality of functions, Hahn–Banach extension, choice, PDE solvability, Lean verification, or bridge checking.

Theorem 7287.2 (SobolevDual NameCert obligations)**.** *For every accepted* $\mathsf{SobolevDual}^{\uparrow}$ *carrier*

$$D^* = (S, T, A, R, B, M, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{SobolevDual}^{\uparrow}}$ *surface consists exactly of carrier admission, test-action coverage, dual-budget exactness, SobolevSpace handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No dual obligation is stored outside those finite rows, and no consumer may escape to a host distribution-dual quotient before reading the displayed Sobolev source and test-action route.*

Proof. Carrier admission is projection from Definition 7287.1. The accepted packet displays the Sobolev source row S, test-action family T, action ledger A, scalar row R, dual-budget row B, completion handoff M, and structural rows H, C, P, L.

Test-action coverage is finite. Every action value must first name a test window in T and then read the action ledger A against the displayed $\mathsf{SobolevSpace}^{\uparrow}$ source row S; there is no separate coordinate for a host distribution space or a quotient representative.

Dual-budget exactness is read through R and B. The scalar seal R is the only real-valued readback, while B records the bound and tolerance data that make the action available to dual-facing consumers.

The handoff to SobolevSpace is therefore prior to every dual read. The rows H, C, P, L transport, replay, source, and name the same finite route, so replay and provenance cannot add Hahn–Banach, choice, PDE-solvability, verification, or bridge data. □

Falsifiable prediction: Every accepted $\mathsf{SobolevDual}^{\uparrow}$ dual-facing consumer reads SobolevSpaceUp, WeakDerivativeUp, NormUp, RealUp, MetricCompletionUp, BHist, hsame, Cont, Pkg, and NameCert rows before receiving a test-action value or dual budget.

Independence witness: sobolev-space, weak-derivative, norm, real, metric-completion: no listed sibling is bijective to $\mathsf{SobolevDual}^{\uparrow}$ because this packet jointly binds a Sobolev source row, test-action family, action ledger, scalar readback, dual budget, completion handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevDual}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SobolevDual}^{\uparrow}$ packet is generated from a displayed SobolevSpaceUp source row, finite test-action family, action ledger, RealUp scalar readbacks, norm and dual-budget data, MetricCompletionUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SobolevDual}^{\uparrow}}$, seed)

Scope closed: Definition 7287.1 and Definition 7287.2 seed the finite Sobolev-dual carrier from source Sobolev rows through test actions, scalar readback, dual budget, completion handoff, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SobolevDual}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach duality, quotient functions, Hahn–Banach extension, choice, PDE solvability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-action coverage, dual-budget exactness, SobolevSpace handoff, transport, replay, provenance, and local naming for BEDC.Derived.SobolevDualUp.

Chapter 7288

A Concrete Naming Certificate for $\mathsf{CauchyFilterCompleteness}^{\uparrow}$

Following Bourbaki, Kelley, and Bishop–Bridges, the $\mathsf{CauchyFilterCompleteness}^{\uparrow}$ packet records the finite L10 route by which a located Cauchy filter may be read toward a Real-facing completion seal. It sits after the Cauchy-filter carrier of chapter 333, the located-filter boundary of chapter 1661, the Real-induced uniformity of chapter 1624, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the displayed rows a completion consumer may inspect; it does not quotient filters, select limits, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7288.1 (Cauchy filter completeness carrier)**.** *A* $\mathsf{CauchyFilterCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, L, U, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, exposing the filter base, directed refinements, and Cauchy request ledger.*
2. *L is the located-tail row, read through* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *and carrying the finite interval or apartness evidence needed by a completion-facing request.*
3. *U is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *uniform-entourage row used to compare the displayed tails by Real-induced metric balls.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected stages.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and uniform requests.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, L, U, S, R have been displayed.*
7. *H records componentwise* hsame *transport of F, L, U, S, R, E.*
8. *C records displayed* Cont *replay of the same route.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterCompleteness}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, L, U, S, R, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, countable choice, host equality of completed points, or ambient Real completeness.

Theorem 7288.2 (Cauchy filter completeness NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterCompletenes}$ *carrier $Q = (F, L, U, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompleteness}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy-filter exposure through F, located-tail exposure through L, Real-uniform entourage exposure through U, finite StreamName windows through S, RegSeqRat readback through R, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7288.1. The available analytic rows are exactly F, L, U, S, R, E, and the available structural rows are H, C, P, N.

The source side starts with F, L, U. The Cauchy-filter row supplies the displayed filter requests, the located-tail row supplies finite interval or apartness evidence, and the Real-uniform row supplies the entourage comparison used by the completion-facing read.

The numerical readback is downstream. Rows S and R expose only finite windows and regular rational observations, and the seal row E is available only after those rows have been displayed.

Transport, replay, provenance, and local naming preserve the same packet. Since quotient filters, selected limits, countable choice, host equality, and ambient Real completeness are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7288.3 (Cauchy filter completeness located Real extraction)**.** *Every Real-facing extraction from an accepted* $\mathsf{CauchyFilterCompleteness}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow},\ \mathsf{LocatedCauchyFilter}^{\uparrow},\ \mathsf{RealUniformStructure}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, H, C, P, N.$$

The extraction may expose a terminal Real seal only as the end of this displayed route; it does not provide a quotient filter, selected limit, countable-choice schedule, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the obligation surface of Definition 7288.2. It orders every Real-facing read through the Cauchy-filter row, located-tail row, Real-uniform entourage row, finite windows, regular rational readback, and terminal seal.

The located-tail and uniform-entourage rows are both visible before the seal. Thus the consumer can inspect how the filter request is located and how the Real-induced uniformity compares the inspected tails, but it cannot bypass those rows.

The seal row E is terminal. Rows H, C, P, N transport, replay, source, and name the same finite route, so the Real-facing extraction remains a displayed packet rather than a host completion construction. □

Theorem 7288.4 (Cauchy filter completeness nonescape)**.** *Every completion consumer of an accepted* $\mathsf{CauchyFilterCompleteness}^{\uparrow}$ *packet receives only the displayed rows*

$$F, L, U, S, R, E, H, C, P, N.$$

Consequently the packet refuses quotient filters, selected representatives, selected limits, countable choice, host equality of completed points, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 7288.1 to read the full carrier inventory. The only source rows are the Cauchy-filter, located-tail, uniform-entourage, StreamName, RegSeqRat, and Real-seal rows.

Apply Definition 7288.3. It shows that a Real-facing extraction is downstream from exactly those rows and the structural route H, C, P, N.

The refused objects are not carrier coordinates and are not produced by the structural rows. Therefore no completion consumer can obtain quotient-filter equality, a selected limit, a countable-choice schedule, host equality of completed points, or ambient Real completeness from this packet. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterCompleteness}^{\uparrow}$ read must expose a $\mathsf{CauchyFilter}^{\uparrow}$ row, a $\mathsf{LocatedCauchyFilter}^{\uparrow}$ located-tail row, a $\mathsf{RealUniformStructure}^{\uparrow}$ entourage row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterCompleteness}^{\uparrow}$ packet is generated from a CauchyFilter row, located-tail row, RealUniformStructure entourage row, StreamName finite windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7288.1, Definition 7288.2, Definition 7288.3, and Definition 7288.4 seed the L10 Cauchy-filter completeness route over located filter, Real-uniform, StreamName, RegSeqRat, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchyFilterCompletenessUp`

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, selected representatives, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification of the obligation rows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-tail exposure, Real-uniform entourage exposure, StreamName window inspection, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterCompletenessUp.

Chapter 7289

A Concrete Naming Certificate for $\mathsf{BishopCompletionFilter}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompletionFilter}^{\uparrow}$ packet records the constructive completion route in which a Cauchy filter is read through located filter data, regular Cauchy object rows, uniform completion-filter rows, dense embedding data, and the terminal real-name spine before any quotient completion or selected limit is available. It sits beside the Cauchy-filter carrier of chapter 333, the located filter boundary of chapter 1661, the object-level regular completion of chapter 7177, the uniform-space completion-filter route of chapter 4108, and the dense embedding surface of chapter 3617. Its finite readback path uses the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the $\mathsf{StreamName}^{\uparrow}$ window service of chapter 126.

Definition 7289.1 (Bishop completion-filter carrier)**.** *A* $\mathsf{BishopCompletionFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, L, O, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row, exposing the filter-level Cauchy data before any completion read is attempted.*
2. *L is the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row, recording the located basis-refinement and tail-decision data consumed by the Bishop-style completion route.*
3. *O is the* $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$ *row, naming the regular Cauchy completion object reached from the located filter source.*
4. *U is the* $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$ *row, recording the uniform entourage and filter-completion handoff for the same displayed source.*
5. *D is the* $\mathsf{DenseEmbedding}^{\uparrow}$ *row, exposing the source-to-completion dense image route before a completion-facing consumer reads the endpoint.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by the filter, object, uniform, and dense-image ledgers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, L, O, U, D, W, R are visible.*
9. *H records componentwise* hsame *transport for $F, L, O, U, D, W, R, E, C, P, N$.*

10. *C records displayed* Cont *replay from a completion request through the filter, locatedness, object, uniform, dense-image, window, readback, seal, provenance, and local naming rows.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyCompletionObject}^{\uparrow}$, $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$, $\mathsf{DenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionFilter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient filters, selected representatives, countable choice, host equality of completion points, hidden cofinal subfilters, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7289.2 (Bishop completion-filter NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionFilter}^{\uparrow}$ *carrier*

$$B = (F, L, O, U, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionFilter}^{\uparrow}}$ *surface consists exactly of Cauchy-filter source admission, located-filter exposure, regular completion-object admission, uniform completion-filter handoff, dense-embedding route exposure, StreamName window admission, RegSeqRat readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7289.1. The analytic rows are F, L, O, U, D, W, R, E, and the structural rows are H, C, P, N.

Read the completion source first. The Cauchy filter row F is refined by the located filter row L, and the regular completion-object row O can be consumed only after those source rows are visible.

Next read the completion-facing handoffs. The uniform completion-filter row U and dense embedding row D preserve the same displayed source while the finite window row W and regular rational readback row R provide the observable data used by completion consumers.

Finally the Real seal row E is downstream of F, L, O, U, D, W, R. The transport, replay, provenance, and local naming rows preserve the same finite route, so no quotient filter, selected representative, countable-choice schedule, hidden cofinal subfilter, host equality, or ambient completeness theorem can be exported by the local certificate. □

Theorem 7289.3 (Bishop completion-filter dense completion route)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopCompletionFilter}^{\uparrow}$ *packet factors through*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{LocatedCauchyFilter}^{\uparrow} \longmapsto \mathsf{RegularCauchyCompletionObject}^{\uparrow} \longmapsto \mathsf{UniformSpaceCompletionFilter}^{\uparrow} \vdash$$

The route is a finite Bishop-style completion-filter NameCert route; it does not export quotient completion equality, a selected limit representative, countable choice, host filter equality, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7289.2. They require $F, L, O, U, D, W, R, E, H, C, P, N$ to be read as one packet before a completion-facing consumer may inspect the endpoint.

Use the located and object rows. The located filter row L keeps the completion request attached to finite basis-refinement data, while the regular completion-object row O names the object-level completion carrier without adding a quotient representative.

Apply the uniform completion-filter and dense embedding rows. They route the same source through uniform entourage data and dense-image approximation before the StreamName and RegSeqRat rows expose the finite readback.

The terminal Real seal is then only a downstream seal over that route. Since the carrier has no excluded coordinate, every completion-facing read remains inside the displayed Bishop completion-filter packet. □

Falsifiable prediction: An accepted $\mathsf{BishopCompletionFilter}^{\uparrow}$ read is refuted if a completion-facing consumer reaches a Real seal or dense embedding handoff without first displaying the Cauchy filter row, located filter row, regular completion-object row, uniform completion-filter row, finite StreamName window, RegSeqRat readback, transport, replay, provenance, and local naming rows.

Independence witness: cauchyfilter, locatedcauchyfilter, regularcauchycompletionobject, uniformspacecompletionfilter, denseembedding, real, regseqrat, streamname: none is bijective with $\mathsf{BishopCompletionFilter}^{\uparrow}$ because this packet jointly carries the Bishop-style filter source, located refinement, regular object, uniform completion route, dense image, finite windows, readback, Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionFilter}^{\uparrow}$ packet is generated from CauchyFilter, LocatedCauchyFilter, RegularCauchyCompletionObject, UniformSpaceCompletionFilter, DenseEmbedding, StreamName, RegSeqRat, Real, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7289.1, Definition 7289.2, and Definition 7289.3 seed the Bishop-style completion-filter route over Cauchy filters, located filters, regular completion objects, uniform completion filters, dense embeddings, finite windows, regular readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host filter equality, hidden cofinal subfilters, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-filter exposure, regular completion-object admission, uniform completion-filter handoff, dense embedding route exposure, StreamName windows, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionFilterUp.

Chapter 7290

A Concrete Naming Certificate for $\mathsf{NestedIntervalPrinciple}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{NestedIntervalPrinciple}^{\uparrow}$ packet records the finite nested-interval principle as a displayed route from dyadic interval refinement data to regular rational names and the terminal real-name seal. It sits after the finite tree ledger of **??**, the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the explicit modulus route of chapter 5548. The packet names the finite L10 handoff for nested closed intervals; it is not selected limits, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7290.1 (Nested interval principle carrier)**.** *A* $\mathsf{NestedIntervalPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (T, D, W, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{DyadicIntervalTree}^{\uparrow}$ *source row, carrying the finite nested interval tree and its visible branch-depth ledger.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter and containment row, recording the dyadic shrinkage budget used by every interval read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row extracted from the displayed nested tree and dyadic budget.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after T, D, W, R have been displayed.*
6. *M is the* $\mathsf{CantorIntersectionModulus}^{\uparrow}$ *handoff row that records the explicit modulus by which nested intervals become regular readback data.*
7. *H records componentwise* hsame *transport for the tree, dyadic budget, stream windows, regular readback, real seal, modulus handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from nested interval requests through T, D, W, R, E, M, H.*
9. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalPrinciple}^{\uparrow}$, $\mathsf{DyadicIntervalTree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CantorIntersectionModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for selected limits, open-cover compactness, countable choice, quotient real equality, host interval intersection, or ambient Real completeness.

Theorem 7290.2 (Nested interval principle NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalPrinciple}^{\uparrow}$ *carrier* $J = (T, D, W, R, E, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalPrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed interval tree, dyadic budget, finite windows, regular rational readback, terminal real seal, modulus handoff, transport, replay, provenance, and local naming rows; tree-depth exactness through* T*; dyadic shrinkage exactness through* D*; window generation through* W*; regular readback through* R*; Real sealing through* E*; Cantor-modulus handoff through* M*; and structural preservation through* H, C, P, N*.*

Proof. Project the carrier of Definition 7290.1. The analytic rows are T, D, W, R, E, M, and the structural rows are H, C, P, N.

The tree row T exposes only a finite nested interval ledger. The dyadic row D supplies the diameter and containment budget used by that ledger, so no read can appeal to an ambient intersection theorem.

The window and readback rows W, R turn the displayed finite data into regular rational observations. The real seal E is terminal and may be read only after those rows and the modulus row M have been exposed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no excluded object appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7290.3 (Nested interval principle Real-seal handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{NestedIntervalPrinciple}^{\uparrow}$ *carrier must read the finite route*

$$T, D \longmapsto W, R \longmapsto E, M, H, C, P, N$$

before it can consume the terminal $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports dyadic interval tree data, dyadic shrinkage budgets, finite StreamName windows, RegSeqRat readback, Cantor-intersection modulus data, transport, replay, provenance, and local naming; it exports no selected limit, open-cover compactness theorem, countable-choice schedule, quotient real representative, host interval intersection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the source rows. The interval evidence is carried by the displayed finite tree T, and the shrinkage evidence is carried by the dyadic budget row D.

Next read the completion-facing rows. The finite windows W are generated from the same tree and budget, and the regular rational readback R records the observations that the terminal real seal E may consume.

The modulus row M is the only Cantor-intersection handoff in the packet. It records an explicit route into regular readback data rather than a completeness principle.

Transport, replay, provenance, and local naming preserve the same rows. Thus every Real-facing consumer receives exactly the displayed finite route and none of the refused selected-limit, compactness, choice, quotient, host-intersection, or ambient-completeness data. □

Falsifiable prediction: An accepted $\mathsf{NestedIntervalPrinciple}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the rows $T, D, W, R, E, M, H, C, P, N$ refutes the carrier surface.

Independence witness: dyadicintervaltree, dyadicratcore, streamname, regseqrat, real, cantor-intersection-modulus: no listed sibling supplies the joint packet containing a finite dyadic interval

tree, dyadic shrinkage ledger, finite windows, regular rational readback, terminal Real seal, Cantor-intersection modulus handoff, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedIntervalPrinciple}^{\uparrow}$ packet is generated from a finite dyadic interval tree, dyadic shrinkage budget, StreamName windows, RegSeqRat readback, terminal Real seal, Cantor-intersection modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7290.1, Definition 7290.2, and Definition 7290.3 seed the finite nested-interval route into Real-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, open-cover compactness, countable choice, quotient real equality, host interval intersection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{NestedIntervalPrinciple}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, tree-depth exactness, dyadic shrinkage exactness, window generation, regular readback, Real sealing, Cantor-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.NestedIntervalPrincipleUp.

Chapter 7291

A Concrete Naming Certificate for $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$

The $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$ packet realizes the MetaCIC confluence audit map as finite residual-critical-pair data. It sits after the critical-path source of chapter 765, the normalization frontier of chapter 892, the parallel-diamond frontier of chapter 4238, the confluence audit packet of chapter 735, and the normal-form consistency seal of chapter 740. The packet records residual-substitution, local-join, closed-checker, obstruction, transport, replay, provenance, and NameCert rows; it does not claim global confluence, substitution compatibility, closed Church–Rosser, subject reduction, quotient syntax equality, or a hidden reduction oracle.

Definition 7291.1 (MetaCIC residual critical-pair carrier)**.** *A* $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, P, J, D, O, T, R, V, H, C, G, N)$$

with the following displayed rows:

1. *S is the residual-substitution row, naming the substitution-sensitive residual window that must be displayed before a peak can be consumed.*
2. *P is the local peak row, recording the two one-step residual branches and their shared typed source window.*
3. *J is the candidate local-join row, naming the finite common-reduct attempt associated to the displayed peak.*
4. *D is the closed-checker row, restricting the read to the closed or shape-limited fragment currently admitted by the audit map.*
5. *O is the obstruction row, preserving any missing residual-substitution compatibility, parallel diamond, or closed-confluence input as visible boundary data.*
6. *T is the transport row carrying componentwise* hsame *comparisons for $S, P, J, D, O, R, V, G, N$.*
7. *R is the replay row, recording displayed* Cont *replay from residual-substitution inspection through local join checking and obstruction retention.*
8. *V is the verification-frontier row tying the packet to the critical path, normalization frontier, parallel-diamond frontier, confluence audit packet, and normal-form consistency seal.*

9. *H is the audit-history row preserving source labels, shape bounds, peak identifiers, local-join attempts, and obstruction names.*
10. *C is the closed-fragment handoff row consumed by closed-normal or shape-limited confluence readers after S, P, J, D, O have been displayed.*
11. *G is the* Pkg *provenance over* $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}$ $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, $\mathsf{NormalFormConsistencySeal}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualCriticalPair}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose residual-substitution, local peak, candidate join, closed-checker, obstruction, transport, replay, frontier, history, provenance, and local naming rows agree componentwise. It has no coordinate for a global confluence theorem, arbitrary substitution compatibility, a hidden parallel diamond, subject reduction, quotient syntax equality, or off-packet oracle joins.

Theorem 7291.2 (MetaCIC residual critical-pair NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$ *carrier $K = (S, P, J, D, O, T, R, V, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualCriticalP}}$ *surface consists exactly of carrier admission for the displayed rows; residual-substitution admission through S; local peak admission through P; candidate join admission through J; closed or shape-limited checker admission through D; obstruction retention through O; componentwise transport through T; displayed replay through R; critical-path, normalization-frontier, parallel-diamond-frontier, confluence-audit, and normal-form-seal anchoring through V, H, C, G; and local naming through N.*

Proof. Project the carrier of Definition 7291.1. The confluence-facing rows are S, P, J, D, O, and the structural rows are T, R, V, H, C, G, N.

The residual-substitution row S is read before the local peak P and candidate join J. This keeps the packet inside the substitution-sensitive audit map instead of treating a local join as an unconditional diamond.

The closed-checker row D and obstruction row O are then inspected. They separate the available closed or shape-limited fragment from the missing residual-substitution compatibility, parallel-diamond, and closed-confluence inputs.

Finally T, R, V, H, C, G, N transport, replay, anchor, preserve, hand off, source, and name the same finite route. Since the carrier contains no global confluence, subject-reduction, quotient-syntax, or hidden-oracle coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7291.3 (MetaCIC residual critical-pair frontier handoff)**.** *Every confluence-facing consumer of an accepted* $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$ *packet receives the finite route*

$$S, P, J, D, O, T, R, V, H, C, G, N.$$

The route may be handed to $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}$ $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, *and* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *consumers only as residual-critical-pair evidence with an explicit obstruction boundary. It does not export global confluence, arbitrary residual-substitution compatibility, an unconditional parallel diamond, closed Church–Rosser, subject reduction, quotient syntax equality, or a hidden reduction oracle.*

Proof. Start with the residual-substitution and local-peak rows. The packet exposes S before P, J, so the consumer sees the substitution-sensitive residual window together with the candidate join attempt.

Read the closed-checker and obstruction rows next. The row D confines the consumer to the closed or shape-limited fragment, while O names the missing compatibility, parallel-diamond, or closed-confluence input that remains outside the carrier.

The structural rows T, R, V, H, C, G, N then preserve the same route for the critical-path, normalization-frontier, parallel-diamond, confluence-audit, and normal-form-seal consumers. The handoff is therefore residual-critical-pair evidence with a visible obstruction boundary, not a confluence theorem. □

Theorem 7291.4 (MetaCIC residual critical-pair obstruction preservation)**.** *Let $K = (S, P, J, D, O, T, R, V, H, C, G$ be an accepted* $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$ *packet. Any handoff from K to a confluence-facing consumer preserves the obstruction row O until residual-substitution compatibility and parallel-diamond inputs are displayed through the same residual-critical-pair route. In particular, the rows $S, P, J, D, T, R, V, H, C, G, N$ may transport and replay the local peak and candidate join, but they cannot erase O or convert the packet into a global confluence export.*

Proof. Begin with the frontier handoff of Definition 7291.3. It exports the route $S, P, J, D, O, T, R, V, H, C, G, N$ with the obstruction boundary still visible.

The residual-substitution row S, local peak row P, and candidate join row J expose only the local critical-pair data. They do not contain the missing residual-substitution compatibility or parallel-diamond input named by O.

The closed-checker row D then restricts the admissible fragment, while T, R, V, H, C, G, N preserve, replay, anchor, hand off, source, and name the same displayed route. Since O is one of the displayed rows transported by T and replayed by R, every confluence-facing consumer must keep it until the missing inputs are separately displayed. □

Theorem 7291.5 (MetaCIC residual critical-pair closed-checker monotonicity)**.** *For an accepted* $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$ *packet $K = (S, P, J, D, O, T, R, V, H, C, G, N)$, strengthening the closed or shape-limited checker row D can only restrict the admitted local-join route. It may remove a candidate read of S, P, J from the closed-fragment handoff C, but it cannot create residual-substitution compatibility, erase the obstruction row O, produce a parallel diamond, or export global confluence.*

Proof. Use the frontier handoff of Definition 7291.3 as the ambient route. The consumer receives $S, P, J, D, O, T, R, V, H, C, G, N$, not an unrestricted reduction relation or a global confluence theorem.

Strengthening D narrows the closed or shape-limited fragment inspected by the packet. Therefore any local-join read through J that remains admitted still passes through the same residual-substitution row S, local peak row P, obstruction row O, and structural rows T, R, V, H, C, G, N.

If a candidate route is excluded by the stronger checker, it simply leaves the handoff surface. If it remains, the obstruction row is still transported and replayed with the route, so the stronger checker cannot manufacture compatibility, a parallel diamond, subject reduction, quotient syntax equality, or global confluence. □

Falsifiable prediction: An accepted $\mathsf{MetaCICResidualCriticalPair}^{\uparrow}$ consumer that reaches a confluence-facing handoff without displaying residual-substitution row S, local peak row P, candidate join row J, closed-checker row D, obstruction row O, and structural rows T, R, V, H, C, G, N refutes the carrier surface.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, metacic-parallel-diamond-frontier, metacicconfluenceauditpacket, normalformconsistencyseal: no listed sibling is bijective to

MetaCICResidualCriticalPair$^{\uparrow}$ because this packet jointly carries residual-substitution windows, local peaks, candidate joins, closed-checker rows, obstruction retention, transport, replay, audit history, closed-fragment handoff, provenance, and local naming. The Lean TasteGate follow-up must provide Nontrivial and FieldFaithful instances for the packet surface.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualCriticalPair}^{\uparrow}}$.

Constructive story: A MetaCICResidualCriticalPair$^{\uparrow}$ packet is generated from residual-substitution windows, local peaks, candidate joins, closed-checker rows, obstruction rows, componentwise hsame transport, displayed Cont replay, audit-frontier anchoring, history preservation, closed-fragment handoff, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualCriticalPair}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7291.1, Definition 7291.2, Definition 7291.3, Definition 7291.4, and Definition 7291.5 seed the finite residual critical-pair route for the MetaCIC confluence audit map.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualCriticalPair}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global confluence, arbitrary residual-substitution compatibility, unconditional parallel diamond, closed Church–Rosser, subject reduction, quotient syntax equality, Lean verification, or bridge checking for MetaCICResidualCriticalPair$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, residual-substitution admission, local peak admission, candidate join admission, closed-checker admission, obstruction retention, transport, replay, audit-frontier anchoring, history preservation, closed-fragment handoff, provenance, and local naming for BEDC.Derived.MetaCICResidualCriticalPairUp.

Chapter 7292

A Concrete Naming Certificate for BishopCompactIntervalCauchyCompleteness$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the BishopCompactIntervalCauchyCompleteness$^{\uparrow}$ packet records compact-interval Cauchy completeness as finite BEDC NameCert data. It reads the nested-interval completion surface of chapter 6091, the Bishop complete-metric packet of chapter 3424, the compact-metric source of chapter 129, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the dyadic tolerance core of chapter 291. The packet names the classical compact-interval Cauchy route without turning it into global Real$^{\uparrow}$ completeness, a selected limit operator, quotient equality of Cauchy names, trichotomy, or countable choice.

Definition 7292.1 (Bishop compact-interval Cauchy-completeness carrier)**.** *A* BishopCompactIntervalCauchyComp *carrier is a finite* BHist *packet*

$$K = (I, S, D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact interval source row, read through the* CompactMetric$^{\uparrow}$ *and* BishopCompleteMetric$^{\uparrow}$ *surfaces for the displayed closed bounded interval.*
2. *S is the* StreamName$^{\uparrow}$ *Cauchy stream row, storing only the inspected finite windows of the sequence in the compact interval.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *dyadic mesh row, recording the tolerance and interval-mesh comparisons requested by the compactness argument.*
4. *L is the nested interval lock, routing the Cauchy stream and dyadic mesh through the* NestedIntervalCompleteness$^{\uparrow}$ *shrinking-chain surface.*
5. *R is the* RegSeqRat$^{\uparrow}$ *regular rational readback obtained after the stream windows and nested lock have been displayed.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after I, S, D, L, R are read in the same finite route.*
7. *H records componentwise* hsame *transport for the compact interval source, Cauchy stream, dyadic mesh, nested lock, readback, terminal seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Cauchy tolerance request through D, S, L, R, E.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}$, $\mathsf{NestedIntervalCompleteness}^{\uparrow}$, $\mathsf{BishopCompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}}$ *row.*

The carrier has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient equality of Cauchy names, trichotomy, countable choice, hidden stream equality, or host interval compactness.*

Theorem 7292.2 (Bishop compact-interval Cauchy-completeness obligations)**.** *For every accepted* $\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}$ *carrier* $K = (I, S, D, L, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact interval admission for the displayed interval source I through the compact-metric and Bishop complete-metric sibling packets;*
2. *Cauchy stream visibility, requiring each stream window consumed by the argument to appear as a displayed row of S;*
3. *dyadic mesh visibility, requiring every tolerance and endpoint comparison to pass through the displayed row D;*
4. *nested interval locking, requiring L to bind the Cauchy stream and mesh rows to the shrinking interval route before any limit readback is exposed;*
5. *regular rational readback, requiring R to be read only after I, S, D, L are displayed;*
6. *terminal Real sealing, requiring E to factor through the same compact interval, stream, mesh, nested lock, and readback rows;*
7. *transport, replay, provenance, and local naming stability through H, C, P, N;*
8. *ledger nonescape from ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient equality of Cauchy names, trichotomy, countable choice, hidden stream equality, and host interval compactness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7292.1. The accepted packet displays exactly the rows $I, S, D, L, R, E, H, C, P, N$.

The Cauchy and mesh obligations are read before the lock. The row S exposes only finite stream windows, and the row D exposes only the dyadic tolerance and endpoint comparisons needed to place those windows in a displayed interval mesh.

The nested lock L then binds the displayed windows and mesh rows to the $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ route. After that lock is visible, R may read the regular rational name and E may seal the same route as a $\mathsf{Real}^{\uparrow}$-facing row.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no additional coordinate, the excluded principles cannot appear as local obligations. □

Theorem 7292.3 (Bishop compact-interval Cauchy limit route)**.** *Every accepted* BishopCompactIntervalCauchyCom *carrier* $K = (I, S, D, L, R, E, H, C, P, N)$ *hands a completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer the ordered finite route*

$$I \longrightarrow S \longrightarrow D \longrightarrow L \longrightarrow R \longrightarrow E.$$

The consumer first reads the compact interval source, then the Cauchy stream windows, then the dyadic mesh comparisons, then the nested interval lock, then the regular rational readback, and only then the terminal $\mathsf{Real}^{\uparrow}$ *seal. The route exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, selected limit, quotient equality of Cauchy names, trichotomy datum, countable-choice selector, or host interval compactness principle.*

Proof. Begin with the accepted carrier $K = (I, S, D, L, R, E, H, C, P, N)$. Projection supplies the compact interval row I, Cauchy stream row S, dyadic mesh row D, nested lock L, regular readback row R, and terminal seal E.

The compact interval source is read first because the stream windows and dyadic comparisons are interpreted inside that displayed interval. The rows S and D then expose exactly the finite Cauchy and mesh data consumed by the nested lock.

Once L is displayed, the route has the shrinking interval evidence needed for the regular rational readback R. The seal E is downstream of that readback, and the rows H, C, P, N keep the same route stable under transport, replay, provenance, and local naming.

Nothing in this ordered projection adds another coordinate. The consumer therefore receives the finite compact-interval Cauchy route and none of the excluded global or choice-based principles. □

Theorem 7292.4 (Bishop compact-interval Cauchy nonescape)**.** *For every accepted* $\mathsf{BishopCompactIntervalCauchyC}$ *carrier* $K = (I, S, D, L, R, E, H, C, P, N)$*, every public read of a Cauchy limit in the compact interval factors through* $I, S, D, L, R, E, H, C, P, N$*. In particular the packet explicitly refuses ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient equality of Cauchy names, trichotomy, and countable choice; none of these may be recovered from the local* $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}}$ *surface.*

Proof. The public read surface is the carrier surface. By Definition 7292.2, the local NameCert obligations are exhausted by the compact interval source, stream windows, dyadic mesh, nested lock, regular readback, terminal seal, and the structural rows H, C, P, N.

By Definition 7292.3, any completion-facing or Real-facing limit read must pass through the ordered route I, S, D, L, R, E before the structural rows are consulted. The route is finite and displayed at each step.

Ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient equality of Cauchy names, trichotomy, and countable choice are not rows of the carrier and are named as excluded coordinates in Definition 7292.1. Hence no public read of the packet can export them. □

Falsifiable prediction: An accepted $\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}$ limit read is refuted if a completion-facing or $\mathsf{Real}^{\uparrow}$-facing consumer reaches the terminal seal without displaying the compact interval source, Cauchy stream windows, dyadic mesh, nested interval lock, regular rational readback, transport, replay, provenance, and local naming rows.

Independence witness: nested-interval-completeness, bishop-complete-metric, compactmetric, streamname, regseqrat, real, dyadicratcore: none alone is bijective with $\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}$ because the packet jointly records the compact interval source, Cauchy stream, dyadic mesh, nested lock, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCompactIntervalCauchyCompleteness}^{\uparrow}$ packet is generated from a compact interval source, finite Cauchy stream windows, dyadic mesh comparisons, a nested interval lock, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopCompactIntervalCauchyCompleteness}\uparrow}$, seed)

Scope closed: Definition 7292.1, Definition 7292.2, Definition 7292.3, and Definition 7292.4 seed the finite compact-interval Cauchy-completeness certificate over compact metric, nested interval, stream, dyadic, regular-rational, and Real-facing rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopCompactIntervalCauchyCompleteness}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient Real$^{\uparrow}$ completeness, selected limits, quotient equality of Cauchy names, trichotomy, countable choice, host interval compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact interval admission, Cauchy stream visibility, dyadic mesh visibility, nested interval locking, regular rational readback, terminal Real sealing, transport and replay stability, and ledger nonescape for BEDC.Derived.BishopCompactIntervalCauchyCompletenessUp.

Chapter 7293

A Concrete Naming Certificate for $\mathsf{UrysohnRationalMetric}^{\uparrow}$

Following Urysohn and Katetov on finite metric extensions, the $\mathsf{UrysohnRationalMetric}^{\uparrow}$ packet records the rational finite one-point extension substrate before any universal metric-space carrier is selected. It sits over the metric carrier of chapter 57, the separable-metric source of chapter 1458, the complete-metric boundary of chapter 128, the completion handoff of chapter 1506, the terminal real-distance seal of chapter 38, and the larger Urysohn finite-extension packet of chapter 6554. The packet isolates rational support distances, rational requested distances, and finite Katetov inequalities as NameCert rows without constructing a host Urysohn space, a completion quotient, a dense extension chain, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7293.1 (Urysohn rational metric carrier)**.** *A* $\mathsf{UrysohnRationalMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, S, D, F, A, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *source row whose finite support points and support distances are inspected.*
2. *S is the* $\mathsf{SeparableMetric}^{\uparrow}$ *finite support schedule naming exactly the support points used by the extension request.*
3. *D is the rational distance table row. It records the already displayed support distances and the proposed rational distance from the new point to each support point.*
4. *F is the finite rational Katetov request row. It lists the triangle and reverse-triangle inequalities checked for each displayed support pair.*
5. *A is the admission ledger row. It records that every inequality in F is verified using only the rational table D and the source metric row M.*
6. *E is the one-point extension handoff row. It allows a consumer to read the rational extension request after M, S, D, F, A have been exposed.*
7. *H records componentwise* hsame *transport for the source metric, support schedule, rational table, Katetov request, admission ledger, extension handoff, replay, provenance, and local name.*
8. *C records displayed* Cont *replay for the same finite request and admission rows.*
9. *P is the* Pkg *provenance over* $\mathsf{UrysohnRationalMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{SeparableMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, rational finite metric tables,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UrysohnRationalMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, D, F, A, E, H, C, P, N$. It has no coordinate for a host universal metric space, a selected completion point, quotient completion equality, an arbitrary countable extension schedule, choice, Lean verification, a standard bridge, or ambient real completeness.

Theorem 7293.2 (Urysohn rational metric NameCert obligations)**.** *For every accepted* $\mathsf{UrysohnRationalMetric}^{\uparrow}$ *carrier*

$$Q = (M, S, D, F, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UrysohnRationalMetric}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the metric source, finite support schedule, rational distance table, finite Katetov request, admission ledger, extension handoff, transport, replay, provenance, and local name;*
2. *common-source discipline, requiring S, D, F, A to be read over the same metric source row M;*
3. *rational support visibility, requiring every distance in D to be attached to a support point named by S;*
4. *Katetov inequality exposure, requiring F and A to display each triangle and reverse-triangle budget over the rational table;*
5. *extension-handoff order, requiring E to be consumed only after M, S, D, F, A have been exposed;*
6. *nonescape, excluding host Urysohn spaces, quotient completion equality, arbitrary extension chains, selected completion points, countable choice, Lean verification, bridge credentials, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Urysohn rational metric obligation is stored outside these rows.

Proof. Project the carrier of Definition 7293.1. The tuple $M, S, D, F, A, E, H, C, P, N$ is the whole public surface, so carrier admission is exactly admission of those rows.

The common-source and support-visibility obligations follow from M, S, D. The support schedule names the finite points, and the rational distance table is read only over those points and the same source metric row.

The Katetov obligation is recorded by F and A. The request row lists the triangle and reverse-triangle comparisons, while the admission ledger records that each comparison has been checked against the rational table.

Finally E, H, C, P, N preserve only that displayed finite route. Since none of the carrier coordinates stores a host universal space, quotient completion equality, countable extension chain, selected completion point, choice functional, Lean credential, bridge credential, or ambient completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 7293.3 (Urysohn rational metric one-point extension)**.** *Every finite rational one-point extension request accepted by a* $\mathsf{UrysohnRationalMetric}^{\uparrow}$ *carrier factors through*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{SeparableMetric}^{\uparrow} \longmapsto D, F, A \longmapsto E.$$

The request is therefore a displayed rational Katetov route over the current finite support, not a point selected from a universal metric space, a quotient class in a completed space, or an ambient $\mathsf{Real}^{\uparrow}$ *limit.*

Proof. Begin with the metric source row M and finite support schedule S. They expose the only support points and support distances available to the extension request.

Read the rational table D next. It supplies the proposed rational distances from the new point to the displayed support and records the already visible support-distance comparisons.

The rows F and A then check the finite Katetov inequalities. Each compatibility budget is a rational row attached to the displayed support table, so no hidden real-completion datum is introduced.

The handoff row E exports only this finite rational route. Host universal metric spaces, quotient completion representatives, selected completion points, arbitrary countable extension chains, choice functionals, and ambient Real completeness remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{UrysohnRationalMetric}^{\uparrow}$ extension read exposes the $\mathsf{Met}^{\uparrow}$ or $\mathsf{Met}^{\uparrow}$ source, $\mathsf{SeparableMetric}^{\uparrow}$ support schedule, rational distance table, finite Katetov request, and admission ledger before any $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer may inspect the handoff row.

Independence witness: metric, separablemetric, completemetric, metriccompletion, real, urysohnuniversalmetric: $\mathsf{UrysohnRationalMetric}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite rational support tables, finite Katetov inequality rows, admission ledgers, one-point extension handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows while refusing host universal spaces and completion quotients.

Closure status for $\mathsf{NameCert}_{\mathsf{UrysohnRationalMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{UrysohnRationalMetric}^{\uparrow}$ packet is generated from a displayed metric source, finite separable support schedule, rational distance table, finite Katetov request, admission ledger, one-point extension handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UrysohnRationalMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7293.1, Definition 7293.2, and Definition 7293.3 seed the finite rational one-point metric extension substrate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UrysohnRationalMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host Urysohn-space existence, quotient completion equality, countable choice, arbitrary extension chains, selected completion points, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-source discipline, rational support visibility, Katetov inequality exposure, handoff order, and nonescape for BEDC.Derived.UrysohnRationalMetricUp.

Chapter 7294

A Concrete Naming Certificate for DirichletAbelSummability$^{\uparrow}$

Following Hardy's summability treatment and the Bishop–Bridges constructive reading of real series, the DirichletAbelSummability$^{\uparrow}$ packet records the finite handoff in which a displayed real series exposes both Abel-test and Dirichlet-test faces before a completion-facing summability read is allowed to reach a uniform Cauchy route. It sits over the RealSeries$^{\uparrow}$ source of chapter 1581, the AbelTest$^{\uparrow}$ face of chapter 1496, the DirichletTest$^{\uparrow}$ face of chapter 1497, the UniformCauchySeries$^{\uparrow}$ handoff of chapter 1736, the RegSeqRat$^{\uparrow}$ readback of chapter 301, and the terminal Real$^{\uparrow}$ seal of chapter 38. The packet is a Real-and-Completion summability boundary; it does not import host summability, select an infinite sum, quotient series names, invoke countable choice, or assert ambient Real$^{\uparrow}$ completeness.

Definition 7294.1 (Dirichlet–Abel summability carrier)**.** *A* DirichletAbelSummability$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, D, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* RealSeries$^{\uparrow}$ *source row, exposing the real-valued term and partial-sum observations only through the series packet.*
2. *A is the* AbelTest$^{\uparrow}$ *face row, recording the Abel-style monotone coefficient and tail-control evidence available for the same source.*
3. *D is the* DirichletTest$^{\uparrow}$ *face row, recording bounded partial-sum data, null-tail data, and the finite Dirichlet estimate schedule for the same source.*
4. *U is the shared* UniformCauchySeries$^{\uparrow}$ *handoff row reached only after the Abel and Dirichlet faces have both displayed their finite evidence.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the common summability windows.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row available only after S, A, D, U, R are visible.*
7. *H records componentwise* hsame *transport for $S, A, D, U, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from a summability request through the source, the two test faces, the uniform handoff, readback, seal, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* DirichletAbelSummability$^{\uparrow}$, RealSeries$^{\uparrow}$, AbelTest$^{\uparrow}$, DirichletTest$^{\uparrow}$, UniformCauchySeries$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{DirichletAbelSummability}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through these rows. It has no coordinate for host convergence of the series, selected infinite sums, quotient equality of series names, countable choice, detached Abel or Dirichlet witnesses, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7294.2 (Dirichlet–Abel summability NameCert obligations)**.** *For every accepted* DirichletAbelSummabilit *carrier*

$$D = (S, A, D, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DirichletAbelSummability}^{\uparrow}}$ *surface consists exactly of RealSeries source admission, Abel-test face exposure, Dirichlet-test face exposure, shared UniformCauchySeries handoff, RegSeqRat readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7294.1. The analytic rows are S, A, D, U, R, E, and the structural rows are H, C, P, N.

Read the source and the two test faces first. The RealSeries row S fixes the displayed term and partial-sum data, while A and D record the Abel and Dirichlet evidence for that same source.

Next read the completion-facing handoff. The row U is shared by the two faces, so a consumer cannot reach the uniform Cauchy surface from only one detached test witness. The readback row R and terminal seal row E remain downstream of the shared handoff.

Finally the transport, replay, provenance, and local naming rows preserve the same finite route. Since no excluded object is a carrier coordinate, the local certificate cannot export host summability, a selected infinite sum, quotient series equality, countable choice, or ambient real completeness. □

Theorem 7294.3 (Dirichlet–Abel L10 summability handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{DirichletAbelSummability}^{\uparrow}$ *packet factors through*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{AbelTest}^{\uparrow} \longmapsto \mathsf{DirichletTest}^{\uparrow} \longmapsto \mathsf{UniformCauchySeries}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route is a finite L10 handoff from two convergence-test faces to one completion-facing readback; it does not export a host series-summability theorem, selected infinite sum, quotient equality of series names, countable-choice schedule, detached test witness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7294.2. They require the rows $S, A, D, U, R, E, H, C, P, N$ to be read as one packet before a Real-and-Completion consumer inspects the endpoint.

The Abel and Dirichlet faces are both attached to the same RealSeries source. Thus the consumer first reads S, then the Abel face A and the Dirichlet face D as sibling evidence for the same displayed series.

The shared uniform handoff U is downstream of both faces. Once U is visible, the regular rational readback R and the Real seal E can be consumed as completion-facing data, but neither row supplies an independent summability theorem or selected limit.

The structural rows H, C, P, N transport, replay, source, and name the same route. Therefore every L10 read remains inside the displayed summability packet. □

Falsifiable prediction: An accepted $\mathsf{DirichletAbelSummability}^{\uparrow}$ read is refuted if a Real-and-Completion consumer reaches the $\mathsf{UniformCauchySeries}^{\uparrow}$ handoff, $\mathsf{RegSeqRat}^{\uparrow}$ readback, or $\mathsf{Real}^{\uparrow}$ seal without first displaying the $\mathsf{RealSeries}^{\uparrow}$ source together with both the $\mathsf{AbelTest}^{\uparrow}$ and $\mathsf{DirichletTest}^{\uparrow}$ face rows.

Independence witness: realseries, abel-test, dirichlet-test, uniform-cauchy-series, regseqrat, real: none is bijective with $\mathsf{DirichletAbelSummability}^{\uparrow}$ because this packet jointly carries a RealSeries source, Abel and Dirichlet test faces, one shared UniformCauchySeries handoff, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletAbelSummability}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletAbelSummability}^{\uparrow}$ packet is generated from RealSeries source data, AbelTest face data, DirichletTest face data, a shared UniformCauchySeries handoff, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletAbelSummability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7294.1, Definition 7294.2, and Definition 7294.3 seed the Real-and-Completion summability handoff from Abel and Dirichlet test faces to one uniform Cauchy readback route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletAbelSummability}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DirichletAbelSummabilityUp`

Bridge status: none

Not claimed: This chapter does not close host series summability, selected infinite sums, quotient equality of series names, countable choice, detached Abel or Dirichlet witnesses, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Abel-test exposure, Dirichlet-test exposure, shared UniformCauchySeries handoff, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DirichletAbelSummabilityUp.

Chapter 7295

A Concrete Naming Certificate for $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$

Following Arzela, Ascoli, Kelley, and Bishop–Bridges, the $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$ packet records the finite-subfamily surface by which compact-metric finite nets, bounded-family ledgers, and equicontinuity rows are inspected before an Arzela–Ascoli consumer may read compactness-facing data. It sits after the Arzela–Ascoli packet of chapter 412, the equicontinuity-family surface of chapter 413, the bounded-family packet of chapter 3522, the compact-metric source of chapter 129, and the finite epsilon-net rows of chapter 1767. The packet names only the displayed finite subfamily and net-selection readback; it does not claim full Arzela–Ascoli compactness, selected subsequences, quotient function spaces, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7295.1 (Arzela–Ascoli finite-subfamily carrier)**.** *An* $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, F, B, E, Q, W, R, Y, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the compact-metric finite-net schedule on which the subfamily will be inspected.*
2. *F is the finite function-family row. It lists the selected family members as displayed* BHist *entries rather than as a host function space.*
3. *B is the bounded-family ledger read through* $\mathsf{BoundedFunctionFamily}^{\uparrow}$*, recording the pointwise or sup-bound rows needed by each selected member.*
4. *E is the equicontinuity ledger read through* $\mathsf{EquicontinuityFamily}^{\uparrow}$*, exposing the shared finite modulus requests used by the selected members.*
5. *Q is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row, recording the finite source-net centers, tolerance rows, and coverage checks used for the selection surface.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite inspection windows and rational observations.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row attached to the displayed readback, not a global completeness principle.*

8. *Y is the Arzela–Ascoli handoff row, read only by* $\mathsf{ArzelaAscoli}^{\uparrow}$ *or* $\mathsf{AscoliDiagonal}^{\uparrow}$ *consumers after X, F, B, E, Q, W, R are present.*
9. *H records componentwise* hsame *transport of the compact source, finite family, boundedness, equicontinuity, finite-net, readback, seal, and handoff rows.*
10. *C records displayed* Cont *replay of the same finite route.*
11. *P is the* Pkg *provenance over* $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{AscoliDiagonal}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{BoundedFunctionFamily}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, B, E, Q, W, R, Y, H, C, P, N$. It has no coordinate for a host compact-open topology, an arbitrary subsequence selector, quotient equality of functions, open-cover compactness, countable choice, or ambient Real completeness.

Theorem 7295.2 (Arzela–Ascoli finite-subfamily NameCert obligations)**.** *For every accepted* $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$ *carrier $S = (X, F, B, E, Q, W, R, Y, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteSubfami}}$ *surface consists exactly of compact-source admission through X, finite-family admission through F, boundedness admission through B, equicontinuity admission through E, finite epsilon-net admission through Q, StreamName and RegSeqRat readback through W, terminal Real sealing through R, Arzela–Ascoli or Ascoli-diagonal handoff through Y, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7295.1. The analytic rows are exactly X, F, B, E, Q, W, R, Y, and the structural rows are exactly H, C, P, N.

The source and family rows are read first. Row X supplies the compact-metric finite-net schedule, row F supplies the selected finite family, row B supplies the bounded-family ledger, and row E supplies the shared equicontinuity ledger.

The finite inspection rows are downstream from those ledgers. Row Q exposes the finite epsilon-net centers and tolerance checks, row W exposes only finite StreamName windows and RegSeqRat observations, and row R seals that readback as a displayed Real-facing row.

The handoff row Y is therefore a consumer boundary, not a compactness theorem. Rows H, C, P, N transport, replay, source, and name the same finite route, so the listed rows exhaust the local NameCert surface. □

Theorem 7295.3 (Arzela–Ascoli finite-subfamily handoff)**.** *Every* $\mathsf{ArzelaAscoli}^{\uparrow}$ *or* $\mathsf{AscoliDiagonal}^{\uparrow}$ *consumer of an accepted* $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$ *carrier must read the finite subfamily row F, the finite-net row Q, the equicontinuity row E, the boundedness row B, and the Real-seal row R before any compactness-facing conclusion. The handoff factors through*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{BoundedFunctionFamily}^{\uparrow},\ \mathsf{EquicontinuityFamily}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{R}$$

It exports no full Arzela–Ascoli compactness theorem, selected subsequence, quotient function space, open-cover compactness proof, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 7295.2. It orders each consumer read through the compact source, finite family, boundedness, equicontinuity, finite epsilon-net, readback, Real seal, and handoff rows.

The finite subfamily and finite-net checks are visible before the consumer boundary. Thus an $\mathsf{ArzelaAscoli}^{\uparrow}$ or $\mathsf{AscoliDiagonal}^{\uparrow}$ consumer can inspect which family members and net centers were used, together with the boundedness and equicontinuity rows that constrain them.

The Real seal is also a displayed coordinate of the same packet. Since the refused compactness, subsequence, quotient-space, open-cover, choice, and ambient-completeness objects are not carrier coordinates, the handoff cannot export them. □

Falsifiable prediction: An accepted $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$ handoff is refuted if an $\mathsf{ArzelaAscoli}^{\uparrow}$ or $\mathsf{AscoliDiagonal}^{\uparrow}$ consumer reaches a compactness-facing read without displaying the finite subfamily, finite epsilon-net, equicontinuity, boundedness, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local NameCert rows.

Independence witness: arzelaascoli, ascoli-diagonal, equicontinuityfamily, bounded-function-family, compactmetric, finite-epsilon-net: none alone is bijective with $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$ because the packet jointly records the compact source, finite function family, bounded-family ledger, equicontinuity ledger, finite epsilon-net rows, StreamName and RegSeqRat readback, Real seal, handoff boundary, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}}$.

Constructive story: An $\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}$ packet is generated from a compact source, finite function family, bounded-family ledger, equicontinuity ledger, finite epsilon-net rows, StreamName and RegSeqRat readback, a Real seal, an Arzela–Ascoli or Ascoli-diagonal handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7295.1, Definition 7295.2, and Definition 7295.3 seed the finite-subfamily selection surface over compact-metric, bounded-family, equicontinuity, finite-net, StreamName, RegSeqRat, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteSubfamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Arzela–Ascoli compactness, selected subsequences, quotient function spaces, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, finite-family exposure, boundedness exposure, equicontinuity exposure, finite epsilon-net inspection, StreamName and RegSeqRat readback, Real-seal nonescape, handoff ordering, transport, replay, provenance, and local naming for BEDC.Derived.ArzelaAscoliFiniteSubfamilyUp.

Chapter 7296

A Concrete Naming Certificate for $\mathsf{WallmanCompactification}^{\uparrow}$

Following Wallman on compactification by closed-set lattices, the $\mathsf{WallmanCompactification}^{\uparrow}$ packet records the finite route by which a displayed normal lattice of closed rows names boundary filters and their compactification-facing topology. It sits beside the one-point compactification of chapter 2049, the Freudenthal end boundary of chapter 6396, the compact carrier of chapter 60, the indexed topology surface of chapter 88, and the Real/L10 readback route through chapter 38 and chapter 301. The packet names only the finite closed-set lattice and boundary-filter readback; it is not a host powerset of closed sets, a selected ultrafilter, a quotient compactification space, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7296.1 (Wallman compactification carrier)**.** *A* $\mathsf{WallmanCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, L, F, B, J, T, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Topology}^{\uparrow}$ *row, exposing the indexed open and closed-set membership reads available to the packet.*
2. *L is the finite closed-set lattice row. It records displayed finite meets, finite joins, inclusion comparisons, and the normal-separation ledger used by the Wallman route.*
3. *F is the boundary-filter row. Each displayed boundary request names a finite consistent family of closed rows from L together with its finite-refinement witness.*
4. *B is the compact-boundary admission row, read through the compact carrier of chapter 60 without importing an ambient compact host.*
5. *J is the source-inclusion row, sending a displayed source point to the finite closed-neighbourhood filter it determines.*
6. *T is the topology handoff row for the compactification carrier. It translates finite closed-lattice and boundary-filter requests into indexed topology reads.*
7. *R is the L10 readback row, routing finite boundary observations through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seals when a real-valued consumer inspects the compactification.*
8. *H records componentwise* hsame *transport for $X, L, F, B, J, T, R, C, P, N$.*

9. *C records displayed* Cont *replay of closed-lattice, boundary-filter, topology, compactness, and readback requests.*
10. *P is the* Pkg *provenance over* $\mathsf{WallmanCompactification}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{WallmanCompactification}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for a full host closed-set powerset, selected ultrafilter, quotient compactification point, open-cover compactness proof, countable-choice selector, or ambient complete real line.

Theorem 7296.2 (Wallman compactification NameCert obligations)**.** *For every accepted* WallmanCompactification *carrier*

$$K = (X, L, F, B, J, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WallmanCompactification}^{\uparrow}}$ *surface consists exactly of source topology admission, finite closed-lattice admission, boundary-filter consistency, compact-boundary admission, source-inclusion display, topology handoff, L10 readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every compactification-facing read must expose X, L, F, J, T before B or R can be consumed.*

Proof. Project the carrier of Definition 7296.1. The only source data are the topology row X and the finite closed-lattice row L, so every boundary request begins with displayed closed-set membership and finite lattice operations.

The boundary-filter row F is then a finite consistency ledger over L. It records which closed rows are jointly requested and which finite refinement witnesses keep the request admissible, rather than selecting an ultrafilter or forming a quotient point.

Read the source-inclusion and topology handoff rows next. The row J ties displayed source points to their closed-neighbourhood filters, and T converts lattice and filter requests into indexed topology reads before any compact-boundary row is public.

Finally consume B, R, H, C, P, N. The compact-boundary and L10 readback rows are downstream of the same finite route, while transport, replay, provenance, and local naming add no host powerset, selected boundary point, countable-choice selector, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Theorem 7296.3 (Wallman compactification L10 boundary)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer reading a* $\mathsf{WallmanCompactification}^{\uparrow}$ *packet receives only the finite route*

$$X, L, F, J, T \longmapsto B, R, H, C, P, N.$$

Thus an L10 readback may inspect finite closed-set lattice requests, boundary-filter consistency, source inclusion, topology handoff, compact-boundary admission, and the real-valued readback row, but it cannot export a second compactification point, host closed-set powerset, quotient filter equality, selected ultrafilter, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a real-valued or regular-rational consumer. By carrier projection, the consumer first sees the topology source X, closed-lattice row L, boundary-filter row F, source-inclusion row J, and topology handoff row T.

The compact-boundary admission row B and L10 readback row R are downstream of that prefix. They may cite the compact, RegSeqRat, and Real sibling chapters named in the provenance row, but they receive only the displayed finite route rather than an ambient compactification object.

Transport and replay preserve the same route through H and C, and P, N only package and name it. Hence the L10 boundary cannot produce quotient filter equality, selected ultrafilters, countable choice, a second compactification point, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{WallmanCompactification}^{\uparrow}$ consumer that reaches compact-boundary or Real readback data without displaying the source topology, finite closed-set lattice, boundary-filter consistency, source inclusion, and topology handoff rows refutes the carrier surface.

Independence witness: one-point-compactification, freudenthal-compactification, compact, topology, regseqrat, real: no listed sibling supplies the whole closed-lattice boundary packet $K = (X, L, F, B, J, T, R, H, C, P, N)$, because each sibling contributes only a point-boundary, end-boundary, compactness, topology, or L10 readback surface while this chapter binds all of them through one Wallman closed-set lattice route.

Closure status for $\mathsf{NameCert}_{\mathsf{WallmanCompactification}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{WallmanCompactification}^{\uparrow}$ packet is generated from a source topology row, a finite closed-set lattice row, a boundary-filter consistency row, compact-boundary admission, source inclusion, topology handoff, RegSeqRat and Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WallmanCompactification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7296.1, Definition 7296.2, and Definition 7296.3 seed the Wallman compactification packet over displayed topology, finite closed-set lattice, boundary-filter, compact-boundary, and L10 readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WallmanCompactification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host closed-set powersets, selected ultrafilters, quotient compactification points, open-cover compactness, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source topology admission, finite closed-lattice operations, boundary-filter consistency, compact-boundary admission, source inclusion, topology handoff, L10 readback, transport, replay, provenance, and local naming for BEDC.Derived.WallmanCompactificationUp.

Chapter 7297

A Concrete Naming Certificate for $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$

Following Ciarlet and Brenner–Scott, the $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$ packet records the finite stiffness matrix obtained by reading local element energy rows, assembling them over a displayed mesh, and exposing the result as BEDC NameCert data. It sits after the matrix carrier of chapter 49, the linear-map handoff of chapter 48, the finite-difference stencil surface of chapter 5135, the PDE relation carrier of chapter 194, the terminal real-name seal of chapter 38, and the metric-space source of chapter 4230. The packet names the finite energy matrix and its Galerkin-facing handoff; it does not assert a host weak solution, mesh-limit convergence, global coercivity theorem, quotient function equality, selected basis outside the displayed rows, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7297.1 (Finite element stiffness matrix carrier)**.** *A* $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, E, B, A, L, R, D, V, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite mesh row, listing element names, incidence data, boundary tags, and the finite trial-test basis labels inspected by the assembly route.*
2. *E is the element-energy row, recording the local bilinear energy contributions read on each displayed element.*
3. *B is the boundary-condition row, separating constrained degrees of freedom, interior degrees of freedom, and boundary load routes.*
4. *A is the* $\mathsf{Mat}^{\uparrow}$ *assembly row whose entries are obtained by summing only the displayed element contributions from E over the incidence row M.*
5. *L is the* $\mathsf{LinMap}^{\uparrow}$ *handoff row reading the same assembled matrix as a finite operator on the displayed trial-test coordinate window.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for matrix entries, local energy values, symmetry comparisons, and positive-energy tests.*
7. *D is the* $\mathsf{FiniteDifference}^{\uparrow}$ *or quadrature-facing local-difference row used when the element energy is read from displayed finite stencil data.*

8. *V is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *geometric row naming the finite metric observations used to orient element neighbourhoods and boundary faces.*
9. *H records componentwise* hsame *transport for $M, E, B, A, L, R, D, V, C, P, N$.*
10. *C records displayed* Cont *replay from mesh and local-energy reads through assembly, linear-map interpretation, scalar sealing, local-difference data, and metric geometry.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{FiniteDifference}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient finite-element space, a selected external basis, host weak-form equality, mesh-limit convergence, PDE solvability, global coercivity, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7297.2 (Finite element stiffness matrix NameCert obligations)**.** *For every accepted* $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$ *carrier*

$$K = (M, E, B, A, L, R, D, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}}$ *surface consists exactly of finite mesh admission, element-energy admission, boundary-condition separation, Matrix assembly, LinearMap handoff, Real scalar sealing, local finite-difference or quadrature readback, metric-geometric orientation, componentwise transport, displayed replay, provenance, and local naming through $M, E, B, A, L, R, D, V, H, C, P, N$.*

Proof. Project the carrier of Definition 7297.1. The mesh row M, element-energy row E, and boundary row B are the only source rows from which the assembly route may draw element and boundary data.

The assembled row A is then a $\mathsf{Mat}^{\uparrow}$ readback of those displayed local contributions. The row L reads exactly the same table as a finite $\mathsf{LinMap}^{\uparrow}$ handoff, while R seals every entry and comparison as displayed $\mathsf{Real}^{\uparrow}$ data.

The local-difference row D and metric row V keep the finite stencil, quadrature, and geometric observations visible. They do not supply a host weak form or a mesh-limit object.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since every obligation is one of the displayed rows and no excluded analytic endpoint is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7297.3 (Finite element stiffness matrix symmetric positive ledger)**.** *Every symmetry or positive-energy read of an accepted* $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$ *packet factors through the same displayed rows $M, E, B, A, L, R, D, V, H, C, P, N$. Symmetry is read as equality of the paired finite matrix-entry ledgers in A after the element incidences in M and local energies in E have been displayed; positive-energy evidence is read as a finite* $\mathsf{Real}^{\uparrow}$ *comparison over the displayed coordinate window and does not assert global coercivity, spectral positivity, elliptic regularity, or PDE solvability.*

Proof. Start with the matrix assembly row A. Each entry comparison in a symmetry read is attached to the mesh incidence row M and the element-energy row E, so the comparison is a finite ledger over displayed element contributions.

For positive-energy evidence, the consumer reads the coordinate window through L and the scalar comparisons through R. Boundary rows B and metric or local-difference rows D, V remain visible before the comparison is exported.

Transport and replay through H, C preserve the same rows, and P, N record provenance and local naming. The packet therefore supplies only a finite symmetric positive ledger for the displayed matrix, not a global coercivity theorem, spectral theorem, regularity theorem, PDE solution, or mesh-limit conclusion. □

Theorem 7297.4 (Finite element stiffness matrix Galerkin handoff)**.** *Every Galerkin-facing or PDE-facing consumer of an accepted* $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$ *carrier must read the assembly route*

$$M, E, B, A, L, R, D, V, H, C, P, N$$

before it may use the stiffness matrix as input to a finite variational calculation. The handoff reaches $\mathsf{Pde}^{\uparrow}$ *only through the displayed Matrix, LinearMap, Real, finite-difference, and metric rows, and exports no weak solution, convergence theorem, quotient finite-element function, selected external basis, unbounded solver trace, or ambient completeness principle.*

Proof. Begin with a Galerkin-facing consumer. The consumer first sees the finite mesh row M, element-energy row E, and boundary row B, so the variational data are tied to displayed element and boundary coordinates.

Next it reads the assembled matrix A and the linear-map handoff L. This makes the stiffness object a finite matrix and operator row, rather than an ambient bilinear form over an unspecified function space.

The scalar, local-difference, and metric rows R, D, V then expose the real comparisons, stencil or quadrature evidence, and geometric observations that a PDE-facing read may consume. The PDE route is therefore a provenance and replay handoff, not a proof of a host solution theorem.

Finally H, C, P, N preserve and name the same finite route. Since the carrier has no coordinate for weak solutions, convergence, quotient functions, selected external bases, solver traces, or ambient completeness, none of those endpoints can be exported by the Galerkin handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}$ packet is generated from finite mesh rows, local element-energy rows, boundary-condition rows, a displayed MatrixUp assembly table, a LinearMapUp handoff, RealUp scalar seals, finite-difference or quadrature readbacks, MetricSpace or Metric geometry rows, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7297.1, Definition 7297.2, Definition 7297.3, and Definition 7297.4 seed the finite stiffness-matrix carrier, its symmetric positive ledger, and its Galerkin-facing handoff over displayed Matrix, LinearMap, Real, finite-difference, PDE, and metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteElementStiffnessMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host weak solutions, mesh-limit convergence, global coercivity, spectral positivity, elliptic regularity, quotient finite-element functions, selected external bases, solver traces, Lean verification, or a standard bridge.

Upgrade path: Scoped treatment asks for checked carrier admission, element-energy admission, boundary separation, matrix assembly, linear-map handoff, scalar sealing, local-difference or quadrature readback, metric geometry, transport, replay, provenance, and local naming.

Chapter 7298

Baire open-dense intersection NameCert construction

Following Baire and Bishop–Bridges, the $\mathsf{BaireOpenDenseIntersection}^{\uparrow}$ packet records the complete-metric nested-ball construction for an open-dense intersection as finite BEDC NameCert data. It sits beside the theorem-level category route of chapter 3570, the schedule surface of chapter 6530, the complete-metric source of chapter 128, the metric carrier of chapter 57, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names only the displayed nested-ball route; it is not a host comeager set, a countable-choice selector, a quotient of Cauchy streams, or an ambient real-completeness principle.

Definition 7298.1 (Baire open-dense intersection carrier)**.** *A* $\mathsf{BaireOpenDenseIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, D, B, \rho, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}/\mathsf{Met}^{\uparrow}$ *source row, naming the complete metric service and the metric ball classifier used by the construction;*
2. *D is the* $\mathsf{OpenDenseSequence}^{\uparrow}$ *schedule row, listing the finite dense-open requests and predecessor-ball refinements visible to the packet;*
3. *B is the nested-ball choice row, a displayed finite window of centers, radii, containment certificates, and dense-open admissions obtained from the rows M and D;*
4. *ρ is the radius-budget row, recording the positive rational bounds and shrinkage comparisons used to keep the nested balls Cauchy-facing;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row that names the finite prefix windows through which centers, radii, and dense-open requests are inspected;*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the Cauchy thread assembled from B, ρ, S;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback has been displayed;*
8. *H records componentwise* hsame *transport for the complete-metric source, schedule, nested-ball choices, radius budget, stream observations, regular readback, real seal, continuation rows, provenance row, and local naming row;*

9. *C records the displayed* Cont *replay routes by which a consumer rereads the complete-metric source, each dense-open request, each nested-ball refinement, the radius budget, the stream windows, the regular readback, and the real seal without changing the finite packet;*
10. *P is the* Pkg *provenance over* $\mathsf{BaireOpenDenseIntersection}^{\uparrow}$, $\mathsf{BaireCategoryTheorem}^{\uparrow}$, $\mathsf{OpenDenseSequence}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireOpenDenseIntersection}^{\uparrow}}$ *row.*

The carrier has no coordinate for a countable-choice selector, a host intersection object, a comeager-set predicate, quotient equality of names, an arbitrary completed point, open-cover compactness, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 7298.2 (Baire open-dense intersection NameCert obligations)**.** *For an accepted* BaireOpenDenseIntersect *packet $I = (M, D, B, \rho, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireOpenDenseIntersection}^{\uparrow}}$ *obligation surface is exhausted by five rows: source exposure through M, D, nested construction exposure through B, ρ, observation and readback exposure through S, Q, E, componentwise transport and replay through H, C, and provenance with local naming through P, N.*

Proof. Project the carrier of Definition 7298.1. The complete-metric and dense-open source obligations are exactly the rows M, D.

The constructive route is the displayed nested-ball row B together with the radius-budget row ρ. These rows record the finite predecessor/successor-ball data and the positive rational shrinkage comparisons needed by the open-dense intersection read.

The terminal observation surface is S, Q, E. The stream windows expose the inspected finite data, the regular rational row reads back the Cauchy thread, and the real seal is available only after those rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no selector, host intersection, comeager predicate, quotient equality, selected completed point, open-cover compactness, or ambient real-completeness coordinate, the five listed rows exhaust the local NameCert obligations. □

Theorem 7298.3 (Baire open-dense intersection nested-ball route)**.** *Every completion-facing consumer of an accepted* $\mathsf{BaireOpenDenseIntersection}^{\uparrow}$ *packet must pass through the finite route*

$$\mathsf{CompleteMetric}^{\uparrow}, \quad \mathsf{OpenDenseSequence}^{\uparrow}, \quad B, \rho, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The route is transported and replayed only by H, C, P, N. No accepted read may replace it by a countable-choice selector, host comeager set, quotient equality of Cauchy names, arbitrary completed point, open-cover compactness, or ambient real completeness.

Proof. Read the source rows first. The complete-metric and metric-ball classifier row M supplies the ball service, while the schedule row D supplies the finite open-dense requests.

The nested construction then proceeds through B and ρ. Each visible refinement reads the next dense-open request, records the retained successor ball, and displays the positive rational radius comparison before any Cauchy-facing read is exported.

The consumer reaches the completion-facing surface only through S, Q, E. The finite stream row exposes the inspected window, the regular rational row reads the assembled Cauchy thread, and the real seal is the terminal value-facing row.

The structural rows H, C, P, N preserve that same route under componentwise transport, displayed replay, provenance, and local naming. Therefore every completion-facing read passes through the complete-metric, dense-open, nested-ball, radius-budget, StreamName, RegSeqRat, and Real-seal rows, with no hidden selector or host topological object. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireOpenDenseIntersection}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireOpenDenseIntersection}^{\uparrow}$ packet is generated from a complete-metric source row, an open-dense schedule, displayed nested-ball choices, a positive radius budget, finite StreamName observations, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireOpenDenseIntersection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7298.1, Definition 7298.2, and Definition 7298.3 seed the finite complete-metric open-dense intersection route for completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireOpenDenseIntersection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host comeager set, arbitrary countable intersections, countable choice, quotient equality of Cauchy names, selected completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{BaireOpenDenseIntersection}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exposure, nested-ball refinement, radius-budget exactness, finite-window readback, regular rational readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BaireOpenDenseIntersectionUp.

Chapter 7299

A Concrete Naming Certificate for $\mathsf{SequentialLimitPoint}^{\uparrow}$

Following Kelley and Bourbaki on limit points and filters, together with Bishop–Bridges constructive sequence practice, the $\mathsf{SequentialLimitPoint}^{\uparrow}$ packet names the sequence-specific route by which a displayed sequence supplies a limit-point candidate through finite tail evidence. It consumes the tail filter of chapter 1564, the cluster handoff of chapter 6155, the finite source windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a finite NameCert interface for sequence-limit arguments; it does not import a selected host limit, quotient filter equality, ambient compactness, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7299.1 (Sequential limit-point carrier)**.** *A* $\mathsf{SequentialLimitPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, F, Q, R, E, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *sequence row, exposing only finite observation windows of the named sequence;*
2. *F is the* $\mathsf{FrechetFilter}^{\uparrow}$ *tail row, recording the eventual-tail requests through which subsequence or neighbourhood reads are inspected;*
3. *Q is the* $\mathsf{ClusterFilter}^{\uparrow}$ *handoff row, used only after the Frechet tail row has been displayed;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite source and tail windows;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after S, F, Q, R have been exposed;*
6. *H records componentwise* hsame *transport of S, F, Q, R, E;*
7. *C records displayed* Cont *replay from a sequence-window request through the tail and cluster rows to the terminal seal;*
8. *P records* Pkg *provenance over* $\mathsf{SequentialLimitPoint}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{ClusterFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialLimitPoint}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected host limit, quotient filter equality, arbitrary subnet selection, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7299.2 (Sequential limit-point NameCert obligations)**.** *For the carrier of Definition 7299.1, the local* $\mathsf{NameCert}_{\mathsf{SequentialLimitPoint}^{\uparrow}}$ *surface consists exactly of source StreamName admission through* S*, Frechet tail admission through* F*, ClusterFilter handoff through* Q*, RegSeqRat readback through* R*, Real seal handoff through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The source sequence row S and Frechet tail row F are the only rows that expose sequence observations and eventual-tail requests.

Read the cluster handoff and regular readback next. The row Q is downstream of the tail filter, and R reads only the displayed finite windows supplied by S and F before any real-facing seal is available.

Finally the seal and structural rows E, H, C, P, N replay, transport, source, and name the same finite route. Since the carrier contains no host-limit, quotient-filter, subnet-choice, compactness, countable-choice, or completeness coordinate, none of those principles can be exported by the local NameCert surface. □

Theorem 7299.3 (Sequential limit-point Frechet cluster route)**.** *Every accepted* $\mathsf{SequentialLimitPoint}^{\uparrow}$ *packet reaches a cluster-facing or real-facing consumer only through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{FrechetFilter}^{\uparrow} \longmapsto \mathsf{ClusterFilter}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Equivalently, a consumer must first inspect the source sequence windows, then the Frechet tail row, then the cluster handoff, then the regular rational readback, and only then the terminal real seal.

Proof. Start with the carrier row S. It supplies finite sequence windows and no infinite representative.

The Frechet tail row F then fixes the eventual-tail request, and the cluster row Q may be consumed only after that tail request is displayed. Thus cluster use remains sequence-specific rather than an arbitrary filter import.

The readback row R and seal row E finish the route through regular rational data and the terminal $\mathsf{Real}^{\uparrow}$ boundary. The structural rows H, C, P, N preserve that order, so the route cannot bypass the Frechet tail or cluster handoff by selecting a host limit or using quotient filter equality. □

Falsifiable prediction: Every $\mathsf{SequentialLimitPoint}^{\uparrow}$ read displays one StreamName sequence row, one Frechet tail row, one ClusterFilter handoff row, one RegSeqRat readback row, one Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any limit-point consumer is public.

Independence witness: streamname, frechetfilter, cluster-filter, regseqrat, real: $\mathsf{SequentialLimitPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a sequence source, a Frechet tail row, a cluster-filter handoff, regular rational readback, a terminal Real seal, transport, replay, provenance, and local naming as one sequence-specific limit-point certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialLimitPoint}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SequentialLimitPoint}^{\uparrow}$ packet is generated from source StreamName sequence rows, Frechet tail rows, ClusterFilter handoff rows, RegSeqRat readback, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialLimitPoint}^{\uparrow}}$, seed)

Scope closed: Definition 7299.1, Definition 7299.2, and Definition 7299.3 seed the sequence-specific limit-point route over StreamName, FrechetFilter, ClusterFilter, RegSeqRat, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentialLimitPoint}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected host limits, quotient filter equality, arbitrary subnet selection, open-cover compactness, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.SequentialLimitPointUp.

Chapter 7300

A Concrete Naming Certificate for $\mathsf{PeetreKFunctional}^{\uparrow}$

Following Peetre and the real interpolation tradition, the $\mathsf{PeetreKFunctional}^{\uparrow}$ packet names the finite carrier that exposes a K-functional request before any interpolation-scale consumer reads it. It sits between the $\mathsf{NormedSpace}^{\uparrow}$ pair boundary of chapter 1950, the $\mathsf{Real}^{\uparrow}$ value seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ finite-window discipline of chapter 126, the positive-radius ledger of chapter 291, and the regularity-scale siblings $\mathsf{BesovSpace}^{\uparrow}$, $\mathsf{TriebelLizorkinSpace}^{\uparrow}$, and $\mathsf{RieszThorinInterpolation}^{\uparrow}$ of chapter 4204, chapter 6330, and chapter 5725. The packet records a displayed decomposition budget and value-readback route; it does not assert a quotient interpolation space, selected infimum, countable choice, host norm equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7300.1 (Peetre K-functional carrier)**.** *A* $\mathsf{PeetreKFunctional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, X, T, B, V, Q, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source row naming the interpolation request and the finite expression whose decomposition is inspected.*
2. *X is the* $\mathsf{NormedSpace}^{\uparrow}$ *pair row, displaying the two normed sources used by the request.*
3. *T is the positive tolerance row for the $K(t, x)$ read, exposed as a finite request rather than a completed infimum.*
4. *B is the decomposition-budget row listing the finite candidate splits visible to the certificate.*
5. *V is the value-readback row for the displayed norm-sum comparisons attached to the visible splits.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the finite value windows.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording which coordinates of the value stream have been inspected.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger controlling tolerance and comparison requests.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, X, T, B, V, Q, W, D are visible.*
10. *H records componentwise* hsame *transport for all displayed rows.*

11. *C records displayed* Cont *replay from the interpolation request through decomposition budget, value readback, regular rational stream, dyadic ledger, Real seal, provenance, and local naming.*
12. *P is the* Pkg *provenance over* $\mathsf{PeetreKFunctional}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BesovSpace}^{\uparrow}$, $\mathsf{TriebelLizorkinSpace}^{\uparrow}$, $\mathsf{RieszThorinInterpolation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PeetreKFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient interpolation spaces, selected infima, countable choice, host norm equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.PeetreKFunctionalUp`

Theorem 7300.2 (Peetre K-functional NameCert obligations)**.** *For every accepted* $\mathsf{PeetreKFunctional}^{\uparrow}$ *carrier*

$$K = (S, X, T, B, V, Q, W, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PeetreKFunctional}^{\uparrow}}$ *surface consists exactly of source admission,* $\mathsf{NormedSpace}^{\uparrow}$ *pair exposure, positive tolerance exposure, finite decomposition-budget display, value-readback routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback,* $\mathsf{StreamName}^{\uparrow}$ *finite-window inspection,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius control,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7300.1. The analytic rows are $S, X, T, B, V, Q, W, D, E$, and the structural rows are H, C, P, N.

Read the normed pair and tolerance rows first. The row X displays the two normed sources, while T records the positive request scale. The decomposition row B is therefore a finite budget over displayed candidate splits, not a hidden selector for an extremal split.

Next read the value and completion-facing rows. The rows V, Q, W, D, E carry finite norm-sum comparisons through regular rational readback, stream windows, dyadic radii, and the terminal Real seal. None of these rows supplies quotient equality or ambient completeness.

Finally the transport, replay, provenance, and local naming rows preserve the same finite route. Since no excluded object is a coordinate of the carrier, the local certificate cannot export quotient interpolation spaces, selected infima, countable choice, host norm equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7300.3 (Peetre interpolation-scale handoff)**.** *Every Besov, Triebel–Lizorkin, or real-interpolation consumer of an accepted* $\mathsf{PeetreKFunctional}^{\uparrow}$ *packet must read the* $\mathsf{NormedSpace}^{\uparrow}$ *pair row, positive tolerance row, finite decomposition-budget row, value-readback row,* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows before it can route data to* $\mathsf{BesovSpace}^{\uparrow}$, $\mathsf{TriebelLizorkinSpace}^{\uparrow}$, *or* $\mathsf{RieszThorinInterpolation}^{\uparrow}$. *The handoff exports the finite K-functional value route only; it exports no quotient interpolation space, selected infimum, countable-choice schedule, host norm equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7300.2. They require the rows $S, X, T, B, V, Q, W, D, E, H$ to be read as one packet before any interpolation-scale consumer inspects the endpoint.

The decomposition budget B is downstream of the normed-pair row X and the tolerance row T. Thus a consumer first reads the finite pair and request scale, then inspects only the displayed candidate splits.

The value route is completion-facing but finite. The rows V, Q, W, D, E carry the displayed comparisons through regular rational readback, stream windows, dyadic-radius control, and the terminal Real seal before any regularity-scale sibling reads the result.

The structural rows H, C, P, N transport, replay, source, and name the same route. Therefore the consumer receives only the finite K-functional handoff and none of the excluded host interpolation claims. □

Theorem 7300.4 (Peetre K-functional decomposition-window route)**.** *For every accepted* $\mathsf{PeetreKFunctional}^{\uparrow}$ *carrier*

$$K = (S, X, T, B, V, Q, W, D, E, H, C, P, N),$$

any read of a K-functional value routes through the displayed $\mathsf{NormedSpace}^{\uparrow}$ *pair row X, the positive tolerance row T, the finite decomposition-budget row B, the value-readback row V, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger D, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{PeetreKFunctional}^{\uparrow}}$ *row N. The route exports only this finite decomposition window; it exports no selected infimum, quotient interpolation space, countable-choice schedule, host norm equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7300.1. The value read has no independent coordinate outside $S, X, T, B, V, Q, W, D, E, H, C, P, N$, so the normed pair, tolerance, decomposition budget, readback, window, radius, and Real-seal rows are visible before the structural rows are consumed.

Apply the obligation surface of Definition 7300.2. It identifies the local NameCert rows as source admission, $\mathsf{NormedSpace}^{\uparrow}$ pair exposure, positive tolerance exposure, finite budget display, value-readback routing, regular rational readback, finite-window inspection, dyadic-radius control, Real sealing, transport, replay, provenance, and local naming.

Apply the interpolation handoff of Definition 7300.3. It ensures that any regularity-scale consumer reads the same rows before routing data to $\mathsf{BesovSpace}^{\uparrow}$, $\mathsf{TriebelLizorkinSpace}^{\uparrow}$, or $\mathsf{RieszThorinInterpolation}^{\uparrow}$.

The carrier contains no coordinate for an extremal split, quotient interpolation object, countable-choice schedule, host norm equality, or ambient completeness principle. Thus the decomposition-window route is exactly the finite route displayed by the carrier and its NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{PeetreKFunctional}^{\uparrow}$ read is refuted if a Besov, Triebel–Lizorkin, or real-interpolation consumer reaches the $\mathsf{Real}^{\uparrow}$ value seal without first displaying the $\mathsf{NormedSpace}^{\uparrow}$ pair, positive tolerance, finite decomposition budget, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{StreamName}^{\uparrow}$ window, and $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger.

Independence witness: normedspace, real, regseqrat, streamname, dyadicratcore, besovspace, triebel-lizorkin-space, riesz-thorin-interpolation: none is bijective with $\mathsf{PeetreKFunctional}^{\uparrow}$ because this packet jointly carries a normed-pair source, tolerance request, decomposition budget, value readback, regular rational stream, dyadic radius ledger, Real seal, interpolation-scale handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{PeetreKFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PeetreKFunctional}^{\uparrow}$ packet is generated from a source request, NormedSpace pair row, positive tolerance row, finite decomposition-budget row, value-readback row, RegSeqRat row, StreamName finite-window row, DyadicRatCore radius ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PeetreKFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7300.1, Definition 7300.2, and Definition 7300.3 seed the finite Peetre K-functional carrier and its interpolation-scale handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PeetreKFunctional}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.PeetreKFunctionalUp`

Bridge status: none

Not claimed: This chapter does not claim quotient interpolation spaces, selected infima, countable choice, host norm equality, ambient $\mathrm{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, decomposition-budget exposure, value-readback routing, interpolation-scale handoff, transport, replay, provenance, and local naming for BEDC.Derived.PeetreKFunctionalUp.

Chapter 7301

A Concrete Naming Certificate for $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$

Following Bishop–Bridges constructive analysis, a regulated real function on a compact interval is controlled by finite step approximations and dyadic mesh refinements before a Riemann-sum consumer may read an integral value. The $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$ packet records that integrability certificate as BEDC NameCert data. It sits beside the regulated-function schedule of chapter 1906, the Darboux finite-sum surface of chapter 1880, the Riemann-integral readback of chapter 1526, the Real seal of chapter 38, and the dyadic mesh ledger of chapter 358. The packet names finite mesh-and-sum evidence only; it does not import measure completion, selected limits, quotient function equality, host integration, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7301.1 (Regulated Riemann integrability carrier)**.** *A* $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, M, G, D, T, H, C, P, L)$$

with the following displayed rows:

1. *A is the* $\mathsf{Real}^{\uparrow}$ *interval-domain row, naming the left endpoint, right endpoint, orientation data, and the compact interval on which the certificate is read.*
2. *M is the* $\mathsf{DyadicMesh}^{\uparrow}$ *mesh ledger, recording the dyadic subdivision request, refinement order, and finite mesh width used by the certificate.*
3. *G is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *step-approximation schedule, listing the step functions and oscillation bounds inspected on the dyadic mesh.*
4. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *finite-sum handoff row, exposing lower and upper finite sums computed from the displayed step-approximation data.*
5. *T is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *tagged-mesh read, available only after A, M, G, D have been displayed and the Darboux gap is inside the requested dyadic tolerance.*
6. *H records componentwise* hsame *transport for interval domain, mesh ledger, step schedule, finite-sum handoff, tagged-mesh read, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an interval request through dyadic mesh refinement, regulated step approximation, Darboux finite sums, and tagged-mesh readback.*

8. *P is the* Pkg *provenance over* $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *L is the local* $\mathsf{NameCert}_{\mathsf{RegulatedRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, G, D, T, H, C, P, L$. It has no coordinate for a measure algebra, host function quotient, selected limiting partition, ambient compactness proof, or external completeness principle.

Theorem 7301.2 (Regulated Riemann integrability NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$ *carrier*

$$I = (A, M, G, D, T, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the Real interval domain, dyadic mesh ledger, regulated step-approximation schedule, Darboux finite-sum handoff, tagged-mesh read, transport, replay, provenance, and local naming rows;*

2. *mesh coverage, requiring M to refine the interval row A before the step schedule G is inspected;*

3. *regulated approximation exactness, requiring the entries of G to be step data over the mesh cells named by M;*

4. *Darboux handoff exactness, requiring D to compute finite lower and upper sums only from A, M, G and to expose the dyadic gap budget;*

5. *tagged-mesh non-escape, requiring T to be read only after A, M, G, D and the structural rows H, C, P, L are visible.*

Thus an accepted regulated-integrability certificate is a finite NameCert packet over interval data, mesh data, regulated approximation data, finite Darboux sums, tagged-mesh readback, transport, replay, provenance, and local naming.

Proof. Project the displayed carrier of Definition 7301.1. The tuple lists exactly the interval, mesh, approximation, finite-sum, tagged-read, and structural rows.

First read the source side. The interval row A supplies the $\mathsf{Real}^{\uparrow}$ domain, while M supplies the dyadic mesh ledger on that same interval. The regulated schedule G is therefore inspected only cellwise over displayed mesh data.

Next read the finite-sum side. The Darboux row D is computed from the step schedule and mesh cells already displayed, so its lower and upper sums cannot be replaced by a hidden host integral or selected limiting partition.

Finally read T, H, C, P, L. The tagged-mesh row T is downstream of the finite Darboux gap, and the transport, replay, provenance, and local-name rows preserve the same route. Since no further coordinate remains, the five obligations exhaust the local $\mathsf{NameCert}_{\mathsf{RegulatedRiemannIntegrability}^{\uparrow}}$ surface. □

Falsifiable prediction: A $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$ consumer that reaches a $\mathsf{RiemannIntegral}^{\uparrow}$ tagged-mesh read without displaying the $\mathsf{Real}^{\uparrow}$ domain row, $\mathsf{DyadicMesh}^{\uparrow}$ mesh ledger, $\mathsf{RegulatedFunction}^{\uparrow}$ step schedule, and $\mathsf{DarbouxSum}^{\uparrow}$ finite-sum handoff refutes the carrier of Definition 7301.1.

Independence witness: regulatedfunction, darbouxsum, riemannintegral, real, dyadicmesh: $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries interval-domain rows, dyadic mesh rows, regulated step-approximation rows, Darboux finite-sum rows,

tagged-mesh readback, hsame transport, Cont replay, Pkg provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedRiemannIntegrability}^{\uparrow}$ packet is generated from a Real interval-domain row, DyadicMesh ledger, RegulatedFunction step-approximation schedule, DarbouxSum finite-sum handoff, RiemannIntegral tagged-mesh read, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7301.1 and Definition 7301.2 seed the finite regulated-integrability carrier and its mesh-to-Darboux-to-tagged-read route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter explicitly refuses measure completion, selected limits, quotient function equality, host integration, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh coverage, regulated approximation exactness, Darboux finite-sum exactness, tagged-mesh ordering, hsame transport, Cont replay, provenance, and local naming for BEDC.Derived.RegulatedRiemannIntegrabilityUp.

Chapter 7302

A Concrete Naming Certificate for $\mathsf{FinitePowerBoundedOperator}^{\uparrow}$

Following Dunford–Schwartz and Bishop–Bridges normed-operator analysis, the $\mathsf{FinitePowerBoundedOperator}^{\uparrow}$ packet records finite iterates of a bounded linear operator before spectral-radius or Neumann-series consumers inspect the bound. It sits between the bounded-operator route of chapter 1644, the scalar-bound surface of chapter 3603, the finite inverse-series route of chapter 3917, the spectral-radius boundary of chapter 2352, and the rational-to-real readback chain of chapter 301 and chapter 38. The packet names a finite power corridor; it does not assert a spectral-radius limit, a Neumann inverse, a quotient equality of operators, or an ambient completeness theorem.

Definition 7302.1 (Spectral-radius finite-power carrier)**.** *A* $\mathsf{FinitePowerBoundedOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, n, A, B, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the source endpoint, target endpoint, endpoint action, linearity ledger, and displayed norm-bound surface.*
2. *n is the unary power-depth row specifying the finite iterate window that may be inspected.*
3. *A is the finite iterate row. It records the accepted powers $T^0, T^1, \ldots, T^n$ only as displayed operator rows and product ledgers.*
4. *B is the displayed norm-bound ledger for the same finite window. Each entry reads its scalar bound through the* $\mathsf{OperatorNorm}^{\uparrow}$ *surface and keeps the product-bound ancestry visible.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback route for the rational bound entries and terminal real seals used by downstream comparisons.*
6. *H records componentwise* hsame *transport for T, n, A, B, R and the structural rows.*
7. *C records displayed* Cont *replay from a bounded-operator power request through the same finite iterate and norm-bound rows.*
8. *P is the* Pkg *provenance over* $\mathsf{FinitePowerBoundedOperator}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{NeumannSeries}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePowerBoundedOperator}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through the bounded-operator source row, unary depth, finite iterate ledger, displayed norm-bound ledger, rational and real readback, transport, replay, provenance, and local naming.

Theorem 7302.2 (Spectral-radius finite-power bound)**.** *For every accepted* $\mathsf{FinitePowerBoundedOperator}^{\uparrow}$ *carrier*

$$F = (T, n, A, B, R, H, C, P, N),$$

all public finite-power and norm-bound information is exposed only through the rows $T, n, A, B, R, H, C, P, N$*. A* $\mathsf{SpectralRadius}^{\uparrow}$ *consumer may read the finite iterate window and displayed norm bounds, and a* $\mathsf{NeumannSeries}^{\uparrow}$ *consumer may read the same finite corridor before checking residual rows, but neither consumer receives a spectral-radius limit, a Neumann-series inverse, quotient operator equality, selected representative data, or an ambient completeness coordinate from this packet.*

Proof. Project the carrier of Definition 7302.1. The bounded operator is the row T, and the only iteration budget is the unary depth row n.

The finite powers are then exactly the entries of A. Their scalar controls are exactly the entries of B, with rational and real readback passing through R.

Transport and replay do not add analytic coordinates. The rows H and C move and replay the same finite iterate and norm-bound ledger, while P and N only source and name that surface.

Thus a spectral-radius or Neumann-series consumer can inspect the finite corridor but cannot recover a limiting radius, an inverse, quotient equality of operators, selected representatives, or ambient completeness data from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{FinitePowerBoundedOperator}^{\uparrow}$ read exposes a BoundedLinearOperatorUp row, unary power depth, finite iterate row, displayed norm-bound ledger, RegSeqRatUp and RealUp readback, hsame transport, Cont replay, Pkg provenance, and local NameCert before any spectral-radius or Neumann-series consumer may cite the corridor.

Independence witness: boundedlinearoperator, operatornorm, neumann-series, spectral-radius, regseqrat, real: BoundedLinearOperatorUp supplies the operator row without a finite iterate corridor; OperatorNormUp supplies scalar bound rows without a power-depth ledger; NeumannSeriesUp supplies residual and inverse-check rows only after a separate finite corridor is read; SpectralRadiusUp supplies a radius boundary without exporting a limiting theorem from this packet; RegSeqRatUp and RealUp seal bounds without naming operator powers.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePowerBoundedOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitePowerBoundedOperator}^{\uparrow}$ packet is generated from a BoundedLinearOperatorUp row, unary power depth, finite iterate rows, displayed norm-bound ledgers, RegSeqRatUp and RealUp readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePowerBoundedOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7302.1, Definition 7302.2, the falsifiable prediction, and the independence witness seed the finite bounded-operator power corridor consumed by spectral-radius and Neumann-series packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePowerBoundedOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a spectral-radius limit, Neumann-series inverse, quotient operator equality, selected representative data, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite iterate stability, norm-bound ledger readback, rational and real bound sealing, transport and replay stability, and consumer nonescape for BEDC.Derived.FinitePowerBoundedOperatorU

Chapter 7303

A Concrete Naming Certificate for $\mathsf{RealTree}^{\uparrow}$

Following Tits and Morgan on real trees and Bridson–Haefliger on geodesic metric spaces, the $\mathsf{RealTree}^{\uparrow}$ packet records the finite metric-geometry route by which a uniquely tripod-shaped geodesic metric object is named inside BEDC. It sits beside the metric source of chapter 57, the geodesic segment surface of chapter 2213, the hyperconvex comparison packet of chapter 4013, the completion boundary of chapter 128, and the distance readback seal of chapter 38. The packet names only displayed distance rows, segment witnesses, and branch-point uniqueness ledgers; it is not a host path space, a selected geodesic family, an ambient dendrite, or a global completion theorem.

Definition 7303.1 (Real-tree carrier)**.** *A* $\mathsf{RealTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, G, R, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the distance observations available to the packet.*
2. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *segment-witness row, recording the finite segment reads that support the tree route.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *distance-readback row for the displayed segment lengths and comparison budgets.*
4. *B is the branch-point and tripod-uniqueness ledger. It records, for each displayed triple of endpoints, the finite witness that the three segment reads meet in one branch row and that any competing branch row is componentwise identical under the packet classifier.*
5. *H records componentwise* hsame *transport for metric source, segment witnesses, Real readbacks, branch ledgers, continuation rows, provenance, and local naming.*
6. *C records displayed* Cont *replay for distance reads, segment reads, tripod reads, uniqueness checks, and downstream handoffs.*
7. *P is the* Pkg *provenance over* $\mathsf{RealTree}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{HyperconvexMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through M, G, R, B, H, C, P, N. It has no coordinate for a host path space, selected global geodesic family, ambient continuum, quotient tree model, or completion principle.

Theorem 7303.2 (Real-tree NameCert obligations)**.** *For every accepted* $\mathsf{RealTree}^{\uparrow}$ *carrier* $T = (M, G, R, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealTree}^{\uparrow}}$ *surface consists exactly of metric-source admission, geodesic-segment witness exposure, Real distance readback, branch-point and tripod-uniqueness ledger exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the real-tree packet must factor through*

$$M, G, R, B, H, C, P, N$$

before it reads a tree-shaped metric datum.

Proof. Project the carrier of Definition 7303.1. The metric source row M supplies the only distance observations, while the segment row G supplies the only geodesic witnesses visible to the packet.

Read the Real distance row R and the branch ledger B next. The row R seals the finite distance budgets, and B records the displayed tripod meeting row and uniqueness comparison for each named triple.

The structural rows H, C, P, N transport, replay, source, and name only those displayed rows. Since the carrier has no coordinate for host paths, selected geodesics, quotient tree models, or ambient completion, the listed rows exhaust the local NameCert obligations. □

Theorem 7303.3 (Real-tree geodesic-tripod handoff)**.** *Every boundary, completion, or hyperconvex-style consumer of an accepted* $\mathsf{RealTree}^{\uparrow}$ *packet receives only the finite handoff*

$$\mathsf{Met}^{\uparrow}, \mathsf{GeodesicMetric}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto B, H, C, P, N.$$

Thus it may inspect displayed distance observations, segment witnesses, Real-valued length reads, and branch-point uniqueness rows, but it cannot import a host path space, a selected family of geodesics, a global hyperconvex hull, or an ambient completion object.

Proof. Start with the metric row M and the geodesic row G. These rows are the only source of distance and segment information available to a consumer.

The Real readback row R turns the visible distances into the same finite Real-sealed comparisons used by the sibling $\mathsf{Real}^{\uparrow}$ route. The branch ledger B then supplies the tripod meeting row and uniqueness check for each displayed endpoint triple.

Finally route the handoff through H, C, P, N. The hyperconvex and completion siblings may consume the same finite metric rows, but the carrier never exports a host path space, selected geodesic family, global hull, or completion object. □

Falsifiable prediction: An accepted $\mathsf{RealTree}^{\uparrow}$ consumer that uses a branch point without displaying the metric row, geodesic segment witnesses, Real distance readbacks, and tripod-uniqueness ledger refutes the carrier surface.

Independence witness: metric, geodesic-metric, hyperconvex-metric, completemetric, real: no listed sibling supplies the whole packet $T = (M, G, R, B, H, C, P, N)$, because the real-tree route binds metric distance, segment witnesses, Real readback, branch-point uniqueness, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RealTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealTree}^{\uparrow}$ packet is generated from MetricUp distance rows, GeodesicMetricUp segment witnesses, RealUp distance readbacks, a branch-point and tripod-uniqueness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealTree}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7303.1, Definition 7303.2, and Definition 7303.3 seed the real-tree packet over displayed metric, geodesic, Real-distance, branch-ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealTree}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, selected global geodesics, ambient dendrites, quotient tree models, global hyperconvex hulls, ambient completion objects, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, segment-witness exposure, Real distance readback, tripod uniqueness, transport, replay, provenance, and local naming for BEDC.Derived.RealTreeUp.

Chapter 7304

A Concrete Naming Certificate for $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$

Doob's martingale convergence and upcrossing tradition isolates finite stopped windows before any limiting path statement is read. The $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$ packet records that finite route between the martingale, stopping, optional-stopping, upcrossing, Doob-upcrossing, and convergence-preparation certificates of chapter 190, chapter 344, chapter 383, chapter 1629, chapter 1630, and chapter 2246. It names the finite stopping-window carrier consumed by later convergence preparation, not an almost-sure quotient, completed filtration, unbounded stopping theorem, or measure-completion object.

Definition 7304.1 (Martingale stopping-convergence carrier)**.** *A* $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (\Omega, X, E, M, T, O, U, D, W, A, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *probability row.*
2. X *is the* $\mathsf{RandomVar}^{\uparrow}$ *endpoint-family row for the inspected martingale prefix.*
3. E *is the* $\mathsf{CondExp}^{\uparrow}$ *row exposing the successor faces used by the martingale law.*
4. M *is the consumed* $\mathsf{Martingale}^{\uparrow}$ *finite adapted-sequence packet.*
5. T *is the* $\mathsf{StoppingTime}^{\uparrow}$ *bounded decision row.*
6. O *is the* $\mathsf{OptionalStopping}^{\uparrow}$ *stopped-window readback row.*
7. U *is the* $\mathsf{Upcrossing}^{\uparrow}$ *crossing-count ledger for displayed lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoints.*
8. D *is the* $\mathsf{DoobUpcrossing}^{\uparrow}$ *inequality row bounding the displayed crossing-count ledger.*
9. W *is the finite stopping-window ledger naming the inspected horizon, stopped endpoints, crossing counts, and boundary endpoints available to convergence preparation.*
10. A *is the* $\mathsf{MartingaleConvergence}^{\uparrow}$ *admission row that may consume only the finite window named by* W*.*
11. H *records componentwise* hsame *transport for* $\Omega, X, E, M, T, O, U, D, W, A, C, P, N$*.*

12. *C records displayed* Cont *replay through the finite endpoint, stopped-window, upcrossing, Doob-bound, and convergence-admission rows.*
13. *P is the* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, $\mathsf{MartingaleConvergence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{MartingaleStoppingConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their componentwise transports. It has no coordinate for an almost-sure quotient, selected exceptional set, completed sigma-algebra, unbounded stopping-time family, or ambient convergence theorem.

Theorem 7304.2 (Martingale stopping-convergence NameCert obligations)**.** *For every accepted* $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$ *carrier*

$$S = (\Omega, X, E, M, T, O, U, D, W, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MartingaleStoppingConvergence}^{\uparrow}}$ *surface consists exactly of probability exposure, endpoint exposure, conditional-expectation exposure, martingale-prefix exposure, bounded stopping-decision exposure, optional-stopping stopped-window exposure, upcrossing ledger exposure, Doob-bound exposure, finite stopping-window exactness through W, convergence-admission routing through A, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7304.1. The rows $\Omega, X, E, M, T, O, U, D$ are the only stochastic and upcrossing inputs, while W and A are the only convergence-facing rows.

The stopped-window side is finite. The row T supplies bounded decisions, O supplies stopped endpoint reads, U supplies crossing counts, and D supplies the Doob-bound row over the same displayed horizon.

The convergence-facing row A is downstream of W. Since W lists only the finite horizon, stopped endpoints, crossing counts, and boundary endpoints already displayed by T, O, U, D, the local certificate cannot import an almost-sure quotient, a selected exceptional set, completed sigma-algebras, unbounded stopping, or an ambient convergence theorem.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Therefore the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{MartingaleStoppingConvergence}^{\uparrow}}$ surface. □

Theorem 7304.3 (Stopping-window upcrossing route)**.** *Every accepted* $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$ *carrier routes convergence preparation through the finite chain*

$$\mathsf{Martingale}^{\uparrow}, \mathsf{StoppingTime}^{\uparrow}, \mathsf{OptionalStopping}^{\uparrow} \longmapsto \mathsf{Upcrossing}^{\uparrow}, \mathsf{DoobUpcrossing}^{\uparrow} \longmapsto \mathsf{MartingaleStoppingConvergen}$$

The exported object is the displayed stopping-window ledger W and the admission row A over the same endpoint, stopped-window, crossing-count, and Doob-bound rows. It is not an almost-sure convergence theorem, a completed-measure argument, an unbounded stopping theorem, or a quotient equality of stochastic processes.

Proof. Start with the martingale source row M and the stopping row T. They expose only a finite adapted prefix and a bounded decision row.

Next read O, U, D. Optional stopping supplies the stopped endpoints, the upcrossing row supplies the lower-to-upper crossing ledger, and the Doob row supplies the finite bound for that ledger.

The stopping-window row W is then a repacking of the same displayed horizon, endpoint, stopped-value, boundary, crossing, and bound rows. The convergence-admission row A may cite W, but no carrier coordinate contains an almost-sure event, a completed measure space, an unbounded stopping family, or a quotient of processes. □

Falsifiable prediction: Every accepted $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$ consumer displays $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, finite stopping-window, convergence-admission, hsame, Cont, Pkg, and local NameCert rows before reading convergence preparation.

Independence witness: martingale, stoppingtime, optionalstopping, upcrossing, doob-upcrossing, martingale-convergence: none is bijective to $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$ because this packet jointly carries bounded stopping decisions, stopped endpoints, crossing counts, Doob bounds, a stopping-window ledger, convergence admission, transport, replay, provenance, and local naming as one finite route.

Lean4 (statement) `BEDC.Derived.MartingaleStoppingConvergenceUp`

Closure status for $\mathsf{NameCert}_{\mathsf{MartingaleStoppingConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{MartingaleStoppingConvergence}^{\uparrow}$ packet is generated from probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, upcrossing, Doob-upcrossing, finite stopping-window, convergence-admission, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MartingaleStoppingConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7304.1, Definition 7304.2, and Definition 7304.3 seed the finite stopping-window route from optional stopping and upcrossing control to martingale-convergence preparation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MartingaleStoppingConvergence}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close almost-sure convergence, completed filtrations, measure completion, unbounded stopping, quotient process equality, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stopped-window exactness, upcrossing handoff exactness, Doob-bound consumption, convergence-admission nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MartingaleStoppingConvergenceUp.

Chapter 7305

A Concrete Naming Certificate for $\mathsf{ObserverExperienceTrace}^{\uparrow}$

The $\mathsf{ObserverExperienceTrace}^{\uparrow}$ packet realizes the consciousness-observer vision hub of section 9417.8 as finite observer-history, locality, classifier, transport, replay, provenance, and NameCert rows. It sits beside the finite multi-history packet of chapter 468, the locality-cell route of chapter 509, the no-global-synchronization ledger of chapter 1106, and the cross-history causal surface of chapter 478. The packet names a finite trace surface for observer-facing reads; it does not assert a private mental-state oracle, privileged observer frame, global synchronization map, host phenomenology predicate, or physical consciousness law.

Definition 7305.1 (Observer experience trace carrier)**.** *An* $\mathsf{ObserverExperienceTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (H, L, I, Q, R, V, A, S, C, P, N)$$

with the following displayed rows:

1. *H is the finite observer-history row, listing the displayed local histories being traced.*
2. *L is the inter-history locality ledger, recording which observations may be compared without a global synchronization row.*
3. *I is the observer-identity and perspective-classifier row, separating local identity reads from cross-history alignment reads.*
4. *Q is the finite query row for the experience trace: displayed observation sites, local classifier tags, and allowed read windows.*
5. *R is the replay row tying each query in Q back to the displayed observer-history and locality rows.*
6. *V is the provenance row from the consciousness-observer hub, recording which finite vision-site claims are being concretized.*
7. *A is the TasteGate-facing audit row requiring a future Lean* `Nontrivial` *instance and a* `FieldFaithful` *instance to expose at least two distinguishable trace fields and to account for all public carrier rows.*
8. *S records componentwise* hsame *transport for $H, L, I, Q, R, V, A, C, P, N$.*
9. *C records displayed* Cont *replay from observer-history reads through locality, perspective classification, trace queries, audit rows, and local naming.*

10. *P is the* Pkg *provenance over* ObserverExperienceTrace$^{\uparrow}$, FiniteMultiHistPacket$^{\uparrow}$, LocalityCell$^{\uparrow}$, NoGlobalSynchronizationLedger$^{\uparrow}$, CrossHistCausal$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{ObserverExperienceTrace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed histories, locality rows, identity-classifier rows, query rows, replay rows, audit rows, structural transports, provenance, and local name.

Theorem 7305.2 (Observer experience trace boundary)**.** *Every accepted* ObserverExperienceTrace$^{\uparrow}$ *carrier exposes observer-facing trace data only through the finite rows*

$$H, L, I, Q, R, V, A, S, C, P, N.$$

The public boundary permits local observer-history reads, inter-history locality checks, perspective-classifier reads, replay of finite trace queries, vision provenance, and TasteGate-facing `Nontrivial` *and* `FieldFaithful` *obligations. It exports no private Self access, host phenomenology predicate, privileged global observer, global synchronization map, physical consciousness law, or quotient equality of observer histories.*

Proof. Project the carrier of Definition 7305.1. The trace source is H, L, I, Q, and the only replay route is R together with the displayed Cont row C.

The audit row A is explicit. It requires future Lean evidence that the carrier has a nontrivial trace distinction and that the displayed fields are faithful, but it does not itself add an external consciousness predicate.

The structural rows S, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for private Self access, host phenomenology, global synchronization, physical consciousness laws, or quotient observer-history equality, the stated boundary is exact. □

Theorem 7305.3 (Observer experience trace sibling independence)**.** *The* ObserverExperienceTrace$^{\uparrow}$ *carrier is not bijective to any single sibling among* FiniteMultiHistPacket$^{\uparrow}$, LocalityCell$^{\uparrow}$, NoGlobalSynchronizationLed *or* CrossHistCausal$^{\uparrow}$. *It jointly carries finite observer histories, inter-history locality, perspective-classifier rows, finite trace queries, replay provenance, TasteGate-facing audit fields, transport, continuation, package provenance, and local naming as one packet.*

Proof. The finite multi-history packet supplies displayed histories but not the trace query row Q or TasteGate-facing audit row A.

The locality-cell and no-global-synchronization packets supply locality and refusal rows, but they do not jointly carry the observer identity classifier I, replay row R, or vision provenance row V.

The cross-history causal packet supplies a causal comparison surface, while ObserverExperienceTrace$^{\uparrow}$ records a finite trace read with its own query, replay, audit, provenance, and local naming rows. Thus no listed sibling is bijective to the full carrier. □

Falsifiable prediction: An accepted ObserverExperienceTrace$^{\uparrow}$ consumer that reads an observer experience trace without displaying finite observer histories, inter-history locality rows, perspective-classifier rows, finite trace queries, replay provenance, TasteGate-facing audit rows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows refutes the carrier boundary.

Independence witness: finite-multihist-packet, localitycell, noglobalsynchronizationledger, crosshist-causal: no listed sibling is bijective because ObserverExperienceTrace$^{\uparrow}$ jointly carries observer-history, locality, perspective-classifier, finite query, replay, provenance, TasteGate-audit, transport, continuation, package, and local NameCert rows.

Lean4 (statement) `BEDC.Derived.ObserverExperienceTraceUp`

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverExperienceTrace}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverExperienceTrace}^{\uparrow}$ packet is generated from finite observer histories, inter-history locality rows, perspective-classifier rows, trace queries, replay provenance, TasteGate-facing audit rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObserverExperienceTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7305.1, Definition 7305.2, Definition 7305.3, the falsifiable prediction, and the independence witness seed a finite observer-experience trace carrier with explicit locality, classifier, replay, provenance, audit, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObserverExperienceTrace}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close private Self access, host phenomenology, privileged observer frames, global synchronization, physical consciousness laws, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, observer-history exposure, locality exposure, classifier exactness, replay provenance, TasteGate Nontrivial and FieldFaithful instances, transport, continuation, package provenance, and local naming for BEDC.Derived.ObserverExperienceTraceUp.

Chapter 7306

Regular Cauchy Finite Splice NameCert Construction

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyFiniteSplice}^{\uparrow}$ packet records finite prefix replacement of a regular rational Cauchy name while preserving the displayed tail route. It sits over the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the tail-shift route of chapter 1578, and the finite prefix certificate of chapter 7253. The packet gives Real and Completion consumers a finite means of changing observation windows without exporting quotient stream equality, a selected host limit, countable choice, host real equality, or ambient Real completeness.

Definition 7306.1 (Regular Cauchy finite splice carrier)**.** *A* $\mathsf{RegularCauchyFiniteSplice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (k, X, Y, W, D, R, H, C, P, N)$$

with the following displayed rows:

1. *k is the unary splice-depth row naming the last replaced prefix index.*
2. *X is the original* $\mathsf{RegSeqRat}^{\uparrow}$ *stream row whose tail regularity is being retained.*
3. *Y is the replacement finite-prefix row, read only through displayed cells at indices $0, \ldots, k$.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that aligns the original and replacement observations at the splice boundary.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed prefix cells and the retained tail comparison.*
6. *R is the tail* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row consumed after depth k.*
7. *H records componentwise* hsame *transport for the splice depth, original row, replacement prefix, window, dyadic ledger, tail readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the finite splice request through $k, X, Y, W, D, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFiniteSplice}^{\uparrow}$, $\mathsf{RegularCauchyShift}^{\uparrow}$, $\mathsf{FinitePrefixStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSplice}^{\uparrow}}$ *row naming exactly this finite splice packet.*

The classifier compares accepted packets only through $k, X, Y, W, D, R, H, C, P, N$. It has no coordinate for quotient stream equality, selected host limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyFiniteSpliceUp.RegularCauchyFiniteSpliceTasteGate single carrier alignment`

Theorem 7306.2 (Regular Cauchy finite splice NameCert obligations)**.** *For every accepted* RegularCauchyFiniteSpli *carrier $S = (k, X, Y, W, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSplice}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *splice-depth exposure: the unary row k is visible before any replacement cell is read;*
2. *prefix replacement locality: the replacement row Y supplies only the displayed cells at indices $0, \ldots, k$;*
3. *boundary-window alignment: the* $\mathsf{StreamName}^{\uparrow}$ *row W and dyadic ledger D expose the finite splice boundary before the retained tail is consumed;*
4. *tail readback preservation: the row R reads the post-k tail as regular rational data downstream of the* $\mathsf{RegularCauchyShift}^{\uparrow}$ *route;*
5. *structural locality: the rows H, C, P, N preserve exactly the same splice packet under transport, replay, provenance, and naming.*

The obligation surface may cite the finite prefix certificate of chapter 7253 and the regular Cauchy shift route of chapter 1578; it cannot add quotient stream equality, selected host limits, countable choice, host real equality, ambient Real completeness, or a bridge certificate.

Proof. Project the carrier of Definition 7306.1. The finite analytic rows are exactly the splice depth k, the source row X, the replacement prefix Y, the window W, the dyadic ledger D, and the retained tail readback R.

Read the finite prefix certificate and the regular Cauchy shift route. The prefix certificate bounds the replacement cells by k, while the shift route ensures that all post-k reads are taken from the displayed tail rather than from an external selector.

The rows H, C, P, N then repack the same finite data under transport, replay, provenance, and naming. Since no excluded principle is a coordinate of the carrier or a result of the cited sibling routes, no local NameCert obligation can export quotient stream equality, selected host limits, countable choice, host real equality, ambient Real completeness, or bridge checking. □

Theorem 7306.3 (Regular Cauchy finite splice tail stability)**.** *Let $S = (k, X, Y, W, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyFiniteSplice}^{\uparrow}$ *carrier. Every Real or Completion-facing consumer of the spliced name reads the post-k tail by the displayed route*

$$X, Y, k \longmapsto W \longmapsto D \longmapsto R \longmapsto H, C, P, N.$$

Thus finite prefix replacement preserves the regular Cauchy tail route after depth k: the consumer may inspect the replacement prefix and the retained tail readback, but it obtains no quotient equality of streams, no host sequence equality, no selected limiting value, no countable-choice tail selector, and no ambient completeness row.

Proof. Start with the NameCert obligations of Definition 7306.2. They force the splice depth, replacement prefix, boundary window, dyadic ledger, and retained readback to remain visible before any downstream real-name use.

Use the finite prefix certificate for the cells up to k. Those cells are the only part of the name supplied by Y, so the replacement cannot affect a post-k read except through the displayed boundary rows W and D.

Use the regular Cauchy shift route for the tail after k. The readback row R is downstream of that shift route and therefore preserves the regular tail as displayed RegSeqRat data.

Finally replay the structural rows H, C, P, N. They transport and name the same finite route, so the Real or Completion-facing consumer receives a stable tail route and none of the excluded quotient, equality, choice, limit-selection, or completeness principles. □

Theorem 7306.4 (Regular Cauchy finite splice nonescape)**.** *Every exported use of an accepted* $\mathsf{RegularCauchyFiniteSplice}^{\uparrow}$ *packet remains downstream of the displayed finite splice rows* $k, X, Y, W, D, R, H, C, P, N$ *The packet exports finite prefix replacement and retained tail regularity only; it does not export quotient stream equality, a selected host limit, countable choice, host real equality, ambient Real completeness, or a bridge certificate.*

Proof. Apply the carrier definition. The accepted packet has no field for quotient stream equality, selected host limits, countable choice, host real equality, ambient completeness, or bridge checking.

Apply tail stability from Definition 7306.3. Any Real or Completion-facing read passes through the finite replacement prefix and retained regular tail route before it reaches the structural rows.

The structural rows preserve the same displayed packet under hsame, Cont, Pkg, and local NameCert naming. They do not add analytic principles absent from the carrier, so the exported surface remains the finite splice certificate alone. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSplice}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFiniteSplice}^{\uparrow}$ packet is generated from a unary splice depth, original RegSeqRat row, replacement finite-prefix row, StreamName boundary window, DyadicRatCore tolerance ledger, retained RegSeqRat tail readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSplice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7306.1, Definition 7306.2, Definition 7306.3, and Definition 7306.4 seed the finite prefix-replacement route that preserves the displayed regular Cauchy tail after the splice depth.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteSplice}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyFiniteSpliceUp.RegularCauchyFiniteSpliceTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked splice-depth admission, finite-prefix replacement locality, boundary-window alignment, dyadic tolerance exactness, tail readback stability, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFiniteSpliceUp.

Chapter 7307

A Concrete Naming Certificate for $\mathsf{SequentialFilterBridge}^{\uparrow}$

Following Bourbaki on Cauchy filters and Bishop–Bridges on regular Cauchy sequences, the $\mathsf{SequentialFilterBridge}^{\uparrow}$ packet records the finite bridge by which sequence-indexed Cauchy data is read as filter-style completion data without quotienting representatives. It sits between the finite $\mathsf{StreamName}^{\uparrow}$ window route of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational tail route of chapter 301, the saturated $\mathsf{CauchyFilter}^{\uparrow}$ surface of chapter 333, the $\mathsf{CauchyFilterBase}^{\uparrow}$ basis route of chapter 1915, and the separated completion boundary of chapter 402. The bridge exposes only displayed tails, finite windows, basis refinements, Cauchy-filter reads, separated-completion checks, transport, replay, provenance, and local naming rows; it does not add a quotient stream, selected representative, countable-choice schedule, host equality of limits, or ambient completeness.

Definition 7307.1 (Sequential-filter bridge carrier)**.** *A* $\mathsf{SequentialFilterBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, T, F, A, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly which sequence indices are inspected.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row for the inspected tail values and tolerances.*
3. *T is the sequential tail ledger recording unary tail bounds, tail inclusions, and finite requests made after a chosen depth.*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row generated from those tail requests.*
5. *A is the* $\mathsf{CauchyFilterBase}^{\uparrow}$ *row listing the finite basis refinements used by F.*
6. *Q is the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated-completion boundary read after S, R, T, F, A are visible.*
7. *H records componentwise* hsame *transport for the stream-window, regular-readback, tail, filter, base, and separated-completion rows.*
8. *C records displayed* Cont *replay from a completion request through the sequence windows, regular tails, generated filter, basis refinements, separated boundary, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialFilterBridge}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBase}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialFilterBridge}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient representatives, selected subsequences, selected filter points, countable choice, host equality of Cauchy names, or ambient completion.

Theorem 7307.2 (Sequential-filter bridge NameCert obligations)**.** *For every accepted* $\mathsf{SequentialFilterBridge}^{\uparrow}$ *carrier*

$$B = (S, R, T, F, A, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialFilterBridge}^{\uparrow}}$ *surface consists exactly of StreamName finite-window admission through* S*, RegSeqRat regular-tail readback through* R*, sequential tail-budget exposure through* T*, CauchyFilter generation through* F*, CauchyFilterBase refinement through* A*, HausdorffCompletion separated-boundary exposure through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7307.1. The sequence-facing rows are S, R, T, the filter-facing rows are F, A, Q, and the structural rows are H, C, P, N.

The sequence rows expose the finite means of the bridge. A completion request can inspect only the StreamName windows named by S, the regular rational readback supplied by R, and the tail-budget ledger T that says which later requests those windows answer.

The filter rows then consume that same displayed tail data. The generated Cauchy filter row F and basis row A are downstream of S, R, T, while the separated completion boundary Q is downstream of the filter-style read. The structural rows preserve the same dependency, so no quotient representative, selected filter point, countable-choice schedule, host equality, or ambient completeness object can appear in the local certificate. □

Theorem 7307.3 (Sequential-filter finite-window induction)**.** *Let* $B = (S, R, T, F, A, Q, H, C, P, N)$ *be an accepted* $\mathsf{SequentialFilterBridge}^{\uparrow}$ *carrier. Every Cauchy-filter or Cauchy-filter-base read exported by* B *is obtained by induction on finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *tail rows: the base read uses the displayed initial window and tail budget, and each successor read extends the same tail ledger before exposing the corresponding* $\mathsf{CauchyFilter}^{\uparrow}$ *and* $\mathsf{CauchyFilterBase}^{\uparrow}$ *rows. The terminal* $\mathsf{HausdorffCompletion}^{\uparrow}$ *boundary is readable only after that finite induction has displayed* S, R, T, F, A*.*

Proof. The base step reads the first displayed finite window in S together with the matching regular tail row in R. The tail ledger T records that this finite observation already answers the initial filter request, so the generated F and basis row A have a visible source.

For the successor step, extend the inspected window by one finite tail request. The $\mathsf{StreamName}^{\uparrow}$ row records the new index set, the $\mathsf{RegSeqRat}^{\uparrow}$ row records the corresponding regular readback and tolerance, and T appends the tail-budget comparison without changing the earlier rows.

The filter-style read is then rebuilt from the extended finite data. The $\mathsf{CauchyFilter}^{\uparrow}$ row F consumes the extended tail request, the $\mathsf{CauchyFilterBase}^{\uparrow}$ row A records the basis refinement, and transport through H plus replay through C preserve the same finite route.

Thus every exported filter-style completion read is reached by finite induction on displayed sequence windows and regular tail rows. Since Q is downstream of F and A, the $\mathsf{HausdorffCompletion}^{\uparrow}$ boundary cannot be read before the induction has exposed the sequence-to-filter route. □

Theorem 7307.4 (Sequential-filter representative nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{SequentialFilterBridge}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilterBase}^{\uparrow} \longmapsto \mathsf{HausdorffCompletion}^{\uparrow}.$$

The bridge exports a finite route from sequential Cauchy data to filter-style completion data, not a quotient class, selected representative, hidden limit, host equality proof, countable-choice schedule, or ambient completeness theorem.

Proof. Apply the NameCert obligations and the finite-window induction theorem. They force any completion-facing read to expose S, R, T before F, A, Q are public.

The displayed route is therefore sequence first, filter second, and separated completion last. The carrier has no row that can store a quotient class, selected representative, hidden limit, host equality proof, choice schedule, or ambient completeness witness.

Consequently every completion consumer receives only the finite bridge rows and their structural transport, replay, provenance, and local naming data. □

Falsifiable prediction: An accepted $\mathsf{SequentialFilterBridge}^{\uparrow}$ read is refuted if a $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBase}^{\uparrow}$, or $\mathsf{HausdorffCompletion}^{\uparrow}$ consumer reaches its row without first displaying the corresponding $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ tail readback, and finite tail ledger.

Independence witness: streamname, regseqrat, cauchyfilter, cauchyfilterbase, hausdorffcompletion: none is bijective with $\mathsf{SequentialFilterBridge}^{\uparrow}$ because the bridge jointly carries finite sequence windows, regular tail readback, tail budgets, generated Cauchy-filter rows, basis refinements, separated-completion boundary data, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialFilterBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialFilterBridge}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat regular tail rows, sequential tail budgets, CauchyFilter generation, CauchyFilterBase refinements, HausdorffCompletion separated boundaries, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialFilterBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7307.1, Definition 7307.2, Definition 7307.3, and Definition 7307.4 seed the finite sequence-to-filter completion bridge over StreamName windows, RegSeqRat tails, CauchyFilter rows, CauchyFilterBase refinements, and HausdorffCompletion boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialFilterBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host equality of limits, countable choice, ambient completeness, Lean verification, axiom-clean audit, or bridge checking for $\mathsf{SequentialFilterBridge}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, StreamName window exposure, RegSeqRat tail readback, finite-window induction, CauchyFilter generation, CauchyFilterBase refinement, HausdorffCompletion boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SequentialFilterBridgeUp.

Chapter 7308

A Concrete Naming Certificate for $\mathsf{ConstructiveCompactUniformFan}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the fan-theorem route for compact metric sources, the $\mathsf{ConstructiveCompactUniformFan}^{\uparrow}$ packet records the finite branch data by which compact-uniform continuity is read as a bounded finite-window induction. It sits between the fan-uniform route of chapter 6152, the compact metric source of chapter 129, the map graph of chapter 130, the downstream modulus surface of chapter 369, and the real-name seal of chapter 38. The packet names the constructive fan ledger; it does not assert an ambient open-cover theorem, a choice-selected branch, quotient function equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7308.1 (Constructive compact uniform fan carrier)**.** *A* $\mathsf{ConstructiveCompactUniformFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, B, T, W, D, M, U, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the compact finite-net and metric-window data inspected by the fan.*
2. *B is the finite branch ledger, listing the branch prefixes over which the fan induction ranges.*
3. *T is the terminal-bar row, recording that every inspected branch reaches a displayed terminal prefix.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row attached to the inspected branch prefixes.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and diameter row for the finite windows.*
6. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-continuity row whose local data is read at each branch prefix.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced after the branch ledger and tolerance rows have been exhausted.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for codomain distance and tolerance comparisons.*
9. *H records componentwise* hsame *transport for K, B, T, W, D, M, U, E and the local packet shape.*
10. *C records displayed* Cont *replay from compact-metric source data through the branch ledger, terminal-bar row, windows, dyadic tolerances, continuous-map reads, uniform-modulus handoff, and real seal.*

11. *P is the* Pkg *provenance over* ConstructiveCompactUniformFan$^{\uparrow}$, FanUniformContinuity$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{ConstructiveCompactUniformFan}^{\uparrow}}$ *row.*

The carrier exports no open-cover compactness theorem, infinite bar object, branch selector, quotient equality of functions, global choice coordinate, or ambient Real$^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.ConstructiveCompactUniformFanUp.ConstructiveCompactUniformFanTasteGate`
`single carrier alignment`

Theorem 7308.2 (Constructive compact uniform fan NameCert obligations)**.** *For every accepted* ConstructiveCompactUniformFan$^{\uparrow}$ *carrier*

$$F = (K, B, T, W, D, M, U, E, H, C, P, N),$$

the local NameCert$_{\text{ConstructiveCompactUniformFan}^{\uparrow}}$ *surface consists exactly of compact-metric source exposure through K, finite branch-ledger exposure through B, terminal-bar exposure through T, finite-window exposure through W, dyadic tolerance exposure through D, pointwise continuous-map exposure through M, uniform-modulus handoff through U, real sealing through E, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7308.1. The finite packet exposes exactly the compact source, branch ledger, terminal bar, windows, dyadic tolerances, continuous-map rows, uniform-modulus row, real seal, and structural rows.

Read the compact and fan rows first. The compact-metric row K supplies the inspected finite-net source, while B and T record the branch prefixes and the terminal-bar stops used by the fan-uniform route of chapter 6152.

The analytic rows are downstream of that finite branch data. The window row W and dyadic row D supply the finite observations and tolerance budgets; the continuous-map row M supplies pointwise continuity data at the displayed prefixes; the uniform-modulus row U is exposed only after those rows have been read.

Finally E, H, C, P, N seal, transport, replay, package, and name the same route. Since no additional coordinate exists, the listed rows exhaust the local NameCert surface and cannot export open-cover compactness, a selected branch, quotient function equality, global choice, or ambient Real completeness. □

Theorem 7308.3 (Constructive compact uniform fan finite-branch induction)**.** *Let $F = (K, B, T, W, D, M, U, E, H$ be an accepted* ConstructiveCompactUniformFan$^{\uparrow}$ *carrier. Every fan-uniform read accepted by F is exhausted by induction over the finite branch ledger B. At each branch prefix, the induction preserves the compact-metric source row K, the terminal-bar row T, the window row W, the dyadic tolerance row D, the continuous-map row M, the uniform-modulus handoff U, the real seal E, and the structural rows H, C, P, N.*

Consequently a downstream UniformModulus$^{\uparrow}$ *consumer receives only the displayed finite route*

$$K, B, T, W, D, M, U, E, H, C, P, N$$

and receives no branch selector, infinite fan object, host open-cover compactness theorem, quotient function equality, global choice coordinate, or ambient Real$^{\uparrow}$ *completeness witness.*

Proof. Induct on the displayed finite branch ledger B.

For the empty ledger, no branch prefix is available to inspect. The packet can therefore expose only the compact source and structural rows already present in the carrier, and no dyadic tolerance, continuous-map read, or uniform-modulus handoff can be detached from the displayed route.

For a successor branch prefix, first read the terminal-bar row T and the finite-window row W. These rows keep the successor prefix inside the same compact-metric source K and prevent the consumer from replacing it by a selected external branch.

Next consume the dyadic tolerance row D and the pointwise continuous-map row M for that prefix. The row D records the local diameter and tolerance budget, while M supplies only the displayed continuity data attached to the prefix.

The induction hypothesis preserves every earlier prefix with the same rows $K, T, W, D, M, U, E, H, C, P, N$. Combining the earlier route with the successor prefix exhausts the finite branch ledger, and the handoff row U reaches the $\mathsf{Real}^{\uparrow}$ seal E without importing open-cover compactness, quotient function equality, global choice, or ambient real completeness. □

Falsifiable prediction: A compact-uniform consumer that claims a $\mathsf{ConstructiveCompactUniformFan}^{\uparrow}$ read while omitting the compact-metric source row, finite branch ledger, terminal-bar row, finite-window row, dyadic tolerance row, continuous-map row, uniform-modulus handoff, Real seal, transport, replay, provenance, or local naming row refutes the carrier of Definition 7308.1.

Independence witness: fanuniformcontinuity, compactmetric, continuousmap, uniformmodulus, real: $\mathsf{ConstructiveCompactUniformFan}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact-metric source data, finite branch prefixes, terminal-bar stops, finite windows, dyadic tolerance budgets, pointwise continuous-map rows, a uniform-modulus handoff, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCompactUniformFan}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCompactUniformFan}^{\uparrow}$ packet is generated from a CompactMetric source row, a finite branch ledger, a terminal-bar row, StreamName finite windows, DyadicRatCore tolerance rows, ContinuousMap pointwise rows, a UniformModulus handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ConstructiveCompactUniformFan}^{\uparrow}}$, seed)

Scope closed: Definition 7308.1, Definition 7308.2, and Definition 7308.3 seed the L10 compact-uniform fan route over compact-metric, finite-branch, continuous-map, uniform-modulus, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ConstructiveCompactUniformFan}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, infinite fan objects, branch selectors, quotient function equality, global choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, terminal-bar exposure, finite-window coverage, dyadic tolerance exactness, pointwise continuous-map routing, uniform-modulus handoff, RealUp seal nonescape, and branch-selector refusal for BEDC.Derived.ConstructiveCompactUniformFanUp.

Chapter 7309

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedRealModulus}^{\uparrow}$ packet records the constructive located-real modulus surface as finite BEDC data before any $\mathsf{Real}^{\uparrow}$ or Completion consumer treats a located Cauchy name as a real object. It sits beside the located Cauchy interface of chapter 1850, the sequence-modulus surface of chapter 1801, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite modulus route for located real reads; it is not trichotomy, a Dedekind cut, quotient real equality, a selected limit, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 7309.1 (Bishop located real modulus carrier)**.** *A* $\mathsf{BishopLocatedRealModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, L, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *source row, exposing the located Cauchy real interface before any modulus request is read.*
2. *L is the* $\mathsf{LocatedSequenceModulus}^{\uparrow}$ *row, carrying the finite tolerance-to-window schedule for located real sequence reads.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the locatedness request and the regular Cauchy readback.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the modulus schedule.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows and dyadic tolerances.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after B, L, D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for B, L, D, S, R, E and the local packet shape.*
8. *C records displayed* Cont *replay from a located modulus request through the source row, modulus row, tolerance ledger, windows, readback, seal, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealModulus}^{\uparrow}$, $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$, $\mathsf{LocatedSequenceModulus}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, D, S, R, E, H, C, P, N$. It has no coordinate for trichotomy, Dedekind cuts, quotient real equality, selected limits, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7309.2 (Bishop located real modulus NameCert obligations)**.** *For every accepted* BishopLocatedRealMod *carrier $M = (B, L, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the located Cauchy source row, the located sequence modulus row, the dyadic tolerance ledger, finite stream windows, regular rational readback, terminal real seal, componentwise transport, displayed replay, package provenance, and local naming.*

Every accepted obligation is read through those rows and through the sibling chapters named above. No obligation is stored in trichotomy, Dedekind cuts, quotient real equality, a selected limit, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the carrier of Definition 7309.1. The accepted tuple lists exactly the source, modulus, dyadic, stream, regular-readback, seal, transport, replay, provenance, and naming rows.

Read B and L first. The source row exposes the Bishop located Cauchy real interface, while the modulus row gives the finite tolerance-to-window schedule already displayed by the located sequence modulus chapter.

The analytic readback rows are downstream of that schedule. The dyadic row D, stream row S, and regular rational row R supply the finite data that a $\mathsf{Real}^{\uparrow}$ consumer may inspect before the terminal seal E is available.

Finally H, C, P, N preserve, replay, source, and name the same route. Since no additional coordinate occurs in the carrier, the local NameCert surface cannot export any excluded real-completeness, quotient, selection, trichotomy, compactness, verification, or bridge object. □

Theorem 7309.3 (Bishop located real modulus RegSeqRat readback)**.** *Let $M = (B, L, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopLocatedRealModulus}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exported by M is reached through the finite route*

$$B, L, D, S \longmapsto R \longmapsto E, H, C, P, N.$$

Consequently the readback remains attached to the located Cauchy source, the displayed modulus schedule, the dyadic tolerance ledger, and the finite stream window; it cannot be replaced by a quotient stream, selected limit, host real equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from the source row B and the modulus row L. A located real modulus request first fixes the located Cauchy interface and the finite schedule that tells which stream window is inspected.

The rows D and S then expose the tolerance ledger and the finite window. The regular rational readback R is read only after those rows are fixed, so it is not a detached representative or a quotient stream.

The terminal seal E and the structural rows H, C, P, N only preserve and replay this displayed route. Thus every $\mathsf{RegSeqRat}^{\uparrow}$ handoff remains finite and carries no selected limit, host equality, countable choice, or ambient completeness coordinate. □

Theorem 7309.4 (Bishop located real modulus Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read by an accepted* $\mathsf{BishopLocatedRealModulus}^{\uparrow}$ *carrier is downstream of B, L, D, S, R. The seal therefore records a terminal real-name boundary for the displayed located-modulus route and does not create trichotomy, Dedekind cuts, quotient real equality, selected limits, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Apply Definition 7309.2. The only seal coordinate in the accepted packet is E, and it is listed after the source, modulus, dyadic, stream, and regular-readback rows.

Apply Definition 7309.3. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff already forces the route through B, L, D, S, R before any Real-facing read may occur.

The structural rows H, C, P, N do not add a second seal or an external real object. Since the carrier contains no excluded coordinate, the terminal seal cannot escape to trichotomy, Dedekind cuts, quotient real equality, selected limits, open-cover compactness, ambient completeness, Lean verification, or bridge checking. □

Falsifiable prediction: A consumer that claims a $\mathsf{BishopLocatedRealModulus}^{\uparrow}$ read while omitting the located Cauchy source row, located sequence modulus row, dyadic tolerance ledger, finite stream windows, regular rational readback, Real seal, transport, replay, provenance, or local naming row refutes the carrier of Definition 7309.1.

Independence witness: bishoplocatedcauchyreal, locatedsequencemodulus, regseqrat, dyadicratcore, real: $\mathsf{BishopLocatedRealModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the located Cauchy source, reusable located sequence modulus, shared dyadic tolerance ledger, finite windows, regular rational readback, terminal seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealModulus}^{\uparrow}$ packet is generated from a BishopLocatedCauchyReal row, a LocatedSequenceModulus row, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7309.1, Definition 7309.2, Definition 7309.3, and Definition 7309.4 seed the finite located real modulus route over BishopLocatedCauchyReal, LocatedSequenceModulus, DyadicRatCore, StreamName, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, Dedekind cuts, quotient real equality, selected limits, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located sequence modulus exposure, dyadic tolerance exactness, RegSeqRat readback, RealUp seal nonescape, transport stability, replay preservation, provenance, and local naming targets for BEDC.Derived.BishopLocatedRealModulusUp.

Chapter 7310

Bishop Regular Cauchy Reindexing NameCert Construction

Following Bishop and Bridges, the $\mathsf{BishopRegularCauchyReindexing}^{\uparrow}$ packet records the finite certificate by which a regular Cauchy name may be read along a monotone cofinal unary route without changing its Real-facing finite windows. It sits beside the regular rational readback of chapter 301, the finite stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers stable reindexing data before a $\mathsf{Real}^{\uparrow}$ name consumes the source as public finite-window evidence; it does not import quotient representatives, countable choice, a selected host limit, host stream equality, or ambient completeness.

Definition 7310.1 (Bishop regular Cauchy reindexing carrier)**.** *A* $\mathsf{BishopRegularCauchyReindexing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, I, M, C, D, T, R, H, A, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *name, including its regular Cauchy modulus and finite rational readback rows.*
2. *I is the unary index-route row, displaying the finite graph of the reindexing map on every requested window.*
3. *M is the monotonicity row, certifying inside the packet that the displayed route is nondecreasing on the inspected unary indices.*
4. *C is the cofinality row, giving for every requested tail depth a displayed later source index reached by the route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic bounds used to compare the source and reindexed windows.*
6. *T is the tail-stability row, showing that every post-depth read of the reindexed name is backed by a post-depth read of S.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *finite-window read surface exported only after S, I, M, C, D, T are visible.*
8. *H records componentwise* hsame *transport for source, index route, monotonicity, cofinality, dyadic tolerance, tail stability, read surface, replay, provenance, and local naming rows.*

9. *A records displayed* Cont *replay from a reindexing request through* $S, I, M, C, D, T, R, H, P, N$.
10. P *is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyReindexing}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. N *is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyReindexing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, I, M, C, D, T, R, H, A, P, N$. *It has no coordinate for quotient stream representatives, selected limits, countable choice, host equality of sequences, or an ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Theorem 7310.2 (Bishop regular Cauchy reindexing NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyReindexing}^{\uparrow}$ *carrier* $J = (S, I, M, C, D, T, R, H, A, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyRe}}$ *surface consists exactly of eight obligation groups:*

1. *carrier admission for the source name, displayed index route, monotonicity row, cofinality row, dyadic tolerance row, tail-stability row, Real-facing read surface, transport, replay, provenance, and local naming;*
2. *source regularity readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S;
3. *classifier exactness through the displayed finite index route* I;
4. *monotonicity exposure through* M *before any tail comparison is consumed;*
5. *cofinality exposure through* C *before any downstream real-name read is exported;*
6. *dyadic tolerance preservation through* D *for every inspected source and reindexed window;*
7. *tail stability through* T, *binding each reindexed tail read to a later source tail read;*
8. *ledger, transport, replay, provenance, and local naming through* R, H, A, P, N.

Thus the packet names stable monotone cofinal reindexing of regular Cauchy names as finite BEDC data, not as quotient equality of streams or as a selected limit operation.

Proof. Project the carrier of Definition 7310.1. The analytic rows are the source regular Cauchy name S, the displayed index route I, the monotonicity row M, the cofinality row C, the dyadic tolerance row D, and the tail-stability row T.

Read the classifier and route obligations first. The route I is finite on each requested window, while M and C certify that the displayed route is monotone and eventually reaches every required source tail depth.

Next read the dyadic and tail rows. The row D preserves the requested tolerances under the source and reindexed windows, and T ensures that a reindexed tail read is backed by a later tail read of the original $\mathsf{RegSeqRat}^{\uparrow}$ name.

Finally R, H, A, P, N expose the Real-facing finite-window surface and preserve the same packet under transport, replay, provenance, and local naming. Since no excluded quotient, choice, selected-limit, host-equality, or completeness principle is a carrier coordinate, the listed rows exhaust the local obligation surface. □

Theorem 7310.3 (Bishop regular Cauchy reindexing tail stability)**.** *Let* $J = (S, I, M, C, D, T, R, H, A, P, N)$ *be an accepted* $\mathsf{BishopRegularCauchyReindexing}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *finite-window consumer of the reindexed regular Cauchy name reads the same public surface through*

$$S, I, M, C \longmapsto D \longmapsto T \longmapsto R, H, A, P, N.$$

Consequently stable monotone cofinal reindexing preserves the $\mathsf{Real}^{\uparrow}$ *finite-window read surface of the source name: the consumer may inspect the reindexed windows and their displayed source tail witnesses, but it obtains no quotient representative, countable-choice selector, host stream equality, selected host limit, or ambient completeness row.*

Proof. Start with the NameCert obligations of Definition 7310.2. They require source regularity, route exactness, monotonicity, cofinality, dyadic tolerance preservation, and tail stability to be displayed before any Real-facing read.

Use monotonicity and cofinality together. Monotonicity prevents the displayed route from returning to earlier source windows, while cofinality supplies a later source index for every requested tail depth.

Use dyadic tolerance preservation next. The row D records the same requested tolerance against the source and reindexed windows, so the reindexed read has no independent tolerance scale.

Finally apply tail stability and the structural rows. The row T binds every reindexed tail read to a later source tail read, and R, H, A, P, N replay and name that finite route for the $\mathsf{Real}^{\uparrow}$ consumer. Since quotient representatives, choice selectors, host stream equality, selected host limits, and ambient completeness are absent from the carrier, the public read surface is preserved without importing them. □

Falsifiable prediction: A claimed $\mathsf{BishopRegularCauchyReindexing}^{\uparrow}$ read that exports a $\mathsf{Real}^{\uparrow}$ finite-window surface without displaying monotonicity, cofinality, dyadic tolerance preservation, and tail stability is outside the carrier.

Independence witness: regseqrat, streamname, real: $\mathsf{RegSeqRat}^{\uparrow}$ supplies source regularity but not the monotone cofinal route, $\mathsf{StreamName}^{\uparrow}$ supplies finite observation windows but not tail cofinality, and $\mathsf{Real}^{\uparrow}$ supplies the terminal read surface but not the reindexing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyReindexing}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyReindexing}^{\uparrow}$ packet is generated from a source RegSeqRat row, a displayed unary index route, monotonicity, cofinality, dyadic tolerance preservation, tail stability, a RealUp finite-window read surface, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyReindexing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7310.1, Definition 7310.2, and Definition 7310.3 seed the finite certificate for stable monotone cofinal reindexing of regular Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyReindexing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream representatives, countable choice, selected host limits, host stream equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, monotonicity, cofinality, dyadic tolerance preservation, tail stability, ledger, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyReir

Chapter 7311

A Concrete Naming Certificate for $\mathsf{BalancedTruncation}^{\uparrow}$

Following Moore's balanced realization construction and Antoulas's reduced-order modeling treatment, the $\mathsf{BalancedTruncation}^{\uparrow}$ packet records the finite certificate surface that turns reachability and observability energy rows into a reduced state-space model with an explicit error ledger. It sits after the state-space presentation of chapter 329, the Gramian surfaces of chapter 455 and chapter 5787, the Hankel window of chapter 6634, and the Riccati/control consumers of chapter 307, chapter 296, and chapter 348.

Definition 7311.1 (Balanced truncation carrier)**.** *A* $\mathsf{BalancedTruncation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, G_r, G_o, H, k, E, T, R, Q, C, P, N)$$

with the following displayed rows:

1. *S is the finite state-space row read through* $\mathsf{StateSpaceModel}^{\uparrow}$*, including the state, input, output, and transition matrices used by the reduction request.*
2. *G_r is the* $\mathsf{ReachabilityGramian}^{\uparrow}$ *row and G_o is the* $\mathsf{ObservabilityGramian}^{\uparrow}$ *row, both attached to the same displayed state-space row S.*
3. *H is the* $\mathsf{HankelOperator}^{\uparrow}$ *window comparing the reachable and observable energy coordinates visible in G_r and G_o.*
4. *k is the truncation-order row, bounded by the displayed state dimension and recorded as finite BEDC data rather than as an ambient spectral projection.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *error-bound row for the discarded Hankel window.*
6. *T is the reduced state-space row obtained by reading S, G_r, G_o, H, k, E and exposing only the retained coordinates.*
7. *R is the* $\mathsf{Riccati}^{\uparrow}$ *dependency row available to control consumers that compare reduced Riccati data with the source model.*
8. *Q records componentwise* hsame *transport for the state-space, Gramian, Hankel, order, error, reduced-model, Riccati, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from every reduction request through $S, G_r, G_o, H, k, E, T, R, Q, P, N$.*

10. *P is the* Pkg *provenance over* BalancedTruncation$^{\uparrow}$, StateSpaceModel$^{\uparrow}$, ReachabilityGramian$^{\uparrow}$, ObservabilityGramian$^{\uparrow}$, HankelOperator$^{\uparrow}$, Riccati$^{\uparrow}$, LQR$^{\uparrow}$, ModelPredictiveControl$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{BalancedTruncation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, G_r, G_o, H, k, E, T, R, Q, C, P, N$. It has no coordinate for an unlogged infinite-dimensional Hankel operator, hidden singular-vector basis, host norm equality, external optimality theorem, selected controller, or ambient completeness principle.

Theorem 7311.2 (Balanced truncation NameCert obligations)**.** *For every accepted* BalancedTruncation$^{\uparrow}$ *carrier $B = (S, G_r, G_o, H, k, E, T, R, Q, C, P, N)$, the local* NameCert$_{\text{BalancedTruncation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *common state-space admission, requiring G_r and G_o to be read as Gramian rows over the same displayed* StateSpaceModel$^{\uparrow}$ *row S;*
2. *Hankel-window exposure, requiring H to display the finite comparison window between reachable and observable energy rows before any truncation order is consumed;*
3. *order and error binding, requiring k and the* Real$^{\uparrow}$ *error-bound row E to be visible before the reduced row T is exported;*
4. *downstream control handoff, requiring Riccati, LQR, and model-predictive-control consumers to read only the displayed reduced row and its source rows;*
5. *ledger non-escape, requiring Q, C, P, N to transport, replay, source, and name only the displayed packet, with no hidden singular-vector basis, host norm equality, detached optimality theorem, selected controller, or ambient completeness coordinate.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 7311.1. The reachability and observability rows are both tied to the same state-space row S, so the energy comparison cannot be read from two unrelated models.

The Hankel row H is downstream of G_r and G_o. Thus the truncation order k and the error-bound row E are attached to a displayed finite Hankel window rather than to an unlogged operator or hidden basis.

The reduced row T is exported only after S, G_r, G_o, H, k, E are visible. Control consumers then receive a finite handoff through R and the provenance rows, not an external controller or an ambient optimality principle.

Finally, Q, C, P, N preserve and name the same coordinates. Since the refused objects do not occur in the carrier, the listed obligations exhaust the certificate surface. □

Theorem 7311.3 (Balanced truncation Hankel-Riccati handoff)**.** *Every downstream* Riccati$^{\uparrow}$, LQR$^{\uparrow}$, *or* ModelPredictiveControl$^{\uparrow}$ *consumer of an accepted* BalancedTruncation$^{\uparrow}$ *packet must pass through the displayed* HankelOperator$^{\uparrow}$ *window H, truncation-order row k,* Real$^{\uparrow}$ *error-bound row E, and reduced state-space row T before reading any Riccati or finite-horizon control data. The handoff exports no hidden singular-vector basis, detached Hankel norm equality, selected controller, infinite-horizon optimality theorem, or ambient state-space completion.*

Proof. Project the rows $S, G_r, G_o, H, k, E, T, R, Q, C, P, N$ from Definition 7311.1. The Riccati dependency row R appears only after the Hankel window, truncation order, error-bound row, and reduced model have been displayed.

Use the obligation surface of Definition 7311.2. Hankel-window exposure binds H to the two Gramian rows, while order and error binding force k, E, T to precede any exported reduced-control read.

The downstream handoff clause then restricts Riccati, LQR, and model-predictive-control consumers to the displayed reduced row and its provenance. Transport and replay through Q and C keep the handoff inside the same finite packet.

Because no hidden basis, detached norm equality, selected controller, infinite-horizon optimality theorem, or ambient completion coordinate is present in B, none can be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BalancedTruncation}^{\uparrow}}$.

Constructive story: A $\mathsf{BalancedTruncation}^{\uparrow}$ packet is generated from a finite StateSpaceModelUp row, ReachabilityGramianUp and ObservabilityGramianUp rows over the same state-space source, a HankelOperatorUp comparison window, a truncation-order row, a RealUp error-bound row, a reduced state-space row, a RiccatiUp dependency row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BalancedTruncation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7311.1, Definition 7311.2, and Definition 7311.3 seed the finite reduced-order control route through state-space, Gramian, Hankel, truncation-order, error-bound, Riccati, LQR, and model-predictive-control rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BalancedTruncation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close analytic balanced realization existence, singular-vector computation, host Hankel norm equality, optimal reduced-order control, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked common state-space admission, Hankel-window exposure, order and error binding, downstream control handoff, transport, replay, provenance, and local naming for BEDC.Derived.BalancedTruncationUp.

Chapter 7312

A Concrete Naming Certificate for $\mathsf{ObserverModulusClock}^{\uparrow}$

The $\mathsf{ObserverModulusClock}^{\uparrow}$ packet realizes the modulus-as-temporal-rate route of Definition 9418.17 as finite NameCert data: a regular convergence request exposes a stream window, a modulus threshold, a regular rational readback, and a terminal real seal, and the observer reads the modulus as the local rate of the associated Hist time stream rather than as a global clock.

Definition 7312.1 (Observer modulus clock carrier)**.** *An* $\mathsf{ObserverModulusClock}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, S, M, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the local* $\mathsf{HistTimeStream}^{\uparrow}$ *row, exposing the observer's finite Cont-step window and no global synchronization coordinate.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose observations are read by the regular convergence request.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row, interpreted as the number of local time steps required before the requested precision window stabilizes.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same S, M route.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the stream window, modulus threshold, and regular readback have been displayed.*
6. *A is the observer-selection row, recording which local Hist time stream reads the modulus threshold.*
7. *H records componentwise* hsame *transport for the local time stream, stream window, modulus threshold, regular readback, real seal, observer-selection, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from every observer precision request through $L, S, M, Q, R, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{ObserverModulusClock}^{\uparrow}$, $\mathsf{HistTimeStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ObserverModulusClock}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, S, M, Q, R, A, H, C, P, N$. It has no coordinate for a global observer clock, synchronized Hist stream, hidden convergence oracle, selected real limit, quotient stream equality, host real equality, or ambient completeness principle.

Theorem 7312.2 (Observer modulus clock NameCert obligations)**.** *For every accepted* $\mathsf{ObserverModulusClock}^{\uparrow}$ *carrier $O = (L, S, M, Q, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ObserverModulusClock}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *local-time admission, requiring L and A to name the observer's finite Hist time stream before any modulus rate is read;*
2. *stream-window exposure, requiring the* $\mathsf{StreamName}^{\uparrow}$ *row S to display the finite observations inspected by the request;*
3. *modulus-rate binding, requiring M to be read as a local temporal threshold for S before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q is consumed;*
4. *real-seal handoff, requiring the terminal* $\mathsf{Real}^{\uparrow}$ *row R to be downstream of L, S, M, Q, A;*
5. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed packet, with no global clock, synchronized Hist stream, hidden convergence oracle, selected real limit, quotient stream equality, host real equality, or ambient completeness coordinate.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 7312.1. The observer-selection row A chooses a local Hist time stream L, so the modulus read is attached to a finite Cont-step window rather than to a global clock.

The stream row S supplies the observations inspected by the regular convergence request. The modulus row M is consumed as the local threshold for that displayed window, and the regular readback Q is downstream of the same S, M route.

The real seal R is available only after the local time stream, observer selection, stream window, modulus threshold, and readback are visible. Thus a Real-facing consumer receives a finite temporal-rate route, not a selected limit or quotient stream.

Finally, H, C, P, N preserve and name exactly these rows. Since no global clock, synchronized Hist stream, hidden convergence oracle, host equality, or ambient completeness coordinate appears in the carrier, the listed obligations exhaust the certificate surface. □

Theorem 7312.3 (Observer modulus clock sibling route)**.** *Every accepted* $\mathsf{ObserverModulusClock}^{\uparrow}$ *read consumes the sibling rows of chapter 603, chapter 126, chapter 292, chapter 301, and chapter 38 before the observer-selection and temporal-rate rows can be read.*

Proof. Project the accepted carrier $O = (L, S, M, Q, R, A, H, C, P, N)$. The carrier of Definition 7312.1 displays L as the local Hist time stream, S as the finite StreamName window, M as the CauchyModulus threshold, Q as the RegSeqRat readback, and R as the terminal Real seal.

Apply the obligation surface of Definition 7312.2. Its local-time, stream-window, modulus-rate, and real-seal clauses force those sibling rows to be read before A may select the observer route or before M may be interpreted as a temporal rate.

The remaining rows H, C, P, N transport, replay, source, and name the same route. Since no global clock, hidden convergence oracle, selected limit, quotient stream equality, host real equality, or ambient completeness coordinate occurs in O, the accepted read cannot bypass the five sibling chapters listed in the statement. □

Falsifiable prediction: An accepted $\mathsf{ObserverModulusClock}^{\uparrow}$ read is refuted if a $\mathsf{Real}^{\uparrow}$ seal or $\mathsf{RegSeqRat}^{\uparrow}$ readback is reached without displaying the local $\mathsf{HistTimeStream}^{\uparrow}$ row, observer-selection row, $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{CauchyModulus}^{\uparrow}$ threshold, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: histtimestream, streamname, cauchymodulus, regseqrat, real: no listed sibling is bijective with $\mathsf{ObserverModulusClock}^{\uparrow}$ because this packet alone binds a local Hist time stream, observer selection, finite stream window, modulus-as-rate threshold, regular readback, Real seal, transport, replay, provenance, and local naming as one temporal-rate carrier.

The Lean follow-up for this chapter must provide explicit Nontrivial $\mathsf{ObserverModulusClock}^{\uparrow}$ and FieldFaithful $\mathsf{ObserverModulusClock}^{\uparrow}$ instances preserving $L, S, M, Q, R, A, H, C, P, N$ as distinct rows before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverModulusClock}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverModulusClock}^{\uparrow}$ packet is generated from a local HistTimeStreamUp row, StreamNameUp finite-window row, CauchyModulusUp threshold row, RegSeqRatUp readback row, terminal RealUp seal, observer-selection row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ObserverModulusClock}^{\uparrow}}$, seed)

Scope closed: Definition 7312.1 and Definition 7312.2 seed the finite observer-history route that reads a modulus as a local temporal rate over StreamName, CauchyModulus, RegSeqRat, and RealUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ObserverModulusClock}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a global observer clock, inter-Hist synchronization, selected real limits, quotient stream equality, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked local-time admission, stream-window exposure, modulus-rate binding, real-seal handoff, ledger non-escape, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for BEDC.Derived.ObserverModulusClockUp.

Chapter 7313

RiemannPartitionUp NameCert construction

Following Riemann and Darboux, the $\mathsf{RiemannPartition}^{\uparrow}$ packet records a finite subdivision of a displayed $\mathsf{Real}^{\uparrow}$ interval as NameCert data before tags, sums, or integrability claims are available. It sits after the dyadic partition route of chapter 1863, the equal-mesh route of chapter 2033, and the finite mesh-refinement surface of chapter 3496. The packet gives L10 interval consumers a standard finite-subdivision interface without importing host finite lists, quotient partition equality, selected mesh limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7313.1 (RiemannPartition carrier)**.** *A* $\mathsf{RiemannPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, D, U, M, R, H, C, Q, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval source row, carrying the named left and right endpoint seals through which the subdivision is read.*
2. *D is the* $\mathsf{DyadicPartition}^{\uparrow}$ *row, listing the dyadic breakpoint cells that refine the displayed interval.*
3. *U is the* $\mathsf{UniformPartition}^{\uparrow}$ *row, recording any equal-mesh window used by the same subdivision request.*
4. *M is the* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *row, exposing the mesh bound, adjacency, endpoint coverage, and common-refinement witness for the displayed cells.*
5. *R is the downstream readback row for Darboux, Riemann-sum, regulated-function, or interval-estimate consumers that inspect the subdivision only after I, D, U, M have been displayed.*
6. *H records componentwise* hsame *transport for interval endpoints, dyadic cells, uniform mesh data, finite mesh witnesses, downstream readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an interval-subdivision request through I, D, U, M, R, H, Q, N.*
8. *Q is the* Pkg *provenance over* $\mathsf{RiemannPartition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{UniformPartition}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, U, M, R, H, C, Q, N$. It has no coordinate for tagged Riemann sums, Darboux equality, host finite-list equality, quotient partitions, selected mesh limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7313.2 (RiemannPartition mesh refinement)**.** *Every accepted* $\mathsf{RiemannPartition}^{\uparrow}$ *carrier* $P = (I, D, U, M, R, H, C, Q, N)$ *refines its displayed* $\mathsf{Real}^{\uparrow}$ *interval through the existing* $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{UniformPartition}^{\uparrow}$, *and* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *carrier rows before any subdivision consumer can read the packet. The refinement route exposes dyadic cells through* D*, equal-mesh windows through* U *when present, and mesh-bound and common-refinement witnesses through* M*; it exports no Riemann integrability theorem, Darboux equality, host finite-list presentation, quotient partition equality, or selected limiting partition.*

Proof. Project the accepted carrier of Definition 7313.1. The interval source I is the only endpoint row, while D, U, M are the only subdivision and mesh rows available to a consumer.

Read the dyadic side through chapter 1863. The row D supplies the finite dyadic cells and their ordered interval coverage, so a consumer cannot replace the subdivision by a host list of breakpoints.

Next read the equal-mesh and mesh-refinement rows through chapter 2033 and chapter 3496. These rows expose uniform windows, mesh bounds, adjacency, endpoint coverage, and common-refinement data before R is public.

Finally replay the structural rows H, C, Q, N. Transport, continuation replay, provenance, and local naming preserve the same finite subdivision packet, so the accepted route remains a NameCert interface for interval work rather than an integrability theorem, Darboux equality, quotient partition principle, selected mesh-limit construction, or host finite-list assertion. □

Falsifiable prediction: A $\mathsf{RiemannPartition}^{\uparrow}$ consumer that reads a subdivision without exposing the $\mathsf{Real}^{\uparrow}$ interval row, dyadic partition row, optional uniform-mesh row, finite mesh-refinement row, transport, replay, provenance, and local NameCert row refutes the carrier surface.

Independence witness: dyadic-partition, uniform-partition, finite-partition-mesh: $\mathsf{RiemannPartition}^{\uparrow}$ is not bijective with any listed sibling because it joins the interval source, dyadic cells, optional uniform window, and common mesh-refinement handoff as one subdivision packet for downstream interval consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannPartition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RiemannPartition}^{\uparrow}$ packet is generated from a RealUp interval row, DyadicPartition cells, optional UniformPartition mesh windows, FinitePartitionMesh refinement witnesses, downstream readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannPartition}^{\uparrow}}$, seed)

Scope closed: Definition 7313.1 and Definition 7313.2 seed the finite Real interval subdivision interface through DyadicPartitionUp, UniformPartitionUp, and FinitePartitionMeshUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannPartition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Riemann integrability, equality of Darboux upper and lower values, host finite-list presentation, quotient partition equality, selected mesh limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-cell coverage, uniform-window compatibility, mesh-refinement exactness, downstream readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannPartitionUp.

Chapter 7314

A Concrete Naming Certificate for $\mathsf{CountableProductMetric}^{\uparrow}$

Following Bourbaki and Kelley on product uniformities and Bishop–Bridges constructive metric practice, the $\mathsf{CountableProductMetric}^{\uparrow}$ packet records the finite-prefix product metric used when certified metric streams are read by Real and Completion consumers. It sits over the finite schedule of chapter 126, the metric carrier surface of chapter 57, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names the finite-prefix weighted route only; it is not a host countable product, a selected family of points, a quotient completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7314.1 (Countable product metric carrier)**.** *A* $\mathsf{CountableProductMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, M, D, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-prefix schedule. It records which coordinate windows of the certified stream are visible to the consumer.*
2. *M is the finite family of* $\mathsf{Met}^{\uparrow}$ *rows indexed by the visible prefix of S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *weighted finite-prefix tolerance ledger. It records coordinate weights, requested coordinate tolerances, the finite product-radius budget, and the comparison allowance used by the packet.*
4. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *to* $\mathsf{Real}^{\uparrow}$ *seal handoff that reads the weighted finite-prefix sum as a regular rational name before any terminal real seal is consumed.*
5. *H records componentwise* hsame *transport for the stream schedule, metric rows, dyadic ledger, regular-real handoff, continuation, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a product-metric request through S, M, D, W.*
7. *P is the* Pkg *provenance over* $\mathsf{CountableProductMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableProductMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, M, D, W, H, C, P, N. It has no coordinate for host countable products, a choice-selected stream of points, infinite sums, quotient completion equality, detached real carriers, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7314.2 (Countable product metric NameCert obligations)**.** *For every accepted* $\mathsf{CountableProductMetric}^{\uparrow}$ *carrier* $Q = (S, M, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CountableProductMetric}^{\uparrow}}$ *surface consists exactly of finite-prefix schedule admission, metric-row admission for the visible coordinates, weighted dyadic tolerance accounting, regular-rational readback, terminal Real seal handoff, componentwise transport, displayed continuation replay, package provenance, local naming, and refusal of host countable products, choice-selected point streams, infinite sums, quotient completion equality, detached real carriers, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 7314.1. The accepted packet exposes exactly the finite schedule S, the metric rows M over the visible prefix, the dyadic ledger D, the regular-real handoff W, and the structural rows H, C, P, N.

The finite-prefix route reads S before it reads M or D. Thus the product metric read is bounded by the displayed prefix and cannot import a host countable product or a choice-selected infinite point stream.

The weighted ledger D is then read before W. It supplies the coordinate weights, coordinate tolerances, and product-radius budget that the $\mathsf{RegSeqRat}^{\uparrow}$ readback turns into the terminal $\mathsf{Real}^{\uparrow}$ seal handoff.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores infinite sums, quotient completion equality, detached real carriers, ambient Real completeness, Lean verification, or bridge checking, the listed obligations exhaust the local certificate surface. □

Theorem 7314.3 (Countable product metric finite-prefix stability)**.** *Let* $Q = (S, M, D, W, H, C, P, N)$ *be an accepted* $\mathsf{CountableProductMetric}^{\uparrow}$ *packet. If* $Q' = (S', M', D', W', H', C', P', N')$ *is obtained by componentwise* hsame *transport of the finite schedule, visible metric rows, weighted dyadic ledger, regular-real handoff, continuation, provenance, and local naming rows, then* Q' *preserves the same finite-prefix product metric read. The transported packet may rename the displayed prefix and rows, but it may not add an unseen coordinate, an infinite product metric, quotient completion equality, a selected limit, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with carrier admission for Q. The finite schedule S determines exactly which coordinate metric rows can be inspected, and the ledger D is attached to that same prefix.

Apply componentwise hsame transport. The transported schedule S' names the same visible prefix up to the history classifier, while M' and D' are the transported metric rows and weighted ledger over that prefix.

Replay the displayed continuation. The row C' reads the transported route through S', M', D', W' in the same order, so the regular-real handoff preserves the product metric value exposed by the finite prefix.

The exclusions follow from the carrier shape. No coordinate of Definition 7314.1 stores unseen coordinates, infinite product metrics, quotient completion equality, selected limits, or ambient Real completeness, and transport cannot create rows absent from the packet. □

Theorem 7314.4 (Countable product metric Cauchy consumer route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion consumer of an accepted* $\mathsf{CountableProductMetric}^{\uparrow}$ *packet must first expose the finite-prefix weighted ledger* D *together with the schedule* S *and metric rows* M *before reading the handoff row* W*. The Cauchy-facing seal is therefore a routed finite-prefix weighted read, not a host completion of a countable product, a quotient of streams, a selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a completion-facing read of $Q = (S, M, D, W, H, C, P, N)$. Carrier admission makes the schedule and visible metric rows available before any regular-rational or Real-facing seal can be read.

The dyadic ledger D records the weights and tolerance budgets for that displayed prefix. A consumer that omits D has no certified product-radius budget and therefore has no $\mathsf{CountableProductMetric}^{\uparrow}$ metric read to pass to $\mathsf{RegSeqRat}^{\uparrow}$.

Now read the handoff row W. It turns the finite weighted ledger into the regular rational route and then into the terminal $\mathsf{Real}^{\uparrow}$ seal, while H, C, P, N keep the readback tied to the same displayed rows.

Thus every Cauchy or Real completion consumer factors through S, M, D, W, H, C, P, N in order. The packet exports only that finite-prefix weighted route and none of the host product, quotient, selected-limit, choice, or ambient-completeness exits. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountableProductMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CountableProductMetric}^{\uparrow}$ packet is generated from a $\mathsf{StreamName}^{\uparrow}$ finite-prefix schedule, visible $\mathsf{Met}^{\uparrow}$ rows, a $\mathsf{DyadicRatCore}^{\uparrow}$ weighted tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountableProductMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7314.1, Definition 7314.2, Definition 7314.3, and Definition 7314.4 seed the finite-prefix weighted product metric route for certified metric streams.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountableProductMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host countable products, choice-selected point streams, infinite sums, quotient completion equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weighted finite-prefix ledger exactness, finite-prefix transport stability, Cauchy consumer routing, replay, provenance, and local naming for BEDC.Derived.CountableProductMetricUp.

Chapter 7315

A Concrete Naming Certificate for $\mathsf{BauerSimplex}^{\uparrow}$

Following Bauer and Choquet compact-convex theory, the $\mathsf{BauerSimplex}^{\uparrow}$ packet records the finite NameCert surface where a Choquet simplex is read with a closed extreme-boundary handoff. It sits over the Choquet simplex carrier of chapter 6611, the compact source of chapter 60, the convex-set interface of chapter 208, the Radon-measure readback route of chapter 2263, and the finite extreme-point witness surface of chapter 3610. The chapter names the Bauer-simplex packet only as a finite compact-convex certificate with a closed extreme-boundary route; it does not assert selected representing measures, host simplex equality, quotient measure equality, ambient locally convex completeness, or a bridge theorem.

Definition 7315.1 (Bauer simplex carrier)**.** *A* $\mathsf{BauerSimplex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, K, V, R, E, Z, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{ChoquetSimplex}^{\uparrow}$ *source row, carrying the compact-convex probability-boundary interface already named by the Choquet simplex packet.*
2. *K is the* $\mathsf{Compact}^{\uparrow}$ *row whose compact source observations bound the ambient simplex and the extreme-boundary request.*
3. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row exposing affine-combination and convex subcarrier data available to the packet.*
4. *R is the* $\mathsf{RadonMeasure}^{\uparrow}$ *readback row for finite probability-window and boundary-facing measure data.*
5. *E is the* $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ *finite extreme-witness row, opened only as displayed exposed-face and candidate-extreme evidence.*
6. *Z is the closed extreme-boundary ledger, recording finite closedness tests for the boundary route after S, K, V, R, E have been displayed.*
7. *H records componentwise* hsame *transport for Choquet, compact, convex, Radon, finite extreme, closed-boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact-convex probability requests through the finite extreme-boundary route.*

9. *P is the* Pkg *provenance over* $\mathsf{BauerSimplex}^{\uparrow}$, $\mathsf{ChoquetSimplex}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BauerSimplex}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, K, V, R, E, Z, H, C, P, N$. It has no coordinate for a host Bauer simplex object, selected barycentric measure, quotient measure equality, ambient locally convex completeness, choice-selected extreme point, or bridge witness.

Theorem 7315.2 (Bauer simplex NameCert obligations)**.** *For every accepted* $\mathsf{BauerSimplex}^{\uparrow}$ *carrier $B = (S, K, V, R, E, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BauerSimplex}^{\uparrow}}$ *surface consists exactly of Choquet-simplex source admission through S, compact-source exposure through K, convex-carrier exposure through V, Radon-measure readback through R, finite extreme-witness admission through E, closed extreme-boundary ledger visibility through Z, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every compact-convex probability-boundary consumer of the packet must read

$$S, K, V, R, E, Z, H, C, P, N$$

before treating the packet as Bauer-simplex evidence. The route exports no selected representing measure, quotient measure equality, host closed-boundary theorem, ambient locally convex completeness, or bridgeChecked evidence.

Proof. Project the carrier of Definition 7315.1. The Choquet source, compact source, convex source, Radon readback, finite extreme witness, and closed extreme-boundary ledger are exactly the rows S, K, V, R, E, Z.

Read the source rows first. The Choquet simplex row already packages compact convex probability-boundary data, while K and V keep the compact and affine convex observations displayed as separate finite rows.

Next attach measure and extreme-boundary data. The Radon row R supplies only finite regular-measure readback, the Krein–Milman row E supplies only finite exposed-face and candidate-extreme evidence, and Z records closed extreme-boundary tests over those displayed rows.

Finally H, C, P, N transport, replay, source, and name the same route. Since no remaining coordinate stores a selected representing measure, quotient measure equality, host closed-boundary theorem, ambient locally convex completeness, or bridge witness, the listed rows exhaust the local NameCert obligations. □

Theorem 7315.3 (Bauer simplex closed extreme-boundary handoff)**.** *Every closed extreme-boundary read exported by an accepted* $\mathsf{BauerSimplex}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{ChoquetSimplex}^{\uparrow}, \quad \mathsf{Compact}^{\uparrow}, \quad \mathsf{ConvexSet}^{\uparrow}, \quad \mathsf{RadonMeasure}^{\uparrow}, \quad \mathsf{KreinMilmanFiniteExtreme}^{\uparrow}.$$

The handoff reaches the boundary ledger Z only after the Choquet source, compact source, convex affine row, Radon readback row, and finite Krein–Milman extreme-witness row have been displayed. It exports no selected extreme point, no global representation theorem, no quotient measure equality, no host closed-subset equality, and no ambient compact-convex completeness principle.

Proof. Start with the Choquet source. chapter 6611 supplies the compact-convex probability-boundary surface but refuses representing-measure uniqueness and selected extreme points.

Next read the compact and convex rows. The compact source of chapter 60 and the convex carrier of chapter 208 remain visible as K and V, so the handoff cannot replace them by a host compact convex body.

Now attach measure and finite extreme evidence. chapter 2263 contributes only the displayed regular-measure readback, while chapter 3610 contributes only finite exposed-face and candidate-extreme rows.

Therefore the closed extreme-boundary ledger Z is downstream from the listed route. Because the carrier has no selected extreme point, global representation theorem, quotient measure equality, host closed-subset equality, or ambient compact-convex completeness row, the handoff is exactly the finite boundary route stated above. □

Falsifiable prediction: An accepted $\mathsf{BauerSimplex}^{\uparrow}$ consumer that reaches a closed extreme-boundary read without first displaying the $\mathsf{ChoquetSimplex}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, and $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ rows refutes the carrier surface.

Independence witness: choquet-simplex, compact, convexset, radon-measure, krein-milman-finite-extreme: no listed sibling is bijective to $\mathsf{BauerSimplex}^{\uparrow}$, because the packet jointly carries Choquet simplex source data, compact and convex rows, Radon readback, finite extreme-witness data, a closed extreme-boundary ledger, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BauerSimplex}^{\uparrow}}$.

Constructive story: A $\mathsf{BauerSimplex}^{\uparrow}$ packet is generated from a Choquet simplex source row, compact source row, convex-set row, Radon-measure readback, finite Krein–Milman extreme-witness row, closed extreme-boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BauerSimplex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7315.1, Definition 7315.2, and Definition 7315.3 seed the finite Bauer-simplex certificate over Choquet, compact, convex, Radon, finite extreme-witness, closed-boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BauerSimplex}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected representing measures, quotient measure equality, host closed-boundary theorems, ambient locally convex completeness, Lean verification, or bridge checking for $\mathsf{BauerSimplex}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, Choquet-source exposure, compact and convex source visibility, Radon readback, finite extreme-witness admission, closed extreme-boundary exactness, transport, replay, provenance, and local naming for BEDC.Derived.BauerSimplexUp.

Chapter 7316

A Concrete Naming Certificate for $\mathsf{TopologistSineCurve}^{\uparrow}$

Following Kelley and classical point-set topology, the $\mathsf{TopologistSineCurve}^{\uparrow}$ packet records the finite NameCert surface by which the oscillatory graph of $x \mapsto \sin(1/x)$ and its limiting vertical segment are read as Real- and topology-facing boundary data. It sits after the Real carrier of chapter 38, the finite stream window of chapter 126, the regular rational readback of chapter 301, the topology handoff of chapter 88, and the continuous-map route of chapter 130. The packet names only the finite boundary example; it does not assert connectedness, compactness, quotient equality, host subset equality, Real completeness, or a bridge theorem.

Definition 7316.1 (Topologist sine curve carrier)**.** *A* $\mathsf{TopologistSineCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, V, W, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *G is the oscillatory graph-window row, recording finitely many rational observation windows for the graph-side read of $x \mapsto \sin(1/x)$ away from the limiting axis.*
2. *V is the limiting vertical-segment row, recording the displayed endpoint and interval observations used by the boundary read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window that names the graph and segment samples before any Real readback is consumed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the finite stream observations into regular rational approximants.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the graph and limiting-segment coordinates read through W and R.*
6. *T is the topology and continuous-map handoff row, available only after the graph window, segment row, stream window, regular-rational readback, and Real seal have been displayed.*
7. *H records componentwise* hsame *transport for graph-window, segment, stream, regular-rational, Real, topology, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from graph-window and segment requests through $G, V, W, R, E, T, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{TopologistSineCurve}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{TopologistSineCurve}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $G, V, W, R, E, T, H, C, P, N$. It has no coordinate for a host subset of $\mathbb{R}^2$, quotient equality, Real completeness, compactness, connectedness, path-connectedness, or ambient topological closure.

Theorem 7316.2 (Topologist sine curve NameCert obligations)**.** *For every accepted* $\mathsf{TopologistSineCurve}^{\uparrow}$ *carrier $S = (G, V, W, R, E, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TopologistSineCurve}^{\uparrow}}$ *surface consists exactly of oscillatory graph-window admission through G, limiting vertical-segment visibility through V, finite stream observation through W, regular rational readback through R, terminal Real sealing through E, topology and continuous-map handoff through T, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every boundary consumer of the packet must read

$$G, V, W, R, E, T, H, C, P, N$$

before treating the packet as topologist-sine-curve evidence. The route exports no connectedness theorem, compactness theorem, quotient equality, host subset equality, Real completeness principle, or bridgeChecked evidence.

Proof. Project the carrier of Definition 7316.1. The graph-window row G and vertical-segment row V are separate displayed coordinates, so the limiting segment is not inferred from an ambient subset closure.

Read the finite observation rows next. The stream window W supplies only finite samples, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R converts those samples into regular rational readback before the terminal Real seal E is available.

The topology and continuous-map handoff row T is downstream from G, V, W, R, E. Thus a consumer may cite the topology-facing boundary route only after the Real-facing finite data has already been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores host subset equality, quotient equality, Real completeness, connectedness, compactness, or bridge evidence, the listed rows exhaust the local NameCert obligations. □

Theorem 7316.3 (Topologist sine curve Real-topology handoff)**.** *Every topology-facing read of an accepted* $\mathsf{TopologistSineCurve}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{Topology}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}.$$

The handoff reaches the topology and continuous-map row T only after the oscillatory graph window G, limiting vertical-segment row V, finite stream window W, regular rational readback row R, and terminal Real seal E have been displayed. It exports no connectedness claim, compactness claim, quotient equality, host subset equality, or Real completeness principle.

Proof. Start with the graph and segment rows. The graph-window coordinate G records only finite oscillatory observations, while V records the displayed limiting-segment observations; neither row is a host subset of the plane.

Next read the Real-facing route. chapter 126 supplies the finite observation window, chapter 301 supplies the regular rational readback, and chapter 38 supplies the terminal Real seal.

Only after those rows are visible may the packet reach chapter 88 and chapter 130. The topology-facing row is therefore a handoff from finite Real data, not a replacement for it.

Because the carrier has no row for connectedness, compactness, quotient equality, host subset equality, or Real completeness, the handoff cannot export any of those endpoints. □

Falsifiable prediction: An accepted $\mathsf{TopologistSineCurve}^{\uparrow}$ consumer that reads the topology handoff without first displaying G, V, W, R, E refutes the carrier surface.

Independence witness: real, streamname, regseqrat, topology, continuousmap: none carries the oscillatory graph-window row, limiting vertical-segment row, finite stream window, regular rational readback, terminal Real seal, topology handoff, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{TopologistSineCurve}^{\uparrow}}$.

Constructive story: A $\mathsf{TopologistSineCurve}^{\uparrow}$ packet is generated from an oscillatory graph-window row, limiting vertical-segment row, StreamName finite observation window, RegSeqRat readback, terminal RealUp seal, topology and continuous-map handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TopologistSineCurve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7316.1, Definition 7316.2, and Definition 7316.3 seed the finite Real/topology boundary certificate over graph-window, segment, stream, regular-rational, Real, topology, continuous-map, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TopologistSineCurve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close connectedness, compactness, quotient equality, host subset equality, Real completeness, Lean verification, or bridge checking for $\mathsf{TopologistSineCurve}^{\uparrow}$.

Upgrade path: Obligation closure requires checked graph-window admission, limiting vertical-segment visibility, finite stream observation, regular rational readback, terminal Real sealing, topology and continuous-map handoff, transport, replay, provenance, and local naming for BEDC.Derived.TopologistSineCurveUp.

Chapter 7317

A Concrete Naming Certificate for $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$

Following Bishop and Bridges, a regular Cauchy construction carries its usable modulus as displayed finite evidence, not as a selected limit or a quotient completion. The $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$ packet records that evidence on the L10 Real and Completion route: it reads dyadic tolerances from chapter 291, finite windows from chapter 126, regular rational schedules from chapter 301, and the terminal Real seal from chapter 38. The packet is a constructive Cauchy-modulus witness; it is not a quotient, selected limit, countable-choice object, or $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 7317.1 (Bishop Cauchy modulus witness carrier)**.** *A* $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, S, Q, A, R, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the requested dyadic precision and the rational comparisons used to inspect it.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, recording the finite windows opened on the source stream before any modulus claim is read.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *schedule row, recording the regular rational readbacks whose tails must be controlled.*
4. *A is the* $\mathsf{Rat}^{\uparrow}$ *arithmetic row, carrying the rational addition, subtraction, and bound comparisons used inside the modulus witness.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *handoff row, recording only the terminal seal route available after the displayed rational schedule has been inspected.*
6. *M is the modulus-witness row, assigning each displayed dyadic tolerance in D a finite index boundary for the schedule in Q.*
7. *H records componentwise* hsame *transport for D, S, Q, A, R, M and the structural rows.*
8. *C records displayed* Cont *replay from a tolerance request through stream windows, rational readbacks, rational arithmetic, the modulus witness, and the terminal seal route.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusWitness}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7317.2 (Bishop Cauchy modulus witness obligation surface)**.** *For the carrier of Definition 7317.1, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusWitness}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite stream-window exposure, regular rational schedule readback, rational arithmetic accounting, terminal Real-seal handoff, modulus-witness admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier $W = (D, S, Q, A, R, M, H, C, P, N)$. The rows D, S, Q, A, R, M expose the tolerance request, source windows, regular rational schedule, rational arithmetic checks, terminal Real handoff, and displayed modulus witness.

The structural rows H, C, P, N preserve that same finite inventory. Since the carrier lists no quotient, selected limit, choice schedule, host real equality, or ambient completeness row, the named rows exhaust the local $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusWitness}^{\uparrow}}$ obligation surface. □

Theorem 7317.3 (Bishop Cauchy modulus witness induction)**.** *Every accepted* $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$ *read is determined by finite-window induction on the displayed tolerance requests and the stream windows opened for those requests. At each induction step, the witness row M may inspect only the current* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, the current* $\mathsf{StreamName}^{\uparrow}$ *window, the current* $\mathsf{RegSeqRat}^{\uparrow}$ *schedule segment, and the* $\mathsf{Rat}^{\uparrow}$ *arithmetic row before extending the same packet through H, C, P, N.*

Proof. The base case is the empty inspection window. The displayed rows carry no quotient class, limit point, or host real equality, so the empty route is the unique admitted packet prefix.

For the induction step, extend the finite window by one displayed tolerance request. The row D supplies the dyadic precision, S supplies the newly opened stream window, Q supplies the matching regular schedule segment, and A supplies the rational comparisons needed by the modulus witness.

The row M records the finite index boundary for that request. The rows H, C, P, N then transport, replay, source, and name the same packet prefix, so the induction step stays inside the displayed carrier. □

Theorem 7317.4 (Bishop Cauchy modulus witness Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$ *packet must first read the dyadic tolerance row, finite stream windows, regular rational schedule, rational arithmetic row, and modulus-witness row. The terminal Real seal row is therefore a handoff from displayed modulus evidence, not a completeness principle and not a selected limit.*

Proof. Use Definition 7317.2. Its obligation surface places dyadic tolerance exposure, stream-window exposure, regular rational schedule readback, rational arithmetic accounting, and modulus-witness admission before the terminal Real-seal handoff.

Apply Definition 7317.3. Every finite consumer route is built by extending displayed tolerance and stream windows, so the Real-facing row can only be reached after those finite rows have been inspected.

Finally inspect the carrier inventory. The packet has no row for ambient completeness, selected limits, quotient real equality, countable choice, or host real equality; the Real handoff is exactly the displayed seal route R preserved by H, C, P, N. □

Falsifiable prediction: A consumer that reads a $\mathsf{Real}^{\uparrow}$ seal from a regular Cauchy schedule while bypassing the displayed dyadic tolerance row, stream-window row, rational arithmetic row, or modulus-witness row is not reading a $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$ packet.

Independence witness: dyadicratcore, streamname, regseqrat, real: none is bijective to BishopCauchyModulusWi because the witness packet jointly carries tolerance requests, finite windows, regular rational schedules, rational arithmetic checks, a displayed modulus row, terminal seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyModulusWitness}^{\uparrow}$ packet is generated from dyadic tolerance requests, finite stream windows, regular rational schedule rows, rational arithmetic checks, a displayed modulus-witness row, terminal Real-seal handoff, componentwise transport, displayed continuation replay, package provenance, and local naming evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7317.1, Definition 7317.2, Definition 7317.3, and Definition 7317.4 seed the displayed Cauchy-modulus witness over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completion, selected limits, countable choice, host real equality, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exposure, stream-window exposure, regular schedule readback, rational arithmetic accounting, modulus-witness admission, terminal seal handoff, transport, replay, provenance, and local naming.

Chapter 7318

A Concrete Naming Certificate for $\mathsf{ClaimAuditBoundary}^{\uparrow}$

The $\mathsf{ClaimAuditBoundary}^{\uparrow}$ packet realizes the legitimate-claim audit surface of chapter 9456 as a finite NameCert boundary. It sits beside the writing-item packet of chapter 1222, the named externality boundary of chapter 543, the registry layer of chapter 1220, and the object-knowledge certificate of chapter 1218. Those siblings regulate item-level claim text, apophatic externality, registry admission, and licensed object knowledge; this packet binds the finite expression, claim-status row, refusal or gap/socket row, and permitted-claim row before a theorem-shaped consumer may publish the claim.

Definition 7318.1 (Claim audit boundary carrier)**.** *A* $\mathsf{ClaimAuditBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, S, G, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite communicable-expression row, recording the encoded expression being audited.*
2. *S is the claim-status row, read from the theorem, conditional, route, evidence, non-evidence, meta, refusal,* GAP*, or socket statuses of Definition 9456.6.*
3. *G is the gap or socket row, recording the boundary position whenever the expression requests supply not produced by the closed substrate.*
4. *R is the refusal row, recording the visible refusal that prevents hidden supply from being read as theorem content.*
5. *Q is the permitted-claim row, recording the strongest claim text licensed after E, S, G, R have been displayed.*
6. *H records componentwise* hsame *transport for expression, status, gap or socket, refusal, permitted claim, and the structural rows.*
7. *C records displayed* Cont *replay from expression admission through status assignment, boundary exposure, refusal readback, and permitted-claim publication.*
8. *P is the* Pkg *provenance over* $\mathsf{ClaimAuditBoundary}^{\uparrow}$*,* $\mathsf{ClaimStatusAudit}^{\uparrow}$*,* $\mathsf{WritingItemAuditPacket}^{\uparrow}$*,* $\mathsf{ApophaticName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClaimAuditBoundary}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a theorem row that bypasses the displayed status, refusal, gap or socket, and permitted-claim rows.

Theorem 7318.2 (Claim audit boundary NameCert obligations)**.** *For the carrier of Definition 7318.1, the local* $\mathsf{NameCert}_{\mathsf{ClaimAuditBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-expression readback, claim-status readback, gap or socket exposure, refusal exposure, permitted-claim readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the packet $B = (E, S, G, R, Q, H, C, P, N)$. The rows E, S, G, R, Q expose the expression under audit, the status assigned to it, the gap or socket boundary, the refusal row, and the permitted claim.

The rows H, C, P, N preserve that displayed boundary by transport, replay, provenance, and local naming. Since the carrier has no hidden theorem, status-free claim, refusal-free read, or gap-erasing coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7318.3 (Claim audit boundary status nonescape)**.** *No accepted* $\mathsf{ClaimAuditBoundary}^{\uparrow}$ *packet permits a theorem row, route row, evidence row, or object-knowledge claim to escape the displayed claim-status row S, refusal row R, gap or socket row G, and permitted-claim row Q. If a consumer publishes a claim stronger than Q or bypasses G or R, the consumer is no longer reading the accepted packet.*

Proof. Begin with the obligation surface of Definition 7318.2. Every accepted read exposes S, G, R, Q before local naming, so the status assignment, boundary row, refusal row, and permitted text are part of the public packet.

Read the replay row C. It orders expression admission, status assignment, boundary exposure, refusal readback, and permitted-claim publication; therefore claim publication cannot be separated from the displayed status and boundary rows.

Finally inspect the carrier inventory. There is no row for a hidden theorem, unmarked object-knowledge export, gap-free theorem upgrade, or refusal-free claim. The structural rows H, P, N only preserve and name the same packet, so any stronger or bypassing read exits $\mathsf{ClaimAuditBoundary}^{\uparrow}$. □

Falsifiable prediction: If a consumer publishes a theorem row while bypassing the displayed refusal or GAP row, it is not a $\mathsf{ClaimAuditBoundary}^{\uparrow}$ packet.

Independence witness: writing-item-audit-packet, apophaticname, registrylayer, objectknowledgecertificate: none is bijective to $\mathsf{ClaimAuditBoundary}^{\uparrow}$ because the writing-item packet centers item text, the apophatic name centers externality sockets, the registry layer centers admission rows, and the object-knowledge certificate centers licensed object witnesses, while this packet jointly carries expression, status, gap or socket, refusal, permitted claim, transport, replay, provenance, and local naming rows.

The Lean follow-up must supply explicit Nontrivial $\mathsf{ClaimAuditBoundary}^{\uparrow}$ and FieldFaithful $\mathsf{ClaimAuditBoundary}^{\uparrow}$ instances in lean4/BEDC/Derived/ClaimAuditBoundaryUp/TasteGate.lean. The field-faithfulness witness must keep $E, S, G, R, Q, H, C, P, N$ distinct before the claim-audit boundary can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{ClaimAuditBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClaimAuditBoundary}^{\uparrow}$ packet is generated from a finite expression row, claim-status row, gap or socket row, refusal row, permitted-claim row, componentwise transport, displayed continuation replay, package provenance, and local naming evidence.

Theory closure: TheoryGate(NameCert$_{\mathsf{ClaimAuditBoundary}\uparrow}$, seed)

Scope closed: Definition 7318.1, Definition 7318.2, and Definition 7318.3 seed the finite expression, status, gap or socket, refusal, permitted-claim, hsame, Cont, Pkg, and NameCert boundary for legitimate-claim reads.

Formal verification: FormalStatus(NameCert$_{\mathsf{ClaimAuditBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, registry-wide claim correctness, object-knowledge truth, hidden supply discharge, bridge checking, or theorem status outside the displayed packet rows.

Upgrade path: Obligation closure requires checked carrier admission, status readback, gap or socket exposure, refusal exposure, permitted-claim readback, transport, replay, provenance, and local naming.

Chapter 7319

A Concrete Naming Certificate for $\mathsf{RegularSequenceRegularizer}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers, the $\mathsf{RegularSequenceRegularizer}^{\uparrow}$ packet records the finite route that turns a stream-window Cauchy witness into a regular rational sequence before the terminal real-name seal is consumed. It sits between the finite observation interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the uniform-modulus surface of chapter 4158, and the terminal real-name seal of chapter 38. The packet names a displayed regularization interface for Real and Completion consumers; it does not choose a limit, quotient streams, import countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7319.1 (Regular sequence regularizer carrier)**.** *A* $\mathsf{RegularSequenceRegularizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, D, K, U, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by the Cauchy request;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic endpoint and comparison budgets used by the regularization;*
3. *K is the stream-window Cauchy evidence row, read only through S and D;*
4. *U is the* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *row that supplies one displayed modulus schedule for the regularization route;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from S, D, K, U;*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular readback row has been displayed;*
7. *H records componentwise* hsame *transport for $S, D, K, U, Q, R, C, P, N$;*
8. *C records displayed* Cont *replay through the stream window, dyadic tolerance row, Cauchy evidence, uniform modulus, regular readback, real seal, transport, provenance, and local naming rows;*
9. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceRegularizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceRegularizer}^{\uparrow}}$ *row.*

The carrier has no coordinate for a chosen limit, quotient stream equality, host real equality, countable-choice schedule, hidden convergence oracle, or ambient completeness principle.

Theorem 7319.2 (Regular sequence regularizer NameCert obligations)**.** *For every accepted* RegularSequenceRegula *carrier* $G = (S, D, K, U, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceRegularizer}^{\uparrow}}$ *surface consists exactly of carrier admission for* G*, stream-window exposure through* S*, dyadic tolerance exposure through* D*, Cauchy evidence exposure through* K*, uniform-modulus exposure through* U*, regular rational readback through* Q*, terminal real-seal handoff through* R*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 7319.1. The only observation data are the finite stream windows in S, and the only tolerance arithmetic available to the regularizer is the dyadic ledger D.

The row K records that the inspected windows satisfy the Cauchy request, while U supplies the displayed uniform schedule that converts the request into a regular route. Thus the regular rational readback Q is downstream of S, D, K, U.

The seal R is reached only after the regular readback is visible. The structural rows H, C, P, N transport, replay, source, and name that same finite route, so the NameCert surface cannot add a selected limit, quotient stream equality, host real equality, countable-choice schedule, hidden convergence oracle, or ambient completeness coordinate. □

Theorem 7319.3 (Regularizer RegSeqRat readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exported by an accepted* $\mathsf{RegularSequenceRegularizer}^{\uparrow}$ *packet factors through the displayed route*

$$S, D, K, U \longmapsto Q.$$

Consequently a Real-facing or Completion-facing consumer cannot read the regular sequence as a free stream, a selected limit, or a quotient representative outside the StreamName, DyadicRatCore, Cauchy evidence, and regular uniform-modulus rows.

Proof. Begin with $G = (S, D, K, U, Q, R, H, C, P, N)$. The carrier definition presents Q as the regular rational row produced from the finite-window row S, dyadic tolerance row D, Cauchy evidence row K, and uniform-modulus row U.

Use Definition 7319.2. Its readback clause exposes Q only after the four source rows have been displayed, and its transport and replay clauses preserve that dependency under hsame and Cont.

Therefore any consumer of Q receives a regular readback route rather than an independent stream or chosen representative. The packet carries no coordinate that could supply a selected limit, quotient stream equality, host real equality, countable-choice schedule, or hidden convergence oracle. □

Theorem 7319.4 (Regularizer terminal seal nonescape)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{RegularSequenceRegularizer}^{\uparrow}$ *packet is downstream of the rows*

$$S, D, K, U, Q, H, C, P, N.$$

It cannot be consumed as ambient real completeness, host real equality, quotient stream equality, a selected real limit, or a completion seal independent of the displayed regularization route.

Proof. Project the accepted packet. The carrier row R is the only terminal $\mathsf{Real}^{\uparrow}$ seal coordinate, and it appears after the stream window, dyadic tolerance, Cauchy evidence, uniform modulus, and regular readback rows.

Apply Definition 7319.2. Its terminal handoff clause binds R to Q, while the preceding clauses bind Q to S, D, K, U.

The structural rows H, C, P, N keep the same route visible under transport, replay, provenance, and naming. Since no ambient-completeness or quotient coordinate is stored in the carrier, the terminal seal cannot escape the displayed regularization route. □

Falsifiable prediction: A consumer that claims a $\mathsf{RegularSequenceRegularizer}^{\uparrow}$ read while omitting the $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, Cauchy evidence row, RegularCauchyUniformMo schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert rows refutes the carrier of Definition 7319.1.

Independence witness: streamname, dyadicratcore, regseqrat, regularcauchyuniformmodulus, real: no listed sibling is bijective to $\mathsf{RegularSequenceRegularizer}^{\uparrow}$ because this packet alone binds finite stream windows, dyadic tolerance data, Cauchy evidence, a regular uniform modulus, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming as one regularization interface.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceRegularizer}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceRegularizer}^{\uparrow}$ packet is generated from StreamName finite-window rows, DyadicRatCore tolerance rows, stream-window Cauchy evidence, a RegularCauchyUniformModulus schedule, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceRegularizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7319.1, Definition 7319.2, Definition 7319.3, and Definition 7319.4 seed the finite regularization route between stream-window Cauchy evidence and RegSeqRat and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceRegularizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, selected real limits, host real equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, dyadic tolerance exposure, Cauchy evidence exposure, uniform-modulus exposure, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularSequenceRegularizerUp.

Chapter 7320

A Concrete Naming Certificate for $\mathsf{NakayamaLemma}^{\uparrow}$

Following Atiyah–Macdonald and Matsumura, the $\mathsf{NakayamaLemma}^{\uparrow}$ packet names the finite commutative-algebra handoff by which an ideal action trapped in the Jacobson-radical direction forces a finitely generated module witness to collapse. In BEDC form it sits after the $\mathsf{NameCert}_{\mathsf{Module}^{\uparrow}}$ carrier of chapter 46, the $\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$ carrier of chapter 81, the ring and commutative-ring rows of chapter 43 and chapter 44, and the finite-generation surface of $\mathsf{NameCert}_{\mathsf{NoetherianModule}^{\uparrow}}$ (chapter 3648). The certificate records only the displayed algebraic rows needed for the lemma-shaped non-escape argument; it does not import quotient-module equality, host module equality, full local algebra, or a standard bridge.

7320.1 Carrier

Definition 7320.1 (Nakayama lemma carrier)**.** *A* $\mathsf{NakayamaLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{Nak}(M, R, C, I, F, J, A, H, Q, P, N)$$

with the following displayed rows:

1. M*, the* $\mathsf{Module}^{\uparrow}$ *source surface for the module whose generators are being inspected;*
2. R*, the ambient* $\mathsf{Ring}^{\uparrow}$ *scalar row read by the module action;*
3. C*, the* $\mathsf{CommRing}^{\uparrow}$ *specialization used by the ideal-action rows;*
4. I*, the* $\mathsf{Ideal}^{\uparrow}$ *source surface acting on* M*;*
5. F*, a finite-generator ledger for the displayed module endpoints, read through the* $\mathsf{NoetherianModule}^{\uparrow}$ *finite-generation surface;*
6. J*, a Jacobson-radical containment row for the ideal action;*
7. A*, the action-collapse row recording that the ideal action carries each displayed generator back into the generated submodule boundary;*
8. H*, componentwise* hsame *transport for the module, scalar, ideal, finite-generation, radical-containment, and action-collapse rows;*
9. Q*, displayed* Cont *replay for the finite generator and ideal-action checks;*

10. *P, Pkg provenance for the module, ring, commutative-ring, ideal, finite-generation, radical, and action rows;*
11. *N, the local $\mathsf{NameCert}_{\mathsf{NakayamaLemma}^{\uparrow}}$ row binding these rows as one certificate.*

The packet contains no quotient-module equality, no host equality of module carriers, no local-ring structure theorem, and no chosen maximal ideal.

Theorem 7320.2 (Nakayama NameCert obligations)**.** *For an accepted $\mathsf{NakayamaLemma}^{\uparrow}$ carrier $\mathsf{Nak}(M, R, C, I, F, J, A, H, Q, P, N)$, the local $\mathsf{NameCert}_{\mathsf{NakayamaLemma}^{\uparrow}}$ surface consists exactly of carrier admission for the displayed rows, source compatibility with $\mathsf{Module}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, and $\mathsf{NoetherianModule}^{\uparrow}$, finite-generation access through F, radical-containment access through J, ideal-action collapse through A, componentwise classifier transport through H, displayed continuation replay through Q, provenance non-escape through P, and local naming through N.*

Proof. Project the carrier of Definition 7320.1. The projection exposes exactly the module row, scalar ring row, commutative specialization, ideal row, finite-generation ledger, radical-containment row, action-collapse row, transport, replay, provenance, and local name.

The source compatibility obligations are read componentwise from the first four rows, with F tied to the $\mathsf{NoetherianModule}^{\uparrow}$ finite-generation surface. The radical and action rows are separate finite ledgers, so the certificate does not need a host quotient module or a selected maximal ideal to state the handoff.

Transport and replay preserve only these rows. Thus H, Q, P, and N record movement, finite observation, provenance, and local naming without exporting quotient equality, host module equality, or full local algebra. □

Theorem 7320.3 (Nakayama finite-generation handoff)**.** *Every accepted $\mathsf{NakayamaLemma}^{\uparrow}$ carrier exports finite-generation evidence only through the displayed ledger F over the $\mathsf{Module}^{\uparrow}$ row M and the $\mathsf{NoetherianModule}^{\uparrow}$ finite-generation surface. Downstream algebra consumers may reuse this evidence together with R, C, I, H, Q, P, N, but they cannot read a chosen basis, a quotient-module representative, or a host equality of modules from the packet.*

Proof. Read F from the carrier. It is attached to the module row M and to the finite-generation surface already provided by $\mathsf{NoetherianModule}^{\uparrow}$, so it is the only generator ledger available to a consumer.

The scalar and ideal rows R, C, I give the algebraic context in which the generators are inspected. They do not choose a basis or identify quotient representatives; they only supply the displayed ring, commutative-ring, and ideal surfaces.

Componentwise transport through H, replay through Q, provenance through P, and local naming through N keep the finite-generation row attached to the same packet. Hence the handoff is finite-generation evidence, not host module equality or quotient-module data. □

Theorem 7320.4 (Nakayama nilpotent radical non-escape)**.** *In an accepted $\mathsf{NakayamaLemma}^{\uparrow}$ carrier, radical-action information is confined to the displayed rows J and A: J records the Jacobson-radical containment surface for the ideal row I, and A records the finite action-collapse check over the module row M. Any nilpotent or radical-action read transported by H and replayed by Q remains inside the same $M, R, C, I, F, J, A, H, Q, P, N$ packet and cannot escape into a local-algebra oracle, a maximal-ideal selector, quotient-module equality, or host module equality.*

Proof. Project the radical-facing part of the packet. The row J is the only radical-containment source, and A is the only row that connects the ideal action back to the finite module generator boundary.

The surrounding algebraic rows keep this read finite. The $\mathsf{Module}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Ideal}^{\uparrow}$ sources specify the carrier and action surfaces, while F supplies the finite-generation ledger needed by the collapse argument.

Transport and replay do not add structure. The rows H and Q move and replay the displayed radical and action ledgers componentwise, with P and N recording provenance and local naming. Therefore every radical-action read stays inside the named packet and exports none of the excluded host algebra. □

Closure status for $\mathsf{NameCert}_{\mathsf{NakayamaLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{NakayamaLemma}^{\uparrow}$ packet is generated from ModuleUp, RingUp, CommRingUp, IdealUp, NoetherianModuleUp finite-generation, radical-containment, action-collapse, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NakayamaLemma}^{\uparrow}}$, seed)

Scope closed: Definition 7320.1, Definition 7320.2, Definition 7320.3, and Definition 7320.4 seed the finite Nakayama handoff over ModuleUp, IdealUp, RingUp, CommRingUp, NoetherianModuleUp, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NakayamaLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient module equality, host module equality, full local algebra, maximal-ideal choice, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-generation handoff, radical-containment access, action-collapse access, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.NakayamaLemmaUp.

Chapter 7321

UniversalCoefficientUp NameCert Construction

Following Eilenberg–Steenrod and Mac Lane, the $\mathsf{UniversalCoefficient}^{\uparrow}$ packet records the finite homological-algebra interface by which a chain-complex homology read and the corresponding cohomology read share coefficient data through displayed module or abelian-group rows. It sits beside the homology carrier of chapter 98, the cohomology substrate of chapter 99, the module source of chapter 46, the abelian-group carrier of chapter 42, and the Mayer–Vietoris sequence route of chapter 6740. The packet names coefficient, chain-complex, exact-sequence, transport, replay, provenance, and local naming rows; it does not assert a host derived functor, selected chain representatives, quotient-class equality, spectral-sequence convergence, or ambient exactness outside the displayed finite window.

Definition 7321.1 (Universal coefficient carrier)**.** *A* $\mathsf{UniversalCoefficient}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (C, A, M, H_*, H^*, E, T, R, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{ChainComplex}^{\uparrow}$ *source row, naming the inspected boundary windows and the displayed square-zero compatibility rows.*
2. *A is the* $\mathsf{AbGroup}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *coefficient row, read as the only coefficient carrier available to both homology and cohomology consumers.*
3. *M is the finite coefficient-action ledger, recording the module action or additive group operation rows consumed by the inspected degree.*
4. *H_* is the* $\mathsf{Homology}^{\uparrow}$ *row for the displayed chain-complex degree window.*
5. *H^* is the* $\mathsf{Cohomology}^{\uparrow}$ *row for the matching cochain degree window.*
6. *E is the* $\mathsf{ExactSequence}^{\uparrow}$ *row that records the displayed boundary order, kernel-image contact, and connecting slot for the inspected universal-coefficient window.*
7. *T records componentwise* hsame *transport for chain-complex, coefficient, homology, cohomology, exact-sequence, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay for consumers that ask for the same coefficient window and degree route.*

9. *P is the* Pkg *provenance over* UniversalCoefficient$^\uparrow$, ChainComplex$^\uparrow$, Homology$^\uparrow$, Cohomology$^\uparrow$, Module$^\uparrow$, AbGroup$^\uparrow$, ExactSequence$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniversalCoefficient}^\uparrow}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a global derived functor, a selected cycle or cocycle representative, quotient-class equality, an unrestricted splitting, spectral-sequence data, or ambient exactness beyond E.

Theorem 7321.2 (Universal coefficient NameCert obligations)**.** *For every accepted* UniversalCoefficient$^\uparrow$ *carrier $U = (C, A, M, H_*, H^*, E, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniversalCoefficient}^\uparrow}$ *surface consists exactly of carrier admission for the displayed chain-complex source C, coefficient row A, coefficient-action ledger M, homology row H_*, cohomology row H^*, exact-sequence row E, componentwise transport T, displayed replay R, provenance P, and local naming N. Every consumer must read the coefficient row before either the* Homology$^\uparrow$ *or* Cohomology$^\uparrow$ *face, and must read the displayed* ExactSequence$^\uparrow$ *row before using the homology-to-cohomology handoff.*

Proof. Project the carrier of Definition 7321.1. The tuple lists the only rows available to the classifier: chain-complex source, coefficient carrier, coefficient action, homology, cohomology, exact-sequence, transport, replay, provenance, and local naming.

The coefficient row is shared. A homology-facing read and a cohomology-facing read both pass through A and M, so the packet cannot silently change coefficient systems between H_* and H^*.

The exact-sequence row is then the unique handoff route. The row E records the displayed kernel-image contact and connecting slot for the inspected degree window, while T and R transport and replay that same finite route. Thus no selected representative, unrestricted splitting, quotient equality, or ambient exactness principle can be exported. □

Theorem 7321.3 (Universal coefficient homology-cohomology handoff)**.** *Let $U = (C, A, M, H_*, H^*, E, T, R, P, N)$ be an accepted* UniversalCoefficient$^\uparrow$ *packet. Any downstream consumer that moves from the* Homology$^\uparrow$ *row H_* to the* Cohomology$^\uparrow$ *row H^* must first expose the common coefficient row A, the coefficient-action ledger M, the* ChainComplex$^\uparrow$ *source C, and the* ExactSequence$^\uparrow$ *row E. The handoff supplies a finite displayed universal-coefficient route for the inspected degree window, not a chosen splitting, selected chain representative, quotient-class equality, host derived-functor computation, or spectral-sequence convergence claim.*

Proof. Begin with the shared coefficient surface. The rows A and M are the only coefficient data named by the packet, so both homology and cohomology reads must use the same displayed AbGroup$^\uparrow$ or Module$^\uparrow$ source.

Read the chain-complex and exact-sequence rows next. The row C fixes the inspected boundary windows, and E records the finite exact-sequence contact through which the homology and cohomology rows are related.

The structural rows preserve this route for downstream consumers. Componentwise transport T, replay R, provenance P, and local naming N carry the displayed C, A, M, H_*, H^*, E surface without adding a selected representative, a split sequence, quotient equality, a host derived functor, or spectral-sequence data. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniversalCoefficient}^\uparrow}$.

Constructive story: A UniversalCoefficient$^\uparrow$ packet is generated from a displayed ChainComplexUp source row, a shared AbGroupUp or ModuleUp coefficient row, a coefficient-action ledger, HomologyUp and CohomologyUp degree-window rows, an ExactSequenceUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniversalCoefficient}^\uparrow}$, seed)

Scope closed: Definition 7321.1, Definition 7321.2, and Definition 7321.3 seed the finite carrier and handoff surface for universal-coefficient packets over homology, cohomology, chain-complex, module, abelian-group, and exact-sequence rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{UniversalCoefficient}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a global derived functor, selected chain representatives, quotient-class equality, unrestricted splitting, spectral-sequence convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier, coefficient, homology, cohomology, exact-sequence, transport, replay, provenance, and local naming rows for BEDC.Derived.UniversalCoefficientUp.

Chapter 7322

A Concrete Naming Certificate for $\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}$

Following Bishop and Bridges on choice sequences and constructive real numbers, the ConstructiveChoiceSequenceSp packet names the finite-window space in which a displayed stream name is read together with a regular Cauchy rational row and a terminal Real seal. It sits between the finite stream discipline of chapter 126, the regular Cauchy rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the Real boundary of chapter 38. The chapter records only the finite rows needed for a named constructive choice-sequence space; it does not add countable choice, quotient stream equality, selected limits, trichotomy, or ambient Real completeness.

Definition 7322.1 (Constructive choice-sequence space carrier)**.** *A* $\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, Q, R, D, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, exposing only the finite windows of the sequence name that the packet inspects.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, reading those windows as regular Cauchy rational approximants.*
3. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S and Q have been displayed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare requested windows and regularity bounds.*
5. *W is the finite window-budget row, recording which stream positions, rational approximants, and dyadic tolerances are visible to the packet.*
6. *H records componentwise* hsame *transport for S, Q, R, D, W and for the replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a finite stream-window request through regular rational readback and the terminal Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, R, D, W, H, C, P, N$. It has no coordinate for countable choice, quotient stream equality, selected limits, trichotomy, or ambient Real completeness.

Theorem 7322.2 (Constructive choice-sequence space NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}$ *carrier* $X = (S, Q, R, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveChoiceSequenc}}$ *surface consists exactly of carrier admission for the finite stream windows, regular Cauchy rational readback, terminal Real seal, dyadic tolerance ledger, finite window budget, componentwise transport, displayed replay, provenance, and local naming rows. Every consumer must read the route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *before treating the packet as a constructive choice-sequence space.*

Proof. Project the carrier of Definition 7322.1. The visible analytic rows are exactly the stream-window row S, regular rational readback Q, Real seal R, dyadic tolerance ledger D, and finite window budget W.

The NameCert obligations are therefore local. A request first exposes the finite stream positions in S and the budget row W; it then reads regular rational approximants through Q and the dyadic tolerance ledger D before the Real seal R is available.

Transport and replay do not create new sequence data. Componentwise hsame in H preserves the displayed rows, while Cont in C repeats the same finite-window route for every accepted request.

Finally, provenance and naming are exhausted by P and N. Since countable choice, quotient stream equality, selected limits, trichotomy, and ambient Real completeness are not carrier rows, the certificate cannot export them. □

Theorem 7322.3 (Constructive choice-sequence space finite-window law)**.** *Every read of an accepted* $\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}$ *packet is determined by a finite window budget W and factors through the sibling rows* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *named by chapter 126, chapter 301, chapter 291, and chapter 38. Enlarging the budget may expose additional displayed windows, but no read bypasses the same* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *route.*

Proof. Start with an accepted carrier $X = (S, Q, R, D, W, H, C, P, N)$. The row W lists the only stream positions, rational approximants, and dyadic tolerances visible to the packet, so a consumer begins with a finite budget rather than an infinite selector.

Apply the carrier route. The stream row S supplies the displayed finite windows, Q reads them as regular Cauchy rational approximants, and D supplies the dyadic tolerance comparisons needed before R seals the data as $\mathsf{Real}^{\uparrow}$.

If the budget is enlarged, the same construction is repeated with a larger displayed row W'. The transport row H and replay row C preserve the componentwise route, and P, N name no additional source.

Thus the finite-window law is stable under budget enlargement but never becomes countable choice, quotient stream equality, selected limit data, trichotomy, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveChoiceSequenceSpace}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a Real seal, a DyadicRatCore tolerance ledger, a finite window budget, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ConstructiveChoiceSequenceSpace}\uparrow}$, seed)

Scope closed: The chapter seeds the finite-window carrier and NameCert obligation surface for Bishop-style constructive choice-sequence spaces.

Formal verification: FormalStatus(NameCert$_{\mathsf{ConstructiveChoiceSequenceSpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: The chapter does not claim countable choice, quotient stream equality, selected limits, trichotomy, or ambient Real completeness.

Upgrade path: A Lean carrier and checked finite-window gate would move the verification axis beyond the unformalized seed.

Chapter 7323

A Concrete Naming Certificate for $\mathsf{FiniteProductCover}^{\uparrow}$

Following Bishop and Bridges and Kelley on finite products of compact metric covers, the $\mathsf{FiniteProductCover}^{\uparrow}$ packet records the finite product-cover route used by compact metric and uniform-modulus consumers. It sits between the product metric carrier of chapter 424, the compact product route of chapter 1822, the compact metric source surface of chapter 129, the finite refinement route of chapter 3430, and the product constructor surface of chapter 34. The packet names a finite cover of a displayed product metric object; it does not choose subcovers, assert open-cover compactness, import countable choice, or identify quotient product points.

Definition 7323.1 (Finite product cover carrier)**.** *A* $\mathsf{FiniteProductCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (L, R, J, M, K, B, H, C, P, N)$$

with the following displayed rows:

1. *L is the left finite cover row, a finite list of* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *cells over the left* $\mathsf{CompactMetric}^{\uparrow}$ *source;*
2. *R is the right finite cover row, a finite list of* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *cells over the right* $\mathsf{CompactMetric}^{\uparrow}$ *source;*
3. *J is the product pairing row, recording the* $\mathsf{Prod}^{\uparrow}$ *cell pairs obtained from the displayed left and right cover cells;*
4. *M is the* $\mathsf{ProductMetric}^{\uparrow}$ *ledger that reads distances only through the displayed left and right metric rows;*
5. *K records the* $\mathsf{CompactMetricProduct}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *source rows consumed by the product-cover request;*
6. *B is the finite radius budget row, recording the product-radius allowance and the component radius budgets assigned to L and R;*
7. *H records componentwise* hsame *transport for $L, R, J, M, K, B, C, P, N$;*
8. *C records displayed* Cont *replay through the left cover, right cover, product pairing, product metric ledger, compact metric sources, radius budget, transport, provenance, and local naming rows;*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteProductCover}^{\uparrow}$, $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{CompactMetricProduct}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteProductCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary open cover, a selected subcover, countable choice, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7323.2 (Finite product cover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteProductCover}^{\uparrow}$ *carrier $F = (L, R, J, M, K, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteProductCover}^{\uparrow}}$ *surface consists exactly of left finite cover exposure, right finite cover exposure, product pairing exposure, product metric ledger exposure, compact metric source exposure, finite radius budget exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7323.1. The cover data are exactly the finite left and right rows L, R, and the product-cover cells are exactly the product pairing row J.

The metric and compactness-facing reads are displayed separately. The row M supplies the $\mathsf{ProductMetric}^{\uparrow}$ ledger, K supplies the $\mathsf{CompactMetricProduct}^{\uparrow}$ and $\mathsf{CompactMetric}^{\uparrow}$ source rows, and B records the finite radius budget used by the product-cover request.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the carrier stores no arbitrary open cover, selected subcover, countable-choice schedule, quotient point equality, ambient Real completeness, Lean theorem, or bridge row, the listed rows exhaust the local NameCert obligations. □

Theorem 7323.3 (Finite product cover product-net route)**.** *Every product-net consumer of an accepted* $\mathsf{FiniteProductCover}^{\uparrow}$ *packet factors through the displayed route*

$$L, R, B \longmapsto J \longmapsto M, K.$$

It first reads the left and right finite cover rows and the finite radius budget, then forms only the displayed $\mathsf{Prod}^{\uparrow}$ *pair cells, and only then consumes the* $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{CompactMetricProduct}^{\uparrow}$, *and* $\mathsf{CompactMetric}^{\uparrow}$ *rows.*

Proof. Begin with $F = (L, R, J, M, K, B, H, C, P, N)$. The left and right finite cover rows are the only available component cover data, and B is the only radius budget attached to them.

Read the product pairing row J. It pairs cells already present in L and R, so it cannot introduce an unseen component cover cell, an arbitrary open cover, or a selected subcover.

Now consume the product metric ledger M and the compact metric source row K. These rows read the paired cells as a product metric cover over the displayed compact metric sources, while H, C, P, N keep the route stable under transport, replay, provenance, and naming.

Thus every product-net route is componentwise and finite. No step supplies countable choice, quotient product point equality, ambient Real completeness, Lean verification, or bridge checking. □

Falsifiable prediction: A consumer that claims a $\mathsf{FiniteProductCover}^{\uparrow}$ read while omitting the left finite cover row, right finite cover row, product pairing row, product metric ledger, compact metric source rows, finite radius budget, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row refutes the carrier of Definition 7323.1.

Independence witness: productmetric, compactmetricproduct, compactmetric, finitecoverrefinement, prod: no listed sibling is bijective to $\mathsf{FiniteProductCover}^{\uparrow}$ because this packet alone binds

paired finite cover rows, a product pairing row, a product metric ledger, compact metric source rows, finite radius budgeting, transport, replay, provenance, and local naming as one product-cover certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteProductCover}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteProductCover}^{\uparrow}$ packet is generated from left and right finite cover rows, product pairing rows, a ProductMetric ledger, CompactMetricProduct and CompactMetric source rows, a finite radius budget, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteProductCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7323.1, Definition 7323.2, and Definition 7323.3 seed the finite product-cover route for compact metric and uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteProductCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, component cover exposure, product pairing exactness, product metric ledger exposure, compact metric source exposure, finite radius budget exactness, transport, replay, provenance, and local naming for BEDC.Derived.FiniteProductCoverUp.

Chapter 7324

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailLimit}^{\uparrow}$

Following Bishop–Bridges regular Cauchy sequences, the $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ packet records the finite tail-window limit route from inspected regular rational data to a terminal real-name seal. It sits between the finite observation interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the tail-certificate route of chapter 1230, and the terminal real-name seal of chapter 38. The packet names a finite tail-limit handoff; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, select a quotient representative, or import countable choice.

Definition 7324.1 (Regular Cauchy tail limit carrier)**.** *A* $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, Q, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window row inspected by the limit request;*
2. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational sequence visible on that window;*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the requested precision, tail index budget, and comparison allowance;*
4. R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only through the displayed* S, Q, D *route;*
5. A *is the tail-stability row, recording that later inspected windows replay the same regular-Cauchy tail route at the requested tolerance;*
6. H *records componentwise* hsame *transport for* S, Q, D, R, A, C, P, N*;*
7. C *records displayed* Cont *replay through the stream window, regular rational readback, dyadic tolerance row, real seal, tail-stability row, transport, provenance, and local naming rows;*
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchyTailLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden limit choice, quotient stream equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7324.2 (Regular Cauchy tail limit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ *carrier* $T = (S, Q, D, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailLimit}^{\uparrow}}$ *surface consists exactly of finite StreamName window exposure, RegSeqRat readback exposure, DyadicRatCore tolerance exposure, Real seal handoff, tail-stability exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7324.1. The finite observation is S, the regular rational readback is Q, and the tolerance budget is D.

The terminal real seal R is downstream of those three rows. The tail-stability row A records that later inspected windows replay the same route at the displayed tolerance; it is not a hidden choice of a limit.

The structural rows H, C, P, N preserve, replay, source, and name this finite route. Because the carrier stores no quotient stream equality, countable-choice schedule, ambient Real completeness, Lean theorem, or bridge row, the listed rows exhaust the local NameCert obligations. □

Theorem 7324.3 (Regular Cauchy tail limit nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ *packet factors through*

$$S, Q, D, A, H, C, P, N$$

before it can read the seal row R*. The terminal seal is therefore a finite tail-window limit handoff, not an ambient completeness principle, selected quotient representative, countable-choice output, or detached host real.*

Proof. Start with $T = (S, Q, D, R, A, H, C, P, N)$. Carrier admission makes the finite tail window, regular rational readback, dyadic tolerance row, and tail-stability row visible before a consumer can reach the terminal seal.

Use Definition 7324.2. Its Real seal handoff clause binds R to the displayed S, Q, D, A route, while the transport and replay clauses keep that route componentwise stable.

The packet has no coordinate for quotient stream equality, selected representatives, countable choice, detached host reals, or ambient completeness. Thus the terminal seal cannot escape the finite StreamName, RegSeqRat, DyadicRatCore, tail-stability, transport, replay, provenance, and local naming rows. □

Theorem 7324.4 (Regular Cauchy tail limit window exposure)**.** *Every accepted* $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ *carrier* $T = (S, Q, D, R, A, H, C, P, N)$ *must expose the* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window row* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *before any tail-limit read can consume the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R*.*

Proof. Project the carrier of Definition 7324.1. The rows S and Q are displayed coordinates, so a consumer cannot read the tail-limit packet without naming both the inspected finite stream window and its regular rational readback.

Apply Definition 7324.3. The seal row R is available only after the route through S, Q, D, A, H, C, P, N is visible, hence the window and readback rows precede every terminal tail-limit read. □

Theorem 7324.5 (Regular Cauchy tail limit tolerance exactness)**.** *For every accepted* $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ *carrier* $T = (S, Q, D, R, A, H, C, P, N)$*, the dyadic tolerance row* D *and tail-stability row* A *are the complete finite control of the tail budget. No hidden choice of a tail index, quotient representative, or ambient completion witness is available outside* D, A, H, C, P, N*.*

Proof. Use the carrier definition to isolate the tolerance coordinates. The dyadic row D records the requested precision, tail index budget, and comparison allowance, while A records replay of later inspected windows at that displayed tolerance.

The structural rows H, C, P, N transport, replay, source, and name this same budget. Since the carrier has no coordinate for hidden limit choice, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the pair D, A is the exact tolerance surface. □

Theorem 7324.6 (Regular Cauchy tail limit Real seal handoff)**.** *In every accepted* $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ *carrier* $T = (S, Q, D, R, A, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *is reachable only through the displayed finite route*

$$S, Q, D, A, H, C, P, N.$$

The handoff exports no detached host real, quotient-stream equality, selected representative, countable-choice schedule, or ambient completeness theorem.

Proof. Start from the nonescape theorem, Definition 7324.3. It forces every Real-facing consumer through the StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, and tail-stability row before R is read.

Now apply the NameCert obligation surface of Definition 7324.2. The transport, replay, provenance, and local naming rows preserve that finite route, so the seal cannot be consumed through any unlisted completion, representative-selection, or quotient-equality channel. □

Falsifiable prediction: A consumer that claims a $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ read while omitting the $\mathsf{StreamName}^{\uparrow}$ finite tail window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{Real}^{\uparrow}$ seal, tail-stability row, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row refutes the carrier of Definition 7324.1.

Independence witness: streamname, regseqrat, dyadicratcore, real, regularcauchytailcertificate: no listed sibling is bijective to $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ because this packet alone binds finite tail windows, regular rational readbacks, dyadic tolerance budgets, terminal Real seals, tail-stability, transport, replay, provenance, and local naming as one tail-limit certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailLimit}^{\uparrow}$ packet is generated from StreamName tail-window rows, RegSeqRat readback rows, DyadicRatCore tolerance rows, a Real seal, tail-stability evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailLimit}^{\uparrow}}, \text{obligation})$

Scope closed: Definition 7324.1, Definition 7324.2, Definition 7324.3, Definition 7324.4, Definition 7324.5, and Definition 7324.6 expose the finite regular-Cauchy tail-window limit obligations for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailLimit}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected representatives, countable choice, hidden limit selection, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance exactness, Real seal handoff, tail-stability exactness, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailLimitUp.

Chapter 7325

A Concrete Naming Certificate for $\mathsf{FanTheoremBoundary}^{\uparrow}$

Following Brouwer and Bishop–Bridges finite-fan analysis, the $\mathsf{FanTheoremBoundary}^{\uparrow}$ packet records the L10 boundary row that lets finite fan and bar evidence be consumed as displayed BEDC data before any compactness theorem is read. It sits beside the finite prefix-bar certificate of chapter 5863, the finite fan-bar modulus packet of chapter 4297, the stream-window carrier of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names the boundary object that prevents finite bar evidence from being re-read as open-cover compactness, a chosen branch, countable choice, quotient stream equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7325.1 (Fan theorem boundary carrier)**.** *A* $\mathsf{FanTheoremBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, B, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *finite prefix-bar row, exposing the admitted fan depth and the retained branch-prefix window.*
2. *B is the* $\mathsf{FiniteFanBarModulus}^{\uparrow}$ *bar-modulus row, exposing the finite lower-bound handoff available to uniform-modulus consumers.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row read by downstream Real and Completion consumers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the finite prefix and bar windows.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that keeps rational sequence data inside the displayed finite window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for any real-name comparison reached from the finite bar data.*
7. *H records componentwise* hsame *transport for T, B, S, D, Q, E and the local packet shape.*
8. *C records displayed* Cont *replay from finite fan evidence through the bar-modulus row and into the analytic readback rows.*
9. *P is the* Pkg *provenance over* $\mathsf{FanTheoremBoundary}^{\uparrow}$, $\mathsf{FiniteFanTheorem}^{\uparrow}$, $\mathsf{FiniteFanBarModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FanTheoremBoundary}^\uparrow}$ *row.*
The carrier has no coordinate for open-cover compactness, selected branches, countable choice, quotient stream equality, selected limits, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 7325.2 (Fan theorem boundary NameCert obligations)**.** *For every accepted* $\mathsf{FanTheoremBoundary}^\uparrow$ *carrier*

$$F = (T, B, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FanTheoremBoundary}^\uparrow}$ *surface consists exactly of finite prefix-bar admission through T, finite fan-bar modulus admission through B, stream-window exposure through S, dyadic tolerance exposure through D, regular-rational readback through Q, real-name sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Thus a Real or Completion consumer may use the packet only after the finite fan theorem row, finite bar-modulus row, observation window, tolerance row, rational readback row, real seal, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Project the carrier of Definition 7325.1. The tuple displays exactly the finite fan theorem row, finite fan-bar modulus row, stream window, dyadic tolerance row, regular-rational readback row, real seal, transport, replay, provenance, and local naming row.

The fan and bar evidence is finite because T and B are the only rows through which branch-facing information enters the packet. The row T exposes a retained prefix window, while B exposes the lower-bound handoff available after the finite bar rows have been inspected.

The analytic readback is downstream of those finite rows. The rows S, D, Q, E record the observation window, tolerance ledger, rational readback, and terminal real seal; none of them contains a selected branch or an open-cover subcover.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for open-cover compactness, selected branches, countable choice, quotient stream equality, selected limits, or ambient real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7325.3 (Fan theorem boundary uniform-bar readback)**.** *Every Real or Completion read of an accepted* $\mathsf{FanTheoremBoundary}^\uparrow$ *packet factors through*

$$\mathsf{FiniteFanTheorem}^\uparrow \longrightarrow \mathsf{FiniteFanBarModulus}^\uparrow \longrightarrow \mathsf{StreamName}^\uparrow \longrightarrow \mathsf{DyadicRatCore}^\uparrow \longrightarrow \mathsf{RegSeqRat}^\uparrow \longrightarrow \mathsf{Real}^\uparrow$$

and then through H, C, P, N. The readback is a boundary read: it may consume the finite bar row and the finite modulus handoff, but it exports no open-cover compactness, selected branch, countable-choice functional, quotient stream equality, selected limit, or ambient $\mathsf{Real}^\uparrow$ *completeness principle.*

Proof. Start from the NameCert obligations of Definition 7325.2. They force every accepted consumer to expose T before B, because the bar-modulus handoff is meaningful only after the finite prefix-bar row has been displayed.

After T and B are visible, the read proceeds through the analytic rows S, D, Q, E. The stream window supplies the finite observation schedule, the dyadic row supplies the tolerance ledger, the regular-rational row supplies sequence readback, and the real seal records the terminal comparison.

The structural rows H, C, P, N do not add new analytic principles. They preserve and name the same finite route under componentwise transport, displayed replay, provenance, and local NameCert packaging.

Therefore the read remains a boundary read. It carries finite fan and bar evidence into Real and Completion consumers, while the excluded compactness, selection, quotient, choice, limit, and completeness data remain outside the carrier. □

Falsifiable prediction: Every $\mathsf{FanTheoremBoundary}^{\uparrow}$ read factors through one $\mathsf{FiniteFanTheorem}^{\uparrow}$ prefix-bar row, one $\mathsf{FiniteFanBarModulus}^{\uparrow}$ finite bar-modulus row, one $\mathsf{StreamName}^{\uparrow}$ observation window, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: finite fan theorem, finite fan-bar modulus, streamname, dyadicratcore, regseqrat, real: $\mathsf{FanTheoremBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the boundary between finite fan/bar evidence and Real-or-Completion readback while refusing compactness, selection, quotient, choice, limit, and completeness data.

Closure status for $\mathsf{NameCert}_{\mathsf{FanTheoremBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{FanTheoremBoundary}^{\uparrow}$ packet is generated from finite fan theorem rows, finite fan-bar modulus rows, StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FanTheoremBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7325.1, Definition 7325.2, and Definition 7325.3 seed the L10 boundary route from finite fan and bar evidence into Real and Completion readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FanTheoremBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected branches, countable choice, quotient stream equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite fan theorem exposure, finite bar-modulus exposure, stream-window coverage, dyadic tolerance exactness, rational readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FanTheoremBoundaryUp.

Chapter 7326

A Concrete Naming Certificate for $\mathsf{SobolevExtensionOperator}^{\uparrow}$

Following Adams–Fournier and Evans-style Sobolev extension theory, the $\mathsf{SobolevExtensionOperator}^{\uparrow}$ packet records the finite BEDC rows needed by a boundary-to-interior extension read. It sits beside the Sobolev source of chapter 5911, the trace packet of chapter 3647, the boundary package of chapter 6445, the compact-metric support of chapter 129, and the complete-metric readback surface of chapter 128. The packet names only a finite extension route from displayed boundary data back to displayed Sobolev rows; it does not select a global host operator, identify quotient function spaces, or assert an unrestricted trace theorem.

Definition 7326.1 (Sobolev extension operator carrier)**.** *A* $\mathsf{SobolevExtensionOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, T, B, K, M, R, X, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SobolevSpace}^{\uparrow}$ *or* $\mathsf{Sobolev}^{\uparrow}$ *source row, exposing only the interior Sobolev carrier data already named by the corresponding packet.*
2. *T is the* $\mathsf{SobolevTrace}^{\uparrow}$ *row, recording the boundary trace read that the extension route is allowed to address.*
3. *B is the* $\mathsf{SobolevTraceBoundary}^{\uparrow}$ *row. It fixes the boundary carrier, trace-read arrow, compact boundary window, and complete-metric readback needed by the extension request.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *support row, used only as a finite boundary-window and compact-source ledger.*
5. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *readback row for the interior target and boundary compatibility checks.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for norm budgets, boundary radii, and extension estimates.*
7. *X is the extension-route classifier. It distinguishes source Sobolev reads, boundary trace reads, compact-window reads, complete-metric readbacks, and scalar budget reads, but has no coordinate for a selected global operator or quotient equality of functions.*
8. *H stores componentwise* hsame *transport for S, T, B, K, M, R, X and the structural rows.*
9. *C stores displayed* Cont *replay from an extension request through the Sobolev source, trace row, boundary row, compact support, complete-metric readback, and scalar seal.*

10. *P is the* Pkg *provenance over* $\mathsf{SobolevExtensionOperator}^{\uparrow}$, $\mathsf{SobolevSpace}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{SobolevTrace}^{\uparrow}$, $\mathsf{SobolevTraceBoundary}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SobolevExtensionOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, B, K, M, R, X, H, C, P, N$. It does not contain an unrestricted host trace theorem, a selected extension operator on all boundary data, quotient function-space equality, open-cover compactness, countable choice, or ambient completeness.

Theorem 7326.2 (Sobolev extension operator NameCert obligations)**.** *For every accepted* SobolevExtensionOperato *carrier*

$$E = (S, T, B, K, M, R, X, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SobolevExtensionOperator}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Sobolev source, trace row, boundary row, compact-metric support, complete-metric readback, scalar seal, classifier, transport, replay, provenance, and local naming rows;*
2. *trace-source compatibility, requiring every extension request to read T and B before it can claim a boundary value belongs to the extension route;*
3. *compact and complete-metric exactness, requiring K and M to expose only finite boundary-window, compact-source, distance, and Cauchy-readback rows;*
4. *scalar budget exactness, requiring norm and radius comparisons to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row R;*
5. *structural stability under X, H, C, P, N, which classifies, transports, replays, sources, and names only the displayed finite route.*

No $\mathsf{SobolevExtensionOperator}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 7326.1. The analytic rows visible to the classifier are exactly S, T, B, K, M, R, and the structural rows are X, H, C, P, N.

The trace-source compatibility obligation is forced before any extension read. A consumer must first expose the Sobolev trace row T and the boundary package B, so the boundary datum is read through the finite trace and boundary ledgers already present in the carrier.

The compact and complete-metric obligations are then attached to K and M. These rows provide only finite boundary-window support and displayed Cauchy or distance readbacks, while scalar budget comparisons reach the Real seal only through R.

Finally X, H, C, P, N classify, transport, replay, source, and name the same row order. Since the carrier has no coordinate for a host operator, quotient equality, open-cover compactness, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7326.3 (Sobolev trace-extension handoff)**.** *Every downstream trace or boundary-analysis consumer citing an accepted* $\mathsf{SobolevExtensionOperator}^{\uparrow}$ *carrier receives only the finite handoff*

$$\mathsf{SobolevSpace}^{\uparrow}, \mathsf{Sobolev}^{\uparrow} \longmapsto \mathsf{SobolevTrace}^{\uparrow} \longmapsto \mathsf{SobolevTraceBoundary}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{Real}$$

followed by the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows of the same packet. The handoff is a finite extension-route certificate; it is not a host extension theorem, a selected linear operator, or an equality of completed Sobolev quotients.*

Proof. Start with an accepted trace-extension request. The request first reads the Sobolev source row S, so it inherits only the interior Sobolev data displayed by the source packet.

Next it reads T and B. These rows fix the boundary trace and boundary carrier before compact support or complete-metric readback can be consulted.

The remaining analytic read passes through K, M, R. Thus compact-window data, Cauchy or distance readback, and scalar estimates are finite rows of the same packet.

The structural rows X, H, C, P, N only classify, transport, replay, source, and name this route. No carrier coordinate remains from which a host extension theorem, selected operator, or quotient-space equality could be read. □

Theorem 7326.4 (Sobolev extension operator nonescape boundary)**.** *Every accepted* $\mathsf{SobolevExtensionOperator}^{\uparrow}$ *consumer that reaches the complete-metric or scalar extension estimate must first display the boundary route T, B and the compact support row K. Consequently the consumer cannot replace the boundary route by an unrestricted host trace theorem, a detached boundary representative, open-cover compactness, ambient completeness, or a selected global extension operator.*

Proof. Project an accepted consumer of the carrier. The complete-metric row M and scalar seal R occur downstream of S, T, B, K, so neither readback can be reached before the boundary trace and compact support rows are fixed.

The classifier row X records this row order as part of the accepted packet. Componentwise transport H and replay C preserve that order, while P and N source and name the same route.

Any consumer omitting T, B, or K would be reading a coordinate absent from the displayed carrier. Hence complete-metric and scalar extension estimates cannot escape the finite boundary route. □

Falsifiable prediction: Every accepted $\mathsf{SobolevExtensionOperator}^{\uparrow}$ extension read factors through displayed SobolevSpaceUp or SobolevUp, SobolevTraceUp, SobolevTraceBoundaryUp, CompactMetricUp, CompleteMetricUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows before any downstream consumer receives an extension estimate.

Independence witness: sobolev-space, sobolev, sobolev-trace, sobolev-trace-boundary, compactmetric, completemetric, real: $\mathsf{SobolevExtensionOperator}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source Sobolev data, trace data, boundary data, compact support, complete-metric readback, scalar estimates, classifier, transport, replay, provenance, and local naming in one finite extension-route carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevExtensionOperator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SobolevExtensionOperator}^{\uparrow}$ packet is generated from a Sobolev source row, Sobolev trace row, Sobolev trace boundary row, compact-metric support row, complete-metric readback row, Real scalar seal, extension-route classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SobolevExtensionOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7326.1, Definition 7326.2, Definition 7326.3, and Definition 7326.4 seed the finite Sobolev extension-route surface over Sobolev, trace, boundary, compact-metric, complete-metric, and real neighbours.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SobolevExtensionOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an unrestricted host trace theorem, quotient function-space equality, a selected global extension operator, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trace-source compatibility, compact and complete-metric exactness, scalar budget exactness, classifier nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SobolevExtensionOperatorUp.

Chapter 7327

A Concrete Naming Certificate for $\mathsf{LocatedUniformExtension}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedUniformExtension}^{\uparrow}$ packet records the finite surface by which a uniformly continuous source map on a located dense domain is read as an extension candidate through explicit modulus, Cauchy handoff, window, readback, and real-seal rows. It refines the uniformly continuous extension route of chapter 769 and the Cauchy-controlled extension route of chapter 1632 by requiring the source domain to be displayed as located data before any completion-facing extension read is exposed.

The packet is a non-quotient L10 extension certificate: it keeps the modulus and located-domain rows visible, routes Cauchy evidence through finite StreamName windows and RegSeqRat readback, and reaches $\mathsf{Real}^{\uparrow}$ only through a terminal seal. It does not identify host functions, select representatives, import ambient completeness, or replace the displayed domain by an impredicative subset.

Definition 7327.1 (Located uniform extension carrier)**.** *A* $\mathsf{LocatedUniformExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, M, E, K, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the located domain row, naming the source subcarrier, its located comparison data, and the finite membership boundary read by the extension.*
2. *M is the modulus row, recording the uniform continuity tolerance-to-radius data consumed from the source map before completion-facing reads are available.*
3. *E is the extension candidate row, aligned with the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *handoff of chapter 769.*
4. *K is the Cauchy handoff row, aligned with the* $\mathsf{CauchyContinuousExtension}^{\uparrow}$ *route of chapter 1632.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which source and target observations are requested at finite precision.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carrying the regular rational data used by the Cauchy and extension rows.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the located domain, modulus, extension candidate, Cauchy handoff, window, and readback rows have been replayed.*

8. *H records componentwise* hsame *transport for $D, M, E, K, W, Q, R, C, P, N$.*
9. *C records displayed* Cont *replay from located-domain reads to modulus reads, from modulus reads to extension-candidate reads, and from Cauchy handoff through windows and readback to the Real seal.*
10. *P is the* Pkg *provenance over* LocatedUniformExtension$^{\uparrow}$, UniformContinuousExtension$^{\uparrow}$, CauchyContinuousExtensi StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{LocatedUniformExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, E, K, W, Q, R, H, C, P, N$. There is no coordinate for quotient function equality, selected completion representatives, host subset extensionality, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7327.2 (Located uniform extension NameCert obligations)**.** *For every accepted* LocatedUniformExtension *carrier*

$$L = (D, M, E, K, W, Q, R, H, C, P, N),$$

the local NameCert$_{\text{LocatedUniformExtension}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located domain, modulus, extension candidate, Cauchy handoff, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *located-domain visibility, requiring every extension read to project D before using the modulus row;*
3. *modulus exactness, requiring M to be the only tolerance-to-radius source for the extension candidate E;*
4. *Cauchy handoff ordering, requiring K to consume the same located-domain and modulus data before window or readback rows are public;*
5. *readback and seal exactness, requiring W, Q, R to be consumed in the displayed finite order before any Real-facing value is exported;*
6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed packet.*

No obligation row stores a host function, quotient completion point, selected representative, ambient completeness principle, or choice functional.

Proof. Project the carrier of Definition 7327.1. Carrier admission is the display of the rows $D, M, E, K, W, Q, R, H, C, P, N$ as one finite BHist packet.

The located-domain and modulus clauses are read from D and M. The row D is the only source-domain coordinate, and M is the only modulus coordinate, so the extension candidate E cannot be read before those two rows have been consumed.

The Cauchy handoff clause is read from K. It shares the same located-domain and modulus data as E, matching the sibling extension surfaces cited above while retaining finite window and readback access through W and Q.

Finally inspect R, H, C, P, N. The Real seal is terminal for the displayed window-readback route, and the structural rows only transport, replay, source, and name that route. Since the excluded objects have no carrier coordinate, the local NameCert obligations are exactly the listed finite rows. □

Theorem 7327.3 (Located uniform extension Cauchy handoff)**.** *Every Cauchy-facing read of an accepted* $\mathsf{LocatedUniformExtension}^{\uparrow}$ *packet factors through the finite route*

$$D \longmapsto M \longmapsto E, K \longmapsto W, Q \longmapsto R, H, C, P, N.$$

Thus the Cauchy handoff row cannot bypass the located domain, cannot replace the uniform modulus by a hidden host continuity assertion, and cannot reach the $\mathsf{Real}^{\uparrow}$ *seal without the StreamName and RegSeqRat rows.*

Proof. Begin with the NameCert obligations of Definition 7327.2. They force each extension read to project the located domain row D and the modulus row M before the extension candidate or Cauchy handoff is public.

The sibling uniform-extension route supplies the role of E, while the Cauchy-continuous extension route supplies the role of K. Both rows are attached to the same located source and modulus data, so neither can serve as an independent completion source.

The readback rows W, Q mediate all finite observation requests before the terminal seal R is available. The structural rows H, C, P, N preserve this order by componentwise transport, displayed replay, provenance, and local naming.

Therefore every Cauchy-facing read remains on the displayed finite route, with no quotient function equality, selected representative, hidden host continuity assertion, or ambient completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedUniformExtension}^{\uparrow}$ packet is generated from a located domain row, a uniform-modulus row, an extension candidate, a Cauchy handoff, finite StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7327.1, Definition 7327.2, and Definition 7327.3 give the seed carrier and Cauchy handoff surface for located uniform extension packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient extension equality, selected completion representatives, full extension uniqueness, Lean verification, axiom-purity certification, or bridge checking for $\mathsf{LocatedUniformExtension}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, located-domain visibility, modulus exactness, Cauchy handoff ordering, StreamName-RegSeqRat-Real readback, transport, replay, provenance, and local naming for BEDC.Derived.LocatedUniformExtensionUp.

Chapter 7328

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$

Following Bishop–Bridges regular Cauchy real construction, the $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ packet records the finite BEDC rows needed to replace a displayed Cauchy modulus by a normalized dyadic schedule. It sits beside the stream naming surface of chapter 126, the regular rational sequence packet of chapter 301, the dyadic rational core of chapter 291, the real seal of chapter 38, and the diagonal selector of chapter 4080. The packet names only the finite normalization route from a stream-indexed modulus to a regular dyadic handoff; it does not assert located order, completion uniqueness, countable choice, or a global real-equality theorem.

Definition 7328.1 (Regular Cauchy modulus-normalization carrier)**.** *A* $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, Q, D, R, \Delta, A, X, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row. It supplies the stream-indexed name whose successive entries are allowed to be queried by the normalization route.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row. It stores the regular rational sequence read that receives the normalized modulus schedule.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row. It supplies dyadic radii, dyadic comparison rows, and denominator-depth data used by the normalized schedule.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal. It records only the scalar real-read interface reached after the regular rational sequence row has accepted the normalized schedule.*
5. *Δ is the* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *row. It records the finite diagonal read that chooses a common index for the stream name, dyadic depth, and regular rational row.*
6. *A is the admission ledger. It records the original Cauchy modulus row, the normalized dyadic modulus row, and the finite proof that the normalized row is at least as demanding as the original row at every displayed depth.*
7. *X is the normalization classifier. It distinguishes stream-name reads, regular rational reads, dyadic-depth reads, real-seal reads, diagonal-selection reads, and admission-ledger reads, but has no coordinate for global choice or completed real equality.*

8. *H stores componentwise* hsame *transport for S, Q, D, R, Δ, A, X and the structural rows.*
9. *C stores displayed* Cont *replay from a modulus-normalization request through the stream name, dyadic-depth row, diagonal selector, regular rational target, and real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyDiagonalSelection}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, D, R, \Delta, A, X, H, C, P, N$. It does not contain a located-order decision, a completed-real quotient equality, a countable-choice principle, or an unrestricted completeness theorem.

Theorem 7328.2 (Regular Cauchy modulus-normalization NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ *carrier*

$$M = (S, Q, D, R, \Delta, A, X, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-name, regular rational sequence, dyadic rational core, real seal, diagonal-selection, admission-ledger, classifier, transport, replay, provenance, and local naming rows;*
2. *modulus dominance, requiring the normalized dyadic row in A to dominate the original Cauchy modulus row at each displayed depth before Q may read the schedule;*
3. *diagonal compatibility, requiring Δ to expose a common finite index for the stream row S, dyadic-depth row D, and regular rational target Q;*
4. *scalar exactness, requiring every real-read budget to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *seal R after the normalized schedule has been accepted by Q;*
5. *structural stability under X, H, C, P, N, which classifies, transports, replays, sources, and names only the displayed finite route.*

No $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 7328.1. The analytic rows visible to the classifier are exactly S, Q, D, R, Δ, A, and the structural rows are X, H, C, P, N.

The modulus-dominance obligation is attached to A. A regular rational consumer may read Q only after the normalized dyadic row has been shown to dominate the displayed Cauchy modulus row at the relevant depth.

The diagonal obligation then passes through Δ. This row exposes the common finite index needed by the stream name S, dyadic-depth row D, and regular rational target Q.

Finally scalar reads reach R only after the normalized schedule has passed through Q. Since X, H, C, P, N classify, transport, replay, source, and name the same row order, and since the carrier has no coordinate for located order, quotient equality, countable choice, or unrestricted completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7328.3 (Regular Cauchy modulus-normalization handoff)**.** *Every downstream regular-sequence or real-construction consumer citing an accepted* $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ *carrier receives only the finite handoff*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{CauchyDiagonalSelection}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

followed by the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows of the same packet. The handoff is a finite modulus-normalization certificate; it is not located order, completed-real equality, countable choice, or a standalone completeness theorem.*

Proof. Start with an accepted normalization request. The request first reads the stream-name row S and dyadic-depth row D, so it inherits only the displayed stream entries and dyadic budget data.

Next it reads the diagonal selector Δ and admission ledger A. These rows fix a common finite index and require dominance of the original Cauchy modulus by the normalized dyadic schedule before the regular rational target can be consulted.

The remaining analytic read passes through Q and then R. Thus the regular rational sequence and real seal receive only the normalized finite schedule named by the same packet.

The structural rows X, H, C, P, N only classify, transport, replay, source, and name this route. No carrier coordinate remains from which located order, completed-real equality, countable choice, or unrestricted completeness could be read. □

Theorem 7328.4 (Regular Cauchy modulus-normalization nonescape boundary)**.** *Every accepted* $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ *consumer that reaches the regular rational target or real seal must first display the stream-name row S, dyadic-depth row D, diagonal selector Δ, and admission ledger A. Consequently the consumer cannot replace the finite normalization route by a detached modulus choice, a located-order decision, a completed-real quotient equality, countable choice, or an unrestricted completeness theorem.*

Proof. Project an accepted consumer of the carrier. The regular rational row Q and real seal R occur downstream of S, D, Δ, A, so neither read can be reached before the stream, dyadic-depth, diagonal, and admission rows are fixed.

The classifier row X records this row order as part of the accepted packet. Componentwise transport H and replay C preserve that order, while P and N source and name the same route.

Any consumer omitting S, D, Δ, or A would be reading a coordinate absent from the displayed carrier. Hence the regular rational and real reads cannot escape the finite modulus-normalization route. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ normalization read factors through displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyDiagonalSelection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows before any downstream consumer receives a regular rational or real read.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy-diagonal-selection: $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries stream-indexed modulus data, dyadic-depth data, diagonal index selection, regular rational target data, real-seal readback, classifier, transport, replay, provenance, and local naming in one finite normalization-route carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalization}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusNormalization}^{\uparrow}$ packet is generated from a StreamName row, RegSeqRat row, DyadicRatCore row, Real seal, CauchyDiagonalSelection row, admission ledger, normalization classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalization}^{\uparrow}}$, seed)

Scope closed: Definition 7328.1, Definition 7328.2, Definition 7328.3, and Definition 7328.4 seed the finite modulus-normalization surface over StreamName, RegSeqRat, DyadicRatCore, Real, and CauchyDiagonalSelection neighbours.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close located order, completed-real quotient equality, countable choice, unrestricted completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus dominance, diagonal compatibility, scalar exactness, classifier nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyModulusNormalization

Chapter 7329

A Concrete Naming Certificate for $\mathsf{PolynomialResultant}^{\uparrow}$

Following Sylvester and van der Waerden, the $\mathsf{PolynomialResultant}^{\uparrow}$ packet records the finite elimination row by which two displayed univariate polynomial coefficient lists expose a determinant obstruction to a shared root. It sits after the coefficient carrier of chapter 50, the finite matrix carrier of chapter 49, and the scalar arithmetic surface of chapter 45. The packet names only the Sylvester matrix assembly, determinant readback, degree ledger, transport, replay, provenance, and local naming rows; it is not an algebraic closure theorem, a selected common root, a quotient-polynomial equality, a Euclidean division oracle, or a host elimination procedure.

Definition 7329.1 (Polynomial resultant carrier)**.** *A* $\mathsf{PolynomialResultant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, G, D, S, M, \Delta, H, C, P, N)$$

with the following displayed rows:

1. *F and G are* $\mathsf{Poly}^{\uparrow}$ *coefficient-list rows for the two input polynomials.*
2. *D is the finite degree and leading-coefficient ledger that fixes the Sylvester block sizes.*
3. *S is the Sylvester assembly row, listing the shifted coefficient rows used to build the matrix.*
4. *M is the* $\mathsf{Mat}^{\uparrow}$ *row that exposes the assembled Sylvester matrix as finite matrix data.*
5. *Δ is the* $\mathsf{Field}^{\uparrow}$ *scalar determinant readback row for the matrix M.*
6. *H records componentwise* hsame *transport for F, G, D, S, M, Δ and the local packet shape.*
7. *C records displayed* Cont *replay from polynomial coefficient reads through Sylvester assembly and determinant readback.*
8. *P is the* Pkg *provenance over* $\mathsf{PolynomialResultant}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PolynomialResultant}^{\uparrow}}$ *row.*

The carrier has no coordinate for algebraic closure, selected roots, quotient-polynomial equality, Euclidean division, subresultant chains, ambient field completion, or host elimination.

Theorem 7329.2 (Polynomial resultant Sylvester determinacy)**.** *For every accepted* $\mathsf{PolynomialResultant}^{\uparrow}$ *carrier*

$$R = (F, G, D, S, M, \Delta, H, C, P, N),$$

the determinant row Δ is determined only after the two polynomial rows F, G, the degree ledger D, the Sylvester assembly row S, and the finite matrix row M have all been displayed. A consumer may therefore read the resultant scalar only along the route

$$\mathsf{Poly}^{\uparrow}, \mathsf{Poly}^{\uparrow} \longmapsto D \longmapsto S \longmapsto \mathsf{Mat}^{\uparrow} \longmapsto \mathsf{Field}^{\uparrow},$$

followed by H, C, P, N; no accepted packet reads Δ from a selected common root, a quotient-polynomial equality, a Euclidean algorithm transcript, or an ambient elimination theorem.

Proof. Project the carrier of Definition 7329.1. The scalar row Δ appears only after the two coefficient rows, the degree ledger, the Sylvester assembly row, and the matrix row have been named.

The Sylvester row S is finite because it is built from shifted copies of the displayed coefficient rows with block sizes fixed by D. The matrix row M is therefore a displayed $\mathsf{Mat}^{\uparrow}$ read, not a host array or an implicit linear operator.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no selected root, quotient-polynomial equality, Euclidean transcript, or host elimination theorem, the determinant row is determined exactly by the displayed Sylvester route. □

Theorem 7329.3 (Polynomial resultant NameCert obligations)**.** *For every accepted* $\mathsf{PolynomialResultant}^{\uparrow}$ *carrier*

$$R = (F, G, D, S, M, \Delta, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PolynomialResultant}^{\uparrow}}$ *surface consists exactly of polynomial coefficient exposure through F, G, degree and leading-coefficient exposure through D, Sylvester block assembly through S, matrix readback through M, field determinant readback through Δ, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Thus every downstream elimination, discriminant, or algebraic-geometry consumer receives a finite resultant packet only through the sibling surfaces of chapter 50, chapter 49, and chapter 45.

Proof. Start from the carrier projection. The polynomial source rows F, G and the ledger D provide the only coefficient and degree data available to the packet.

Next apply Definition 7329.2. It forces every determinant read to pass through S and M before the scalar row Δ is exposed.

The structural rows do not add algebraic content. They only transport, replay, source, and name the same finite packet, so the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{PolynomialResultant}^{\uparrow}$ read displays two PolynomialUp coefficient rows, a finite degree ledger, a Sylvester assembly row, a MatrixUp row, a FieldUp determinant readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before any resultant scalar is consumed.

Independence witness: polynomial, matrix, field: $\mathsf{PolynomialResultant}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two polynomial coefficient rows, the Sylvester block assembly, the finite matrix readback, the determinant scalar, and the local NameCert ledger in one elimination packet.

Lean4 (statement) `BEDC.Derived.PolynomialResultantUp`

Closure status for $\mathsf{NameCert}_{\mathsf{PolynomialResultant}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PolynomialResultant}^{\uparrow}$ packet is generated from two PolynomialUp coefficient rows, a degree and leading-coefficient ledger, a Sylvester assembly row, a MatrixUp readback, a FieldUp determinant row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PolynomialResultant}\uparrow}$, seed)

Scope closed: Definition 7329.1, Definition 7329.2, and Definition 7329.3 seed the finite Sylvester-resultant route over polynomial, matrix, and field sibling surfaces.

Formal verification: FormalStatus(NameCert$_{\text{PolynomialResultant}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.PolynomialResultantUp`

Bridge status: none

Not claimed: This chapter does not close algebraic closure, selected roots, quotient-polynomial equality, Euclidean division, subresultant chains, ambient field completion, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Sylvester assembly determinacy, matrix readback exactness, determinant row exposure, transport, replay, provenance, and local naming for BEDC.Derived.PolynomialResultantUp.

Chapter 7330

A Concrete Naming Certificate for CompactUniformContinuityFiniteModulus$^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Heine–Cantor theorem, the CompactUniformContinuityFinite packet names the finite modulus route that turns compact finite-net data and continuous pointwise-modulus data into a single tolerance-only uniform-modulus row. It sits after the compact carrier of chapter 60, the continuous-map surface of chapter 59, the metric comparison rows of chapter 57, the rational and dyadic tolerance ledgers of chapter 37 and chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite fold described in chapter 9237. The packet records a finite ProbeBundle rational-fold handoff only; it does not assert open-cover compactness, choose a pointwise modulus from a host theorem, import Real$^{\uparrow}$ completeness, or identify quotient functions.

Definition 7330.1 (Compact uniform continuity finite-modulus carrier)**.** *A* CompactUniformContinuityFiniteModul *carrier is a finite* BHist *packet*

$$U = (K, F, M, E, B, R, D, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row read through* Compact$^{\uparrow}$*;*
2. *F is the continuous pointwise-modulus row read through* Continuous$^{\uparrow}$*;*
3. *M is the* Met$^{\uparrow}$ *distance-comparison row used by the finite-net and pointwise-modulus reads;*
4. *E is the positive* Rat$^{\uparrow}$ *tolerance request;*
5. *B is the finite* ProbeBundle *of centers, radii, and subordinate pointwise-modulus witnesses;*
6. *R is the* Rat$^{\uparrow}$ *lower-bound fold over the displayed bundle radii;*
7. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row that converts the rational lower bound into the requested dyadic budget;*
8. *Q is the* RegSeqRat$^{\uparrow}$ *readback row used when the modulus is consumed by regular rational names;*
9. *S is the* Real$^{\uparrow}$ *seal reached only after the finite compact, continuous, metric, rational-fold, dyadic, and regular-readback rows are visible;*
10. *H records componentwise* hsame *transport for $K, F, M, E, B, R, D, Q, S, C, P, N$;*

11. *C records displayed* Cont *replay through the compact source, continuous pointwise-modulus source, metric comparison, rational fold, dyadic tolerance row, regular readback, real seal, transport, provenance, and local naming rows;*
12. *P is the* Pkg *provenance over* $\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for an open-cover compactness theorem, a selected global modulus, ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of functions, Lean verification, or bridge checking.*

Theorem 7330.2 (Compact uniform continuity finite-modulus obligations)**.** *For every accepted* $\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}$ *carrier* $U = (K, F, M, E, B, R, D, Q, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}}$ *surface consists exactly of compact finite-net exposure, continuous pointwise-modulus exposure, metric comparison, positive rational tolerance exposure, finite* ProbeBundle *exposure, rational lower-bound fold exposure, dyadic tolerance handoff, regular rational readback, real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7330.1. The compact source row K, continuous row F, metric row M, tolerance row E, and finite bundle row B are the only data from which the lower-bound fold can be read.

The rational fold row R is computed over the displayed bundle; the dyadic row D and regular-readback row Q only transport that finite lower bound to the consumer side. The real seal S is therefore downstream of the same finite compact-continuous route.

The structural rows H, C, P, N preserve, replay, source, and name the packet. Since the carrier stores no open-cover compactness theorem, selected global modulus, ambient completeness claim, quotient function equality, Lean theorem, or bridge row, the listed rows exhaust the NameCert obligations. □

Theorem 7330.3 (Compact uniform continuity finite-modulus nonescape)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}$ *packet must first read*

$$K, F, M, E, B, R, D, Q, H, C, P, N$$

before it can consume the real-seal row S. The finite modulus is therefore the ProbeBundle rational-fold route of the compact-uniform-continuity construction, not an open-cover compactness principle, selected host modulus, quotient-function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with $U = (K, F, M, E, B, R, D, Q, S, H, C, P, N)$. Carrier admission makes the compact finite net, continuous pointwise-modulus row, metric comparison, positive rational tolerance request, finite ProbeBundle, rational lower-bound fold, dyadic tolerance handoff, and regular rational readback visible before the seal is available.

Use Definition 7330.2. Its handoff clauses bind the consumer route to the displayed K, F, M, E, B, R, D, Q rows, while the transport and replay clauses keep the route componentwise stable.

The packet has no coordinate for open-cover compactness, a selected host modulus, quotient equality of functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$. Thus no downstream consumer can detach the seal from the finite ProbeBundle rational-fold route. □

Falsifiable prediction: A consumer that claims a $\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}$ read while omitting the $\mathsf{Compact}^{\uparrow}$ finite-net row, $\mathsf{Continuous}^{\uparrow}$ pointwise-modulus row, $\mathsf{Met}^{\uparrow}$ comparison

row, positive $\mathsf{Rat}^{\uparrow}$ tolerance row, finite ProbeBundle, rational lower-bound fold, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance handoff, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row refutes the carrier of Definition 7330.1.

Independence witness: compact, continuous, metric, rat, dyadicratcore, regseqrat, real: no listed sibling is bijective to $\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}$ because this packet alone binds compact finite-net data, continuous pointwise-modulus data, metric comparison, rational ProbeBundle folding, dyadic tolerance routing, regular readback, real sealing, transport, replay, provenance, and local naming as one finite modulus certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}$ packet is generated from compact finite-net rows, continuous pointwise-modulus rows, metric comparison rows, positive rational tolerance rows, finite ProbeBundle rows, rational lower-bound fold rows, dyadic tolerance rows, regular rational readback rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7330.1, Definition 7330.2, and Definition 7330.3 seed the finite ProbeBundle rational-fold modulus route for compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityFiniteModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, a selected global modulus, quotient equality of functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous pointwise-modulus exposure, metric comparison, positive rational tolerance exposure, finite ProbeBundle exposure, rational lower-bound fold exactness, dyadic tolerance handoff, regular rational readback, real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformContinuityFiniteModulusUp.

Chapter 7331

A Concrete Naming Certificate for $\mathsf{DyadicMidpointInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicMidpointInterval}^{\uparrow}$ packet records the finite dyadic interval-halving data used when a Real and Completion construction inspects a retained interval before passing to regular rational names. It sits over the dyadic arithmetic core of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the nested interval route of chapter 320. The packet names only midpoint-halving rows in finite BHist data; it does not import Dedekind cuts, host interval equality, open-cover compactness, selected limits, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7331.1 (Dyadic midpoint interval carrier)**.** *A* $\mathsf{DyadicMidpointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, R, M, W, D, H, C, P, N)$$

with the following displayed rows:

1. *L is the left endpoint row, read as a dyadic rational endpoint supplied by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger.*
2. *R is the right endpoint row, read as a dyadic rational endpoint in the same ledger and displayed with $L \leq R$ by finite comparison data.*
3. *M is the midpoint row, recording the dyadic value obtained from the displayed halving operation on L and R.*
4. *W is the width and tolerance row. It records the original width, the halved width, and the tolerance budget consumed by Real and Completion requests.*
5. *D is the dyadic ledger. It contains the addition, comparison, halving, and denominator-clearance rows needed to read L, R, M, W without leaving* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
6. *H records componentwise* hsame *transport for endpoint, midpoint, width, dyadic-ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an interval-halving request through L, R, M, W, D, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicMidpointInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicMidpointInterval}^{\uparrow}}$ *row naming exactly this midpoint-halving certificate. The classifier compares accepted packets only through $L, R, M, W, D, H, C, P, N$. It has no coordinate for Dedekind cuts, host interval equality, open-cover compactness, selected limits, quotient equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7331.2 (Dyadic midpoint interval halving)**.** *For every accepted* $\mathsf{DyadicMidpointInterval}^{\uparrow}$ *carrier $I = (L, R, M, W, D, H, C, P, N)$, the midpoint row M and width row W display a finite halving route: the original endpoint interval $[L, R]$ is read through the dyadic ledger D, the midpoint is the dyadic half-sum recorded in M, and each retained child interval has width bounded by the halved width recorded in W. Any* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of this halving route must pass through D, H, C, P, N before reading the resulting finite window or real-name seal.*

Proof. Project the carrier of Definition 7331.1. The only endpoint, midpoint, and width data available to a consumer are the displayed rows L, R, M, W together with the dyadic ledger D.

The halving step is read inside $\mathsf{DyadicRatCore}^{\uparrow}$. The ledger D supplies the endpoint comparison, half-sum row, denominator-clearance row, and width comparison row, so the retained left or right child interval is certified by finite dyadic arithmetic rather than by host interval equality.

Next attach the Real and Completion handoff. The finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38 may consume the halved interval only after the rows L, R, M, W, D are displayed.

Finally compare with the nested route of chapter 320. A retained nested cell reads this midpoint packet as one finite refinement step, and the structural rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded object is a carrier coordinate, no Dedekind cut, host interval equality, open-cover compactness, selected limit, quotient equality, countable choice, or ambient completeness principle is exported. □

Theorem 7331.3 (Dyadic midpoint interval NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMidpointInterval}^{\uparrow}$ *carrier $I = (L, R, M, W, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicMidpointInterval}^{\uparrow}}$ *surface consists exactly of endpoint admission, midpoint-halving admission, width and tolerance admission, dyadic-ledger exactness, componentwise transport, displayed replay, provenance, and local naming. The obligation surface may cite the dyadic arithmetic core of chapter 291, the stream window surface of chapter 126, the regular rational handoff of chapter 301, the terminal real-name surface of chapter 38, and the nested interval route of chapter 320; it cannot add Dedekind cuts, host interval equality, open-cover compactness, selected limits, quotient equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Carrier admission is Definition 7331.1. It exposes exactly $L, R, M, W, D, H, C, P, N$ and no host interval object.

The halving obligation is Definition 7331.2. It forces every midpoint and child-width read through the dyadic ledger before any downstream finite window, regular rational row, or real seal can be consumed.

The remaining obligations are structural. Componentwise hsame transport is the row H, displayed replay is the row C, provenance is the row P, and local naming is the row N. These rows preserve the same finite packet, so the local certificate has no route to Dedekind cuts, host interval equality, open-cover compactness, selected limits, quotient equality, countable choice, ambient completeness, Lean verification, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMidpointInterval}^{\uparrow}}$.

Constructive story: A DyadicMidpointInterval$^{\uparrow}$ packet is generated from left and right dyadic endpoint rows, a midpoint row, a width and tolerance row, a dyadic arithmetic ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicMidpointInterval}\uparrow}$, seed)

Scope closed: Definition 7331.1, Definition 7331.2, and Definition 7331.3 seed the finite midpoint-halving certificate used by Real and Completion construction routes.

Formal verification: FormalStatus(NameCert$_{\text{DyadicMidpointInterval}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, host interval equality, open-cover compactness, selected limits, quotient equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, midpoint-halving exactness, width and tolerance readback, dyadic-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.DyadicMidpointIntervalUp.

Chapter 7332

A Concrete Naming Certificate for $\mathsf{CantorCylinderCompactness}^{\uparrow}$

Following Brouwer and Bishop–Bridges, the $\mathsf{CantorCylinderCompactness}^{\uparrow}$ packet records the compact finite-prefix surface of Cantor cylinders as displayed NameCert data. It refines the cylinder basis of chapter 2153, reads its ambient Cantor carrier through chapter 1475, uses the finite request windows of chapter 126, and routes tolerance comparisons through chapter 291. The packet gives later StreamName and completion consumers a finite-net handoff surface; it does not assert open-cover compactness, choice-selected branches, quotient stream equality, or ambient Real completeness.

Definition 7332.1 (Cantor cylinder compactness carrier)**.** *A* $\mathsf{CantorCylinderCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, C, R, W, D, F, T, H, K, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{CantorCylinderBasis}^{\uparrow}$ *source row, including the finite binary prefix basis and refinement data.*
2. *C is the ambient* $\mathsf{CantorSpace}^{\uparrow}$ *carrier row read only through finite prefix observations.*
3. *R is the finite binary prefix row family inspected by the compactness request.*
4. *W is the finite cylinder-cover row family, listing the displayed cylinders whose prefixes cover the inspected window.*
5. *D is the* $\mathsf{StreamName}^{\uparrow}$ *request-window row that bounds which prefix lengths and stream positions are visible to the consumer.*
6. *F is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and tolerance ledger attached to the same finite request.*
7. *T is the compact finite-net handoff row, giving the finite prefix representatives delivered to StreamName and completion-facing consumers.*
8. *H stores componentwise* hsame *transport for the basis, Cantor carrier, prefix rows, cover rows, request windows, tolerance ledger, finite-net handoff, replay route, provenance, and local naming.*
9. *K is the displayed* Cont *replay route from request windows to cylinder-cover rows, from cover rows to dyadic tolerance rows, and from those rows to the finite-net handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorCylinderCompactness}^{\uparrow}$, $\mathsf{CantorCylinderBasis}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorCylinderCompactness}^{\uparrow}}$ *row.*

The carrier compares compactness reads only through these finite rows. It has no coordinate for arbitrary open covers, selected infinite branches, quotient equality of streams, or a completeness principle for ambient real numbers.

Theorem 7332.2 (Cantor cylinder compactness NameCert obligations)**.** *For every accepted* CantorCylinderCompac *carrier*

$$Q = (B, C, R, W, D, F, T, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorCylinderCompactness}^{\uparrow}}$ *surface consists exactly of the finite carrier admission, prefix-cover visibility, StreamName request-window discipline, dyadic tolerance discipline, finite-net handoff, componentwise transport, continuation replay, provenance, and nonescape obligations displayed by*

$$B, C, R, W, D, F, T, H, K, P, N.$$

Every obligation is checked inside the finite-prefix rows inherited from $\mathsf{CantorCylinderBasis}^{\uparrow}$ *and* $\mathsf{CantorSpace}^{\uparrow}$ *and the finite request and tolerance rows inherited from* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$.

Proof. Carrier admission is projection of the displayed tuple in Definition 7332.1. The rows B, C, R, W supply the finite cylinder basis, Cantor source, inspected prefix rows, and finite cover rows before any compactness-facing handoff is available.

The request and tolerance obligations are then forced by D and F. A consumer may ask only for the prefix lengths and stream positions exposed by the $\mathsf{StreamName}^{\uparrow}$ row D, and each radius or tolerance comparison must pass through the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger F.

The finite-net handoff is the row T. It packages exactly the displayed prefix representatives selected by the finite cover rows and tolerance ledger, without adding a branch selector or an infinite product coordinate.

Finally H, K, P, N transport, replay, source, and locally name the same route. Since no displayed row contains an arbitrary open-cover principle, quotient stream equality, selected branch, or ambient Real-completeness certificate, the local NameCert surface cannot export one. □

Theorem 7332.3 (Cantor cylinder compactness prefix-net handoff)**.** *Every StreamName-facing read of an accepted* $\mathsf{CantorCylinderCompactness}^{\uparrow}$ *packet reaches the compact finite-net handoff row T only after the finite binary prefix rows R, finite cylinder-cover rows W, request-window row D, and dyadic radius or tolerance ledger F have been displayed over the source rows B and C. The handoff delivered through H, K, P, N is a finite-prefix net surface, not an open-cover compactness theorem, choice-selected branch, quotient stream equality, or ambient Real-completeness claim.*

Proof. Start with a StreamName-facing request. The source cylinder basis B and Cantor carrier C expose only finite prefix observations, so the request cannot inspect an infinite stream as a host function.

Read the finite rows in order. The prefix family R supplies the visible binary prefixes, the cover family W records which displayed cylinders cover the inspected window, the request row D bounds the visible stream positions, and the tolerance ledger F records the dyadic radius data attached to that same request.

Only then can the compact handoff row T be consumed. It exports the finite representatives already displayed by R, W, D, F to later StreamName and completion-facing consumers.

The structural rows H, K, P, N preserve this route componentwise. They do not add open-cover compactness, a branch selector, quotient stream equality, or ambient Real completeness, so the exported handoff remains a finite-prefix compactness packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorCylinderCompactness}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorCylinderCompactness}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7332.1, Definition 7332.2, and Definition 7332.3 seed the StreamName-facing finite-prefix compactness surface over Cantor cylinder basis, CantorSpace, StreamName windows, DyadicRatCore tolerance rows, compact finite-net handoff rows, transport, replay, provenance, and local NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorCylinderCompactness}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim open-cover compactness, choice-selected branches, quotient stream equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: The next step is obligationClosure: carrier admission, prefix-cover visibility, StreamName request-window discipline, dyadic tolerance discipline, finite-net handoff, and nonescape must be discharged as local rows.

Constructive story: The construction starts from finite Cantor cylinder prefixes, displays the requested StreamName window, attaches DyadicRatCore tolerance rows, and exports only the finite-net handoff preserved by hsame transport, Cont replay, Pkg provenance, and local NameCert.

Chapter 7333

Rational squeeze NameCert construction

Following Bishop and Bridges constructive analysis, the $\mathsf{RationalSqueeze}^{\uparrow}$ packet records the finite rational lower–upper squeeze data used by the L10 regular-Cauchy and Real completion route. It sits between the dyadic arithmetic core of chapter 291, the regular rational sequence surface of chapter 301, the terminal Real seal of chapter 38, the located comparison route of chapter 1730, and the Cauchy-tail basis of chapter 1868. The packet is a finite means certificate for reading a rational squeeze as a regular rational name and then as a sealed Real row; it is not a Dedekind cut, quotient real equality, selected limit, open-cover compactness principle, or ambient completeness axiom.

Definition 7333.1 (Rational squeeze carrier)**.** *A* $\mathsf{RationalSqueeze}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, M, D, R, E, O, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower rational bound stream, read as finite rational endpoint rows with monotone lower-side comparison data.*
2. *U is the upper rational bound stream, read as finite rational endpoint rows with monotone upper-side comparison data.*
3. *M is the middle stream row, obtained by finite dyadic midpoint or rational averaging rows from the displayed lower and upper bounds.*
4. *D is the dyadic tolerance row supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*; it records denominator clearance, dyadic width budgets, and the visible tolerance cell inspected by a consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row; it records the regular rational name obtained by reading the middle stream against the dyadic tolerance row.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, displaying the terminal real-name package obtained from the regular rational readback.*
7. *O is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *order route, recording the lower–middle and middle–upper comparisons needed by a located-order consumer.*
8. *H records componentwise* hsame *transport for lower bounds, upper bounds, middle stream, dyadic tolerance, regular readback, Real seal, located-order rows, replay rows, provenance, and local naming.*

9. *C records displayed* Cont *replay for rereading the squeeze request through $L, U, M, D, R, E, O, H, P, N$ without changing the finite packet.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalSqueeze}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, $\mathsf{CauchyTailBasis}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalSqueeze}^{\uparrow}}$ *row naming exactly this squeeze packet.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host real equality, quotient interval equality, a selected limit point, countable choice, open-cover compactness, or ambient Real completeness.

Lean4 (statement) `BEDC.Derived.RationalSqueezeUp`

Theorem 7333.2 (Rational squeeze NameCert obligations)**.** *For every accepted* $\mathsf{RationalSqueeze}^{\uparrow}$ *carrier $S = (L, U, M, D, R, E, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalSqueeze}^{\uparrow}}$ *obligations are exhausted by lower-bound exposure, upper-bound exposure, middle-stream exposure, dyadic-tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal exposure, located-order route exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7333.1. The only numerical rows available to a consumer are L, U, M, D, R, E, O, and each row is displayed inside the finite packet before any downstream read occurs.

The NameCert surface is therefore rowwise. The lower and upper bounds expose the squeeze interval, the middle row exposes the finite averaging stream, the dyadic tolerance row exposes the visible width budget, the regular readback row exposes the rational name, the Real seal row exposes the terminal package, and the located-order row exposes the comparison route.

The remaining rows are structural. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming preserve precisely the same packet, so the certificate has no route to host real equality, quotient interval equality, selected limits, countable choice, open-cover compactness, or ambient completeness. □

Theorem 7333.3 (Rational squeeze RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalSqueeze}^{\uparrow}$ *packet must read the middle stream row M through the dyadic tolerance row D and the Cauchy-tail basis supplied by* $\mathsf{CauchyTailBasis}^{\uparrow}$ *before it may consume the readback row R. The handoff exports a regular rational sequence surface, not an arbitrary Cauchy wrapper or a host quotient name.*

Proof. Read the middle stream and tolerance rows of Definition 7333.1. The row M supplies the rational approximants, while D supplies the dyadic width and denominator-clearance data needed by a regular rational name.

Next apply the Cauchy-tail basis route. A consumer may inspect only the finite tolerance cell named by D and the corresponding middle-stream window, so the regularity read is forced through $\mathsf{CauchyTailBasis}^{\uparrow}$ before the row R is available.

Finally attach the structural rows. The transports, replay, provenance, and local name keep the readback componentwise identical to the displayed squeeze packet. Thus the handoff exports the finite $\mathsf{RegSeqRat}^{\uparrow}$ readback row and no host quotient name. □

Theorem 7333.4 (Rational squeeze Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalSqueeze}^{\uparrow}$ *packet must obtain the real-name seal E from the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, with the lower and upper rational rows L, U and the dyadic tolerance row D still visible as the finite witness surface. The seal does not identify quotient reals or select an external limit.*

Proof. First expose the regular rational row R from Definition 7333.3. This row is already tied to M and D, with L and U recording the squeeze bounds that constrain the middle stream.

The Real seal row E is then read as the terminal package over that regular rational name. Because the carrier keeps the squeeze rows displayed, the Real consumer receives the lower bound, upper bound, middle stream, tolerance, and readback evidence together.

The rows H, C, P, N preserve the same package during transport, replay, provenance, and local naming. No quotient real equality, selected external limit, countable choice, or ambient completeness principle is introduced by the seal. □

Theorem 7333.5 (Rational squeeze located-order route)**.** *Every located-order read exported by an accepted* $\mathsf{RationalSqueeze}^{\uparrow}$ *packet factors through the displayed row O: the lower-bound stream is compared with the middle stream, the middle stream is compared with the upper-bound stream, and each comparison is reread through the same dyadic tolerance row D before a* $\mathsf{LocatedRealComparison}^{\uparrow}$ *consumer can inspect it.*

Proof. Project the order route row O. It is displayed as part of the carrier and can mention only the lower, middle, upper, and tolerance rows already present in L, U, M, D.

The located comparison is therefore finite. Lower–middle and middle–upper reads are replayed at the visible dyadic tolerance, and the same tolerance row is transported by H before any consumer sees the route.

The provenance and local naming rows export this comparison as a $\mathsf{LocatedRealComparison}^{\uparrow}$ dependency of the squeeze packet. Since no host interval or quotient real equality is a carrier coordinate, the route remains a finite located-order read. □

Theorem 7333.6 (Rational squeeze Cauchy-window consumer)**.** *Every Cauchy-window consumer of an accepted* $\mathsf{RationalSqueeze}^{\uparrow}$ *packet receives a finite window consisting of the lower and upper rational bounds L, U, the middle stream M, the dyadic tolerance row D, the* $\mathsf{CauchyTailBasis}^{\uparrow}$ *handoff, and the structural rows H, C, P, N. The consumer cannot replace this window by an infinite choice sequence, an open-cover compactness argument, or ambient Real completeness.*

Proof. Read the squeeze window directly from the carrier. The rows L, U, M, D display the lower endpoint, upper endpoint, middle stream, and tolerance budget of the finite window.

The Cauchy-tail handoff is the same handoff used by Definition 7333.3. It lets a consumer reread a visible tolerance cell and its corresponding middle-stream approximant before passing to the regular rational readback.

Finally, H, C, P, N transport, replay, source, and name that finite window. These rows do not add an infinite choice sequence, an open-cover compactness argument, selected limits, quotient equality, or ambient Real completeness, so the Cauchy-window consumer remains bound to the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalSqueeze}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalSqueeze}^{\uparrow}$ packet is generated from lower rational bounds, upper rational bounds, a middle rational stream, dyadic tolerance rows, a RegSeqRat readback, a Real seal, a located-order route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalSqueeze}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7333.1, Definition 7333.2, Definition 7333.3, Definition 7333.4, Definition 7333.5, and Definition 7333.6 seed the finite squeeze certificate used by the L10 regular-Cauchy and Real completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalSqueeze}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, quotient real equality, selected limits, countable choice, open-cover compactness, ambient Real completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked lower-bound exposure, upper-bound exposure, middle-stream readback, dyadic-tolerance exactness, RegSeqRat handoff, Real seal, located-order route, transport, replay, provenance, and local naming for BEDC.Derived.RationalSqueezeUp.

Chapter 7334

A Concrete Naming Certificate for $\mathsf{IsaacsEquation}^{\uparrow}$

Following Isaacs and Fleming–Soner on differential games and viscosity solutions, the $\mathsf{IsaacsEquation}^{\uparrow}$ packet records the finite BEDC surface by which a two-player dynamic-programming boundary can be read as an Isaacs-equation certificate. It sits after the dynamic-programming route of chapter 5875, the viscosity-solution boundary of chapter 2177, the PDE carrier of chapter 194, the ODE evolution surface of chapter 193, and the terminal real-name seal of chapter 38. The packet names a finite game-PDE handoff only; it does not assert comparison, existence, uniqueness, measurable strategy selection, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7334.1 (Isaacs equation carrier)**.** *An* $\mathsf{IsaacsEquation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, A, B, V, D, E, O, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the differential-game state and payoff row;*
2. *A and B are the two finite control-action boundary rows;*
3. *V is the value-function candidate row read through* $\mathsf{DynamicProgramming}^{\uparrow}$*;*
4. *D is the dynamic-programming handoff row recording the local min-max or max-min route;*
5. *E is the* $\mathsf{PDE}^{\uparrow}$ *row that displays the Hamilton-Jacobi-Isaacs expression;*
6. *O is the* $\mathsf{ODE}^{\uparrow}$ *row that records the controlled state-evolution boundary;*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the game, control, dynamic-programming, PDE, and ODE rows are visible;*
8. *H records componentwise* hsame *transport for $G, A, B, V, D, E, O, R, C, P, N$;*
9. *C records displayed* Cont *replay through the game, control, dynamic-programming, viscosity, PDE, ODE, real-seal, transport, provenance, and local naming rows;*
10. *P is the* Pkg *provenance over* $\mathsf{IsaacsEquation}^{\uparrow}$, $\mathsf{DynamicProgramming}^{\uparrow}$, $\mathsf{ViscositySolution}^{\uparrow}$, $\mathsf{PDE}^{\uparrow}$, $\mathsf{ODE}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{IsaacsEquation}^{\uparrow}}$ *row.*

The carrier has no coordinate for a full PDE comparison theorem, an existence theorem, a uniqueness theorem, selected measurable strategies, quotient equality of value functions, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.IsaacsEquationUp.IsaacsEquationTasteGate single carrier alignment`

Theorem 7334.2 (Isaacs equation NameCert obligations)**.** *For every accepted* $\mathsf{IsaacsEquation}^{\uparrow}$ *carrier* $I = (G, A, B, V, D, E, O, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IsaacsEquation}^{\uparrow}}$ *surface consists exactly of game-state exposure, both finite control-action rows, value-candidate exposure, dynamic-programming handoff, viscosity-facing PDE exposure, controlled ODE exposure, real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside those rows.*

Proof. Project the carrier of Definition 7334.1. The rows G, A, B, V, D, E, O, R are the only analytic data visible to the local certificate.

Read the dynamic-programming and viscosity boundaries through the named siblings. The dynamic-programming row supplies the finite min-max handoff, while the viscosity-solution, PDE, and ODE rows keep the Hamilton-Jacobi-Isaacs expression attached to displayed evolution data.

The structural rows H, C, P, N preserve, replay, source, and name the packet. Since the carrier contains no comparison theorem, existence theorem, uniqueness theorem, selected strategy, quotient value-function equality, Lean theorem, or bridge row, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.IsaacsEquationUp.IsaacsEquationCarrier namecert obligations`

Theorem 7334.3 (Isaacs equation dynamic-programming route)**.** *Every* $\mathsf{ViscositySolution}^{\uparrow}$*,* $\mathsf{PDE}^{\uparrow}$*,* $\mathsf{ODE}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{IsaacsEquation}^{\uparrow}$ *packet must first read*

$$G, A, B, V, D, E, O, H, C, P, N$$

before it can consume the real-seal row R*. The route is the displayed dynamic-programming handoff for a differential-game equation, not a proof of PDE comparison, existence, uniqueness, selected optimal strategies, or ambient completeness.*

Proof. Start from the accepted packet $I = (G, A, B, V, D, E, O, R, H, C, P, N)$. The carrier orders the value-candidate row and dynamic-programming handoff before the PDE, ODE, and real-seal rows can be consumed.

Use Definition 7334.2. Its obligations bind every downstream read to the same game-state, control-action, dynamic-programming, PDE, ODE, transport, replay, provenance, and local naming rows.

The sibling chapters then supply the horizontal route: dynamic programming supplies the finite handoff, viscosity solutions supply the weak PDE reading discipline, PDE and ODE supply the displayed equation and evolution rows, and Real supplies only the terminal seal. No comparison, existence, uniqueness, strategy-selection, quotient, or ambient-completeness coordinate can be substituted for that route. □

Falsifiable prediction: A consumer that claims an $\mathsf{IsaacsEquation}^{\uparrow}$ read while omitting the differential-game row, one of the two control-action rows, the $\mathsf{DynamicProgramming}^{\uparrow}$ value handoff, the $\mathsf{ViscositySolution}^{\uparrow}$ discipline, the $\mathsf{PDE}^{\uparrow}$ expression row, the $\mathsf{ODE}^{\uparrow}$ evolution row, the $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row refutes the carrier of Definition 7334.1.

Independence witness: dynamic-programming, viscosity-solution, pde, ode, real: no listed sibling is bijective to $\mathsf{IsaacsEquation}^{\uparrow}$ because this packet alone binds two-player game rows, min-max dynamic-programming handoff, viscosity-facing PDE expression, controlled ODE evolution, real sealing, transport, replay, provenance, and local naming as one finite differential-game certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{IsaacsEquation}^{\uparrow}}$.

Constructive story: An $\mathsf{IsaacsEquation}^{\uparrow}$ packet is generated from differential-game source rows, two finite control-action rows, a value-candidate row, a dynamic-programming handoff, viscosity-facing PDE and ODE rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IsaacsEquation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7334.1, Definition 7334.2, and Definition 7334.3 seed the finite differential-game dynamic-programming route for Isaacs-equation consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IsaacsEquation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim PDE comparison, PDE existence, uniqueness, measurable strategy selection, quotient equality of value functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked game-row admission, control-action exposure, dynamic-programming handoff, viscosity-facing PDE and ODE routing, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.IsaacsEquationUp.

Chapter 7335

A Concrete Naming Certificate for $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$

The $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ packet realizes the missing-certificate analysis of section 9462.7 as finite NameCert data. It sits beside the classifier boundary of chapter 595, the classifier morphism surface of chapter 590, the classifier-shift ledger residue of chapter 6985, and the audit gate boundary of chapter 526. The packet separates supported-but-uncertified behavior from unexplained behavior and ledger-complete explanation; it is not a hidden explanation theorem or a classifier-correctness proof.

Definition 7335.1 (Black-box certificate deficit carrier)**.** *A* $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, S, M, L, F, X, R, V, H, C, P, N)$$

with the following displayed rows:

1. *T is the behavior-target row;*
2. *S is the support-classifier row witnessing that a classifier candidate supports T;*
3. *M is the missing-row inventory for source, pattern, classifier, stability, ledger, or verification rows;*
4. *L is the deficit ledger that records which NameCert rows are absent or incomplete;*
5. *F is the closed-explanation refusal row;*
6. *X is the classifier transport row from* $\mathsf{ClassifierBoundary}^{\uparrow}$ *and* $\mathsf{ClassifierMorphism}^{\uparrow}$ *surfaces;*
7. *R is the replay row for behavior, support, missing-row, ledger, and refusal reads;*
8. *V is the provenance row tying the packet to the black-box missing-certificate vision and the classifier-facing siblings;*
9. *H records componentwise* hsame *transport for $T, S, M, L, F, X, R, V, C, P, N$;*
10. *C records displayed* Cont *replay through the behavior target, support classifier, missing-row inventory, deficit ledger, refusal, transport, replay, provenance, and local naming rows;*
11. *P is the* Pkg *provenance over* $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$, $\mathsf{ClassifierBoundary}^{\uparrow}$, $\mathsf{ClassifierMorphism}^{\uparrow}$, $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$, $\mathsf{AuditGateBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BlackBoxCertificateDeficit}^{\uparrow}}$ *row.*

The carrier has no coordinate for unexplained behavior with no support classifier, ledger-complete certified explanation, global classifier correctness, hidden causal proof, Lean verification, or bridge checking.

Theorem 7335.2 (Black-box certificate deficit NameCert obligations)**.** *For every accepted* $\mathsf{BlackBoxCertificateDefic}$ *carrier* $B = (T, S, M, L, F, X, R, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BlackBoxCertificateDeficit}^{\uparrow}}$ *surface consists exactly of behavior-target exposure, support-classifier exposure, missing-row inventory, deficit-ledger exposure, closed-explanation refusal, classifier transport, displayed replay, provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7335.1. The behavior target T and support classifier S are visible before any deficit claim can be read.

Read the missing-row inventory and ledger rows next. The inventory M identifies which NameCert rows are absent or incomplete, while L records the deficit as finite ledger data and F refuses a closed-explanation read until those rows are supplied.

The classifier-facing siblings constrain transport. Classifier boundary and classifier morphism rows supply the support route, classifier-shift ledger residue records whether a classifier disagreement is present, and audit gate boundary records the local admission route. The structural rows R, V, H, C, P, N preserve and name exactly that surface. □

Theorem 7335.3 (Black-box certificate deficit closed-explanation refusal)**.** *An accepted* $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ *packet may be read as black-box behavior only when the support-classifier row* S *is displayed and the missing-row inventory* M *or deficit ledger* L *is nonempty. It may not be read as unexplained behavior, because* S *is present, and it may not be read as ledger-complete explanation, because* F *records the closed-explanation refusal.*

Proof. Start with the behavior target and support classifier. The carrier stores T and S as distinct rows, so the packet is not an unexplained-behavior row.

Use the deficit rows M, L, F. Missing or incomplete certificate rows are recorded before the refusal row is consumed, and F blocks any closed-explanation read that lacks the named NameCert rows.

Finally inspect the transport, replay, provenance, and local naming rows. They preserve the supported-but-uncertified status and provide no hidden certificate row, classifier-correctness proof, or ledger-complete explanation outside the displayed packet. □

Falsifiable prediction: Any closed-explanation read of a $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ packet without a local $\mathsf{NameCert}_{\mathsf{BlackBoxCertificateDeficit}^{\uparrow}}$ row and the displayed missing-row inventory refutes the carrier of Definition 7335.1.

Independence witness: classifierboundary, classifiermorphism, classifier-shift-ledger-residue, auditgateboundary, namecert-facing siblings: $\mathsf{ClassifierBoundary}^{\uparrow}$ exposes classifier admission without the deficit ledger; $\mathsf{ClassifierMorphism}^{\uparrow}$ transports classifier rows without recording missing explanation rows; $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ records classifier disagreement without forcing a black-box deficit; $\mathsf{AuditGateBoundary}^{\uparrow}$ localizes admission without carrying the behavior-support pair; NameCert-facing siblings close certificates rather than naming the supported-but-uncertified gap. None is bijective to $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ under NameCert-row preservation.

The Lean follow-up for this carrier must provide $\mathsf{Nontrivial}\ \mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ instances in `BEDC.Derived.BlackBoxCertificateDeficitUp.TasteGate` before any checked TasteGate theorem can serve as a closure witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BlackBoxCertificateDeficit}\uparrow}$.

Constructive story: A $\mathsf{BlackBoxCertificateDeficit}^{\uparrow}$ packet is generated from a behavior target, support classifier, missing-row inventory, deficit ledger, closed-explanation refusal, classifier transport, replay, provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BlackBoxCertificateDeficit}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7335.1, Definition 7335.2, and Definition 7335.3 seed the finite certificate-deficit route for supported but uncertified behavior.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BlackBoxCertificateDeficit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unexplained behavior, ledger-complete explanation, classifier correctness, hidden causal explanation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked behavior-target exposure, support-classifier exposure, missing-row inventory, deficit-ledger accounting, closed-explanation refusal, classifier transport, replay, provenance, local naming, Nontrivial, and FieldFaithful rows for BEDC.Derived.BlackBoxCertificateDeficitUp.

Chapter 7336

A Concrete Naming Certificate for $\mathsf{Sheafification}^{\uparrow}$

Following Grothendieck's SGA 4 site formalism and the Mac Lane–Moerdijk account of sheaves in geometry and logic, the $\mathsf{Sheafification}^{\uparrow}$ packet records the finite BEDC surface by which a displayed presheaf is routed to a sheaf-facing carrier. It sits after the categorical source of chapter 61, the topological and site carriers of chapter 88 and chapter 6718, the presheaf restriction surface of chapter 150, and the gluing target of chapter 151. The packet names the separated-refinement, cover-local matching, plus-style gluing, transport, replay, provenance, and local naming rows; it is not a host sheafification functor, not a quotient of compatible families, and not a topos-level reflector.

Definition 7336.1 (Sheafification carrier)**.** *A* $\mathsf{Sheafification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (C, T, J, P, L, G, S, H, R, Q, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Cat}^{\uparrow}$ *source row naming the displayed objects and arrows over which the presheaf is read.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *or site-open row supplying the indexed open windows used by cover requests.*
3. *J is the* $\mathsf{GrothendieckTopology}^{\uparrow}$ *coverage row, including covering sieves, pullback-stability rows, and local-transitivity rows.*
4. *P is the* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row over C, T, J, with section carriers and restriction comparison data.*
5. *L is the locality-refinement ledger, recording matching families after every displayed cover refinement.*
6. *G is the gluing ledger, recording the accepted glued section row for each compatible local family.*
7. *S is the resulting* $\mathsf{Sheaf}^{\uparrow}$ *target row, exposed only through the same locality and gluing data.*
8. *H records componentwise* hsame *transport for the category, topology, site, presheaf, locality, gluing, sheaf, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay from presheaf restriction reads through the locality and gluing ledgers to the sheaf target.*

10. *Q is the* Pkg *provenance over* $\mathsf{Sheafification}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{GrothendieckTopology}^{\uparrow}$, $\mathsf{PreSheaf}^{\uparrow}$, $\mathsf{Sheaf}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, T, J, P, L, G, S, H, R, Q, N$. It has no coordinate for a host reflector, quotient of compatible families, global choice of covers, topos object, ambient powerset equality, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.SheafificationUp.TasteGate.SheafificationTasteGate single carrier alignment`

Theorem 7336.2 (Sheafification NameCert obligations)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier*

$$A = (C, T, J, P, L, G, S, H, R, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *surface consists exactly of category-source exposure through C, topology-window exposure through T, Grothendieck coverage through J, presheaf restriction exposure through P, locality-refinement rows through L, gluing rows through G, the sheaf target row through S, componentwise transport through H, displayed replay through R, provenance through Q, and local naming through N.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCarrier namecert obligations`

Proof. Project the carrier of Definition 7336.1. The source side is the displayed category, topology or site window, Grothendieck coverage row, and presheaf restriction row.

The locality ledger L records the cover-refinement comparisons that make matching families visible. The gluing ledger G records the resulting glued section row only after those matching-family rows have been displayed.

The sheaf target S is therefore read from P, L, G over the same C, T, J source. The structural rows H, R, Q, N transport, replay, source, and name that same route. Since no host reflector, quotient family, selected cover, topos object, or powerset equality is a carrier coordinate, the listed rows exhaust the local certificate surface. □

Theorem 7336.3 (Sheafification locality-gluing scope)**.** *Every accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier routes presheaf restriction, cover-local matching, separated refinement, plus-style gluing,* $\mathsf{Sheaf}^{\uparrow}$ *target exposure,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows through the displayed dependencies*

$$\mathsf{Cat}^{\uparrow}, \mathsf{Topology}^{\uparrow}, \mathsf{GrothendieckTopology}^{\uparrow}, \mathsf{PreSheaf}^{\uparrow}, \mathsf{Sheaf}^{\uparrow}.$$

Thus any locality or gluing consumer that preserves the local certificate must read the same category source, topology windows, Grothendieck coverage, presheaf restriction, locality ledger, gluing ledger, sheaf target, transport, replay, provenance, and naming rows; it cannot substitute a host reflector, quotient of compatible families, selected cover system, ambient powerset equality, or topos-level object for the displayed BEDC route.

Proof. Project the carrier rows of Definition 7336.1. The source side is fixed by C, T, J, P: category data, topology windows, Grothendieck coverage, and presheaf restrictions are visible before locality can be read.

Apply the NameCert obligations of Definition 7336.2. They identify L as the cover-local matching and separated-refinement ledger, G as the plus-style gluing ledger, and S as the sheaf target row exposed only after those rows are displayed.

The remaining rows H, R, Q, N preserve that same route by componentwise transport, displayed replay, provenance, and local naming. Since the obligation theorem exhausts the accepted certificate surface, a locality or gluing consumer cannot leave the displayed $\mathsf{Cat}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{GrothendieckTopology}^{\uparrow}$, $\mathsf{PreSheaf}^{\uparrow}$, and $\mathsf{Sheaf}^{\uparrow}$ dependencies. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalityGluingScope`

Theorem 7336.4 (Sheafification sheaf handoff)**.** *Every downstream* $\mathsf{Sheaf}^{\uparrow}$ *consumer of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet receives only the displayed sheaf row* S *together with its dependency route*

$$\mathsf{Cat}^{\uparrow}, \mathsf{Topology}^{\uparrow}, \mathsf{GrothendieckTopology}^{\uparrow}, \mathsf{PreSheaf}^{\uparrow} \longmapsto L \longmapsto G \longmapsto \mathsf{Sheaf}^{\uparrow}.$$

The handoff exposes the category source, topology or site windows, coverage row, presheaf restriction row, locality ledger, gluing ledger, transport row, replay row, provenance row, and local naming row; it does not expose a host sheafification functor, quotient of compatible families, selected cover system, topos object, or ambient powerset equality.

Proof. Start with the carrier projection. A sheaf-facing consumer can read S only after C, T, J, P, L, G have been displayed, because S is the target row of that finite route.

Use the topology and site rows to interpret covers as displayed $\mathsf{Topology}^{\uparrow}$ windows and $\mathsf{GrothendieckTopology}^{\uparrow}$ covering sieves. The presheaf row P supplies restriction data on those windows, while L records locality under cover refinement and G records the glued section row.

The handoff to $\mathsf{Sheaf}^{\uparrow}$ is therefore the same row package, transported by H and replayed by R. The provenance and local naming rows Q, N name the consumed siblings without adding a host reflector or quotient object. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSheafHandoff`

Theorem 7336.5 (Sheafification coverage exactness)**.** *Every cover-local read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet*

$$A = (C, T, J, P, L, G, S, H, R, Q, N)$$

must expose the category row C*, topology-window row* T*, Grothendieck-coverage row* J*, and presheaf-restriction row* P *before any locality data in* L *may be consumed.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverageExactness`

Proof. Project the displayed carrier tuple. The only cover source coordinates are C, T, J, P: C supplies the $\mathsf{Cat}^{\uparrow}$ objects and arrows, T supplies the $\mathsf{Topology}^{\uparrow}$ windows, J supplies the $\mathsf{GrothendieckTopology}^{\uparrow}$ covering and pullback-stability rows, and P supplies the $\mathsf{PreSheaf}^{\uparrow}$ restriction data over that source.

The locality ledger L is typed by those displayed cover and restriction rows. A read that reaches L without first exposing C, T, J, P has no BEDC row from which cover-locality can be interpreted.

The structural rows H, R, Q, N preserve this order. Componentwise hsame transport, Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row can carry the exposed source route, but none of them supplies an independent coverage coordinate. Thus coverage exactness forces every locality read through C, T, J, P first. □

Theorem 7336.6 (Sheafification locality refinement)**.** *For an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet, every matching-family row recorded in* L *is stable under displayed* $\mathsf{GrothendieckTopology}^{\uparrow}$ *refinement and componentwise* hsame *transport: replacing a cover by a displayed refinement in* J *and transporting the component section rows by* H *yields another locality row still recorded by* L *over the same presheaf row* P*.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalityRefinement`

Proof. Read L from the carrier tuple after C, T, J, P have been exposed. By definition, L is the locality-refinement ledger, so its entries are indexed by the displayed cover-refinement comparisons carried by the Grothendieck-topology row J.

Now apply the transport row H. It records componentwise hsame transport for the category, topology, site, presheaf, locality, gluing, sheaf, replay, provenance, and local naming rows. Transporting the component sections therefore preserves the same P-restriction comparisons rather than changing to a host family.

The replay row R and provenance row Q keep this refinement inside the same $\mathsf{Sheafification}^{\uparrow}$ package, and N names it as part of the local $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ surface. Hence matching-family rows in L are stable under the displayed refinement and transport data. □

Theorem 7336.7 (Sheafification gluing exactness)**.** *The sheaf target row S of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet is consumed only after the locality ledger L and gluing ledger G have displayed compatible local sections for the presheaf row P over the cover rows T, J.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationGluingExactness`

Proof. Begin with the route theorem Definition 7336.4. It places the sheaf-facing row S downstream of the displayed category, topology, Grothendieck coverage, presheaf, locality, and gluing rows.

The ledger L records the matching-family and refinement checks. The ledger G records the accepted glued section row for compatible local families. Therefore S has no independent coordinate from which a sheaf target can be read before L and G have been displayed.

Finally use H, R, Q, N. Componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert naming preserve the same route from P through L and G to the $\mathsf{Sheaf}^{\uparrow}$ target row. They do not introduce a quotient of compatible families or a host sheafification functor, so the gluing read is exact at the displayed BEDC surface. □

Theorem 7336.8 (Sheafification separated refinement exactness)**.** *Let*

$$A = (C, T, J, P, L, G, S, H, R, Q, N)$$

be an accepted $\mathsf{Sheafification}^{\uparrow}$ *carrier. Every separated-refinement read of A must pass through the displayed category row C, topology-window row T, Grothendieck-coverage row J, presheaf-restriction row P, and locality ledger L before any separated sheaf-facing row may be consumed. The route is transported by* hsame *through H, replayed by* Cont *through R, sourced by* Pkg *through Q, and named only by the local* $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row N.*

Proof. The carrier definition exposes separated refinement only as a locality entry in L. That row is indexed by the displayed source data C, T, J, P, so a separated read with no prior source exposure has no cover, no restriction comparison, and no matching-family ledger on which to stand.

Now apply the structural rows. The hsame transport H moves the same displayed components, Cont replay R records the same route, Pkg provenance Q identifies the sibling packets, and N names the local certificate. None of these rows creates an independent host reflector or quotient-compatible-family object.

Thus every separated-refinement read factors through C, T, J, P, L before reaching the sheaf-facing surface. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSeparatedRefinementExactness`

Theorem 7336.9 (Sheafification plus gluing replay)**.** *For an accepted* Sheafification$^{\uparrow}$ *carrier*

$$A = (C, T, J, P, L, G, S, H, R, Q, N),$$

every plus-style gluing replay must pass through the locality ledger L, gluing ledger G, sheaf row S, componentwise transport row H, and displayed replay row R. The replay remains a finite BHist *route using* hsame*,* Cont*,* Pkg*, and* NameCert *data; it is not a quotient construction of compatible families.*

Proof. First read L. It records the compatible matching-family rows over the displayed cover and restriction data. Then read G, which records the accepted glued section row for those compatible families.

The sheaf row S is downstream of that locality-and-gluing pair. Transport through H and replay through R carry the same finite route into a sheaf-facing consumer without adding a separate plus object.

Finally Q and N package and name the route. Since the carrier has no coordinate for quotient families or selected covers, the plus-style replay is exactly the displayed path through L, G, S, H, R. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPlusGluingReplay`

Theorem 7336.10 (Sheafification plus-construction boundary)**.** *For an accepted* Sheafification$^{\uparrow}$ *carrier*

$$A = (C, T, J, P, L, G, S, H, R, Q, N),$$

every plus-construction read factors through $C, T, J, P, L, G, S, H, R, Q, N$ and cannot read quotient compatible-family data. The plus-facing consumer receives the displayed category source, topology window, Grothendieck coverage, presheaf restriction, locality ledger, gluing ledger, sheaf target row, transport, replay, provenance, and local naming rows, but no host quotient object and no selected compatible-family representative.

Proof. Project the carrier from Definition 7336.1. The tuple exposes exactly the rows $C, T, J, P, L, G, S, H, R, Q, N$, so any plus-construction read starts inside that finite surface.

Use Definition 7336.5 and Definition 7336.9. Coverage exactness forces the source rows C, T, J, P before locality is consumed, while plus gluing replay keeps the plus-style route inside L, G, S, H, R.

Finally apply Definition 7336.21. Since quotient compatible-family data and selected representatives are absent from the carrier and excluded by the local certificate boundary, the plus-construction read cannot escape the displayed rows. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPlusConstructionBoundary`

Theorem 7336.11 (Sheafification separated-reflection route)**.** *For an accepted* Sheafification$^{\uparrow}$ *carrier, separated reflection is visible only through the displayed presheaf restriction row P and locality row L before the sheaf row S is consumed. The route may use C, T, J to interpret covers and H, R, Q, N to transport, replay, source, and name the read, but it has no independent host reflector row.*

Proof. Begin with Definition 7336.8. A separated-refinement read must expose C, T, J, P, L before any sheaf-facing row is available.

The presheaf row P supplies the restriction comparisons, and the locality row L records their cover-local separated behavior. The sheaf row S is downstream of that pair by Definition 7336.7, so it cannot be consumed as an independent reflector.

The structural rows H, R, Q, N preserve the same route. They transport, replay, source, and name the displayed separated-reflection boundary without adding a host reflector or quotient compatible-family object. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSeparatedReflectionRoute`

Theorem 7336.12 (Sheafification cover-gluing nonescape)**.** *Every cover-gluing read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier consumes* $\mathsf{GrothendieckTopology}^{\uparrow}$ *coverage,* $\mathsf{PreSheaf}^{\uparrow}$ *restriction, the locality ledger L, and the gluing ledger G before reaching the sheaf row S. The read exports no host reflector, selected cover family, quotient of compatible families, or topos-level reflection object.*

Proof. First expose the cover source. By Definition 7336.5, the Grothendieck coverage row J and presheaf restriction row P are read before any locality ledger entry in L can be consumed.

Next apply Definition 7336.7. The gluing ledger G is the displayed row that records accepted glued sections, and the sheaf row S is read only after locality and gluing data are available.

The non-escape boundary follows from Definition 7336.21. Since host reflectors, selected cover families, quotient compatible-family objects, and topos-level reflectors are not carrier coordinates, cover gluing remains inside $J, P, L, G, S, H, R, Q, N$. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverGluingNonescape`

Theorem 7336.13 (Sheafification source obligation package)**.** *For an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet*

$$A = (C, T, J, P, L, G, S, H, R, Q, N),$$

every sheaf-facing consumer must expose the $\mathsf{Cat}^{\uparrow}$ *source C, the* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{GrothendieckTopology}^{\uparrow}$ *cover rows T, J, the* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row P, locality rows L, gluing rows G, the* $\mathsf{Sheaf}^{\uparrow}$ *target row S, componentwise* hsame *transport H, displayed* Cont *replay R,* Pkg *provenance Q, and the local* $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row N before it reads S.*

Proof. First apply Definition 7336.5. It forces every locality read through C, T, J, P before the ledger L is available.

Next use Definition 7336.6 and Definition 7336.7. Locality rows in L are stable under displayed refinement, and the sheaf target S is consumed only after L and G have displayed compatible local sections over the presheaf row P.

The structural rows complete the package. The tuple projection supplies H, R, Q, N, and these rows transport, replay, source, and name the same route rather than adding a host reflector, quotient family, selected cover, or topos object. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSourceObligationPackage`

Theorem 7336.14 (Sheafification source exposure obligation)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet*

$$A = (C, T, J, P, L, G, S, H, R, Q, N),$$

any sheafification read must expose the $\mathsf{Cat}^{\uparrow}$ *row C, the* $\mathsf{Topology}^{\uparrow}$ *window row T or* $\mathsf{GrothendieckTopology}^{\uparrow}$ *coverage row J, and the* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row P before it consumes locality data in L. The exposure is the finite BEDC source surface for the read, not a host site, chosen cover family, quotient compatible-family object, or reflector.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSourceExposureObligation`

Proof. Project the carrier of Definition 7336.1. The rows C, T, J, P are the only source rows that type a cover-local sheafification request, and L is downstream of those rows in the displayed tuple.

Apply Definition 7336.5 and Definition 7336.13. Coverage exactness forces the coverage and presheaf restriction data to be visible before locality is read, while the source package records the same order for every sheaf-facing consumer.

The structural rows H, R, Q, N only preserve this source route by transport, replay, provenance, and local naming. Since no carrier coordinate supplies a host site, selected cover family, quotient compatible-family object, or reflector, the read remains a finite source exposure through C, T, J, P before L. □

Theorem 7336.15 (Sheafification local gluing obligation)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, a consumer may read the* $\mathsf{Sheaf}^{\uparrow}$ *target row* S *only after the locality ledger* L *and gluing ledger* G *have both been consumed over the displayed source rows* C, T, J, P*. The route records locality and gluing exactness inside the carrier and exports no quotient of compatible families or host reflector.*

Proof. Start with source exposure from Definition 7336.14. It places C, T, J, P before locality, so every gluing request is already typed by the displayed category, topology or coverage, and presheaf restriction rows.

Use Definition 7336.6 to keep locality data in L stable under displayed cover refinement. Then apply Definition 7336.7: the gluing ledger G is consumed after locality and before the target sheaf row S.

Finally invoke Definition 7336.21. The local certificate boundary excludes quotient compatible-family data and host reflectors, so the target row can only be reached through L, G, H, R, Q, N inside the finite carrier. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalGluingObligation`

Theorem 7336.16 (Sheafification target handoff obligation)**.** *For an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet*

$$A = (C, T, J, P, L, G, S, H, R, Q, N),$$

every final target handoff to a $\mathsf{Sheaf}^{\uparrow}$ *consumer factors through the complete route* $C, T, J, P, L, G, S, H, R, Q, N$*. The consumer may inspect the category source, topology or Grothendieck coverage, presheaf restrictions, locality ledger, gluing ledger, sheaf target row, transport, replay, provenance, and local name, but it cannot bypass them through a quotient compatible-family object, a host reflector, or a detached sheafification functor.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationTargetHandoffObligation`

Proof. First expose the source and locality rows. By Definition 7336.14, every target-facing read starts with C, T, J, P and reaches L only through that source surface.

Next consume the gluing rows. Definition 7336.15 places G between L and the $\mathsf{Sheaf}^{\uparrow}$ row S, and Definition 7336.7 identifies this as the displayed gluing exactness boundary.

The handoff is completed by H, R, Q, N. Componentwise transport, displayed replay, provenance, and local naming preserve the same ordered route C, T, J, P, L, G, S for the downstream consumer. Since Definition 7336.21 excludes host reflectors and quotient compatible-family data, the final handoff has no coordinate outside $C, T, J, P, L, G, S, H, R, Q, N$. □

Theorem 7336.17 (Sheafification source cover locality)**.** *Every locality read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *source package exposes the* $\mathsf{Cat}^{\uparrow}$ *row* C*, the* $\mathsf{Topology}^{\uparrow}$ *window row* T*, the* $\mathsf{GrothendieckTopology}^{\uparrow}$ *coverage row* J*, and the* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row* P *before any locality row in* L *is consumed. The exposure is a finite source obligation surface, not a host cover selector or ambient reflector.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSourceCoverLocality`

Proof. Project the carrier of Definition 7336.1. The only rows that can type a cover-local request are C, T, J, P.

Apply coverage exactness and the source obligation package, Definition 7336.5 and Definition 7336.13. These force the category source, topology window, Grothendieck coverage, and presheaf restriction rows to be displayed before L is read.

The structural rows H, R, Q, N only transport, replay, source, and name that displayed route. They do not add a host cover choice, so every source-cover locality read remains inside the finite package. □

Theorem 7336.18 (Sheafification presheaf locality transport)**.** *For an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet, locality rows in* L *transport along the displayed* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row* P *and the componentwise* hsame *row* H*. After transport, the locality read still lies over the same* C, T, J, P *source surface and still precedes the gluing row* G*.*

Proof. Read P and L from the carrier. The presheaf row records restriction comparisons over the displayed category, topology, and coverage rows, while L records matching-family rows over those restrictions.

Use locality refinement, Definition 7336.6. Refining a displayed cover and transporting component sections by H preserves locality over the same presheaf row rather than creating a new family outside the packet.

Finally apply gluing exactness, Definition 7336.7. The transported locality rows remain before G and S, so the presheaf-locality transport is still a finite BEDC route through P, L, H, R, Q, N. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPresheafLocalityTransport`

Theorem 7336.19 (Sheafification gluing ledger scope)**.** *Every gluing ledger row* G *of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet is consumed only after the locality ledger* L *has displayed compatible local data and only before the* $\mathsf{Sheaf}^{\uparrow}$ *row* S *is read. A gluing consumer therefore sees the route* $C, T, J, P, L, G, S, H, R, Q, N$ *and no detached quotient of compatible families.*

Proof. Start with Definition 7336.13. It places source exposure and locality before any sheaf-facing consumer reads S.

Next apply Definition 7336.7 and Definition 7336.9. They identify G as the ledger row consumed after locality and before the sheaf target row, with replay still occurring through H and R.

The local non-escape theorem, Definition 7336.21, rules out host reflectors and quotient compatible-family objects. Thus G is scoped exactly between L and S inside the displayed carrier. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationGluingLedgerScope`

Theorem 7336.20 (Sheafification local gluing induction)**.** *Finite induction over displayed cover-refinement rows in an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet preserves the route from locality to gluing: the base cover reads* C, T, J, P, L*, and each displayed refinement transports matching-family data by* H *and replays the same* Cont *route* R *before the gluing row* G *and sheaf target* S *are consumed. The induction exports no quotient of compatible families, selected cover system, host reflector, or ambient powerset equality.*

Proof. For the base cover, use Definition 7336.5. The locality ledger is typed only after C, T, J, P have been displayed, so the base matching-family row is already inside the finite carrier.

For a refinement step, apply Definition 7336.6. The displayed $\mathsf{GrothendieckTopology}^{\uparrow}$ refinement row and the transport row H preserve matching-family data over the same presheaf row P.

Finally use Definition 7336.7 together with Definition 7336.9. The gluing ledger G and target row S are read only after the preserved locality route has been replayed by R, so finite induction stays inside L, G, S, H, R, Q, N and never produces an external quotient or choice coordinate. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalGluingInduction`

Theorem 7336.21 (Sheafification local NameCert nonescape)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet*

$$A = (C, T, J, P, L, G, S, H, R, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row* N *cannot export a host reflector, a quotient compatible-family object, selected covers, or a topos-level reflector. Any consumer of* N *receives only the finite* BHist *route through* $C, T, J, P, L, G, S, H, R, Q$ *together with the displayed* hsame, Cont, *and* Pkg *evidence.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalNameCertNonescape`

Proof. Inspect the carrier coordinates. The exposed rows are exactly the category, topology-window, coverage, presheaf, locality, gluing, sheaf, transport, replay, provenance, and local naming rows.

The excluded objects are absent from that tuple. A host reflector, quotient compatible-family object, selected cover system, or topos-level reflector would require an additional coordinate or an additional classifier comparison.

Because N names only the displayed package and because H, R, Q preserve the same route, the local certificate has no escape path to any of those excluded host constructions. □

Theorem 7336.22 (Sheafification separated-plus carrier obligation)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, the separated-refinement row and the plus-carrier row are admitted only through the displayed* $\mathsf{Cat}^{\uparrow}$, $\mathsf{GrothendieckTopology}^{\uparrow}$, $\mathsf{PreSheaf}^{\uparrow}$, *and* $\mathsf{Sheaf}^{\uparrow}$ *source rows already present in Definition 7336.1. No separated or plus-facing read may introduce a host reflector, quotient compatible-family object, selected cover system, or topos-level carrier outside those rows.*

Proof. Project the carrier from Definition 7336.1. The only source rows available to a separated or plus-facing read are $C, T, J, P, L, G, S, H, R, Q, N$, with C, J, P, S providing the category, coverage, presheaf, and sheaf-facing endpoints.

Apply the NameCert obligations of Definition 7336.2. They exhaust the local certificate surface by the displayed source, locality, gluing, target, transport, replay, provenance, and naming rows.

The exactness and replay rows then identify the admission boundary. Coverage exactness from Definition 7336.5 forces source exposure before locality is consumed, plus gluing replay from Definition 7336.9 keeps the plus-style route inside L, G, S, H, R, and local non-escape from Definition 7336.21 excludes host reflectors and quotient family objects. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSeparatedPlusCarrierObligation`

Theorem 7336.23 (Sheafification cover-local gluing obligation)**.** *Every cover-local matching-family read and every gluing read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier replays through componentwise* hsame *transport and displayed* Cont *before any sheaf-facing carrier row is consumed. Thus the route from* P *through* L *and* G *to* S *remains the finite BEDC route named by* H, R, Q, N*.*

Proof. Begin with Definition 7336.5. It forces any locality read to expose C, T, J, P before the ledger L can be used.

Next apply Definition 7336.9. A plus-style gluing read must pass through L, G, S, H, R, so the matching-family rows are transported by H and replayed by R before the sheaf-facing carrier row is consumed.

Finally use Definition 7336.2 and Definition 7336.21. The local certificate names only the displayed route, and the non-escape theorem rules out a shortcut through host quotients, selected covers, or topos-level reflectors. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverLocalGluingObligation`

Theorem 7336.24 (Sheafification sheaf handoff ledger obligation)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier, the sheaf handoff ledger records the non-escape boundary from the displayed source rows to the target row S: compatible-family quotients and topos reflectors are excluded, while the only exported handoff is the finite route through Definition 7336.1, Definition 7336.2, Definition 7336.5, Definition 7336.9, and Definition 7336.21.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSheafHandoffLedgerObligation`

Proof. Read the carrier definition first. The handoff ledger has no coordinate for host quotients of compatible families and no coordinate for a topos reflector; it has only the source, locality, gluing, target, transport, replay, provenance, and naming rows.

The NameCert obligations and coverage exactness determine the source side of the ledger. They require category, topology or site, Grothendieck coverage, and presheaf restriction rows before locality and gluing data can be consumed.

The plus gluing replay theorem supplies the target side, routing through L, G, S, H, R. The local non-escape theorem then states that the local certificate cannot export the excluded host constructions, so the handoff ledger records exactly that boundary. □

Theorem 7336.25 (Sheafification plus-localization carrier admission)**.** *Every accepted plus-localization read of a* $\mathsf{Sheafification}^{\uparrow}$ *packet exposes the separated-refinement rows, cover-local matching rows, plus-style gluing rows, componentwise transport row, displayed replay row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row as finite* BHist *data. The exposed rows are exactly the rows admitted by Definition 7336.1 and sourced through the category, topology, Grothendieck topology, presheaf, and sheaf chapters named in the chapter introduction.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPlusLocalizationCarrierAdmission`

Proof. Project the carrier $A = (C, T, J, P, L, G, S, H, R, Q, N)$ from Definition 7336.1. The separated-refinement and cover-local matching rows are the locality entries in L, and the plus-style gluing rows are the accepted glued-section entries in G.

The source chapters named in the introduction supply the endpoints of this route: category source data, topology windows, Grothendieck coverage, presheaf restrictions, and the sheaf-facing target row. The NameCert obligations of Definition 7336.2 then package these rows with H, R, Q, N.

No host reflector or quotient family is admitted, because no such coordinate occurs in the displayed carrier. □

Theorem 7336.26 (Sheafification separated-refinement transport)**.** *For an accepted* Sheafification$^{\uparrow}$ *carrier, componentwise* hsame *transport preserves separated-refinement rows and cover-local matching rows before the sheaf handoff is consumed. Thus a transported read still reaches the sheaf-facing row only through the displayed route from C, T, J, P through L and G to S.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSeparatedRefinementTransport`

Proof. Start with a separated-refinement row in L. By Definition 7336.8, that row is indexed by the displayed category, topology-window, Grothendieck-coverage, and presheaf-restriction data C, T, J, P.

Apply the transport row H. It records componentwise hsame transport for the source rows, locality rows, gluing rows, sheaf row, replay row, provenance row, and local naming row, so the transported separated-refinement read remains over the same displayed cover-local matching data.

Finally use Definition 7336.4. The sheaf-facing row is downstream of L and G, hence transport preserves the pre-handoff boundary rather than exposing a separate sheafification object. □

Theorem 7336.27 (Sheafification cover-local gluing replay)**.** *Every displayed* Cont *replay of an accepted* Sheafification$^{\uparrow}$ *packet carries cover-local matching rows through plus-style gluing into the sheaf-facing carrier. The replay route is the finite path through P, L, G, S, H, R, Q, N and exports no quotient of compatible families, selected cover system, or host sheafification functor.*

Proof. Read the cover-local matching data through P and L. Coverage exactness from Definition 7336.5 supplies the displayed cover and restriction rows before the locality ledger is consumed.

Next apply Definition 7336.9. The plus-style gluing step passes through L, G, S, H, R, so the displayed Cont row R carries the matching rows into the sheaf-facing carrier only after the gluing ledger has been read.

The provenance and local naming rows Q, N record the same route. Since Definition 7336.21 excludes host quotients, selected covers, and topos-level reflectors, the replay remains inside the finite BEDC carrier. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverLocalGluingReplay`

Theorem 7336.28 (Sheafification site-plus boundary obligations)**.** *Every accepted* Sheafification$^{\uparrow}$ *carrier records the site-to-plus boundary as finite* BHist *rows: the displayed site rows C, T, J, presheaf restriction row P, separated-plus locality row L, gluing row G, sheaf handoff row S, componentwise* hsame *transport H, displayed* Cont *replay R,* Pkg *provenance Q, and local* NameCert *row N. A plus consumer must read the site and presheaf rows before it may consume separated-plus, locality, or gluing rows.*

Proof. Project the carrier tuple $A = (C, T, J, P, L, G, S, H, R, Q, N)$ from Definition 7336.1. The displayed site is the finite source surface C, T, J, and the presheaf row is P.

Read the site row before plus construction. The coverage and presheaf restriction obligations force every plus request to expose C, T, J, P before any separated-refinement row in L is available.

Use componentwise transport and replay. The rows H and R preserve this order under hsame transport and displayed Cont replay, while Q, N record provenance and local naming for exactly the same finite route. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSitePlusBoundaryObligations`

Theorem 7336.29 (Sheafification plus separation obligation)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *read, separatedness is consumed as a displayed plus row before any gluing handoff is exported. The finite route is*

$$C, T, J, P, L \longmapsto G \longmapsto S, H, R, Q, N,$$

where C, T, J *are site rows,* P *is the presheaf row,* L *is the separated-plus locality row,* G *is the gluing row,* S *is the sheaf-facing target row, and* H, R, Q, N *are the* hsame*,* Cont*,* Pkg*, and* NameCert *structural rows.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPlusSeparationObligation`

Proof. First project the displayed carrier. The separated-plus information occurs in L, not in a quotient of compatible families and not in a host reflector.

Read separatedness before gluing. By Definition 7336.8 and Definition 7336.26, a consumer reaches G only after L has already been read over the site and presheaf rows.

Finally use the sheaf handoff ledger. The rows S, H, R, Q, N transport, replay, record, and name the post-gluing handoff, so stability is componentwise and no separate sheafification object is introduced. □

Theorem 7336.30 (Sheafification locality gluing obligation)**.** *Every locality-to-gluing read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet is anchored in finite BEDC data:* BHist *site rows,* hsame *transport,* Cont *replay,* Pkg *provenance, the local* NameCert *row, and the displayed site, presheaf, separated-plus, locality, and gluing rows of the carrier. Gluing stability is therefore a componentwise replay property of* $C, T, J, P, L, G, S, H, R, Q, N$*, not a quotient-family or topos-reflection principle.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalityGluingRouteCertificate`

Proof. Start with the locality row L. It is attached to the displayed category, topology or Grothendieck coverage, and presheaf rows C, T, J, P, so local matching has no detached cover selector.

Then read the gluing row G. The plus gluing replay theorem routes the local matching data through G and into the sheaf-facing row S only after the separated-plus boundary has been exposed.

Transport and replay finish the stability claim. Componentwise hsame transport H, displayed Cont replay R, Pkg provenance Q, and local NameCert row N preserve the same finite route for downstream consumers. □

Theorem 7336.31 (Sheafification site source exposure)**.** *Every plus, locality, or gluing read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier must expose the* $\mathsf{Cat}^{\uparrow}$ *row* C*, the* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{GrothendieckTopology}^{\uparrow}$ *cover rows* T, J*, and the* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row* P *before any locality ledger* L*, gluing ledger* G*, or sheaf target row* S *is consumed. The source exposure is therefore the finite route through the displayed category, topology or site, Grothendieck coverage, and presheaf rows, not a host reflector or quotient compatible-family object.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSiteSourceExposure`

Proof. Project the carrier of Definition 7336.1. Its plus and locality data occur only in L and G, and those rows are typed by the displayed source rows C, T, J, P.

Apply the coverage exactness theorem Definition 7336.5. It already forces every locality read to expose the category, topology-window, Grothendieck-coverage, and presheaf-restriction rows before the locality ledger can be consumed.

The separated-refinement and plus-carrier obligations preserve the same order. They admit no host reflector and no quotient compatible-family coordinate, so every plus, locality, or gluing read is sourced by the displayed site and presheaf rows. □

Theorem 7336.32 (Sheafification separated-plus site route)**.** *Every accepted* $\mathsf{Sheafification}^{\uparrow}$ *separated-plus read exposes the finite site route*

$$C, T, J, P, L, G, S, H, R, Q, N$$

in that order: $\mathsf{Cat}^{\uparrow}$ *source row* C*,* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{GrothendieckTopology}^{\uparrow}$ *cover rows* T, J*,* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row* P*, separated-plus locality row* L*, gluing row* G*,* $\mathsf{Sheaf}^{\uparrow}$ *handoff row* S*, componentwise* hsame *transport* H*, displayed* Cont *replay* R*,* Pkg *provenance* Q*, and local* $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row* N*. No separated-plus consumer may read a gluing or sheaf-facing row before the site, presheaf, locality, transport, replay, provenance, and naming rows are displayed.*

Proof. Project the carrier of Definition 7336.1. Its displayed rows already place the category, topology or Grothendieck coverage, presheaf restriction, locality, gluing, sheaf target, transport, replay, provenance, and local naming data in the finite tuple $C, T, J, P, L, G, S, H, R, Q, N$.

Read source exposure through Definition 7336.31. It forces every plus, locality, or gluing read to display C, T, J, P before L, G, S are consumed.

Apply the separated-refinement and plus-gluing transport rows. They keep L before G, keep G before the sheaf-facing handoff S, and keep H, R, Q, N attached to the same displayed route rather than to a host reflector or quotient compatible-family object. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSeparatedPlusSiteRoute`

Theorem 7336.33 (Sheafification Grothendieck locality induction)**.** *Every finite chain of displayed Grothendieck cover refinements read by an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier is handled by induction over the visible refinement rows. The base case reads the source site* C, T, J *and presheaf row* P*; each successor step replays locality refinement through* L*, plus gluing through* G*, componentwise transport through* H*, displayed continuation through* R*, provenance through* Q*, and local naming through* N *before the* $\mathsf{Sheaf}^{\uparrow}$ *handoff row* S *is consumed.*

Proof. Use induction on the finite list of displayed cover-refinement rows in the $\mathsf{GrothendieckTopology}^{\uparrow}$ component J. The empty list is exactly the source exposure route of Definition 7336.31, so the carrier has only C, T, J, P available before locality is read.

For the successor step, assume the previous refinement segment has already been replayed through L, H, R, Q, N. The locality-refinement exactness row supplies the next cover-local read over the same site and presheaf source, and the plus gluing replay row transports that read into G without selecting a host cover system.

The handoff is then the existing sheaf-facing route. The row S is consumed only after the successor locality and gluing rows have been replayed through H and R and recorded by Q, N, so the induction remains finite and internal to the displayed BEDC carrier. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationGrothendieckLocalityInduction`

Theorem 7336.34 (Sheafification presheaf-sheaf route)**.** *The presheaf-to-sheaf handoff of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet is the finite BEDC route*

$$P, L, G, S, H, R, Q, N.$$

Here P is the displayed $\mathsf{PreSheaf}^{\uparrow}$ *restriction row, L is separated-plus locality, G is plus gluing, S is the* $\mathsf{Sheaf}^{\uparrow}$ *target row, H is componentwise* hsame *transport, R is displayed* Cont *replay, Q is* Pkg *provenance, and N is local* NameCert *data. The route excludes host sheafification reflectors, quotient compatible-family objects, selected cover systems, and topos-level carriers.*

Proof. Start from the presheaf row P in the carrier. By source exposure, P is read only together with the displayed site rows C, T, J, so the handoff is not sourced by an ambient presheaf category or a hidden reflector.

Move from P to L and G. The separated-plus and cover-local gluing obligations make locality and gluing into displayed carrier rows, while the plus gluing transport theorem preserves the same route through componentwise transport and replay.

Finally consume S, H, R, Q, N. These rows provide the sheaf-facing target, transport, replay, provenance, and local naming surface for the same packet, so no quotient compatible-family object, selected cover system, or topos-level carrier is exported. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPresheafSheafRoute`

Theorem 7336.35 (Sheafification plus gluing transport)**.** *Every plus-style gluing read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier transports cover-local matching data through componentwise* hsame *and replays it through displayed* Cont *before the* $\mathsf{Sheaf}^{\uparrow}$ *handoff is consumed. The route from P through L and G to S is therefore preserved by H, R, Q, N as finite BEDC data.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPlusGluingTransport`

Proof. Start with the plus gluing replay theorem Definition 7336.9. It places every plus-style gluing read through the locality ledger L, gluing ledger G, sheaf row S, transport row H, and replay row R.

Use the cover-local gluing obligation Definition 7336.23. It says that matching-family and gluing reads replay through componentwise hsame transport and displayed Cont before a sheaf-facing carrier row is consumed.

Finally apply the separated-refinement transport theorem and the local nonescape theorem. They keep the transported read over the same displayed source rows and exclude quotient families, selected covers, host reflectors, and topos-level reflectors. □

Theorem 7336.36 (Sheafification obligation closure package)**.** *The carrier of Definition 7336.1, the source exposure of Definition 7336.31, the plus gluing transport of Definition 7336.35, the* $\mathsf{Sheaf}^{\uparrow}$ *handoff of Definition 7336.4, the* Pkg *provenance row Q, and the local* $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row N assemble the obligation package for* $\mathsf{Sheafification}^{\uparrow}$*. The package consists exactly of the displayed category, topology or site, Grothendieck coverage, presheaf restriction, locality, gluing, sheaf target, componentwise transport, replay, provenance, and local naming rows.*

Proof. First assemble the source side. The carrier definition lists $C, T, J, P, L, G, S, H, R, Q, N$, and the site source exposure theorem forces every plus, locality, and gluing read through C, T, J, P before L, G, S are consumed.

Next assemble the transport and replay side. The plus gluing transport theorem preserves cover-local matching and gluing data through H and R, while the sheaf handoff theorem identifies S as the only sheaf-facing row exported by the packet.

Finally use the package and naming rows. The provenance row Q records the sibling sources, and N names the same finite route as the local NameCert surface. Since no host reflector, quotient compatible-family object, selected cover system, topos object, or ambient powerset equality occurs in the carrier, the obligation package is exactly the displayed BEDC route. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationObligationClosurePackage`

Theorem 7336.37 (Sheafification cover-basis stability)**.** *Every accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet exposes its* $\mathsf{Cat}^{\uparrow}$ *source row* C*, its* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{GrothendieckTopology}^{\uparrow}$ *cover rows* T, J*, and its* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row* P *before any locality row in* L *may be consumed. Thus the cover-basis obligation is the finite source route*

$$C, T, J, P \longmapsto L$$

inside the carrier of Definition 7336.1, not a host cover selector or reflector.

Proof. Project the carrier from Definition 7336.1. The only rows that can type a cover-local request are C, T, J, P: category source data, topological or site windows, Grothendieck coverage, and presheaf restrictions.

Apply the site source exposure theorem Definition 7336.31. It already forces every plus, locality, or gluing read to display those source rows before L, G, S are consumed.

The obligation closure package Definition 7336.36 then records the same order as part of the NameCert route. Since the carrier has no host cover selector or reflector coordinate, cover-basis stability is exactly the displayed source-before-locality route. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverBasisStability`

Theorem 7336.38 (Sheafification plus-locality gluing ledger)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, the locality ledger* L *and the gluing ledger* G *form the finite plus-locality ledger that must be displayed before the* $\mathsf{Sheaf}^{\uparrow}$ *target row* S *can be consumed. No sheaf-facing consumer may read* S *from* P *without first exposing both* L *and* G *over the same source rows* C, T, J, P*.*

Proof. Start with the gluing exactness theorem Definition 7336.7. It places the sheaf target row S downstream of the locality ledger L and the gluing ledger G.

Use the plus gluing replay and plus gluing transport theorems, Definition 7336.9 and Definition 7336.35. They keep the plus-style route inside L, G, S, H, R and preserve the same cover-local matching data under componentwise transport.

Finally use the obligation closure package. It identifies the finite package $C, T, J, P, L, G, S, H, R, Q, N$ as the complete route, so the ledger L, G is not replaceable by a quotient of compatible families, host reflector, selected cover system, or topos-level carrier. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPlusLocalityGluingLedger`

Theorem 7336.39 (Sheafification sheaf target transport)**.** *Let* $A = (C, T, J, P, L, G, S, H, R, Q, N)$ *be an accepted* $\mathsf{Sheafification}^{\uparrow}$ *packet. Componentwise* hsame *transport through* H *and displayed* Cont *replay through* R *preserve the same source-to-sheaf route*

$$C, T, J, P, L, G, S$$

under the provenance row Q *and local naming row* N*. The transported read cannot change the source site, presheaf restriction, locality ledger, gluing ledger, or sheaf target into a host reflector route.*

Proof. Read the transported rows from Definition 7336.1. The transport row H is componentwise: it relates the displayed category, topology or site, presheaf, locality, gluing, sheaf, replay, provenance, and local naming coordinates without adding another coordinate.

Apply the separated-refinement transport theorem Definition 7336.26 and the cover-local gluing replay theorem Definition 7336.27. These theorems keep cover-local matching and plus-style gluing on the same route from P through L and G to S while replaying it through R.

The package rows Q, N then source and name that transported route. By local nonescape, Definition 7336.21, no host reflector, quotient compatible-family object, selected cover system, or topos-level carrier is exported. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSheafTargetTransport`

Theorem 7336.40 (Sheafification restriction compatibility obligation)**.** *Every restriction-compatibility read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$ *keeps each plus and locality row downstream of the displayed* $\mathsf{Cat}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{GrothendieckTopology}^{\uparrow}$*, and* $\mathsf{PreSheaf}^{\uparrow}$ *source rows. In particular, no read may consume* L*,* G*, or* S *before* C, T, J, P *have exposed the category source, topology or site windows, Grothendieck coverage, and presheaf restriction comparisons.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationRestrictionCompatibilityObligation`

Proof. Project the carrier of Definition 7336.1. The only restriction source rows are C, T, J, P, while L, G, S are locality, gluing, and sheaf-target rows downstream of that source.

Apply coverage exactness and locality refinement, Definition 7336.5 and Definition 7336.6. Coverage exactness forces every locality read through the category, topology or site, coverage, and presheaf rows; locality refinement keeps the same presheaf restriction data when displayed cover refinements are replayed.

Finally use gluing exactness Definition 7336.7. Since S is consumed only after L and G over the same P, restriction compatibility remains downstream of C, T, J, P and cannot become an independent reflector route. □

Theorem 7336.41 (Sheafification source-locality obligation)**.** *Every source-locality read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$ *must expose* C, T, J, P *before any locality row in* L *is consumed. Thus locality is read only after the displayed category source, topology or site window, Grothendieck coverage row, and presheaf restriction comparisons are visible in the same finite packet.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationSourceLocalityObligation`

Proof. Project the carrier of Definition 7336.1. The rows C, T, J, P are the only source rows for category objects, open or site windows, covering data, and presheaf restrictions.

The locality ledger L is indexed by those displayed source rows. A read of L without C, T, J, P would have no BEDC cover row and no presheaf restriction comparison from which locality could be interpreted.

The structural rows preserve the order. Componentwise transport through H, replay through R, provenance through Q, and local naming through N carry the displayed source-locality route, but none of them supplies an independent source coordinate. □

Theorem 7336.42 (Sheafification gluing-target obligation)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, the sheaf target row* S *is reachable only through the locality ledger* L *and gluing ledger* G *over the same displayed cover rows* C, T, J *and presheaf row* P*. No consumer may read* S *as a detached sheafification reflector, quotient family, or selected compatible-family representative.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationGluingTargetObligation`

Proof. Begin with the source rows C, T, J, P. They display the category, topology or site windows, Grothendieck coverage, and presheaf restrictions on which the gluing request is based.

The locality row L records matching-family data over that source, and the gluing row G records the accepted glued section. Therefore S is a target row only after the same cover and presheaf rows have passed through L and G.

Use transport and replay through H and R. These rows preserve the displayed route to S, while Q, N source and name it. Since the carrier has no reflector, quotient-family, or selected-representative coordinate, the gluing target cannot be read through any other path. □

Theorem 7336.43 (Sheafification provenance-naming obligation)**.** *In an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, the provenance row* Q *and local naming row* N *name only the displayed route*

$$C, T, J, P, L, G, S, H, R.$$

They cannot add a host reflector, quotient-family datum, selected cover system, topos object, ambient powerset equality, or separate sheafification functor.

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationProvenanceNamingObligation`

Proof. Read Q from the carrier. Its provenance is over the displayed $\mathsf{Sheafification}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{GrothendieckTopology}^{\uparrow}$, $\mathsf{PreSheaf}^{\uparrow}$, $\mathsf{Sheaf}^{\uparrow}$, BHist, hsame, Cont, and $\mathsf{NameCert}$ rows.

Read N next. The local $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ row names the same route from source data through locality and gluing to the sheaf target; it has no separate field for quotient families or host reflectors.

Finally apply the nonescape theorems already present in the chapter. The plus, separated-refinement, and cover-gluing boundaries keep every read inside $C, T, J, P, L, G, S, H, R, Q, N$, so provenance and naming cannot enlarge the packet beyond the displayed route. □

Theorem 7336.44 (Sheafification root-obligation carrier)**.** *Every root-obligation read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$ *must display all eleven carrier rows before the local* $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$ *row is consumed. The sibling route is ordered through* $\mathsf{Cat}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{GrothendieckTopology}^{\uparrow}$*,* $\mathsf{PreSheaf}^{\uparrow}$*, and* $\mathsf{Sheaf}^{\uparrow}$*, and the BEDC primitives visible along the route are* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

Proof. Project the carrier of Definition 7336.1. The rows $C, T, J, P, L, G, S, H, R, Q, N$ are the only coordinates available to a root read.

Read the sibling route in order. Category data in C precedes topological windows in T, coverage in J, presheaf restriction data in P, locality and gluing ledgers in L, G, and the sheaf target in S.

The remaining rows are structural projections. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row record the same ordered carrier and do not transport parameters from an outside reflector. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationRootObligationCarrier`

Theorem 7336.45 (Sheafification kernel-scope package)**.** *For every accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, the kernel-scope package exposed to downstream category or sheaf consumers is exactly*

$$C, T, J, P, L, G, S, H, R, Q, N.$$

The package names the BHist *rows for the sibling route through* Cat$^{\uparrow}$, Topology$^{\uparrow}$, GrothendieckTopology$^{\uparrow}$, PreSheaf$^{\uparrow}$, *and* Sheaf$^{\uparrow}$, *the* hsame *and* Cont *replay rows, the* Pkg *source row, and the local* NameCert *row; it exports no detached reflector or quotient-family carrier.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationKernelScopePackage`

Proof. Start with the displayed package. Each coordinate is a carrier projection from Definition 7336.1, so the kernel scope is finite before any consumer reads it.

The route through the siblings is row-ordered rather than parameter-transported. The presheaf row P is read only after C, T, J, the locality and gluing rows L, G are read only after P, and the sheaf row S is read only after the locality and gluing ledgers.

The structural rows H, R, Q, N then package the same route. Since they are hsame, Cont, Pkg, and NameCert projections over the displayed BHist coordinates, they cannot introduce a separate sheafification object. □

Theorem 7336.46 (Sheafification cover-site gluing ledger)**.** *For every accepted* Sheafification$^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, a cover-site gluing read must expose* $C, T, J, P, L, G, S, H, R, Q, N$ *in the displayed carrier order. The category row* C*, topology row* T*, Grothendieck coverage row* J*, presheaf row* P*, locality row* L*, gluing row* G*, sheaf target row* S*,* hsame *transport* H*,* Cont *replay* R*,* Pkg *provenance* Q*, and local* NameCert *row* N *form the ledger; no site consumer may read* G *or* S *before this source route is visible.*

Proof. Apply Definition 7336.5 to force the source rows C, T, J, P before locality is consumed. Then apply Definition 7336.7 and Definition 7336.9; together they place L before G, G before S, and keep replay inside H, R.

The package rows Q, N name the same route by Definition 7336.2. Hence the cover-site ledger is the displayed finite carrier route rather than a host site object or quotient of compatible families. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverSiteGluingLedger`

Theorem 7336.47 (Sheafification refinement stability budget)**.** *Every finite refinement budget used by an accepted* Sheafification$^{\uparrow}$ *carrier is spent inside* $C, T, J, P, L, G, S, H, R, Q, N$*: refinements are read from* J*, presheaf compatibility from* P*, locality stability from* L*, gluing from* G*, transport from* H*, replay from* R*, provenance from* Q*, and naming from* N *before the sheaf target* S *is consumed.*

Proof. Use Definition 7336.6 for each displayed refinement row. It keeps matching-family data over the same presheaf row P and uses componentwise transport H rather than an external cover selector.

Now apply Definition 7336.51. Finite induction preserves the same L, G, H, R, Q, N structure at every refinement step, and Definition 7336.7 keeps S downstream of locality and gluing. Thus the budget is exhausted by the displayed rows. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationRefinementStabilityBudget`

Theorem 7336.48 (Sheafification target nonescape ledger)**.** *For an accepted* Sheafification$^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, every target-facing read of* S *remains inside the cover, presheaf, locality, gluing, transport, replay, provenance, and local naming rows of that tuple. It exports no host sheafification functor, quotient compatible-family object, selected cover system, topos reflector, or ambient powerset equality.*

Proof. First use Definition 7336.16. The final handoff to a $\mathsf{Sheaf}^{\uparrow}$ consumer factors through $C, T, J, P, L, G, S, H, R, Q, N$.

Then apply Definition 7336.21 and Definition 7336.50. These nonescape boundaries exclude host reflectors, quotient compatible-family data, selected covers, topos objects, and ambient powerset equality because none of them is a carrier coordinate. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationTargetNonescapeLedger`

Theorem 7336.49 (Sheafification locality-gluing ledger readiness)**.** *In an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier* $A = (C, T, J, P, L, G, S, H, R, Q, N)$*, a locality or gluing consumer may read* L *or* G *only after the source route* C, T, J, P *has been displayed and before the sheaf target row* S *is consumed. Thus the ledger is ready exactly when the* $\mathsf{Cat}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{GrothendieckTopology}^{\uparrow}$*, and* $\mathsf{PreSheaf}^{\uparrow}$ *sibling rows are already visible, and its readback to* $\mathsf{Sheaf}^{\uparrow}$ *remains inside the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *packet.*

Proof. Inspect the row order. The source rows C, T, J, P provide the category, topology, coverage, and presheaf restriction data on which any locality or gluing ledger entry depends.

The locality row L and gluing row G are therefore ready only after that source route is displayed. Their output is the sheaf target row S, so a consumer cannot read S before the same ledger has been exposed.

Transport, replay, provenance, and naming preserve the ledger. Rows H, R, Q, N record hsame, Cont, Pkg, and NameCert data for the same finite packet, so ledger readiness is a projection and row-order claim rather than parameter transport. □

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalityGluingLedgerReadiness`

Theorem 7336.50 (Sheafification plus nonescape)**.** *Every plus-style read of an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier remains inside the finite route*

$$C, T, J, P, L, G, S, H, R, Q, N.$$

It exports no quotient compatible-family data, selected cover system, host sheafification reflector, topos reflection object, ambient powerset equality, or cover choice principle outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationPlusNonescape`

Proof. Read the carrier in Definition 7336.1. The plus and locality data occur only as the locality ledger L, gluing ledger G, sheaf target S, and structural rows H, R, Q, N over the source C, T, J, P.

Use coverage exactness and gluing exactness, Definition 7336.5 and Definition 7336.7. They force plus-style gluing to consume source coverage and presheaf restrictions before any sheaf-facing row is read.

The excluded objects are absent from the carrier. Componentwise transport, displayed replay, provenance, and local naming preserve the finite route, so they cannot create quotient compatible-family data, selected covers, host reflectors, or topos reflection objects. □

Theorem 7336.51 (Sheafification cover-refinement finite induction)**.** *For every finite displayed chain of cover refinements in an accepted* $\mathsf{Sheafification}^{\uparrow}$ *carrier, induction over the chain preserves locality rows in* L *and gluing rows in* G *through componentwise* hsame *transport* H *and displayed* Cont *replay* R*. The resulting route remains the same finite sheafification packet* $C, T, J, P, L, G, S, H, R, Q, N$ *and never leaves the displayed coverage, presheaf, locality, gluing, provenance, and local naming surface.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverRefinementFiniteInduction`

Proof. For the base refinement, apply coverage exactness Definition 7336.5. The source rows C, T, J, P are displayed before any locality row in L is available.

For the successor step, use locality refinement Definition 7336.6. The next displayed cover refinement preserves matching-family data over the same presheaf row P and transports it componentwise through H.

Finally apply gluing exactness Definition 7336.7. The gluing row G and sheaf target S are consumed only after the preserved locality data are replayed through R and recorded by Q, N, so the induction stays inside the finite carrier. □

Theorem 7336.52 (Sheafification cover-refinement budget)**.** *Every accepted* Sheafification$^{\uparrow}$ *carrier exposes cover rows, plus-locality rows, separated refinement rows, gluing rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *before any sheaf target consumes the refinement budget. The budget is therefore a finite row obligation over* $C, T, J, P, L, G, S, H, R, Q, N$*, not a host quotient of compatible families, selected cover system, ambient sheafification reflector, topos reflection object, or cover-choice principle.*

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationCoverRefinementBudget`

Proof. Start with the source obligation package in Definition 7336.2. It exposes the source category, topology or Grothendieck topology, presheaf row, locality rows, gluing rows, sheaf target, transport, replay, provenance, and local naming as one finite packet.

Apply cover basis stability and the plus-locality and gluing ledger results already established in the chapter. Coverage exactness keeps every refinement request inside the displayed cover basis, while locality refinement and gluing exactness force the plus and gluing reads to remain attached to the same presheaf route.

Finally use cover-refinement finite induction, Definition 7336.51. Since each refinement step preserves the same L, G, H, R, Q, N structure, a downstream sheaf consumer can spend only the displayed refinement budget and cannot import a host reflector, quotient-family construction, selected covers, or topos object. □

Falsifiable prediction: Every accepted Sheafification$^{\uparrow}$ read displays CategoryUp, TopologyUp or GrothendieckTopologyUp, PreSheafUp, locality, gluing, SheafUp, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any sheaf-facing consumer can use the target row.

Independence witness: category, topology, grothendieck topology, presheaf, sheaf: Sheafification$^{\uparrow}$ is not bijective to any listed sibling because it binds locality refinement and gluing handoff rows between a displayed presheaf source and a displayed sheaf target.

Theorem 7336.53 (Sheafification locality scope addendum)**.** *The presheaf restriction rows, cover-refinement rows, locality witnesses, gluing witnesses, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows of an accepted* Sheafification$^{\uparrow}$ *carrier form one scoped BEDC route*

$$C, T, J, P, L, G, S, H, R, Q, N.$$

Thus locality and gluing are consumed only through the displayed finite packet, not through a host reflector, quotient compatible-family object, selected cover system, or ambient topos construction.

Lean4 ✓ `BEDC.Derived.SheafificationUp.SheafificationLocalityScopeAddendum`

Proof. Read the carrier of Definition 7336.1. The rows C, T, J, P expose the category, cover, topology, and presheaf restriction data before locality or gluing can be used.

Apply cover-refinement finite induction, Definition 7336.51, and the cover-refinement budget of Definition 7336.52. They keep locality rows L and gluing rows G attached to the same finite refinement route.

The structural rows H, R, Q, N transport, replay, source, and name that route. Since the refused host objects are absent from the carrier, every accepted locality or gluing read remains inside the displayed BEDC packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}$.

Constructive story: A $\mathsf{Sheafification}^{\uparrow}$ packet is generated from CategoryUp source rows, TopologyUp or Grothendieck-TopologyUp cover rows, a PreSheafUp restriction row, locality-refinement rows, gluing rows, a SheafUp target row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 7336.1, Definition 7336.2, Definition 7336.4, and Definition 7336.52 bind the finite sheafification route from presheaf restrictions through locality, gluing, transport, replay, provenance, and local naming obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Sheafification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host sheafification functor, quotient of compatible families, global choice of covers, topos objects, ambient powerset equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source exposure, coverage exactness, presheaf restriction exposure, locality refinement, gluing exactness, sheaf handoff, transport, replay, provenance, and local naming for BEDC.Derived.SheafificationUp.

Chapter 7337

A Concrete Naming Certificate for $\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}$

Following Doob and Bishop-style finite upcrossing arguments, the $\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}$ packet records the BEDC route by which a finite upcrossing count, a bounded stopping window, and rational tolerance rows become convergence-preparation data for $\mathsf{MartingaleConvergence}^{\uparrow}$. It sits after the probability, random-variable, martingale, upcrossing, Doob-upcrossing, bounded-variation, and convergence surfaces of chapter 184, chapter 185, chapter 190, chapter 1629, chapter 1630, chapter 398, and chapter 2246. The packet is finite evidence for the convergence route; it is not an almost-sure quotient, a selected exceptional set, a completed filtration, or an ambient limit theorem.

Definition 7337.1 (Martingale convergence finite-upcrossing carrier)**.** *A* $\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (\Omega, X, M, U, D, S, V, R, T, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *row for the inspected probability context.*
2. X *is the* $\mathsf{RandomVar}^{\uparrow}$ *endpoint-family row for the finite martingale window.*
3. M *is the* $\mathsf{Martingale}^{\uparrow}$ *finite adapted-sequence source.*
4. U *is the* $\mathsf{Upcrossing}^{\uparrow}$ *completed-crossing count ledger for displayed lower and upper rational boundary rows.*
5. D *is the* $\mathsf{DoobUpcrossing}^{\uparrow}$ *finite inequality row that bounds* U*.*
6. S *is the bounded stopping-window row recording the inspected horizon and the lower-to-upper hit windows.*
7. V *is the* $\mathsf{BoundedVariation}^{\uparrow}$ *or finite-variation ledger controlling the rational tolerance rows read by the convergence consumer.*
8. R *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for the displayed lower and upper windows.*
9. T *is the* $\mathsf{MartingaleConvergence}^{\uparrow}$ *route row that may consume only* U, D, S, V, R *after the martingale source rows have been displayed.*
10. H *records componentwise* hsame *transport for all displayed rows.*

11. *C records displayed* Cont *replay through the martingale, upcrossing, stopping-window, variation, tolerance, and convergence-route rows.*
12. *P is the* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MartingaleConvergence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows and their componentwise transports.

Theorem 7337.2 (Martingale convergence finite-upcrossing NameCert obligations)**.** *For every accepted carrier*

$$F = (\Omega, X, M, U, D, S, V, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}}$ *surface consists exactly of probability exposure, endpoint exposure, martingale-source exposure, finite upcrossing-count exposure, Doob-bound exposure, bounded stopping-window exposure, bounded-variation or tolerance-ledger exposure, dyadic rational tolerance exposure, convergence-route admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7337.1. The stochastic source rows are Ω, X, M, while the convergence-facing finite evidence is U, D, S, V, R, T.

Read the upcrossing side first. The row U supplies a finite completed-count ledger, D supplies the Doob bound for that ledger, and S records the bounded stopping windows that make the count inspectable.

The tolerance side is also finite. The rows V and R display the bounded variation and dyadic tolerance evidence before the convergence-route row T may be consumed.

The structural rows H, C, P, N transport, replay, source, and name exactly that packet. Since no row stores an almost-sure quotient, selected exceptional set, completed filtration, unbounded stopping family, selected limit, or measure completion, the listed obligations exhaust the local certificate. □

Theorem 7337.3 (Finite upcrossing route to martingale convergence)**.** *Every* $\mathsf{MartingaleConvergence}^{\uparrow}$ *consumer of an accepted* $\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}$ *packet must first read the* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, *and* $\mathsf{Martingale}^{\uparrow}$ *source rows, the* $\mathsf{Upcrossing}^{\uparrow}$ *completed-count ledger, the* $\mathsf{DoobUpcrossing}^{\uparrow}$ *bound, the bounded stopping-window row, the* $\mathsf{BoundedVariation}^{\uparrow}$ *or tolerance ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *rational tolerance row, and the structural* hsame/Cont/Pkg/NameCert *rows. The route exports finite convergence-preparation data only.*

Proof. Start from the martingale source. The rows Ω, X, M display the probability context, endpoint family, and adapted finite window before any crossing count is read.

Apply the upcrossing and Doob-upcrossing routes. The finite count U is read through the displayed lower and upper boundary rows, while the Doob row D records the finite inequality surface that bounds that count.

Now inspect the convergence-facing rows. The bounded stopping window S and the tolerance rows V, R are the only data passed to T, so the downstream $\mathsf{MartingaleConvergence}^{\uparrow}$ packet receives a finite ledger rather than a limiting event.

Transport and replay are componentwise through H and C, with P, N recording provenance and local naming. Therefore the route cannot export an almost-sure quotient, selected exceptional set,

completed filtration, unbounded stopping principle, selected limit, or completed measure carrier. □

Theorem 7337.4 (Martingale convergence finite-upcrossing non-escape)**.** *Every accepted* MartingaleConvergenceFi *packet exports only the probability row, endpoint row, finite martingale row, upcrossing-count row, Doob-bound row, bounded stopping-window row, bounded-variation or tolerance-ledger row, dyadic tolerance row, convergence-route row, componentwise transport, displayed replay, provenance, and local naming rows. It exports no almost-sure quotient, selected exceptional set, completed filtration, unbounded stopping principle, selected limit, measure completion, or ambient convergence theorem.*

Proof. Project the carrier

$$F = (\Omega, X, M, U, D, S, V, R, T, H, C, P, N)$$

from Definition 7337.1. The displayed coordinates are exactly the stochastic source rows, finite upcrossing evidence, tolerance rows, convergence route, and structural rows named in the statement.

Invoke Definition 7337.2. The local NameCert surface admits only probability exposure, endpoint exposure, finite martingale exposure, upcrossing count, Doob bound, bounded stopping window, bounded-variation or tolerance ledger, dyadic tolerance, convergence-route admission, transport, replay, provenance, and naming.

Apply Definition 7337.3. Any $\mathsf{MartingaleConvergence}^{\uparrow}$ consumer receives finite convergence-preparation data only after those rows are displayed.

The refused objects have no carrier coordinate and no structural row. Row exhaustion therefore blocks an almost-sure quotient, selected exceptional set, completed filtration, unbounded stopping principle, selected limit, measure completion, and ambient convergence theorem from escaping the packet. □

Falsifiable prediction: A claimed $\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}$ read that reaches MartingaleConvergenc without displaying the $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, $\mathsf{DoobUpcrossing}^{\uparrow}$, bounded stopping-window, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 7337.1.

Independence witness: probspace, randomvar, martingale, upcrossing, doob-upcrossing, martingale-convergence: no listed sibling is bijective to $\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}$ because this packet alone binds the finite crossing-count ledger, bounded stopping window, Doob-bound row, variation and dyadic tolerance rows, convergence-route admission, transport, replay, provenance, and local naming as one convergence-preparation carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}}$.

Constructive story: A $\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}$ packet is generated from probability, random-variable, finite martingale, upcrossing-count, Doob-bound, bounded stopping-window, bounded-variation, dyadic tolerance, convergence-route, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7337.1, Definition 7337.2, and Definition 7337.3 seed the finite upcrossing route into martingale convergence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MartingaleConvergenceFiniteUpcrossing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure quotient equality, selected exceptional sets, completed filtrations, unbounded stopping, selected limits, measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite upcrossing count, Doob-bound, stopping-window, tolerance-ledger, convergence-route, transport, replay, provenance, and local naming rows for BEDC.Derived.MartingaleConvergenceFi

Chapter 7338

A Concrete Naming Certificate for $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$

Following Doob, the $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$ packet extracts the finite witness surface by which upcrossing control is consumed by $\mathsf{MartingaleConvergence}^{\uparrow}$ without importing the whole convergence-preparation packet. It sits after the martingale convergence route of chapter 2246, the upcrossing ledger of chapter 1629, the Doob bound of chapter 1630, the bounded stopping route of chapter 383, the finite schedule of chapter 126, the regular rational readback of chapter 301, and the terminal Real boundary of chapter 38. The packet is a finite extraction boundary for later martingale convergence consumers; it is not an almost-sure quotient, a selected exceptional set, a completed filtration, a measure-completion object, or an ambient convergence theorem.

Definition 7338.1 (Martingale convergence witness carrier)**.** *A* $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, T, U, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. M *is the* $\mathsf{Martingale}^{\uparrow}$ *finite adapted-source row over the inspected probability and endpoint data.*
2. T *is the bounded stopping-window row consumed through* $\mathsf{StoppingTime}^{\uparrow}$ *and* $\mathsf{OptionalStopping}^{\uparrow}$*.*
3. U *is the* $\mathsf{Upcrossing}^{\uparrow}$ *completed-crossing count for the displayed lower and upper boundary rows.*
4. D *is the* $\mathsf{DoobUpcrossing}^{\uparrow}$ *inequality row bounding the finite count* U*.*
5. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row naming the requested observation windows.*
6. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows and rational budgets.*
7. L *is the* $\mathsf{Real}^{\uparrow}$ *lower and upper boundary row read by the upcrossing and convergence consumers.*
8. H *records componentwise* hsame *transport for the martingale, stopping, upcrossing, Doob-bound, schedule, readback, Real-boundary, replay, provenance, and local naming rows.*
9. C *records displayed* Cont *replay through the same finite route.*
10. P *is the* Pkg *provenance over* $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$*,* $\mathsf{MartingaleConvergence}^{\uparrow}$*,* $\mathsf{Martingale}^{\uparrow}$*,* $\mathsf{StoppingTime}^{\uparrow}$*,* $\mathsf{OptionalStopping}^{\uparrow}$*,* $\mathsf{Upcrossing}^{\uparrow}$*,* $\mathsf{DoobUpcrossing}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MartingaleConvergenceWitness}^{\uparrow}}$ *row.*

The classifier compares accepted witness packets only through these displayed rows and their componentwise transports.

Theorem 7338.2 (Martingale convergence witness NameCert obligations)**.** *For every accepted* $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$ *carrier*

$$W = (M, T, U, D, S, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MartingaleConvergenceWitness}^{\uparrow}}$ *surface consists exactly of martingale-source exposure through M, bounded stopping exposure through T, upcrossing-count exposure through U, Doob-bound exposure through D, finite schedule exposure through S, regular rational readback through R, Real boundary exposure through L, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7338.1. Its stochastic source row is M, its bounded stopping row is T, and its upcrossing witness rows are U, D.

Read the schedule and boundary side next. The rows S, R, L are the finite observation schedule, regular rational readback, and Real lower-upper boundary rows already required by chapter 2246.

The structural rows H, C, P, N transport, replay, source, and name exactly this finite packet. Since no coordinate stores an almost-sure quotient, a selected exceptional set, a completed filtration, a measure-completion object, or an ambient convergence theorem, the listed rows exhaust the local certificate. □

Theorem 7338.3 (Martingale convergence witness upcrossing factorization)**.** *Every upcrossing read exported by an accepted* $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$ *packet factors through*

$$\mathsf{Martingale}^{\uparrow},\ \mathsf{StoppingTime}^{\uparrow},\ \mathsf{OptionalStopping}^{\uparrow},\ \mathsf{Upcrossing}^{\uparrow},\ \mathsf{DoobUpcrossing}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the witness may be consumed by $\mathsf{MartingaleConvergence}^{\uparrow}$ *only after the martingale row, bounded stopping row, completed-crossing count, Doob bound, finite schedule, regular rational readback, and Real boundary rows have all been displayed.*

Proof. Begin with the accepted carrier $W = (M, T, U, D, S, R, L, H, C, P, N)$. The rows M and T expose the finite martingale source and bounded stopping window before any crossing count is read.

Apply the sibling upcrossing packets. The row U is the finite completed-count ledger supplied through chapter 1629, and D is the finite Doob-bound row supplied through chapter 1630.

Now read the consumer-facing rows. The finite schedule S, the regular rational readback R, and the Real boundary row L are precisely the rows through which chapter 2246 admits a convergence-preparation read.

Finally transport and replay are componentwise through H and C, with P, N fixing provenance and local naming. Thus the export route factors through the displayed sibling chapters and cannot bypass them by an ambient limiting event or an almost-sure quotient. □

Theorem 7338.4 (Martingale convergence witness finite extraction)**.** *The finite extraction of an accepted* $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$ *packet is exactly the subpacket*

$$(M, T, U, D, S, R, L, H, C, P, N)$$

needed by a $\mathsf{MartingaleConvergence}^{\uparrow}$ *consumer to read a bounded upcrossing witness. The extraction exports no selected limit, no exceptional null set, no completed filtration, no measure completion, no unbounded stopping principle, and no ambient convergence theorem.*

Proof. Project the carrier and use Definition 7338.2. The local NameCert surface admits only the martingale, bounded stopping, upcrossing count, Doob bound, finite schedule, regular rational readback, Real boundary, transport, replay, provenance, and local naming rows.

Use Definition 7338.3. Any convergence-facing read through $\mathsf{MartingaleConvergence}^{\uparrow}$ receives the witness only along the displayed route through martingale, optional-stopping, upcrossing, Doob-upcrossing, StreamName, RegSeqRat, and Real rows.

The refused objects have no coordinate in the extracted packet and no structural row in H, C, P, N. Row exhaustion therefore prevents the extraction from exporting a selected limit, exceptional null set, completed filtration, measure completion, unbounded stopping principle, or ambient convergence theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{MartingaleConvergenceWitness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MartingaleConvergenceWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7338.1, Definition 7338.2, Definition 7338.3, and Definition 7338.4 seed the finite upcrossing witness boundary consumed by $\mathsf{MartingaleConvergence}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MartingaleConvergenceWitness}^{\uparrow}}, \mathsf{formalTarget})$

Lean4 (statement) `BEDC.Derived.MartingaleConvergenceWitnessUp`

Bridge status: none

Not claimed: This chapter does not close almost-sure quotient equality, selected exceptional sets, completed filtrations, measure completion, selected limits, unbounded stopping principles, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded stopping exposure, upcrossing-count exactness, Doob-bound consumption, finite schedule readback, Real-boundary routing, transport, replay, provenance, and local naming for BEDC.Derived.MartingaleConvergenceWitnessUp.

Constructive story: A $\mathsf{MartingaleConvergenceWitness}^{\uparrow}$ packet is generated from martingale, bounded stopping, finite upcrossing, Doob-bound, StreamName schedule, RegSeqRat readback, Real-boundary, transport, replay, provenance, and local NameCert rows.

Chapter 7339

A Concrete Naming Certificate for MetaCICEtaExpansionAudit$^{\uparrow}$

The MetaCICEtaExpansionAudit$^{\uparrow}$ packet realizes the beta audit map of chapter 9384 as finite eta-expansion boundary data. It sits beside the beta audit packet of chapter 761, the normalization frontier of chapter 892, the critical path of chapter 765, and the closed beta trace envelope of chapter 6692. The packet records eta rows only as auditable finite data adjacent to beta conversion boundaries; it does not prove unrestricted eta conversion, subject reduction, confluence, normalization, or host conversion equality.

Definition 7339.1 (MetaCIC eta-expansion audit carrier)**.** *A* MetaCICEtaExpansionAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (A, B, N, F, O, T, R, V, H, C, P, Q)$$

with the following displayed rows:

1. *A is the* MetaCICBetaAudit$^{\uparrow}$ *source row naming the audited beta boundary.*
2. *B is the finite beta-conversion-boundary row over the displayed* BetaStep *and* BetaConv *relations.*
3. *N is the* MetaCICNormalizationFrontier$^{\uparrow}$ *row naming the bounded normalization frontier inspected by the packet.*
4. *F is the* MetaCICCriticalPath$^{\uparrow}$ *row recording which syntax boundary or typing route is being audited.*
5. *O is the* MetaCICClosedBetaTraceEnvelope$^{\uparrow}$ *obstruction-retention row.*
6. *T is the eta-row ledger, recording the source term, target term, binder shape, and finite eta-expansion request.*
7. *R is the replay row that rechecks the eta ledger against the beta boundary without turning it into a global conversion rule.*
8. *V is the provenance row tying the packet to the beta audit map and the normalization frontier.*
9. *H records componentwise* hsame *transport for all displayed rows.*
10. *C records displayed* Cont *replay through the eta-row, beta-boundary, normalization-frontier, obstruction-retention, transport, replay, provenance, and local naming rows.*

11. *P is the* Pkg *provenance over* MetaCICEtaExpansionAudit$^{\uparrow}$, MetaCICBetaAudit$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICClosedBetaTraceEnvelope$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *Q is the local* $\mathsf{NameCert}_{\mathsf{MetaCICEtaExpansionAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted eta conversion, subject reduction, confluence, normalization, or host conversion equality.

Theorem 7339.2 (MetaCIC eta-expansion audit NameCert obligations)**.** *For every accepted* MetaCICEtaExpansionAudit$^{\uparrow}$ *carrier*

$$E = (A, B, N, F, O, T, R, V, H, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICEtaExpansionAudit}^{\uparrow}}$ *surface consists exactly of beta-audit source exposure, beta-conversion-boundary exposure, normalization-frontier exposure, critical-path exposure, obstruction-retention exposure, finite eta-row exposure, replay exposure, provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7339.1. The source audit row A, beta boundary B, normalization frontier N, critical path F, and closed trace envelope O are displayed before the eta ledger can be consumed.

Read the eta row locally. The row T names a finite source, target, binder shape, and eta request, while R replays that request against the displayed beta boundary.

The obstruction row remains present. Since O is carried with T and R, a consumer cannot erase the boundary cases that separate eta-row auditing from global conversion equality.

Finally H, C, P, Q transport, replay, source, and name exactly that packet. No row supplies unrestricted eta conversion, subject reduction, confluence, normalization, or host conversion equality, so the local certificate is limited to the finite audit obligations named above. □

Theorem 7339.3 (MetaCIC eta-expansion audit boundary)**.** *Every consumer of an accepted* MetaCICEtaExpansionAudit$^{\uparrow}$ *packet reads eta expansion only through finite eta rows, the displayed beta-conversion boundary, the normalization-frontier row, the critical-path row, the retained obstruction row, transport, replay, provenance, and local* NameCert *data. The packet does not authorize unrestricted eta conversion, subject reduction, confluence, normalization, or host conversion equality.*

Proof. Start with the beta audit row. It fixes the audited BetaStep and BetaConv boundary before any eta row is inspected.

The normalization frontier and critical path narrow the read to a finite syntax and typing boundary. The retained obstruction row stays in the packet, so the consumer must keep the cases where conversion, typing preservation, and normalization are not globally available.

The eta ledger is therefore a replayable audit row, not a conversion rule. The hsame, Cont, Pkg, and NameCert rows preserve and name that finite route without adding an external equality principle.

Thus the packet exports only the finite eta/beta audit boundary stated above. It cannot prove or imply unrestricted eta conversion, subject reduction, confluence, normalization, or host conversion equality. □

Falsifiable prediction: A claimed MetaCICEtaExpansionAudit$^{\uparrow}$ read that derives host conversion equality or unrestricted eta conversion while bypassing the MetaCICBetaAudit$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$,

MetaCICCriticalPath$^{\uparrow}$, MetaCICClosedBetaTraceEnvelope$^{\uparrow}$, finite eta-row, obstruction-retention, transport, replay, provenance, and local NameCert rows refutes the carrier of Definition 7339.1.

Independence witness: metacicbetaaudit, metacicnormalizationfrontier, metaciccriticalpath, metacic-closed-beta-trace-envelope: no listed sibling is bijective to MetaCICEtaExpansionAudit$^{\uparrow}$ because this packet alone binds finite eta rows to a beta-conversion boundary, normalization frontier, critical path, retained obstruction envelope, transport, replay, provenance, and local naming while refusing global conversion claims.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICEtaExpansionAudit}^{\uparrow}}$.

Constructive story: A MetaCICEtaExpansionAudit$^{\uparrow}$ packet is generated from beta-audit source rows, beta-conversion boundary rows, normalization-frontier rows, critical-path rows, obstruction-retention rows, finite eta-row data, replay, provenance, transport, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICEtaExpansionAudit}^{\uparrow}}$, seed)

Scope closed: Definition 7339.1, Definition 7339.2, and Definition 7339.3 seed the finite eta-expansion audit boundary for MetaCIC beta-conversion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICEtaExpansionAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted eta conversion, subject reduction, confluence, normalization, host conversion equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked beta-audit exposure, eta-row exposure, beta-boundary retention, normalization-frontier routing, obstruction retention, transport, replay, provenance, and local naming rows for BEDC.Derived.MetaCICEtaExpansionAuditUp.

Chapter 7340

A Concrete Naming Certificate for $\mathsf{MackeyTopology}^{\uparrow}$

Following Mackey and Bourbaki on dual pairs and locally convex topologies, the $\mathsf{MackeyTopology}^{\uparrow}$ packet records the finite BEDC rows that name a Mackey-style topology through displayed dual-pair probes, bounded-set compatibility, and seminorm windows. It sits after the weak topology carrier of chapter 3597, the bounded-family surface of chapter 3370, the barrelled-space boundary of chapter 7269, the topological-vector-space handoff of chapter 205, and the linear-map rows of chapter 48. The packet names only finite dual-pair, comparison, bounded-family, seminorm-window, transport, replay, provenance, and local naming rows; it does not import host locally convex space completeness, Hahn–Banach separation, arbitrary choice, quotient functional equality, Lean verification, or bridge checking.

Definition 7340.1 (Mackey topology carrier)**.** *A* $\mathsf{MackeyTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, W, B, S, T, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the dual-pair source row, naming the vector carrier, displayed functional window, evaluation relation, and finite pairing ledger.*
2. *W is the* $\mathsf{WeakTopology}^{\uparrow}$ *comparison row over the same dual-pair source, recording which weak-neighbourhood reads are consumed before the Mackey row is exposed.*
3. *B is the bounded-set and* $\mathsf{Bornology}^{\uparrow}$ *row, listing the displayed bounded families against which uniform convergence windows are tested.*
4. *S is the seminorm-window ledger, with each row naming a finite bounded-family probe, its seminorm read, and the neighbourhood row generated by that read.*
5. *T is the* $\mathsf{TopVecSpace}^{\uparrow}$ *handoff row, exposing addition-continuity and scalar-continuity only after D, W, B, S have been displayed.*
6. *L is the* $\mathsf{LinMap}^{\uparrow}$ *handoff row for dual-pair evaluations and bounded-family probes that downstream operator consumers may inspect.*
7. *H records componentwise* hsame *transport for D, W, B, S, T, L.*
8. *C records displayed* Cont *replay from a topology request through the same dual-pair, weak-topology, bornology, seminorm, topological-vector-space, and linear-map rows.*

9. *P is the* Pkg *provenance over* $\mathsf{MackeyTopology}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{Bornology}^{\uparrow}$, $\mathsf{BarrelledSpace}^{\uparrow}$, $\mathsf{TopVecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MackeyTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient locally convex topology, a selected full dual, a quotient equality of functionals, a Hahn–Banach separator, a completeness theorem, arbitrary choice, or bridge evidence.

Theorem 7340.2 (Mackey topology NameCert obligations)**.** *For every accepted* $\mathsf{MackeyTopology}^{\uparrow}$ *carrier $M = (D, W, B, S, T, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MackeyTopology}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dual-pair source D;*
2. *weak-topology comparison through W over the same vector and functional windows;*
3. *bounded-family and bornology exposure through B;*
4. *seminorm-window admission through the finite ledger S;*
5. *topological-vector-space and linear-map handoff through T and L;*
6. *nonescape through H, C, P, N, excluding host locally convex space completeness, Hahn–Banach separation, arbitrary choice, quotient functional equality, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 7340.1. The tuple $D, W, B, S, T, L, H, C, P, N$ is the whole accepted packet, so each obligation row is a finite coordinate read.

The topology comparison begins with the dual-pair source D and the weak-topology row W. These rows expose only displayed evaluation and weak-neighbourhood data, so a consumer cannot replace them by an ambient weak topology or by equality of a full dual space.

Next read the bornology and seminorm data. The row B names the bounded-family surface, and every seminorm request must pass through one of the finite windows in S before any topological-vector-space or linear-map handoff is available.

Finally the rows T, L, H, C, P, N transport, replay, source, and name the same finite packet. Since none of those rows stores completeness, Hahn–Banach separation, arbitrary choice, quotient functional equality, Lean verification, or bridge evidence, the listed obligations exhaust the local NameCert surface. □

Theorem 7340.3 (Mackey topology dual-pair finite route)**.** *Every topology read exported by an accepted* $\mathsf{MackeyTopology}^{\uparrow}$ *packet factors through the finite route*

$$D \longmapsto W \longmapsto B \longmapsto S \longmapsto T, L \longmapsto H, C, P, N.$$

Thus a downstream consumer may read the Mackey topology only as displayed dual-pair data compared with weak-topology rows, bounded-family rows, finite seminorm-window rows, and the named topological-vector-space and linear-map handoffs.

Proof. Induct over the displayed row order of the carrier. The base row is the dual-pair source D, which supplies the vector, functional-window, evaluation, and pairing data from which all later rows are read.

For the first step, the weak-topology comparison row W consumes only D. For the next step, the bornology row B consumes the same source and lists the bounded-family tests without selecting a host family or a quotient functional equality.

For the seminorm step, each entry of S names a finite bounded-family probe and its generated neighbourhood row. The handoff rows T and L are therefore reached only after the weak-topology comparison and bounded-family ledger have already been displayed.

The terminal rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Repacking these projections gives the displayed finite route and prevents any consumer from importing completeness, Hahn–Banach separation, arbitrary choice, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{MackeyTopology}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MackeyTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7340.1, Definition 7340.2, and Definition 7340.3 seed the finite Mackey topology packet over dual-pair, weak-topology, bornology, seminorm-window, topological-vector-space, linear-map, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MackeyTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host locally convex space completeness, Hahn–Banach separation, arbitrary choice, quotient functional equality, Lean verification, or bridge checking for $\mathsf{MackeyTopology}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, weak-topology comparison, bornology exposure, seminorm-window exactness, topological-vector-space and linear-map handoff, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.MackeyTopologyUp.

Constructive story: A $\mathsf{MackeyTopology}^{\uparrow}$ packet is generated from displayed dual-pair source rows, weak-topology comparison rows, bornology and bounded-family rows, finite seminorm-window rows, topological-vector-space and linear-map handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7341

A Concrete Naming Certificate for $\mathsf{CylinderSet}^{\uparrow}$

Following Kolmogorov and standard product-measure constructions, the $\mathsf{CylinderSet}^{\uparrow}$ packet records the finite cylinder-event substrate used before any σ-algebra completion or product-measure existence theorem is invoked. It sits between the finite endpoint discipline of chapter 32, the finite observation windows of chapter 126, and the probability-facing packets of chapter 184, chapter 185, and chapter 186.

Definition 7341.1 (Cylinder set carrier)**.** *A* $\mathsf{CylinderSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, A, I, S, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite coordinate window, listing the inspected coordinates and their order of access.*
2. *A is the coordinate-event row, assigning to each displayed coordinate a finite* $\mathsf{Bool}^{\uparrow}$*-readable event decision surface.*
3. *I is the Boolean finite-intersection ledger, recording conjunction, empty-window top event, and pairwise merge rows for the displayed coordinate events.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source window, or the product-style source window, from which the finite coordinate reads are replayed.*
5. *H records componentwise* hsame *transport for the coordinate window, coordinate-event rows, Boolean intersection ledger, source window, replay routes, provenance, and local naming.*
6. *C records displayed* Cont *replay for every finite coordinate read and every Boolean intersection read.*
7. *P is the* Pkg *provenance over* $\mathsf{CylinderSet}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CylinderSet}^{\uparrow}}$ *row.*

The carrier has no coordinate for σ-algebra completion, countable unions, product-measure existence, host set membership, selected infinite branch, quotient stream equality, or ambient probability space semantics.

Theorem 7341.2 (Cylinder set prefix stability)**.** *Let $E = (W, A, I, S, H, C, P, N)$ and $E' = (W', A', I', S', H', C', P', N')$ be accepted* $\mathsf{CylinderSet}^{\uparrow}$ *packets. If W' extends W only by coordinates not inspected by the read, and the rows A, I, S, H, C, P, N transport componentwise under* hsame *through the common prefix, then every consumer restricted to W reads the same cylinder classifier from E and E'.*

Proof. Project both packets to the carrier of Definition 7341.1. The consumer restricted to W can inspect only the listed coordinate rows, the Boolean finite-intersection ledger over those rows, and the source replay window visible through S.

The extension coordinates in W' are outside that finite read. Componentwise hsame transport identifies the shared coordinate-event rows and the shared Boolean ledger rows on the prefix, while C replays the same finite access route.

Since the carrier has no host set coordinate or quotient stream equality coordinate, the classifier visible to the restricted consumer is exhausted by the shared prefix rows. Therefore the two packets determine the same prefix cylinder classifier. □

Theorem 7341.3 (Cylinder set finite-intersection ledger)**.** *For every accepted* $\mathsf{CylinderSet}^{\uparrow}$ *packet $E = (W, A, I, S, H, C, P, N)$, the finite intersection of displayed coordinate events is read entirely from the* $\mathsf{Bool}^{\uparrow}$ *ledger I over the same window W. The empty intersection, binary merge, and finite fold rows are all local to the packet, and no countable union, complement-completion, host set operation, or product-measure row is exported by the ledger.*

Proof. Read the finite window W and the coordinate-event row A. These two rows determine the finite list of Boolean event decisions available to the packet.

The ledger I supplies the empty-window top event, the binary merge row, and the finite fold over that displayed list. Induction over the finite BHist window gives the intersection row without asking for a countable family or an external set operation.

The remaining rows H, C, P, N transport, replay, package, and name the same finite ledger. Because the carrier excludes completion and product-measure coordinates, the finite-intersection read cannot export them. □

Theorem 7341.4 (Cylinder set probability-event readiness)**.** *Every* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, *or* $\mathsf{Distribution}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{CylinderSet}^{\uparrow}$ *packet as an event must first expose the finite coordinate window W, the coordinate-event rows A, the Boolean finite-intersection ledger I, the* $\mathsf{StreamName}^{\uparrow}$ *or product-style source window S, and the structural rows H, C, P, N. The handoff supplies a finite event substrate only; it exports no σ-algebra completion, countable additivity, product-measure existence proof, host set semantics, selected infinite branch, or ambient probability object.*

Proof. Begin with the finite source read. The rows W and S display exactly which stream or product coordinates are inspected before a probability-facing consumer may treat the packet as an event.

Next read A and I. The coordinate-event rows are $\mathsf{Bool}^{\uparrow}$-readable, and the finite-intersection ledger is the only event constructor present in the carrier.

Finally pass through H, C, P, N. These rows preserve the finite read, replay the displayed route, record provenance toward $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, and $\mathsf{Distribution}^{\uparrow}$ consumers, and name the local certificate. Since no completion, countable-additivity, product-measure, or host-set row occurs in the carrier, the handoff is event-ready only at the finite cylinder level. □

Falsifiable prediction: A probability-facing consumer that reads a $\mathsf{CylinderSet}^{\uparrow}$ event without exposing the finite coordinate window, coordinate-event rows, Boolean finite-intersection ledger, $\mathsf{StreamName}^{\uparrow}$ or product-style source window, hsame, Cont, Pkg, and NameCert rows refutes the $\mathsf{CylinderSet}^{\uparrow}$ carrier.

Independence witness: bool, streamname, probspace, randomvar, distribution: $\mathsf{CylinderSet}^{\uparrow}$ binds finite coordinate windows, Boolean coordinate events, finite-intersection rows, source-window replay, and probability-facing provenance in one local NameCert packet; each named sibling lacks at least one of these rows as a local cylinder-event obligation.

Closure status for $\mathsf{NameCert}_{\mathsf{CylinderSet}^{\uparrow}}$.

Constructive story: A $\mathsf{CylinderSet}^{\uparrow}$ packet is generated from a finite coordinate window, coordinate-event rows, a Boolean finite-intersection ledger, a StreamName or product-style source window, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. Its classifier is a finite cylinder-event surface, not a completed measurable set or a product-measure theorem.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CylinderSet}^{\uparrow}}$, seed)

Scope closed: Definition 7341.1, Definition 7341.2, Definition 7341.3, and Definition 7341.4 seed the finite cylinder-event route over $\mathsf{Bool}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CylinderSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: It does not claim σ-algebra completion, countable additivity, product-measure existence, host set semantics, selected infinite branches, quotient stream equality, or ambient probability-space semantics.

Upgrade path: To reach obligationClosure, the prefix-stability, finite-intersection, and probability-event-readiness obligations must be enumerated against a future Lean carrier under `BEDC.Derived.CylinderSetUp`.

Chapter 7342

A Concrete Naming Certificate for $\mathsf{IteratedFunctionSystem}^{\uparrow}$

Following Hutchinson on iterated function systems, the $\mathsf{IteratedFunctionSystem}^{\uparrow}$ packet records a finite family of contraction maps on a compact complete metric carrier as BEDC naming data. It sits after the metric source of chapter 57, the complete-metric limit surface of chapter 128, the compact-metric boundary of chapter 129, the map interface of chapter 130, the contraction route of chapter 1418, the tolerance schedules of chapter 292, and the real seal of chapter 38. The packet names only the finite contraction-family surface and its dependency rows; it does not construct an attractor, a hyperspace completion, a Hausdorff metric fixed point, or a measure on the limit set.

Definition 7342.1 (IteratedFunctionSystem carrier)**.** *An* $\mathsf{IteratedFunctionSystem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, M, K, F, L, R, Q, S, A, H, C, P, N)$$

with the following rows:

- X *is the displayed* $\mathsf{Met}^{\uparrow}$ *source carrier.*
- M *is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit-witness surface for Cauchy reads in* X*.*
- K *is the* $\mathsf{CompactMetric}^{\uparrow}$ *total-bounded and closed-boundary row used by finite cover consumers.*
- F *is a finite ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows whose sources and targets are* X*.*
- L *is the finite Lipschitz ledger, with each entry routed through a* $\mathsf{ContractionMapping}^{\uparrow}$ *row.*
- R *is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold ledger used by the contraction estimates.*
- Q *is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row for the displayed contraction constants.*
- S *is the finite index and family-membership row naming which maps are in the system.*
- A *is the attractor-obligation placeholder row: it records the route a later fixed-set consumer must inspect, but it is not itself an attractor construction.*
- H, C, P, N *are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{IteratedFunctionSystem}^{\uparrow}}$ *rows.*

Two carriers are classified only by the componentwise rows $X, M, K, F, L, R, Q, S, A, H, C, P, N$*. The classifier has no coordinate for quotient hyperspaces, selected fixed compact sets, ambient classical compactness, choice of a point in the attractor, or host equality of functions.*

Lean4 (statement) `BEDC.Derived.IteratedFunctionSystemUp`

Theorem 7342.2 (IteratedFunctionSystem NameCert obligations)**.** *For an accepted* $\mathsf{IteratedFunctionSystem}^{\uparrow}$ *carrier*

$$I = (X, M, K, F, L, R, Q, S, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IteratedFunctionSystem}^{\uparrow}}$ *surface is exhausted by five obligations: the carrier is inhabited by finite displayed rows; classifier equality is reflexive, symmetric, and transitive by componentwise* hsame *over those rows; and classifier transport preserves the metric, complete-metric, compact-metric, continuous-map, contraction, modulus, Real-seal, finite-index, attractor-obligation, replay, provenance, and naming coordinates. No obligation may be discharged by a host hyperspace quotient, selected attractor, global choice principle, or ambient compactness theorem outside the displayed packet.*

Proof. Project the carrier of Definition 7342.1. Every row is a finite BHist coordinate, and the classifier compares only those coordinates through componentwise hsame.

Reflexivity, symmetry, and transitivity are therefore the corresponding componentwise hsame laws for $X, M, K, F, L, R, Q, S, A, H, C, P, N$. The structural rows H, C, P, N then transport, replay, source, and name the same finite packet.

The excluded objects are not carrier coordinates. A NameCert consumer can inspect only the displayed metric, compactness, map-family, contraction, modulus, Real-seal, and structural rows, so no host hyperspace quotient or selected attractor can become a local obligation. □

Theorem 7342.3 (IteratedFunctionSystem contraction route)**.** *Every contraction-family request served by an accepted* $\mathsf{IteratedFunctionSystem}^{\uparrow}$ *carrier*

$$I = (X, M, K, F, L, R, Q, S, A, H, C, P, N)$$

must first read the metric source X, the continuous-map ledger F, the finite family row S, the contraction ledger L, and the modulus threshold ledger R. It may then use the $\mathsf{CompleteMetric}^{\uparrow}$ *row M, the* $\mathsf{CompactMetric}^{\uparrow}$ *row K, and the* $\mathsf{Real}^{\uparrow}$ *seal row Q only through the same componentwise transport, replay, provenance, and naming rows H, C, P, N. Thus the contraction route is a finite displayed BEDC route, not a direct appeal to a Hutchinson attractor theorem.*

Proof. Begin with a contraction-family request. The carrier exposes maps only through the finite continuous-map ledger F and records family membership only through S, both over the metric source X.

Read the contraction ledger L and threshold ledger R next. These rows are the only places where Lipschitz bounds and requested tolerances are stored before a later compact or complete-metric consumer can use them.

Finally pass through M, K, Q, H, C, P, N. The complete-metric, compact-metric, and Real-seal rows are consumed through the same displayed packet, while H, C, P, N preserve and name that packet. Since the carrier does not contain a hyperspace fixed-set row, the route cannot claim an attractor construction. □

Closure status for $\mathsf{NameCert}_{\mathsf{IteratedFunctionSystem}^{\uparrow}}$.

Constructive story: An $\mathsf{IteratedFunctionSystem}^{\uparrow}$ packet is generated from a compact complete metric source, a finite continuous-map family, contraction ledgers, modulus thresholds, Real-seal constants, family-membership rows, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IteratedFunctionSystem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7342.1, Definition 7342.2, and Definition 7342.3 seed the finite contraction-family carrier and its dependency route over $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IteratedFunctionSystem}^{\uparrow}}, \text{unformalized})$

Lean target: `BEDC.Derived.IteratedFunctionSystemUp`

Bridge status: none

Not claimed: This chapter does not close Hutchinson attractors, hyperspace completion, Hausdorff-metric fixed-set existence, invariant measures, Lean theorem coverage, or bridge checking.

Upgrade path: Scoped closure requires checked carrier obligations for the finite family ledger, contraction-modulus route, compact complete metric consumer boundary, and Real-seal nonescape.

Chapter 7343

A Concrete Naming Certificate for $\mathsf{RealUpperLowerApproximation}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers, the $\mathsf{RealUpperLowerApproximation}^{\uparrow}$ packet records the two-sided approximation surface by which lower and upper rational names are read through a shared finite window before any located-real or completion-facing consumer sees a terminal real seal. It sits between the finite stream discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance budget of chapter 291, the located-real boundary of chapter 1933, and the terminal $\mathsf{Real}^{\uparrow}$ certificate of chapter 38. The packet names a finite upper/lower approximation object only; it does not choose representatives or assert ambient completeness.

Definition 7343.1 (Real upper/lower approximation carrier)**.** *A* $\mathsf{RealUpperLowerApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, U, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower approximation row, a finite monotone rational read that may be consumed only as lower evidence.*
2. *U is the upper approximation row, a finite antitone rational read that may be consumed only as upper evidence.*
3. *W is the shared finite* $\mathsf{StreamName}^{\uparrow}$ *window through which both L and U are inspected at the same precision request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the lower and upper rational observations inside W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap budget recording the displayed tolerance between the lower and upper reads.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the shared window, readback, and gap budget have been displayed.*
7. *H records componentwise* hsame *transport for L, U, W, R, D, E.*
8. *C records displayed* Cont *replay from the two-sided approximation rows through the shared window into the terminal seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RealUpperLowerApproximation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUpperLowerApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for Dedekind cuts, quotient real equality, selected representatives, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7343.2 (Real upper/lower approximation NameCert obligations)**.** *For every accepted* $\mathsf{RealUpperLowerApproximation}^{\uparrow}$ *carrier* $A = (L, U, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealUpperLowerApproximatio}}$ *surface consists exactly of carrier admission for the lower approximation, upper approximation, shared finite stream window, regular rational readback, dyadic gap budget, terminal real seal, componentwise transport, displayed replay, provenance, and local naming rows; lower/upper polarity exactness for L and U; shared-window exactness for W; gap-budget visibility for D before E; and nonescape of quotient equality, selected representatives, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7343.1. Its analytic rows are exactly the lower read, upper read, shared window, regular rational readback, dyadic budget, and terminal real seal.

The polarity and shared-window clauses are read from L, U, W, R, D. The lower and upper rows are separate coordinates, and both pass through the same $\mathsf{StreamName}^{\uparrow}$ window before the $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{DyadicRatCore}^{\uparrow}$ gap budget are visible.

The structural rows H, C, P, N transport, replay, source, and name only these displayed rows. Since the carrier has no coordinate for quotient equality, selected representatives, trichotomy, countable choice, or ambient completeness, the listed clauses exhaust the local NameCert surface. □

Theorem 7343.3 (Real upper/lower approximation window handoff)**.** *Every* $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealUpperLowerApproximation}^{\uparrow}$ *packet reads the finite route*

$$L, U, W, R, D, E, H, C, P, N$$

in that order: lower and upper approximation rows, the shared $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap budget, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The handoff may supply a located two-sided approximation boundary, but it does not supply Dedekind completeness, quotient real equality, selected representatives, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier rows. A consumer sees L and U as two-sided rational approximation data, but both rows are tied to the same finite window W.

Read the regular rational and dyadic rows next. The $\mathsf{RegSeqRat}^{\uparrow}$ readback R and $\mathsf{DyadicRatCore}^{\uparrow}$ budget D expose the finite gap discipline required before the terminal $\mathsf{Real}^{\uparrow}$ seal E is available.

Finally transport and replay the route through H, C, P, N. These rows preserve the displayed window handoff for $\mathsf{LocatedReal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers, while all completeness, quotient, representative, trichotomy, and countable-choice claims remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealUpperLowerApproximation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealUpperLowerApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7343.1, Definition 7343.2, and Definition 7343.3 seed the finite two-sided approximation route over lower and upper rational reads, shared stream windows, regular rational readback, dyadic gap budgets, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{RealUpperLowerApproximation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, quotient real equality, selected representatives, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower/upper polarity exactness, shared-window exactness, gap-budget visibility, terminal-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RealUpperLowerAppro

Constructive story: A RealUpperLowerApproximation$^{\uparrow}$ packet is generated from lower and upper rational approximation rows, a shared StreamName window, RegSeqRat readback, DyadicRatCore gap budget, a terminal Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 7344

A Concrete Naming Certificate for $\mathsf{EquicontinuousCompactImage}^{\uparrow}$

Following Arzela–Ascoli and Bishop–Bridges constructive compact metric analysis, the EquicontinuousCompactImag packet records the finite image-window surface obtained from an equicontinuous family over a compact metric source. It sits after the compact source of chapter 129, the displayed function rows of chapter 130, the family modulus surface of chapter 413, the tolerance-only consumer of chapter 369, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet exposes compact-image data only as finite source nets, synchronized family windows, regular readback, and Real seals.

Definition 7344.1 (Equicontinuous compact image carrier)**.** *An* $\mathsf{EquicontinuousCompactImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, M, U, S, R, Q, H, C, P, N)$$

with the following rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, carrying the displayed centers, coverage witnesses, and metric-window data available to the image computation.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family graph row restricted to the inspected maps and source centers.*
3. *M is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row that synchronizes the family at the displayed source windows.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row receiving the finite tolerance schedule induced by K, F, M.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *image-window row exposed only at listed source centers and displayed family indices.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the image values and their tolerance schedule.*
7. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed image values.*
8. *H records componentwise* hsame *transport for compact-source, graph, equicontinuity, uniform-modulus, image-window, readback, seal, continuation, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a target image tolerance through*

$$K, F, M \longmapsto U, S, R, Q.$$

10. *P is the* Pkg *provenance over* $\mathsf{EquicontinuousCompactImage}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuousCompactImage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host image compactness, open-cover compactness, quotient function equality, selected image points outside the finite net, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7344.2 (Equicontinuous compact image NameCert obligations)**.** *For every accepted* $\mathsf{EquicontinuousCompactImage}^{\uparrow}$ *carrier $E = (K, F, M, U, S, R, Q, H, C, P, N)$, the local NameCert obligation surface consists exactly of compact finite-net admission through K, displayed continuous-map image admission through F, equicontinuity-family synchronization through M, uniform-modulus handoff through U, finite image-window exposure through S, regular rational readback through R, terminal Real sealing through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

No obligation row asserts host image compactness, an open-cover finite subcover, quotient equality of functions, a selected image point outside the listed windows, countable choice, or ambient Real completeness.

Proof. Project the carrier of Definition 7344.1. The compactness-facing data is the finite-net row K, the function-facing data is the displayed graph row F, and the family-control data is the equicontinuity row M.

The tolerance handoff is finite. A target tolerance request first reads the source net in K, then the graph rows in F at the displayed centers, and then the family synchronization row M. The resulting tolerance schedule is passed to U.

The image rows are downstream of that handoff. The window row S exposes only listed image observations, R supplies regular rational readback for those observations, and Q seals the resulting Real-facing values.

Finally replay H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the same route, so no host compactness principle, selected subcover, quotient function equality, choice schedule, selected image point, or ambient completeness row is introduced. □

Theorem 7344.3 (Equicontinuous compact image L10 route)**.** *Every L10 consumer of an accepted* $\mathsf{EquicontinuousCompactImage}^{\uparrow}$ *packet must first inspect the finite compact-metric source row, the continuous-map graph row, the equicontinuity-family synchronization row, and the uniform-modulus handoff before reaching image windows, regular rational readback, and the terminal Real seal. Concretely, every such read factors through*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{EquicontinuityFamily}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as displayed carrier rows, not as host compactness or quotient function data.

Proof. Start with an L10 image read of the carrier in Definition 7344.1. The first available source data is K, the compact-metric finite net, so the consumer cannot begin from an open cover or a host image set.

Read the function and family rows next. The graph row F supplies displayed image values at inspected centers, while M forces those reads to share the equicontinuity-family synchronization.

The handoff row U then records the tolerance-only uniform-modulus surface consumed by the downstream route.

Only after K, F, M, U are displayed can the consumer reach S, R, Q. These rows expose finite image windows, regular rational readback, and the terminal Real seal.

The structural rows H, C, P, N preserve this order. Therefore the L10 route exports only the displayed compact-source, map, family-modulus, window, readback, and seal rows, while refusing host image compactness, open-cover compactness, quotient function equality, selected image points, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{EquicontinuousCompactImage}^{\uparrow}$ consumer read factors through CompactMetric finite-net rows, ContinuousMap graph rows, EquicontinuityFamily synchronization rows, UniformModulus handoff, StreamName windows, RegSeqRat readback, RealUp seals, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: compactmetric, continuousmap, equicontinuityfamily, uniformmodulus, streamname, regseqrat, real: no listed sibling supplies the whole eleven-row packet $E = (K, F, M, U, S, R, Q, H, C, P, N)$, because each sibling contributes only a compact source, graph row, family synchronization row, tolerance handoff, finite window, regular readback, or Real seal while this chapter binds the compact-image route through transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuousCompactImage}^{\uparrow}}$.

Constructive story: An $\mathsf{EquicontinuousCompactImage}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap graph rows, EquicontinuityFamily synchronization rows, UniformModulus handoff, StreamName image windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquicontinuousCompactImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7344.1, Definition 7344.2, and Definition 7344.3 seed the finite compact-metric equicontinuous image route before L10 consumers inspect image windows and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquicontinuousCompactImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host image compactness, open-cover compactness, quotient function equality, selected image points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, continuous-map graph admission, family synchronization, uniform-modulus handoff, image-window exposure, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EquicontinuousCompactImageUp.

Chapter 7345

A Concrete Naming Certificate for $\mathsf{LocallyConnectedContinuum}^{\uparrow}$

Following Hahn–Mazurkiewicz and Kelley on compact metric continua, the $\mathsf{LocallyConnectedContinuum}^{\uparrow}$ packet records the compact, connected, locally connected metric layer that Peano-continuum and dendrite consumers read before importing their richer endpoint or image data. It sits over the compact metric carrier of chapter 129, the finite chain-connected route of chapter 2050, the continuous-map surface of chapter 59, and the downstream continuum consumers of chapter 2160 and chapter 5803. The packet names the local connectedness refinement boundary without asserting a space-filling curve, unique-arc data, open-cover compactness, quotient equality of points, or ambient real completeness.

Definition 7345.1 (Locally connected continuum carrier)**.** *A* $\mathsf{LocallyConnectedContinuum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, C, R, W, M, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric carrier, finite compact-window rows, total-boundedness ledger, and completion-facing comparisons used by continuum consumers.*
2. *C is the connectedness source row. It either records a displayed connectedness witness over K or a finite* $\mathsf{ChainConnectedMetric}^{\uparrow}$ *route whose chain ledgers are read as connectedness-facing data for the same compact metric source.*
3. *R is the local connectedness refinement ledger. For each displayed compact window it records connected neighbourhood rows, inclusion refinements, overlap witnesses, radius comparisons, and the refusal of host open-set lattices outside the packet.*
4. *W is the compact-window row, recording the finite family of windows through which later interval, image, and dendrite reads may inspect the continuum.*
5. *M is the continuous-map consumer route, exposing only the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph, modulus, and window-read rows allowed to consume K, C, R, W.*
6. *H records componentwise* hsame *transport for the compact metric source, connectedness row, local connectedness refinement ledger, compact windows, continuous-map route, replay row, provenance row, and local naming row.*

7. *T records displayed* Cont *replay of the route*

$$K, C, R, W \longmapsto M \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{LocallyConnectedContinuum}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ChainConnectedMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnectedContinuum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, C, R, W, M, H, T, P, N$. The carrier has no coordinate for an ambient point-set continuum, a selected Peano parametrization, dendrite arc uniqueness, open-cover compactness, quotient point equality, countable choice, or completed real subset selection.

Lean4 (definition) `BEDC.Derived.LocallyConnectedContinuumUp.LocallyConnectedContinuumUp`

Theorem 7345.2 (Locally connected continuum NameCert obligations)**.** *For every accepted* LocallyConnectedCont *carrier*

$$L = (K, C, R, W, M, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocallyConnectedContinuum}^{\uparrow}}$ *surface consists exactly of compact-metric source exposure through K, connected or chain-connected source exposure through C, local connectedness refinement through R, compact-window visibility through W, continuous-map consumer routing through M, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The displayed tuple lists every row that may be consumed by a continuum-facing reader, so carrier admission and classifier exposure are confined to $K, C, R, W, M, H, T, P, N$.

The compact and connected source data are read first. The row K supplies the compact metric source, and C supplies either displayed connectedness evidence or the finite $\mathsf{ChainConnectedMetric}^{\uparrow}$ route over that same source. No second host space is introduced.

The local connectedness data are confined to R and W. Each compact-window request is answered by finite connected-neighbourhood, inclusion, overlap, and radius-comparison rows, while W records the windows through which downstream image and continuum readers may inspect the packet.

Finally M, H, T, P, N route, transport, replay, source, and name exactly the displayed rows. Since the carrier has no coordinate for a host continuum, selected parametrization, dendrite arc, open-cover principle, quotient point equality, countable choice, or completed real subset, the listed rows exhaust the local NameCert surface. □

Theorem 7345.3 (Locally connected continuum Peano handoff)**.** *Every* $\mathsf{PeanoContinuum}^{\uparrow}$ *or* $\mathsf{Dendrite}^{\uparrow}$ *consumer that reads a compact metric continuum through* $\mathsf{LocallyConnectedContinuum}^{\uparrow}$ *must first pass through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ChainConnectedMetric}^{\uparrow},\ R,\ W,\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto H, T, P, N.$$

Thus the consumer receives the compact metric source, connectedness route, local connectedness refinement ledger, compact windows, continuous-map route, componentwise transport, displayed replay, provenance, and local naming before reading Peano-continuum or dendrite-specific rows. It receives no host continuum, selected Peano parametrization, unique-arc dendrite structure, open-cover compactness, quotient point equality, countable-choice selector, or ambient real-completeness witness.

Proof. Start with the compact source row K. A Peano-continuum or dendrite consumer cannot read local connectedness, image, endpoint, or arc data before the metric carrier, compact windows, and finite compactness-facing rows have been displayed.

Next read connectedness through C. If the source is supplied by a chain-connected route, the consumer sees the finite endpoint, chain, radius, and tolerance ledgers of $\mathsf{ChainConnectedMetric}^{\uparrow}$ over the same compact metric row.

Now read the local connectedness and window rows R, W. These rows provide finite connected-neighbourhood refinements and compact-window boundaries before any $\mathsf{ContinuousMap}^{\uparrow}$ graph or modulus row in M is made public.

The structural rows close the handoff. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve exactly this finite dependency order, so Peano-continuum and dendrite consumers receive the locally connected continuum layer without receiving any refused host-side object. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnectedContinuum}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyConnectedContinuum}^{\uparrow}$ packet is generated from a compact metric source row, connectedness or ChainConnectedMetric row, finite local connectedness refinement ledger, compact-window row, ContinuousMap consumer route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnectedContinuum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7345.1, Definition 7345.2, and Definition 7345.3 seed the finite compact metric, connected, locally connected continuum packet for Peano-continuum and dendrite consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnectedContinuum}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.LocallyConnectedContinuumUp.LocallyConnectedContinuumUp`

Bridge status: none

Not claimed: This chapter does not close selected Peano parametrizations, unique arcs, host point-set continua, open-cover compactness, quotient point equality, countable choice, ambient real completeness, or standard bridges.

Upgrade path: Obligation closure requires checked carrier admission, connectedness visibility, local connectedness refinement, continuous-map consumer routing, transport, replay, provenance, and local naming for BEDC.Derived.LocallyConnectedContinuumU

Chapter 7346

A Concrete Naming Certificate for MetaCICLocalConfluenceFrontier$^{\uparrow}$

The MetaCICLocalConfluenceFrontier$^{\uparrow}$ packet realizes the conditional local-diamond boundary of chapter 9378 as finite critical-pair, conditional-join, substitution-premise, obstruction, transport, replay, provenance, and local naming data. It sits between the critical-path surface of chapter 765, the normal-form consistency seal of chapter 740, the decidable-conversion boundary of chapter 4097, and the parallel-diamond frontier of chapter 4238. The packet records the conditional local confluence surface without claiming full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, residual-substitution compatibility, or kernel consistency.

Falsifiable prediction: Every accepted MetaCICLocalConfluenceFrontier$^{\uparrow}$ read exposes the critical-pair, conditional-join, residual-substitution premise, obstruction, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before any local-diamond handoff can be consumed.

Independence witness: metacic-parallel-diamond-frontier, normal-form-consistency-seal, metaciccriticalpath, metacicdecidableboundary, subject-reduction-discharge-socket: the parallel-diamond frontier retains a stronger residual-diamond route without closing the local confluence premise; the normal-form consistency seal records normal-source consistency without the critical-pair frontier; the critical path records reduction-budget routing without the conditional local-join packet; the decidable boundary records conversion-frontier data without local diamond discharge; and the subject-reduction discharge socket names a typing-preservation boundary rather than a confluence frontier. None is bijective to MetaCICLocalConfluenceFrontier$^{\uparrow}$.

Definition 7346.1 (MetaCIC local confluence frontier carrier)**.** *A* MetaCICLocalConfluenceFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, J, S, O, H, T, P, N)$$

with the following displayed rows:

1. *K is the critical-pair row, exposing the local overlap, source term, two one-step residual branches, and bounded redex-window data consumed by* MetaCICCriticalPath$^{\uparrow}$*.*
2. *J is the conditional-join row, recording the candidate common reduct and the finite local-join check that may be read only after K and S are displayed.*
3. *S is the substitution-premise row, retaining the residual-substitution compatibility boundary required by the conditional local-diamond read.*

4. *O is the obstruction row, recording non-discharge of full parallel diamond, full closed Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, and kernel consistency.*
5. *H records componentwise* hsame *transport for critical pairs, conditional joins, substitution premises, obstruction data, replay, provenance, and local naming.*
6. *T records displayed* Cont *replay of the route*

$$K, S \longmapsto J \longmapsto O, H, P, N.$$

7. *P is the* Pkg *provenance over* MetaCICLocalConfluenceFrontier$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICDecidableConversionFrontier$^{\uparrow}$, SubjectReductionDisc BHist, hsame, Cont, *and* NameCert.
8. *N is the local* NameCert$_{\text{MetaCICLocalConfluenceFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through K, J, S, O, H, T, P, N. It has no coordinate for an unconditional diamond theorem, a subject-reduction theorem, evaluator equality, quotient syntax equality, global normalization, or kernel consistency.

Lean4 (definition) `BEDC.Derived.MetaCICLocalConfluenceFrontierUp.MetaCICLocalConfluenceFrontierUp`

Theorem 7346.2 (MetaCIC local confluence frontier NameCert obligations)**.** *For every accepted* MetaCICLocalConfluenceFrontier$^{\uparrow}$ *carrier*

$$F = (K, J, S, O, H, T, P, N),$$

the local NameCert$_{\text{MetaCICLocalConfluenceFrontier}^{\uparrow}}$ *surface consists exactly of critical-pair exposure through K, conditional-join exposure through J, residual-substitution premise retention through S, obstruction nonescape through O, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The finite tuple displays the critical-pair, conditional-join, substitution-premise, obstruction, transport, replay, provenance, and local naming rows, and the classifier compares only those rows.

The confluence-facing data are K, J, S. A reader first exposes the critical pair K and retained substitution premise S; only then may it inspect the candidate local join J. This preserves the conditional boundary named in chapter 9378.

The obstruction and structural rows prevent nonescape. The row O records that the packet has not supplied full parallel diamond, closed Church–Rosser, subject reduction, evaluator equality, quotient equality, global normalization, or kernel consistency, while H, T, P, N transport, replay, source, and name the same finite rows. □

Theorem 7346.3 (MetaCIC local confluence frontier conditional handoff)**.** *Every confluence-audit consumer that reads an accepted* MetaCICLocalConfluenceFrontier$^{\uparrow}$ *packet must expose the route*

$$\text{MetaCICCriticalPath}^{\uparrow},\ S,\ J,\ O \longmapsto H, T, P, N$$

before using a local-diamond handoff. The handoff may feed the conditional surface of MetaCICParallelDiamondFront *and the consistency-facing rows of* NormalFormConsistencySeal$^{\uparrow}$*, but it does not prove residual-substitution compatibility, full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, decidable conversion, or kernel consistency.*

Proof. Start with the critical-pair row K. It exposes only the local overlap and bounded residual branches consumed by the MetaCIC critical path, so the reader has not yet received any global confluence theorem.

Next read the retained substitution premise S and conditional join row J. The join is public only relative to the displayed premise, which keeps the residual-substitution boundary visible at the handoff.

Finally read O, H, T, P, N. The obstruction row records the endpoints that remain outside the packet, and the structural rows transport, replay, source, and name the same conditional frontier. Therefore the consumer receives a local confluence frontier, not a proof of full confluence, subject reduction, evaluator equality, quotient equality, decidable conversion, or kernel consistency. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICLocalConfluenceFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICLocalConfluenceFrontier}^{\uparrow}$ packet is generated from critical-pair rows, conditional-join rows, residual-substitution premise rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICLocalConfluenceFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7346.1, Definition 7346.2, and Definition 7346.3 seed the finite local confluence frontier over critical-pair, conditional-join, substitution-premise, obstruction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICLocalConfluenceFrontier}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.MetaCICLocalConfluenceFrontierUp.MetaCICLocalConfluenceFrontierUp`

Bridge status: none

Not claimed: This chapter does not close residual-substitution compatibility, full parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, decidable conversion, global normalization, kernel consistency, or standard bridges.

Upgrade path: Obligation closure requires checked carrier admission, critical-pair exposure, conditional-join exposure, residual-substitution premise retention, obstruction nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICLocalConfluenceFrontierUp.

Chapter 7347

A Concrete Naming Certificate for $\mathsf{SmallInductiveDimension}^{\uparrow}$

Following Hurewicz–Wallman and Engelking, the $\mathsf{SmallInductiveDimension}^{\uparrow}$ packet records the boundary-recursive small inductive dimension as finite BEDC separation and cover data. It sits beside the finite cover-order carrier of chapter 1853, the Lebesgue refinement route of chapter 4205, the topology source of chapter 88, the normal-space separation packet of chapter 1866, and the finite refinement carrier of chapter 3430. The packet names only displayed boundary neighborhoods, finite boundary-cover rows, refinement comparisons, transport, replay, provenance, and local naming; it does not assert a host inductive-dimension theorem, arbitrary open-cover compactness, selected separators outside the carrier, or ambient quotient topology equality.

Definition 7347.1 (Small inductive dimension carrier)**.** *A* $\mathsf{SmallInductiveDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, N, B, R, F, L, H, C, P, A)$$

with the following displayed rows:

1. *X is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the finite point, open-neighborhood, closed-set, and boundary observations inspected by the packet.*
2. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *separation row, recording the closed-pair separation route used to choose a displayed neighborhood before its boundary is inspected.*
3. *B is the boundary-cover row, recording the finite* BHist *boundary entries whose own dimension read is one step lower than the surrounding packet.*
4. *R is the boundary-recursion ledger, recording that each boundary read is consumed only through the displayed topology and normal-space rows.*
5. *F is the* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *comparison row, recording the finite refinement handoff used when boundary covers are compared with cover-order packets.*
6. *L is the dimension-neighbor comparison row, recording the finite comparison with* $\mathsf{CoveringDimension}^{\uparrow}$ *and* $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ *without identifying the three dimension notions.*
7. *H stores componentwise* hsame *transport for topology, normal-space, boundary, recursion, refinement, comparison, replay, provenance, and local naming rows.*

8. *C stores displayed* Cont *replay from a topology-neighborhood request through normal-space separation, boundary cover inspection, finite refinement comparison, and dimension-neighbor handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{SmallInductiveDimension}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{LebesgueCoveringDimension}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *A is the local* $\mathsf{NameCert}_{\mathsf{SmallInductiveDimension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $X, N, B, R, F, L, H, C, P, A$. It has no coordinate for a host dimension theorem, arbitrary open-cover compactness, a selected separating family outside the packet, quotient-topology equality, countable choice, or an ambient boundary oracle.

Theorem 7347.2 (Small inductive dimension NameCert obligations)**.** *For every accepted* $\mathsf{SmallInductiveDimension}^{\uparrow}$ *carrier*

$$S = (X, N, B, R, F, L, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{SmallInductiveDimension}^{\uparrow}}$ *surface consists exactly of topology-source admission through X, normal-space separation exposure through N, finite boundary-cover admission through B, boundary-recursion exactness through R, finite refinement comparison through F, covering-dimension and Lebesgue-covering comparison through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through A.*

Proof. Project the carrier of Definition 7347.1. The source, separation, boundary, recursion, refinement, comparison, transport, replay, provenance, and naming rows are precisely the displayed coordinates of the finite packet.

The boundary-recursive part is read from X, N, B, R. A consumer first sees the topology source, then the normal-space separation row, and only then the boundary-cover rows whose lower-dimensional reads are stored by the recursion ledger.

The finite comparison part is read from F, L. These rows permit comparison with finite cover-refinement, covering-dimension, and Lebesgue-covering packets, but they do not identify those packets with the small inductive dimension carrier.

Finally H, C, P, A transport, replay, source, and name the same finite route. Since none of the refused host objects is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7347.3 (Small inductive dimension boundary route)**.** *Every boundary-recursive read of an accepted* $\mathsf{SmallInductiveDimension}^{\uparrow}$ *packet must factor through*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{NormalSpace}^{\uparrow},\ B,\ R,\ H,\ C,\ P,\ A$$

before a lower-dimensional boundary claim is consumed. The route exposes a displayed neighborhood-separation row and a finite boundary-cover row; it exports no selected separating family outside the carrier, no host boundary oracle, no quotient-topology equality, and no countable-choice schedule.

Proof. Begin with the topology source row X. It supplies the displayed point, open-neighborhood, closed-set, and boundary observations available to the packet.

Use the normal-space separation row N next. The boundary that enters the recursion ledger is admitted only after the separation route is visible, so a consumer cannot replace it by an unrecorded host separator.

The rows B and R then record the finite boundary-cover entries and their lower-dimensional reads. Structural rows H, C, P, A preserve, replay, source, and name this route, so the boundary claim remains inside the displayed packet. □

Theorem 7347.4 (Small inductive dimension cover comparison)**.** *Every finite-cover comparison exported by an accepted* $\mathsf{SmallInductiveDimension}^{\uparrow}$ *packet must read the route*

$$\mathsf{FiniteCoverRefinement}^{\uparrow},\ \mathsf{CoveringDimension}^{\uparrow},\ \mathsf{LebesgueCoveringDimension}^{\uparrow} \longmapsto F, L, H, C, P, A.$$

The comparison is a finite handoff from boundary-recursive rows to cover-refinement and cover-order rows. It does not identify small inductive dimension with covering dimension, does not claim equality with Lebesgue covering dimension, and does not import arbitrary open-cover compactness or a host dimension theorem.

Proof. Start with the NameCert obligations of Definition 7347.2. They require the topology source, normal-space separation row, finite boundary-cover row, and recursion ledger before any comparison is exported.

Read the finite refinement row F. It supplies only the displayed refinement handoff, so cover comparison is routed through $\mathsf{FiniteCoverRefinement}^{\uparrow}$ rather than through arbitrary open-cover compactness.

Finally inspect the neighbor comparison row L. It permits cover-order and Lebesgue-covering consumers to see the same finite boundary-refinement route while keeping $\mathsf{SmallInductiveDimension}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, and $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ as distinct packet names. The structural rows H, C, P, A then transport, replay, source, and name the comparison without adding a host theorem. □

Falsifiable prediction: An accepted $\mathsf{SmallInductiveDimension}^{\uparrow}$ boundary read is refuted if it exports a lower-dimensional boundary claim without displaying the TopologyUp source row, NormalSpaceUp separation row, finite boundary-cover row, boundary-recursion ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: coveringdimension, lebesgue-covering-dimension, topology, normalspace, finite-cover-refinement: $\mathsf{SmallInductiveDimension}^{\uparrow}$ jointly carries topology-source, normal-space separation, finite boundary-cover, boundary-recursion, finite refinement comparison, dimension-neighbor comparison, transport, replay, provenance, and local naming rows in one packet; each named sibling lacks at least one of these local boundary-recursive coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{SmallInductiveDimension}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SmallInductiveDimension}^{\uparrow}$ packet is generated from a TopologyUp source row, a NormalSpaceUp separation row, finite BHist boundary-cover rows, a boundary-recursion ledger, a FiniteCoverRefinementUp comparison row, CoveringDimensionUp and LebesgueCoveringDimensionUp neighbor rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SmallInductiveDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7347.1, Definition 7347.2, Definition 7347.3, and Definition 7347.4 seed the boundary-recursive small inductive dimension surface over topology, normal-space, finite-refinement, covering-dimension, and Lebesgue-covering rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SmallInductiveDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host inductive-dimension theorem, equality with covering dimension, equality with Lebesgue covering dimension, arbitrary open-cover compactness, selected separator choice, quotient topology equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked topology-source admission, normal-space separation exactness, finite boundary-cover admission, boundary-recursion exactness, finite refinement comparison, cover-dimension comparison, transport, replay, provenance, and local NameCert rows for BEDC.Derived.SmallInductiveDimensionUp.

Chapter 7348

A Concrete Naming Certificate for $\mathsf{FiniteMetricProjection}^{\uparrow}$

Following Bishop and Bridges on finite metric spaces and Kelley on metric neighbourhoods, the $\mathsf{FiniteMetricProjection}^{\uparrow}$ packet records the finite nearest-point projection interface that is available when all candidate distances are displayed rows. It sits over the parent projection boundary of chapter 2356, the located-distance discipline of chapter 1541, the ambient metric source of chapter 57, the terminal distance seal of chapter 38, and the dyadic comparison core of chapter 291. The packet gives downstream located-set and completion consumers a finite endpoint witness without importing Hilbert projection, closed convexity, quotient subset equality, countable choice, or an ambient nearest-point selector.

Definition 7348.1 (FiniteMetricProjection carrier)**.** *A* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, L, D, E, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row naming the finite metric source.*
2. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *row naming the displayed finite subset and its located-distance ledger.*
3. *D is the finite table of candidate distance rows from the queried point to the displayed subset.*
4. *E is the endpoint evidence row naming a candidate in the finite subset whose displayed distance is minimal among the rows in D.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger used to compare the finite distance rows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *distance seal read after the dyadic comparisons and endpoint evidence have been replayed.*
7. *H records componentwise* hsame *transport for the metric, located-set, distance-table, endpoint, dyadic-comparison, Real-seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a projection request through the finite distance table, dyadic comparisons, endpoint evidence, and terminal distance seal.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteMetricProjection}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricProjection}^{\uparrow}}$ *row.*

The carrier contains no coordinate for Hilbert projection, closed convexity, subset quotient equality, selected minimizers beyond the displayed endpoint row, countable choice, compactness, or ambient completion.

Theorem 7348.2 (FiniteMetricProjection NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *carrier* $F = (M, L, D, E, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricProjection}^{\uparrow}}$ *surface consists exactly of these five obligation rows:*

1. *carrier admission for the displayed metric, located-set, distance-table, endpoint, dyadic-comparison, Real-seal, transport, continuation, provenance, and local naming rows;*
2. *located-set exposure, requiring* L *to be read before any projection consumer may inspect the finite distance table* D*;*
3. *finite comparison exactness, requiring every minimality comparison for* E *to pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* Q*;*
4. *endpoint handoff, requiring the endpoint row* E *and terminal distance seal* R *to be replayed before a* $\mathsf{MetricProjection}^{\uparrow}$ *consumer receives a projection result;*
5. *ledger refusal, excluding Hilbert projection, closed-convex projection, quotient subset equality, hidden minimizer selection, countable choice, compactness, and ambient completion.*

No local NameCert row is stored outside those obligations and the structural rows H, C, P, N*.*

Proof. Project the carrier of Definition 7348.1. Its public rows are exactly $M, L, D, E, Q, R, H, C, P, N$, so carrier admission exposes only the finite metric source, located-set row, candidate distance table, endpoint witness, dyadic comparison ledger, and terminal distance seal.

The located-set and finite-comparison obligations follow from the displayed continuation. A projection request first reads M and L, then the finite table D, and then the dyadic comparison row Q that checks the endpoint row E against every displayed candidate.

The endpoint handoff is the remaining route. The row E is the only projection endpoint visible to the packet, and R is readable only after E, Q and the finite table have been replayed through H, C, P, N. Since the carrier has no further coordinate, none of the refused projection or choice principles can be projected from the NameCert surface. □

Theorem 7348.3 (FiniteMetricProjection nearest-row totality)**.** *Let* $F = (M, L, D, E, Q, R, H, C, P, N)$ *be an accepted* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *packet. Every projection request over the displayed finite subset reaches a nearest-distance row by the finite route*

$$M, L, D, Q \longmapsto E, R \longmapsto H, C, P, N.$$

Thus nearest-row totality is the finite exhaustion of the displayed distance table, with all comparisons read through $\mathsf{DyadicRatCore}^{\uparrow}$ *and the terminal distance exposed as a* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with the finite distance table D in the carrier. Because D is a displayed finite row, the request inspects each candidate distance inside the packet rather than searching an ambient subset.

Use the dyadic comparison ledger Q. It compares the finite distance rows and identifies the endpoint evidence row E as minimal among the displayed candidates.

Finally replay the continuation row C and transport row H. The terminal seal R is read only after M, L, D, Q, E are visible, and provenance and local naming preserve that order. The route therefore gives nearest-row totality without adding a hidden selector, quotient equality, choice schedule, compactness theorem, or completion coordinate. □

Theorem 7348.4 (FiniteMetricProjection LocatedSet route)**.** *Every* $\mathsf{LocatedSet}^{\uparrow}$ *consumer that asks an accepted* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *packet for a projection endpoint must first expose the parent* $\mathsf{Met}^{\uparrow}$ *row* M*, the located-set row* L*, the finite distance table* D*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger* Q*, the endpoint evidence row* E*, the* $\mathsf{Real}^{\uparrow}$ *seal* R*, and the structural rows* H, C, P, N*. The packet supplies the endpoint evidence required outside chapter 1541; it does not turn the located-set distance interface itself into a nearest-point selector.*

Proof. Read the LocatedSet metric-projection admission boundary in Definition 1541.6. It says that a projection consumer must supply endpoint evidence outside the located-set packet.

The carrier of Definition 7348.1 supplies exactly that outside row as E, together with the finite distance table D, dyadic comparison ledger Q, and Real distance seal R.

Combine this with Definition 7348.3. The endpoint is obtained only through the finite metric and located-set rows, the displayed distance table, and the dyadic comparison route, so the LocatedSet interface remains a distance interface while $\mathsf{FiniteMetricProjection}^{\uparrow}$ carries the separate endpoint witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricProjection}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetricProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7348.1, Definition 7348.2, Definition 7348.3, and Definition 7348.4 seed the finite projection route from displayed metric-distance rows to a separate endpoint witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMetricProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hilbert projection, closed-convex projection, quotient subset equality, hidden minimizer selection, countable choice, compactness, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite comparison exactness, endpoint handoff, located-set compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FiniteMetricProjectionUp.

Constructive story: A $\mathsf{FiniteMetricProjection}^{\uparrow}$ packet is generated from a Metric row, a LocatedSet row, a finite distance table, endpoint evidence, a DyadicRatCore comparison ledger, a Real distance seal, componentwise hsame transport, continuation replay, provenance, and a local NameCert row.

Chapter 7349

A Concrete Naming Certificate for $\mathsf{MilnorFibration}^{\uparrow}$

Following Milnor, the $\mathsf{MilnorFibration}^{\uparrow}$ packet records the finite fibration boundary visible near an isolated complex hypersurface singularity before any ambient analytic triviality theorem is imported. It sits after the charted source carrier of chapter 96, the local-trivialization rows of chapter 97, the circle boundary source of chapter 58, the horizontal-lift ledger of chapter 6815, and the cycle-read surface of chapter 98. The chapter names only displayed singular chart rows, punctured-neighbourhood rows, circle-base rows, fibre-bundle rows, connection-lift rows, homology readback, monodromy replay, provenance, transport, and local naming; it does not assert analytic Milnor existence, choose a global tube, identify fibres by host diffeomorphism, or import a Picard–Lefschetz formula.

Definition 7349.1 (Milnor fibration carrier)**.** *A* $\mathsf{MilnorFibration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, U, S, F, B, E, H, L, T, R, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Manifold}^{\uparrow}$ *charted source row carrying the inspected singular neighbourhood and its chart ledger.*
2. *U is the punctured-neighbourhood boundary row, naming the deleted singular point and the finite boundary window used by the read.*
3. *S is the* $\mathsf{S}^{1\uparrow}$ *base-circle row through which phase or argument reads are exposed.*
4. *F is the fibre row over the displayed base-circle observation, with no host fibre quotient or selected representative.*
5. *B is the* $\mathsf{Bundle}^{\uparrow}$ *local-trivialization row for the displayed map over the visible circle window.*
6. *E is the* $\mathsf{EhresmannConnection}^{\uparrow}$ *horizontal-lift row used only after the bundle and base-circle rows have been read.*
7. *H is the* $\mathsf{Homology}^{\uparrow}$ *cycle-read row on the displayed fibre boundary.*
8. *L is the monodromy ledger, recording the finite continuation route from one circle read to the next through E and H.*
9. *T records componentwise* hsame *transport for X, U, S, F, B, E, H, L.*

10. *R records displayed* Cont *replay for the fibration, lift, cycle, and monodromy reads.*
11. *P is the* Pkg *provenance over* $\mathsf{MilnorFibration}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{EhresmannConnection}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MilnorFibration}^{\uparrow}}$ *row.*

The carrier has no coordinate for analytic existence of the Milnor tube, host smooth-fibre equality, selected global trivialization, quotient vanishing-cycle object, or Picard–Lefschetz transformation.

Theorem 7349.2 (Milnor fibration NameCert obligations)**.** *For an accepted* $\mathsf{MilnorFibration}^{\uparrow}$ *packet $M = (X, U, S, F, B, E, H, L, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MilnorFibration}^{\uparrow}}$ *surface is exhausted by carrier admission for M, manifold-source exposure through X, U, circle-base exposure through S, fibre and local-trivialization exposure through F, B, horizontal-lift exposure through E, homology-cycle exposure through H, monodromy-ledger exposure through L, componentwise transport through T, displayed replay through R, provenance through P, and local naming through N. A consumer cannot inspect a monodromy or vanishing-cycle boundary before those rows have been displayed.*

Proof. Project the accepted packet to the carrier of Definition 7349.1. Its coordinates list exactly the manifold, punctured-neighbourhood, circle-base, fibre, bundle, connection, homology, monodromy, transport, replay, provenance, and naming rows.

The NameCert surface is therefore the local package over those displayed rows. The bundle row cannot be read before the manifold and circle rows, the connection row cannot be read before the bundle row, and the homology row cannot be consumed by monodromy before the fibre boundary has been displayed.

Since the carrier contains no host analytic tube, no global trivialization coordinate, and no quotient vanishing-cycle object, any accepted downstream monodromy read is exhausted by the listed rows. □

Theorem 7349.3 (Milnor fibration monodromy route)**.** *Every monodromy-facing consumer of an accepted* $\mathsf{MilnorFibration}^{\uparrow}$ *packet must read the dependency route*

$$\mathsf{Manifold}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow} \longmapsto \mathsf{Bundle}^{\uparrow} \longmapsto \mathsf{EhresmannConnection}^{\uparrow} \longmapsto \mathsf{Homology}^{\uparrow}.$$

The manifold and punctured-neighbourhood rows delimit the inspected singular boundary, the circle row supplies the base loop, the bundle row supplies the local fibre handoff, the Ehresmann row supplies the finite horizontal-lift replay, and the homology row supplies the cycle endpoint read by the monodromy ledger. The route exports no arbitrary analytic fibration theorem, no selected fibre equivalence, and no Picard–Lefschetz formula.

Proof. Begin with the source boundary. The rows X and U expose the charted neighbourhood and deleted-point boundary before any circle or fibre read is available.

Next read the base and bundle rows. The $\mathsf{S}^{1\uparrow}$ row S supplies the visible loop coordinate, and the $\mathsf{Bundle}^{\uparrow}$ row B supplies only the local fibre handoff over that displayed loop.

Finally route continuation through E, H, L. The $\mathsf{EhresmannConnection}^{\uparrow}$ row gives the horizontal-lift replay, the $\mathsf{Homology}^{\uparrow}$ row gives the cycle endpoint on the displayed fibre, and the monodromy ledger records only this finite continuation. Therefore the consumer sees exactly the stated dependency route and none of the excluded host analytic data. □

Falsifiable prediction: A monodromy consumer that reads a $\mathsf{MilnorFibration}^{\uparrow}$ packet without exposing the $\mathsf{Manifold}^{\uparrow}$ source, punctured-neighbourhood boundary, $\mathsf{S}^{1\uparrow}$ base loop, $\mathsf{Bundle}^{\uparrow}$ fibre

handoff, $\mathsf{EhresmannConnection}^{\uparrow}$ lift row, $\mathsf{Homology}^{\uparrow}$ cycle row, hsame, Cont, Pkg, and NameCert rows refutes the carrier.

Independence witness: manifold, bundle, s1, ehresmann-connection, homology: $\mathsf{MilnorFibration}^{\uparrow}$ binds singular-neighbourhood source rows, circle-base rows, local fibre handoff, horizontal-lift replay, homology cycle readback, and monodromy provenance in one local NameCert packet; each named sibling lacks at least one of these rows as a Milnor-fibration obligation.

Closure status for $\mathsf{NameCert}_{\mathsf{MilnorFibration}^{\uparrow}}$.

Constructive story: A $\mathsf{MilnorFibration}^{\uparrow}$ packet is generated from a charted singular-neighbourhood row, punctured-boundary row, circle-base row, fibre and bundle rows, Ehresmann horizontal-lift row, homology cycle row, monodromy ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MilnorFibration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7349.1, Definition 7349.2, and Definition 7349.3 seed the finite Milnor-fibration NameCert surface over $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{EhresmannConnection}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MilnorFibration}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MilnorFibrationUp`

Bridge status: none

Not claimed: This chapter does not close analytic Milnor-fibration existence, selected global tubes, host smooth-fibre equality, Picard–Lefschetz formulas, Lean NameCert verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, singular-boundary exposure, circle-base exposure, bundle-fibre handoff, horizontal-lift replay, homology-cycle readback, monodromy-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.MilnorFibrationUp.

Chapter 7350

A Concrete Naming Certificate for $\mathsf{BoundedConvergence}^{\uparrow}$

Following Bishop–Bridges constructive real analysis and the Lebesgue bounded-convergence theorem, the $\mathsf{BoundedConvergence}^{\uparrow}$ packet records only the finite-window BEDC surface needed when a uniformly bounded real sequence has displayed pointwise convergence windows. It sits over the real-name seal of chapter 38, the regular rational readback of chapter 301, and the bounded real sequence surface of chapter 1415. The packet is a finite observation and averaging ledger for a bounded-convergence consumer; it does not assert a general measure-theoretic dominated-convergence theorem, choose pointwise limits, quotient functions, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7350.1 (Bounded convergence carrier)**.** *A* $\mathsf{BoundedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, L, M, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row, carrying the bounded real observation family inspected by the packet.*
2. *W is the finite observation-window ledger, listing the indices and sample names available to the current tolerance request.*
3. *L is the pointwise convergence-window row, recording finite evidence that the displayed samples eventually enter the requested rational tolerance window.*
4. *M is the finite measure or finite averaging ledger, naming the finite weights or finite sample average through which the consumer reads the bounded source.*
5. *A is the bounded-average comparison row, certifying that bounded tails outside the active window remain inside the displayed bound budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational windows produced by W, L, M, A.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback has been displayed.*
8. *H records componentwise* hsame *transport for the bounded source, windows, convergence ledger, finite measure or averaging row, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a tolerance request through the same finite-window route.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundedConvergence}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedConvergence}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host almost-everywhere relation, a selected limiting function, countable choice, quotient equality of functions, arbitrary dominated convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7350.2 (Bounded convergence NameCert obligations)**.** *For every accepted* $\mathsf{BoundedConvergence}^{\uparrow}$ *carrier $B = (S, W, L, M, A, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedConvergence}^{\uparrow}}$ *surface consists exactly of bounded source admission through S, finite observation-window coverage through W, pointwise convergence-window exposure through L, finite measure or finite averaging admission through M, bounded-average comparison through A, regular rational readback through R,* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7350.1. The analytic rows are the bounded source S, the finite windows W, the pointwise convergence ledger L, the finite measure or averaging row M, and the bounded-average comparison row A.

The readback rows come next. The regular rational row R records the finite rational comparison assembled from those windows, and the real seal E is downstream of that readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate names an external limit selector, arbitrary dominated convergence theorem, quotient function equality, countable choice, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Theorem 7350.3 (Bounded convergence finite-measure handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedConvergence}^{\uparrow}$ *packet reaches the convergence readback only through the finite route*

$$\mathsf{BoundedRealSequence}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The finite measure or finite averaging ledger M and bounded-average comparison row A must be read before R or E is public, and the consumer receives no general dominated-convergence theorem, selected pointwise limit, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Begin with the accepted carrier $B = (S, W, L, M, A, R, E, H, C, P, N)$. The bounded source row S and finite windows W identify the only observations available to the packet.

Read L, M, A before the readback rows. The pointwise convergence windows, finite measure or averaging ledger, and bounded comparison row are the data that justify the finite regular-rational readback.

The row R is then the only $\mathsf{RegSeqRat}^{\uparrow}$ surface exposed to consumers, and the real seal E is downstream of R. Transport and replay through H, C, P, N preserve that route without adding a selected limit or an external convergence principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedConvergence}^{\uparrow}$ packet is generated from a bounded real sequence row, finite observation windows, pointwise convergence windows, a finite measure or averaging ledger, bounded-average comparison, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 7350.1, Definition 7350.2, and Definition 7350.3 seed the finite-window bounded-convergence packet over RealUp and RegSeqRat readback rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BoundedConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close general measure-theoretic dominated convergence, selected pointwise limits, quotient function equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window convergence exposure, finite measure or averaging exactness, bounded comparison, RegSeqRat readback, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.BoundedConvergenceUp.

Chapter 7351

A Concrete Naming Certificate for $\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}$

Following the compact-uniform-continuity construction of chapter 9237, the $\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}$ packet records the finite cover handoff that turns pointwise modulus rows into a tolerance-only uniform-modulus export. It sits over the compact finite-cover surface of chapter 60, the metric source rows of chapter 57, the continuous-map pointwise rows of chapter 130, the rational lower-bound readback of chapter 37, and the downstream uniform-modulus consumer of chapter 369. The packet realizes the subordinate finite cover and pointwise-modulus handoff as finite Compact, ContinuousMap, RatUp, and UniformModulus NameCert rows; it does not export open-cover compactness, an external modulus selector, host minima, quotient point equality, or ambient real analysis.

Definition 7351.1 (Subordinate modulus uniform handoff carrier)**.** *A* $\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, X, F, R, Q, V, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-cover row, exposing the finite center or cover spine inspected by the handoff.*
2. *X is the* $\mathsf{Met}^{\uparrow}$ *source-distance row, recording the finite distance comparisons used by the cover.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row, assigning local precision windows to the displayed compact-cover centers.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *subordinate radius row, recording positive rational radii below the local pointwise-modulus budgets.*
5. *Q is the finite* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, producing a single tolerance-only precision from the displayed subordinate radii.*
6. *V is the* $\mathsf{UniformModulus}^{\uparrow}$ *export row, public only after K, X, F, R, Q have been read.*
7. *H records componentwise* hsame *transport for compact-cover, metric, pointwise-modulus, rational-fold, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through compact cover, pointwise modulus, rational fold, and uniform-modulus export.*

9. *P is the* Pkg *provenance over* $\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite subcover, host Lebesgue-number minimum, external uniform-modulus function, quotient point equality, countable choice, Lean verification, or bridge credentials.

Theorem 7351.2 (Subordinate modulus uniform handoff NameCert obligations)**.** *For every accepted* $\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}$ *carrier* $U = (K, X, F, R, Q, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}}$ *surface consists exactly of compact finite-cover admission through K, metric comparison admission through X, continuous pointwise-modulus admission through F, subordinate positive-radius exposure through R, finite rational lower-bound folding through Q, uniform-modulus export through V, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7351.1. The compact-cover row K and metric row X provide the finite source geometry available to the handoff.

Read the pointwise-modulus row F and subordinate radius row R. Each radius is attached to a displayed cover center and is certified below the corresponding pointwise precision budget.

The fold row Q is a finite $\mathsf{Rat}^{\uparrow}$ lower-bound computation over those radii. The export row V may be read only after that fold has produced a tolerance-only precision for the uniform-modulus consumer.

Finally H, C, P, N transport, replay, source, and name the same finite route. Because no carrier coordinate names an infinite subcover, host minimum, external modulus selector, quotient equality, countable choice, Lean verification, or bridge credentials, the listed rows exhaust the local NameCert obligations. □

Theorem 7351.3 (Subordinate modulus uniform handoff uniform-modulus export)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}$ *packet must first read the compact finite-cover row, metric distance comparisons, continuous-map pointwise-modulus rows, positive* $\mathsf{Rat}^{\uparrow}$ *subordinate radii, and finite* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold. Only then may the consumer read the export row V as a tolerance-only uniform-modulus handoff.*

Proof. Start with the accepted packet $U = (K, X, F, R, Q, V, H, C, P, N)$. The compact and metric rows K, X supply the finite cover and distance data; no open-cover theorem or point quotient is available.

Read F, R, Q in order. The pointwise-modulus row attaches a local precision to each displayed cover center, the subordinate radius row keeps that radius below the local budget, and the rational fold converts the finite family of radii into one precision history.

The uniform-modulus export V is downstream of that fold. Transport and replay through H, C, P, N preserve the same finite route, so the consumer receives a $\mathsf{UniformModulus}^{\uparrow}$ handoff rather than a host modulus selector or ambient compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}$ packet is generated from compact finite-cover rows, metric distance rows, continuous-map pointwise modulus rows, RatUp subordinate radii, a RatUp finite lower-bound fold, a UniformModulus export row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SubordinateModulusUniformHandoff}^{\uparrow}}$, seed)

Scope closed: Definition 7351.1, Definition 7351.2, and Definition 7351.3 seed the finite compact-cover handoff from pointwise moduli to a UniformModulus export.

Formal verification: FormalStatus(NameCert$_{\text{SubordinateModulusUniformHandoff}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, infinite subcover selection, host Lebesgue-number minima, external modulus selectors, quotient point equality, ambient real analysis, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-cover exposure, metric comparison, pointwise-modulus admission, subordinate radius exactness, RatUp lower-bound folding, UniformModulus export, transport, replay, provenance, and local naming for BEDC.Derived.SubordinateModulusUniformHandoffUp.

Chapter 7352

A Concrete Naming Certificate for $\mathsf{RegularCauchyEmbedding}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyEmbedding}^{\uparrow}$ packet records the finite constant-entry route by which a displayed dyadic or rational point is read as a regular Cauchy rational name and then sealed for Real-facing consumers. It sits after the dyadic core of chapter 291, the rational carrier of chapter 37, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the dyadic embedding surface of chapter 467. The chapter names one L10 constant embedding boundary; it does not identify quotient streams, choose limits, assert trichotomy, use countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7352.1 (Regular Cauchy embedding carrier)**.** *A* $\mathsf{RegularCauchyEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, naming the dyadic endpoint when the embedding starts from dyadic data.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source row, naming the rational endpoint when the same route is read through rational data.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *constant-window row, recording that every inspected finite window returns the displayed entry supplied by D or Q.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying the stationary regular Cauchy checks for the constant windows in W.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the source, window, and regular readback rows have been displayed.*
6. *H records componentwise* hsame *transport for the source rows, constant-window row, regular readback row, real-seal row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from the dyadic or rational source through the constant windows, regular readback, and terminal real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, Q, W, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, trichotomy of rationals, countable-choice schedules, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7352.2 (Regular Cauchy embedding NameCert obligations)**.** *For every accepted* RegularCauchyEmbeddir *carrier $K = (D, Q, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEmbedding}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed packet K;*
2. *constant-window exactness for the* $\mathsf{StreamName}^{\uparrow}$ *row W over the displayed source row D or Q;*
3. *regularity handoff from W to the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R;*
4. *real-seal nonescape for the terminal* $\mathsf{Real}^{\uparrow}$ *row E;*
5. *classifier transport through H;*
6. *displayed replay through C;*
7. *provenance and local naming through P and N.*

Proof. Project the carrier of Definition 7352.1. Its analytic rows are precisely the dyadic source D, rational source Q, constant-window row W, regular readback row R, and real-seal row E.

The constant-window obligation is local to W. Every finite observation named by W returns the same displayed source entry, so the regularity handoff can read R as the stationary $\mathsf{RegSeqRat}^{\uparrow}$ witness attached to that entry.
